0.1 SMT-RAT

This is the documentation of SMT-RAT, an Open Source C++ Toolbox for Strategic and Parallel SMT Solving. On this page, you can find introductory information on how to obtain and compile SMT-RAT and a traditional doxygen API documentation. The documentation comes in three flavours:

- API documentation as HTML: the regular web-based doxygen documentation is generated by `make doc-apidoc-html` into `build/doc/apidoc-html/` and online at <https://ths-rwth.de/github.io/smtrat>.
- API documentation as PDF: (almost) the full doxygen documentation as a pdf file is generated by `make doc-apidoc-pdf` into `build/doc/doc_smtrat-*.pdf` and online [here](#).
- Manual as PDF: only the manual, suitable for reading as an introduction into SMT-RAT, is generated by `make doc-manual` into `build/doc/manual_smtrat-*.pdf` and online [here](#).

Note that all the information of the manual is contained in the API documentation (both HTML and PDF) as well. It is much more compact, though, and may thus be more approachable as an introduction. However, references to classes do not work in the manual (as the class documentation is not contained).

If you want to use SMT-RAT and want to know how to get and install it, have a look at [Installation](#). It covers the most important steps including obtaining the actual source code, obtaining dependencies, building the library and running our test suite.

If you already use SMT-RAT and want to dig deeper or submit new code, you can additionally browse in [Developers information](#). It contains information about supplementary features like our logging framework and some basic guidelines for our code like how we use doxygen.

Note that this documentation is, and will probably still be for quite some time, work in progress. If you feel that some topic that is important to you is missing or some explanation is unclear, please let us know!

0.2 Installation

0.2.1 Requirements

SMT-RAT is build and tested on Linux. While MacOS is a secondary target (and should work on the most recent version), we do not target Windows yet. Please contact us if you are interested in changing that.

To build and use SMT-RAT, you need the following other software:

- `git` to checkout the git repository.
- `g++` or `clang` to compile.
- `cmake` to generate the make files.

Optional dependencies

- `ccmake` to set `cmake` flags.
- `doxygen` and `doxygen-latex` to build the documentation.

Additionally, SMT-RAT requires a few external libraries, which are installed automatically by CMake if no local version is available:

- `carl` from <http://smtrat.github.io/carl/> (automatically built locally if necessary).
- `boost` (the boost version from CArL is used).

When installing the dependencies, make sure that you meet the following version requirements:

- `g++ >= 9`
- `clang >= 11`

0.2.2 Download

Here are archived versions of SMT-RAT for download:

- [latest](#)

0.2.3 Configuration

SMT-RAT is configured with cmake. To prepare the build and perform the configuration run the following, starting from the root folder of SMT-RAT:

```
$ mkdir build && cd build && cmake ..  
$ ccmake ..
```

ccmake will show the cmake variables. [TODO: document important cmake variables]

0.2.4 Build

To build SMT-RAT use `make` in the build folder:

```
$ make smtrat-shared
```

Relevant targets you may want to build individually include:

- `smtrat-shared`: Builds the (dynamically linked) executable SMT solver
- `smtrat-static`: Builds the (statically linked) executable SMT solver
- `smtrat`: Builds both `smtrat-shared` and `smtrat-static`.
- `doc-html`: Builds the doxygen documentation as HTML.
- `doc-pdf`: Builds the doxygen documentation as PDF.
- `doc`: Builds both `doc-html` and `doc-pdf`.
- `benchmax`: Builds the benchmarking tool.
- `delta`: Builds the delta debugger.

0.2.5 Check build

You can now find an executable `smtrat-shared` in the build directory. It shows some usage information if you run `./smtrat-shared --help`. To run it on an SMT-LIB file, simply run

```
$ ./smtrat-shared example.smt2
```

0.3 System architecture

0.3.1 Different libraries

The different parts of SMT-RAT are split into multiple libraries (in the sense of a shared object library) that are responsible for the following tasks:

- `smtrat-analyzer`: static analysis of input formulae;
- `smtrat-cad`: back all CAD-based techniques;
- `smtrat-common`: common definitions and includes;
- `smtrat-max-smt`: takes care of max SMT queries;
- `smtrat-mcsat`: utilities for the MCSAT-based solver;
- `smtrat-modules`: all regular SMT-RAT modules;
- `smtrat-optimization`: takes care of optimization queries;
- `smtrat-qe`: methods for quantifier elimination;
- `smtrat-solver`: core solving infrastructure;
- `smtrat-strategies`: strategies for SMT solving;
- `smtrat-unsat-cores`: takes care of unsat core computations.

All of these yield a library, while a full-fledged SMT solver is build from the `cli/` path, in particular the `cli/smtratSolver.cpp`.

0.3.2 Software design

The architecture of SMT-RAT puts its focus on modularity and composability of different solving techniques. Every solving technique, for example SAT solving or the simplex method, is encapsulated in a (derivation of the) module class. These modules are composed to a strategy that governs which modules are used in what order. The execution of a strategy is incumbent upon the manager, that also offers an interface for basic SMT solving to the outside.

More advanced solving techniques like quantifier elimination, computing unsatisfiable cores, or tackling max SMT and optimization queries are implemented as individual components in the frontend. The frontend implements (most of) an SMT-LIB compatible interface and can either be used by a generic SMT-LIB parser, or an external tool. This structure is shown in the following picture.

The parser itself is implemented in `cli/parser/` and run from `cli/tools/execute_smtlib.h`. The template argument `Executor` is usually instantiated with the executor from `cli/tools/Executor.h` which corresponds to the frontend. The components in the frontend are taken from the respective SMT-RAT libraries.

The manager is a generic class from `smtrat-solver/Manager.h` that every strategy (from `smtrat-strategies/`) inherits from and only constructs the strategy graph in its constructor. The strategy graph is at the core of the composition of SMT-RAT modules and the following picture shows how a single module is embedded in a strategy.

Every module has (a pointer to) a set of received formulae that represent its input and a set of passed formulae that represent the formula that is passed on to some backend. The module may "solve" the query from its input on its own, or it may pass (one or more) queries to its backends (in this case B-1, B-2 and B-3). Arrows to backends may be labeled with conditions that restrict whether this particular backend can be used, for example checking whether the passed formulae are linear, contain integer variables or bit-vector formulae.

When a module issues a backend call the manager identifies all suitable backend modules (where the condition evaluates to `true`) and calls all backend modules on the passed formulae. This happens either sequentially (until one backend module solves the query) or in parallel.

0.3.3 Modules

A module m holds a set of formulas, called its set of received formulas and denoted by $C_{rcv}(m)$. The main function of a module is `check (bool full)`, which either decides whether $C_{rcv}(m)$ is satisfiable or not, returning SAT or UNSAT, respectively, or returns UNKNOWN. A set of formulas is semantically defined by their conjunction. If the function's argument `full` is set to `false`, the underlying procedure of m is allowed to omit hard obstacles during solving at the cost of returning UNKNOWN in more cases. We can manipulate $C_{rcv}(m)$ by adding (removing) formulas φ to (from) it with `add (\f$\backslash\varphi\f$)` (`remove (\f$\backslash\varphi\f$)`). Usually, $C_{rcv}(m)$ is only slightly changed between two consecutive `check` calls, hence, the solver's performance can be significantly improved if a module works incrementally and supports backtracking. In case m determines the unsatisfiability of $C_{rcv}(m)$, it has to compute at least one preferably small infeasible subset $C_{inf}(m) \subseteq C_{rcv}(m)$. Moreover, a module can specify *lemmas*, which are valid formulas. They encapsulate information which can be extracted from a module's internal state and propagated among other modules. Furthermore, a module itself can ask other modules for the satisfiability of its *set of passed formulas* denoted by $C_{pas}(m)$, if it invokes the procedure `runBackends (bool full)` (controlled by the manager). It thereby delegates work to modules that may be more suitable for the problem at hand.

0.3.4 Strategy

SMT-RAT allows a user to decide how to compose the modules. For this purpose we provide a graphical user interface, where the user can create a *strategy* specifying this composition. A strategy is a directed tree $T := (V, E)$ with a set V of modules as nodes and $E \subseteq V \times \Omega \times \Sigma \times V$, with Ω being the set of *conditions* and Σ being the set of *priority values*. A condition is an arbitrary Boolean combination of formula properties, such as propositions about the Boolean structure of the formula, e.g., whether it is in conjunctive normal form (CNF), about the constraints, \eg whether it contains equations, or about the polynomials, e.g., whether they are linear. Furthermore, each edge carries a unique priority value from $\Sigma = \{1, \dots, |E|\}$.

0.3.5 Manager

The manager holds the strategy and the SMT solver's input formula C_{input} . Initially, the manager calls the method `check` of the module m_r given by the root of the strategy with $C_{rcv}(m_r) = C_{input}$. Whenever a module $m \in V$ calls `runBackends`, the manager adds a solving task (σ, m, m') to its priority queue Q of solving tasks (ordered by the priority value), if there exists an edge $(m, \omega, \sigma, m') \in E$ in the strategy such that ω holds for $C_{pas}(m)$. If a processor p on the machine where SMT-RAT is executed on is available, the first solving task of Q is assigned to p and popped from Q . The manager thereby starts the method `check` of m' with $C_{rcv}(m') = C_{pas}(m)$ and passes the result (including infeasible subsets and lemmas) back to m . The module m can now benefit in its solving and reasoning process from this shared information. Note that a strategy-based composition of modules works incrementally and supports backtracking not just within one module but as a whole. This is realized by a mapping in each module m of its passed formulas $\varphi \in C_{pas}(m)$ to sets $R_1, \dots, R_n \subseteq C_{rcv}(m)$ such that each R_i forms a reason why m included φ in $C_{pas}(m)$ to ask for its satisfiability. In order to exploit the incrementality of the modules, all parallel executed backends terminate in a consistent state (instead of just being killed), if one of them finds an answer.

0.3.6 Procedures implemented as modules

The heart of an SMT solver usually forms a SAT solver. In SMT-RAT, the module `SATModule` abstracts the received formulae to propositional logic and uses the efficient SAT solver `MiniSat` [**minisat**] to find a Boolean assignment of the abstraction. It invokes `runBackends` where the passed formulae of the `SATModule` contain the constraints abstracted by the assigned Boolean variables in a less-lazy fashion [**sebastiani2007lazy**]. [Todo: Make a concise description here, refer to extensive discussion of modules]

0.3.7 Infeasible subsets and lemmas

Infeasible subsets and lemmas, which contain only formulas from $C_{pas}(SATModule)$ of a preceding SATModule, prune its Boolean search space and hence the number of theory calls. Smaller infeasible subsets are usually more advantageous, because they make larger cuts in the search space. We call lemmas containing new constraints inventive lemmas (non-inventive otherwise). They might enlarge the Boolean search space, but they can reduce the complexity of later theory calls. When using inventive lemmas, it is important to ensure that the set possible constraints introduced in such lemmas is finite for a given module and a given input formula. Otherwise, the termination of this procedure cannot be guaranteed. In general, any module might contribute lemmas and all preceding modules in the solving hierarchy can directly involve them in their search for satisfiability.

0.4 Modules

In this chapter we explain how to implement further modules. A module is a derivation of the class `Module` and we give an introduction to its members, interfaces and auxiliary methods in the following of this chapter. A new module and, hence, the corresponding C++ source and header files can be easily created when using the script `writeModules.py`. Its single argument is the module's name and the script creates a new folder in `src/lib/modules/` containing the source and header file with the interfaces yet to implement. Furthermore, it is optional to create the module having a template parameter forming a settings object as explained in sec-:auxfunctions. A new module should be created only this way, as the script takes care of a correct integration of the corresponding code into SMT-RAT. A module can be deleted belatedly by just removing the complete folder it is implemented in.

0.4.1 Main members of a module

Here is an overview of the most important members of the class `Module`.

- `vector<FormulasT> mInfeasibleSubsets`: stores the infeasible subsets of the so far received formulas, if the module determined that their conjunction is not satisfiable.
- `Manager* const mpManager`: a pointer to the manager which maintains the allocation of modules (including this one) to other modules, when they call a backend for a certain formula.
- `const ModuleInput* mpReceivedFormula`: the received formula stores the conjunction of the so far received formulas, which this module considers for a satisfiability check. These formulas are of the type `FormulaT` and the `ModuleInput` is basically a list of such formulas, which never contains a formula more than once.
- `ModuleInput* mpPassedFormula`: the passed formula stores the conjunction of the formulas which this module passes to a backend to be solved for satisfiability. There are dedicated methods to change this member, which are explained in the following.

The received formula of a module is the passed formula of the preceding module. The owner is the preceding module, hence, a module has only read access to its received formula. The `ModuleInput` also stores a mapping of a sub-formula in the passed formula of a module to its origins in the received formula of the same module. Why this mapping is essential and how we can construct it is explained in Section sec:runbackend.

0.4.2 Interfaces to implement

In the following we explain which methods must be implemented in order to fill the module's interfaces with life. All these methods are the core implementation and wrapped by the actual interfaces. This way the developer of a new module needs only to take care about the implementation of the actual procedure for the satisfiability check. All infrastructure-related actions are performed by the actual interface.

0.4.2.1 Informing about a constraint

```
bool MyModule::informCore( const Formula& _constraint )
{
    // Write the implementation here.
}
```

Informs the module about the existence of the given constraint (actually it is a formula wrapping a constraint) usually before it is actually added to this module for consideration of a later satisfiability check. At least it can be expected, that this method is called, before a formula containing the given constraint is added to this module for consideration of a later satisfiability check. This information might be useful for the module, e.g., for the initialization of the data structures it uses. If the module can already decide whether the given constraint is not satisfiable itself, it returns `false` otherwise `true`.

0.4.2.2 Adding a received formula

```
bool MyModule::addCore( const ModuleInput::const_iterator )
{
    // Write the implementation here.
}
```

Adds the formula at the given position in the conjunction of received formulas, meaning that this module has to include this formula in the next satisfiability check. If the module can already decide (with very low effort) whether the given formula is not satisfiable in combination with the already received formulas, it returns `false` otherwise `true`. This is usually determined using the solving results this module has stored after the last consistency checks. In the most cases the implementation of a new module needs some initialization in this method.

0.4.2.3 Removing a received formula

```
void MyModule::removeCore( const ModuleInput::iterator )
{
    // Write the implementation here.
}
```

Removes the formula at the given position from the received formula. Everything, which has been stored in this module and depends on this formula must be removed.

0.4.2.4 Checking for satisfiability

```
Answer MyModule::checkCore( bool )
{
    // Write the implementation here.
}
```

Implements the actual satisfiability check of the conjunction of formulas, which are in the received formula. There are three options how this module can answer: it either determines that the received formula is satisfiable and returns `true`, it determines unsatisfiability and returns `false`, or it cannot give a conclusive answer and returns `UNKNOWN`. A module has also the opportunity to reason about the conflicts occurred, if it determines unsatisfiability. For this purpose it has to store at least one infeasible subset of the set of so far received formulas. If the method `check` is called with its argument being `false`, this module is allowed to omit hard obstacles during solving at the cost of returning `UNKNOWN` in more cases, we refer to as a *lightweight check*.

0.4.2.5 Updating the model/satisfying assignment

```
void MyModule::updateModel()
{
    // Write the implementation here.
}
```

If this method is called, the last result of a satisfiability check was `true` and no further formulas have been added to the received formula, this module needs to fill its member `mModel` with a model. This model must be complete, that is all variables and uninterpreted functions occurring in the received formula must be assigned to a value of their corresponding domain. It might be necessary to involve the backends using the method `getBackendsModel()` (if they have been asked for the satisfiability of a sub-problem). It stores the model of one backend into the model of this module.

0.4.3 Running backend modules

Modules can always call a backend in order to check the satisfiability of any conjunction of formulas. Fortunately, there is no need to manage the assertion of formulas to or removing of formulas from the backend. This would be even more involved as we do allow changing the backend if it is appropriate (more details to this are explained in Chapter [chapter:composingats](#)). Running the backend is done in two steps:

1. Change the passed formula to the formula which should be solved by the backend. Keep in mind, that the passed formula could still contain formulas of the previous backend call.
2. Call `runBackends(full)`, where `full` being `false` means that the backends have to perform a lightweight check.

The first step is a bit more tricky, as we need to know which received formulas led to a passed formula. For this purpose the `ModuleInput` maintains a mapping from a passed sub-formula to one or more conjunctions of received sub-formulas. We give a small example. Let us assume that a module has so far received the following constraints (wrapped in formulas)

$$c_0 : x \leq 0, c_1 : x \geq 0, c_2 : x = 0$$

and combines the first two constraints c_0 and c_1 to c_2 . Afterwards it calls its backend on the only remaining constraint, that means the passed formula contains only $c_2 : x = 0$. The mapping of c_2 in the passed formula to the received sub-formulas it stems from then is

$$c_2 \mapsto (c_0 \wedge c_1, c_2).$$

The mapping is maintained automatically and offers two methods to add formulas to the passed formulas:

```
pair<ModuleInput::iterator,bool> addReceivedSubformulaToPassedFormula(ModuleInput::const_iterator)
```

Adds the formula at the given position in the received formula to the passed formulas. The mapping to its *original formulas* contains only the set consisting of the formula at the given position in the received formula.

```
pair<ModuleInput::iterator,bool> addSubformulaToPassedFormula(const Formula&)
pair<ModuleInput::iterator,bool> addSubformulaToPassedFormula(const Formula&, const Formula&)
pair<ModuleInput::iterator,bool> addSubformulaToPassedFormula(const Formula&, shared_ptr<vector<FormulaT>>&)
```

Adds the given formula to the passed formulas. It is mapped to the given conjunctions of origins in the received formula. The second argument (if it exists) must only consist of formulas in the received formula.

It returns a pair of a position in the passed formula and a `bool`. The `bool` is `true`, if the formula at the given position in the received formula has been added to the passed formula, which is only the case, if this formula was not yet part of the passed formula. Otherwise, the `bool` is `false`. The returned position in the passed formula points to the just added formula.

The vector of conjunctions of origins can be passed as a shared pointer, which is due to a more efficient manipulation of these origins. Some of the current module implementations directly change this vector and thereby achieve directly a change in the origins of a passed formula. \end{itemize} If, by reason of a later removing of received formulas, there is no conjunction of original formulas of a passed formula left (empty conjunction are removed), this passed formula will be automatically removed from the backends and the passed formula. That does also mean, that if we add a formula to the passed formula without giving any origin (which is done by the first version of `addSubformulaToPassedFormula`), the next call of `removeSubformula` of this module removes this formula from the passed formula. Specifying received formulas being the origins of a passed formula highly improves the incremental solving performance, so we recommend to do so.

The second step is really just calling `runBackends` and processing its return value, which can be `True`, `False`, or `Unknown`.

0.4.4 Auxiliary functions

The Module class provides a rich set of methods for the analysis of the implemented procedures in a module and debugging purposes. Besides all the printing methods, which print the contents of a member of this module to the given output stream, SMT-RAT helps to maintain the correctness of new modules during their development. It therefore provides methods to store formulas with their assumed satisfiability status in order to check them belatedly by any SMT solver which is capable to parse `.smt2` files and solve the stored formula. To be able to use the following methods, the compiler flag `SMT RAT_DEVOPTION_Validation` must be activated, which can be easily achieved when using, e.g., `ccmake`.

- `void checkInfeasibleSubsetForMinimality(vector<FormulasT>::const_iterator, const string&, unsigned)` const This method checks the infeasible subset at the given position for minimality, that is it checks whether there is a subset of it having maximally \$n\$ elements less while still being infeasible. As for some approaches it is computationally too hard to provide always a minimal infeasible subset, they rather provide infeasible subsets not necessarily being minimal. This method helps to analyze how close the size of the encountered infeasible subsets is to a minimal one.
- Another important feature during the development of a new module is the collection of statistics. The script `writeModules.py` for the creation of a new module automatically adds a class to maintain statistics in the same folder in which the module itself is located. The members of this class store the statistics usually represented by primitive data types as integers and floats. They can be extended as one pleases and be manipulated by methods, which have also to be implemented in this class. SMT-RAT collects and prints these statistics automatically, if its command line interface is called with the option `--statistics` or `-s`.
- If the script `writeModules.py` for the creation of a new module is called with the option `-s`, the module has also a template parameter being a `Settings` object. The different `Settings` objects are stored in the `Settings` file again in the same folder as the module is located. Each of these setting objects assigns all settings, which are usually of type `bool`, to values. The name of these objects must be of the form `XY-SettingsN`, if the module is called `XYModule` and with `N` being preferably a positive integer. Fulfilling these requirements, the settings to compile this module with, can be chosen, e.g. with `ccmake`, by setting the compiler flag `SMT RAT_XY_Settings` to `N`. Within the implementation of the module, its settings can then be accessed using its template parameter `Settings`. If, for instance, we want to change the control flow of the implemented procedure in the new module depending on a setting `mySetting` being `true`, we write the following:

```
..  
if(Settings::mySettings)  
{  
    ..  
}  
..
```

This methodology assures that the right control flow is chosen during compilation and, hence, before runtime.

SMT-RAT contributes a toolbox for composing an SMT compliant solver for its supported logics, that means it is incremental, supports backtracking and provides reasons for inconsistency. The resulting solver is either a fully operative SMT solver, which can be applied directly on .smt2 files, or a theory solver, which can be embedded into an SMT solver in order to extend its supported logics by those provided by SMT-RAT.

We are talking about composition and toolbox, as SMT-RAT contains implementations of many different procedures to tackle, \eg \supportedLogics, each of them embedded in a module with uniform interfaces. These modules form the tools in the toolbox and it is dedicated to a user how to use them for solving an SMT formula.

In Section sec::strategy we have already introduced a strategy and in the following of this chapter we give a brief introduction to the existing modules equipped with an estimation of their input-based performances.

0.4.5 Existing module implementation

[Available modules](#)

0.4.6 Available modules

SMT-RAT comes with the following modules that are documented in some more detail below:

BEModule BVMODULE CNFerModule CSplitModule CoCoAGBModule CubeLIAModule CurryModule EMModule
ESModule FPPModule FouMoModule GBModule GBPPModule ICEModule ICPModule IncWidthModule
IntBlastModule IntEqModule LRAModule LVEModule MCBModule NRAILModule NewCADModule NewCoveringModule
PBGaussModule PBPPModule PFEModule SATModule STropModule SplitSOSModule SymmetryModule
UFCegarModule UnionFindModule VSModule

0.4.6.1 BEModule

0.4.6.2 BVMODULE

This module implements an encoder for bitvector formulae to propositional logic. It is described in more detail in [?.](#)

0.4.6.3 CNFerModule

Transforms its received formula into conjunctive normal form CNF.

0.4.6.3.0.1 Efficiency The worst case complexity of this module is polynomial in the number of operators in the formula to transform.

0.4.6.4 CSplitModule

Implements solving for nonlinear integer arithmetic using incremental linearization. This module was implemented in [?](#) based on [?](#).

0.4.6.5 CoCoAGBModule

Uses Gröbner bases for theory solving, very much like [smrat::GBModule](#). However, for the underlying implementation of Gröbner bases, this module does not use `carl::groebner` but `CoCoALib`.

0.4.6.6 CubeLIAModule

Implements cube-based tests for linear integer arithmetic based on [?](#).

0.4.6.7 CurryModule

Implements curryfying preprcessing as described in [?](#).

0.4.6.8 EMModule

This module addempts to eliminate multiple factors from equations and inequations.

0.4.6.9 ESModule

Uses equations (or Boolean assertions) to eliminate variables from the remaining formula. Let the formula have the form $e \wedge \varphi'$, then we use knowledge gained from e to simplify φ' . If e is an arithmetic equation such that we can rewrite it to the form $x = t$ (with x a variable) then we substitute t for x into φ' . Otherwise we simply replace e with `true` in φ' . This is done recursively in the formula.

0.4.6.10 FPPModule

This module implements a generic preprocessing facility. It runs a given strategy on the input and retrieves the simplified formula using the facilities of the [Manager](#) class. This process is iterated until a fix point is reached – no further simplification was done by the strategy – or a predefined number of iterations was performed. The resulting simplified formula is then forwarded to the backend.

The strategy should be a linear sequence of preprocessing modules, as passing simplified formulas back to the caller is not possible in a meaningful way for general [Module](#) classes.

0.4.6.11 FouMoModule

Implements the SMT compliant Fourier-Motzkin algorithm. Hence, this module can decide the consistency of any conjunction consisting only of linear real arithmetic constraints. Furthermore, it might also find the consistency of a conjunction of constraints even if they are not all linear e.g. in the case of a monomial x^i (where i is a positive integer) only occuring in the shape of this monomial. Such a monomial is subsequently eliminated as common linear variables are eliminated. One can tune a threshold parameter in order to determine when, regarding the size of the considered constraints, this module shall call the backends. In the latter case, the backends are called with the constraint set that is obtained after eliminating a certain number of variables.

0.4.6.11.1 Integer arithmetic One can also use this approach for (linear) integer arithmetic as unsatisfiability over the real domain implies unsatisfiability over the integer domain. In addition to that, one can heuristically try to construct integer solutions by considering the lowest upper and the highest lower bound of a variable that can be derived from the respective elimination step. Note that this approach is incomplete.

0.4.6.12 GBModule

Implements the Gröbner bases based procedure as presented in ?. In general, this procedure can detect only the unsatisfiability of a conjunction of equations. This module also supports the usage of these equations to further simplify all constraints in the conjunction of constraints forming its input and passes these simplified constraints to its backends. However, it cannot be guaranteed that backends perform better on the simplified constraints than on the constraints before simplification.

0.4.6.12.0.1 Efficiency The worst case complexity of the underlying procedure is exponential in the number of variables of the input constraints. In the case that the conjunction of constraints to check for satisfiability contains equations, this module can be more efficient than other modules for NRA on finding out inconsistency.

0.4.6.13 GBPPModule

Uses Gröbner basis computations to simplify the input formula. The underlying implementation of Gröbner bases is used from `carl::groebner`.

The fundamental idea is as follows: Separate the input formula into equalities and inequalities and compute the Gröbner basis of the equalities. Now we can replace the equalities with the Gröbner basis (if this "seems easier") and also simplify the inequalities using the Gröbner basis.

0.4.6.14 ICEModule

This module tries to find simple chains of inequalities that can be combined to form a cycle. It converts constraints of the form $x \geq y + z$ to a hypergraph (with an edge going from x to y, z) and uses the coefficients as edge weights. If this hypergraph contains cycles, these can be used to infer additional constraints on the individual variables. In particular, zero cycles induce equality of variables while negative cycles reveal conflicts.

0.4.6.15 ICPModule

Implements a combination of interval constraint propagation equipped with a Newton-based contraction ? and LRA solving, for which we use our LRAModule. The implementation is inspired by ?, but additionally interacts with backends in order to exploit their efficiency on examples, where ICP fails. It thereby incorporates the possibility to invoke lightweight checks and highly benefits from the backends being optimized for small domains as, e.g. described in ?. This module tries to lift splitting decisions as well as lemmas encoding a nonzero contraction to a preceding SATModule. It ensures an efficient processing of these decisions, which are this way shared with other modules.

0.4.6.15.0.1 Efficiency It is very difficult to give a conclusive statement about the efficiency of ICP. Usually, it performs better, if the domains of all variables are bounded intervals, preferably with a small diameter. It might also benefit from a higher number of constraints, as this introduces more chances for the propagation. However, more constraints mean also more overhead.

0.4.6.16 IncWidthModule

This module is meant to be used for solving nonlinear integer arithmetic problems by encoding them into bitvector arithmetic formulas (as done in [smrat::IntBlastModule](#)), as described in [?](#) and [?](#), both (heavily) inspired by [?](#). This approach heavily benefits from knowing bounds on individual variables, both in terms of its ability to find infeasibility and its performance in general.

In this module, we use [smrat::ICPModule](#) to infer new bounds and call the backend incrementally with growing bounds until the computed upper bounds are met.

0.4.6.17 IntBlastModule

This module implements encoding nonlinear integer arithmetic problems into bitvector arithmetic formulas as described in [?](#) and [?](#), both (heavily) inspired by [?](#).

0.4.6.18 IntEqModule

Implements the SMT compliant equation elimination method presented in [?](#). Hence, this module either determines that the equations of an instance are unsatisfiable or calculates a certain number of substitutions for variables. The latter can be used to eliminate the equations by substituting every variable for which a substitution exists by its substitution. The set of constraints that we obtain with this procedure, not containing equations anymore, is passed to the backends.

0.4.6.19 LRAModule

Implements the SMT compliant simplex method presented in [?](#). Hence, this module can decide the consistency of any conjunction consisting only of linear real arithmetic constraints. Furthermore, it might also find the consistency of a conjunction of constraints even if they are not all linear and calls a backend after removing some redundant linear constraints, if the linear constraints are satisfiable and the found solution does not satisfy the non-linear constraints. Note that the [smrat::LRA Module](#) might need to communicate a lemma/tautology to a preceding [smrat::SATModule](#), if it receives a constraint with the relation symbol \neq and the strategy needs for this reason to define a [smrat::SATModule](#) at any position before an [smrat::LRA Module](#).

0.4.6.19.0.1 Integer arithmetic In order to find integer solutions, this module applies, depending on which settings are used, branch-and-bound, the construction of Gomory cuts and the generation of cuts from proofs [?](#). It is also supported to combine these approaches. Note that for all of them the [smrat::LRA Module](#) needs to communicate a lemma/tautology to a preceding SATModule and the strategy needs for this reason to define a SATModule at any position before an [smrat::LRA Module](#).

0.4.6.19.0.2 Efficiency The worst case complexity of the implemented approach is exponential in the number of variables occurring in the problem to solve. However, in practice, it performs much faster, and the worst case applies only on very artificial examples. This module outperforms any module implementing a method that is designed for solving formulas with non-linear constraints. If the received formula contains integer valued variables, the aforementioned methods might not terminate.

0.4.6.20 LVEModule

This module aims to eliminate lone variables that only occur once. We call a variable a lone variable if it only occurs in a single constraint. Furthermore we only try to eliminate the variable if this constraint is a top-level constraint.

0.4.6.21 MCBModule

This module attempts to detect logic structures that essentially encode a multiple-choice on an arithmetic variable. It extracts this information and translates it to a Boolean structure, thereby eliminating the arithmetic variable.

0.4.6.22 NRAILModule

This module implements incremental linearization as described in ?, roughly following ? and ?. In addition, it implements an ICP-based axiom instantiation.

0.4.6.23 NewCADModule

This module is based on the implementation in [smtrat::cad](#). It is described in ? in some detail.

0.4.6.24 PBGaussModule

This module tries to simplify pseudo-Boolean problems using Gauss as described in ?.

0.4.6.25 PBPPModule

This module implements a variety of preprocessing techniques for pseudo-Boolean problems. Many of them are based on ?.

0.4.6.26 PFEModule

Implements factor elimination in polynomials based on factorization and variable bounds.

Given a constraint $p \sim 0$ with $\sim \in \{=, \neq, \geq, >, \leq, <\}$ and bounds b on the variables in p , the module does the following: It computes a factor q such that $p = q \cdot r$ and evaluates q on the intervals represented by the bounds. If the resulting interval $q(b)$ is sign-invariant, the constraint can be simplified or additional constraints can be added. We consider an interval to be sign-invariant, if it is positive, semi-positive, zero, semi-negative or negative.

0.4.6.26.0.1 Simplifications The following simplifications are done for for $q \cdot r \sim 0$:

\sim	$q(b) > 0$	$q(b) \geq 0$	$q(b) = 0$	$q(b) < 0$	$q(b) \leq 0$
$=$	$p := r$	$f := q = 0 \vee r = 0$	$p := 0$	$p := r$	$f := q = 0 \vee r = 0$
\neq	$p := r$	$f := q > 0 \wedge r \neq 0$	$p := 0$	$p := r$	$f := q < 0 \wedge r \neq 0$
\geq	$p := r$	$f := q = 0 \vee r \geq 0$	$p := 0$	$c := r \leq 0$	$f := q = 0 \vee r \leq 0$
$>$	$p := r$	$f := q > 0 \wedge r > 0$	$p := 0$	$c := r < 0$	$f := q < 0 \wedge r < 0$
\leq	$p := r$	$f := q = 0 \vee r \leq 0$	$p := 0$	$c := r \geq 0$	$f := q = 0 \vee r \geq 0$
$<$	$p := r$	$f := q > 0 \wedge r < 0$	$p := 0$	$c := r > 0$	$f := q < 0 \wedge r > 0$

Notation: $p := p'$ replaces the polynomial, $c := p' \sim 0$ replaces the whole constraint by a new one and $f := f'$ replaces the constraint by a new formula.

To maximize the cases where $q(b)$ actually is sign-invariant, we proceed as follows. We compute a factorization of p , that is a number of polynomials p_i such that $p = \prod_{i=1}^k p_i$. We now separate all p_i into two sets: P_q for all sign-invariant p_i and P_r for all other p_i . Thereby, we set $q = \prod_{t \in P_q} t$ and $r = \prod_{t \in P_r}$ and know that $q(b)$ is sign-invariant.

Instead of computing $q(b)$ once again afterwards, we can determine the type of sign-invariance of $q(b)$ from the types of sign-invariances of the factors from P_q . Assume that we start with a canonical factor 1 and a sign-invariance of $>$, we can iteratively combine them like this:

0.4.6.26.0.2 Combining types of sign-invariance Combining two types of sign-invariance is done as follows:

.	>	\geq	=	\leq	<
>	>	\geq	=	\leq	<
\geq	\geq	\geq	=	\leq	\leq
=	=	=	=	=	=
\leq	\leq	\leq	=	\geq	\geq
<	<	\leq	=	\geq	>

0.4.6.27 SATModule

This module abstracts it's received formula, being any SMT formula of the supported logics of \smrat, to it's Boolean skeleton. It thereby replaces all constraints in the formula by fresh Boolean variables. The resulting propositional formula is then solved with \minisat~[where] after each completed decision level the constraints belonging to the assigned Boolean variables are checked for consistency by the backends of this module. In the case of inconsistency, the infeasible subsets of the backends are abstracted and then involved in the search for a satisfying solution.

0.4.6.27.0.1 Efficiency Even though the worst case complexity of this procedure, not considering the complexity of the backend calls, is exponential in the number of variables in the abstracted formula, the procedure is in practice more efficient than any of the theory modules. Hence, it does clearly not form a bottleneck of the SMT solving. However, one should aim at reducing the number and complexity of the theory (backend) calls of this module, which might be influenced by infeasible subsets, which are small and/or involve constraints of earlier decision levels in the SAT solving, and lemmas, which either prune the search space of the SAT solving or ease subsequent theory calls.

0.4.6.28 STropModule

Implements the subtropical satisfiability method as described in ? based on ?.

0.4.6.29 SplitSOSModule

Splits the left hand side of constraints according to their sum-of-squares decomposition.

0.4.6.30 SymmetryModule

This module tries to recognize syntactic symmetries in the input formula and adds symmetry breaking constraints. The core functionality is provided by CArL through carl::formula::breakSymmetries() which internally encodes the formula as a graph and uses bliss to find automorphisms on this graph.

0.4.6.30.0.1 Efficiency Finding automorphisms is as difficult as determining whether two graphs are isomorphic, and it is not known whether this problem can be solved in polynomial or exponential time. In practice, current solvers like bliss perform very good on large graphs and we therefore assume this module to be sufficiently fast.

0.4.6.31 UFCegarModule

This module implements a CEGAR-approach for solving uninterpreted functions (or rather reducing uninterpreted functions to equality logic).

0.4.6.32 UnionFindModule

This module implements a theory solver for equality logic based on a persistent union find structure (based on the immer library).

0.4.6.33 VSModule

Implements the virtual substitution method for a conjunction of constraints as described in ?. This module supports incremental calls, efficient backtracking and infeasible subset generation. Note, that the infeasible subsets are often very small but not necessarily minimal. The implemented approach is not complete, as it maybe cannot decide the satisfiability of a conjunction containing a constraint, which involves a variable with degree \$3\$ or more. Note, that even if no constraint of such form occurs in the received formula, this module might not be able to determine the consistency of its received formula, as it could create constraints of this form in its solving process. Nevertheless, the implemented approach is efficient compared to other approaches for non-linear real arithmetic conjunctions, and therefore well-suited to be used for solving conjunctions of non-linear real arithmetic constraints before complete approaches have their try. In combination with a backend, this module tries to solve the given problem and calls the backend on problems with less variables.

0.4.6.33.0.1 Efficiency The worst case complexity of this approach is exponential in the number of real arithmetic variables occurring in the conjunction to solve. It performs especially good on almost linear instances and slightly prefers problems only containing constraints with the relation symbols \leq , \geq and $=$. It is often the case, that even if the conjunction to solve contains many not suited constraints, this module can determine the consistency on the basis of a well suited subset of the constraints in this conjunction.

0.5 Strategies

To compose modules to a solver, strategies are used. Strategies are represented as trees of modules where the input file is passed to the root module. Every module can issue calls to its **backend modules** (via `runBackends`) which then calls its child modules in the strategy on the formula this module has put in the passed formulas. If no backend module exists, the call returns `unknown`.

A Strategy is specified by deriving from the Manager class and settings its strategy in the constructor using the `setStrategy` member function. A simple example, supporting only propositional logic, would look like this:

```
class PureSAT: public Manager {
public:
    PureSAT(): Manager() {
        setStrategy(
            addBackend<SATModule<SATSettings1>>()
        );
    }
};
```

Each module is added to the strategy tree using `addBackend<Module class>` where the module class is usually a template that is instantiated with some settings. A slightly more complex, where the SATModule has the NewCADModule available for theory calls, might look as follows:

```
class CADOnly: public Manager {
public:
    CADOnly(): Manager() {
        setStrategy(
            addBackend<SATModule<SATSettings1>>(
                addBackend<NewCADModule<NewCADSettingsFOS>>()
            )
        );
    }
};
```

Note that the arguments to `setStrategy` and `addBackend` can not only be a single element, but an `initializer_list` of multiple backends as well. In this case the backends are called in order until one returns a conclusive result (that is: not `unknown`). If SMT-RAT was configured to allow for parallel execution, the backends are executed in parallel and the result of the first backend to terminate is used.

```
class CADVSICP: public Manager {
public:
    CADVSICP(): Manager() {
        setStrategy(
            addBackend<SATModule<SATSettings1>>({
                addBackend<NewCADModule<NewCADSettingsFOS>>(
                    addBackend<VSMModule<VSSettings234>>()
                ),
                addBackend<ICPModule<ICPSettings1>>()
            })
        );
    }
};
```

Finally, we can also attach conditions to individual backends to restrict their applicability. For example, we can construct a strategy that uses separate sub-strategies for linear and nonlinear problems:

```
class RealSolver: public Manager {
    static bool is_nonlinear(carl::Condition condition) {
        return (carl::PROP_CONTAINS_NONLINEAR_POLYNOMIAL <= condition);
    }
    static bool is_linear(carl::Condition condition) {
        return !(carl::PROP_CONTAINS_NONLINEAR_POLYNOMIAL <= condition);
    }
public:
    RealSolver(): Manager() {
        setStrategy({
            addBackend<FPPModule<FPPSettings1>>(
                addBackend<SATModule<SATSettings1>>(
                    addBackend<ICPModule<ICPSettings1>>(
                        addBackend<VSMModule<VSSettings234>>(
                            addBackend<NewCADModule<NewCADSettingsFOS>>()
                        )
                    )
                )
            )
        }).condition( &is_nonlinear ),
        addBackend<FPPModule<FPPSettings1>>(
            addBackend<SATModule<SATSettings1>>(
                addBackend<LRAModule<LRASettings1>>()
            )
        ).condition( &is_linear )
    });
};
```

0.6 Using SMT-RAT

SMT-RAT can be used in two ways, either as a standalone solver or as a C++ library within some other software.

0.6.1 Standalone solver

Before actually compiling SMT-RAT into a binary, an appropriate strategy should be selected. While a number of strategies are available, it sometimes makes sense to craft a strategy for the specific problem at hand. Please refer to [Strategies](#) on how to create strategies. To select a strategy use `ccmake` to set the `SMT RAT_Strategy` variable accordingly and then build the solver binary using `make smtrat-shared`. Use `./smtrat-shared --strategy` to check whether the desired strategy is used.

The solver binary can now be used to solve input in the `smt2` format, either given as a filename or on standard input:

```
./smtrat-shared <input file>
cat <input file> | ./smtrat-shared -
```

Note that the solver binary can perform many other tasks as well that we discuss below. Some of these are enabled (or disabled) by a set of `cmake` options of the form `CLI_ENABLE_*` and the currently available ones can be obtained as follows:

```
$ ./smtrat-shared --help
Usage: ./smtrat-shared [options] input-file

Core settings:
  --help                                show help
  --info                                 show some basic information about this
                                         binary
  --version                             show the version of this binary
  --settings                            show the settings that are used
  --cmake-options                      show the cmake options during
                                         compilation
  --strategy                           show the configured strategy
  --license                            show the license
  -c [ --config ] arg                  load config from the given config file

Solver settings:
  --preprocess                          only preprocess the input
  --pp-output-file arg                 store the preprocessed input to this
                                         file
  --to-cnf-dimacs                     transform formula to cnf as dimacs
  --to-cnf-smtlib                      transform formula to cnf as smtlib
  --print-model                         print a model if the input is
                                         satisfiable
  --print-all-models                   print all models of the input

Validation settings:
  --validation.export-smtlib          store validation formulas to smtlib
                                         file
  --validation.smtlib-filename arg   (=validation.smt2)
                                         filename of smtlib output
  --validation.channel arg            add a channel to be considered

Module settings:
  --module.parameter arg              add a parameter for modules (key=value)

Parser settings:
  --dimacs                            parse input file as dimacs file
  --opb                               parse input file as OPB file
  --input-file arg                    path of the input file
  --disable-uf-flattening           disable flattening of nested
                                         uninterpreted functions
  --disable-theory                   disable theory construction

Analysis settings:
  --analyze.enabled                   enable formula analyzer
  --analyze.projections arg          (=none)
                                         which CAD projections to analyze (all,
                                         collins, hong, mccallum,
                                         mccallum_partial, lazar, brown, none)

CAD Preprocessor settings:
  --cad.pp.no-elimination           disable variable elimination
  --cad.pp.no-resultants            disable resultant rule
```

0.6.1.1 Formula analysis

One sometimes wants to only obtain certain information about the given formula, usually for statistical purposes. SMT-RAT exposes a formula analyzer that gives a number of properties of the formula.

```
$ ./smtrat-shared --analyze.enabled <input file>
```

0.6.1.2 Preprocessing

While many SMT-RAT strategies employ certain preprocessing techniques, it is sometimes convenient to apply this preprocessing ahead of time, for example to normalize the inputs. The result is either printed or written to an output file if `--pp-output-file` is given.

```
$ ./smtrat-shared --preprocess --pp-output-file <output file> <input file>
```

0.6.1.3 Quantifier elimination

NOTE: This feature is currently not maintained. Expect bugs and wrong answers. This feature is disabled in the default build of SMT-RAT.

Instead of regular SMT solving, SMT-RAT can also perform quantifier elimination tasks as described in [Neuhaeuser2018]. This technique is used when the SMTLIB file contains a `eliminate-quantifiers` command like `(eliminate-quantifiers (exists x y) (forall z))`.

0.6.1.4 DIMACS solving

For purely propositional formulae (i.e. SAT solving) one usually uses the (much more compact) DIMACS format instead of SMT-LIB. Note that SMT-RAT still uses the configured strategy to solve the given input instead of only a SAT solver, allowing to use custom preprocessing techniques.

```
$ ./smtrat-shared --dimacs <input file>
```

0.6.1.5 Pseudo-Boolean solving

Another interesting solving task is concerned with pseudo-Boolean formulae where Boolean variables are used in arithmetic constraints (and implicitly considered as being integers over just zero and one). A special input format called OPB exists (rather similar to DIMACS) that can be read and solved with a strategy based on `? as follows:`

```
$ ./smtrat-shared --opb <input file>
```

0.6.1.6 Optimization

For many applications, one wants not only some feasible solution but rather an optimal solution with respect to some objective function. This is used when the SMTLIB file contains one or more `(minimize)` or `(maximize)` commands with semantics similar to what is described for [z3](#).

0.6.2 Embedding in other software

Instead of using SMT-RAT as a standalone solver, it can also be embedded in other software.

0.6.2.1 Interface

The easiest way is to embed a certain strategy.

If for instance the SMT solver based on the strategy of RatOne shall be used (we can also choose any self-composed strategy here), we can create it as follows:

```
smtrat::RatOne yourSolver = smtrat::RatOne();
```

As all strategies are derived from the Manager class, we can thus use the Manager interface. The most important methods are the following:

- `bool inform(const FormulaT&)` Informs the solver about a constraint, wrapped by the given formula. Optimally, the solver should be informed about all constraints, which it will receive eventually, before any of them is added as part of a formula with the interface `add(...)`. The method returns `false` if it is easy to decide (for any module used in this solver), whether the constraint itself is inconsistent.
- `bool add(const FormulaT&)` Adds the given formula to the conjunction of formulas, which will be considered for the next satisfiability check. The method returns `false`, if it is easy to decide whether the just added formula is not satisfiable in the context of the already added formulas. Note, that only a very superficial and cheap satisfiability check is performed and mainly depends on solutions of previous consistency checks. In the most cases this method returns `true`, but in the case it does not the corresponding infeasible subset(s) can be obtained by `infeasibleSubsets()`.
- `Answer check(bool)` This method checks the so far added formulas for satisfiability. If, for instance we extend an SMT solver by a theory solver composed with SMT-RAT, these formulas are only constraints. The answer can either be `SAT`, if satisfiability has been detected, or `UNSAT`, if the formulas are not satisfiable, and `UNKNOWN`, if the composition cannot give a conclusive answer. If the answer has been `SAT`, we get the model, satisfying the conjunction of the given formulas, using `model()` and, if it has been `UNSAT`, we can obtain infeasible subsets by `infeasibleSubsets()`. If the answer is `UNKNOWN`, the composed solver is either incomplete (which highly depends on the strategy but for `QF_NRA` it is actually always possible to define a strategy for a complete SMT-RAT solver) or it communicates lemmas/tautologies, which can be obtained applying `lemmas()`. If we embed, e.g., a theory solver composed with SMT-RAT into an SMT solver, these lemmas can be used in its sat solving process in the same way as infeasible subsets are used. The strategy of an SMT solver composed with SMT-RAT has to involve a `SATModule` before any theory module is used (It is possible to define a strategy using conditions in a way, that we achieve an SMT solver, even if for some cases no `SATModule` is involved before a theory module is applied.) and, therefore, the SMT solver never communicates these lemmas as they are already processed by the `SATModule`. A better explanation on the modules and the strategy can be found in [system architecture](#). If the Boolean argument of the function `check` is `false`, the composed solver is allowed to omit hard obstacles during solving at the cost of returning `UNKNOWN` in more cases.
- `void push()` Pushes a backtrack point to the stack of backtrack points.
- `bool pop()` Pops a backtrack point from the stack of backtrack points and undoes everything which has been done after adding that backtrack point. It returns `false` if no backtrack point is on the stack. Note, that SMT-RAT supports incrementality, that means, that by removing everything which has been done after adding a backtrack point, we mean, that all intermediate solving results which only depend on the formulas to remove are deleted. It is highly recommended not to remove anything, which is going to be added directly afterwards.
- `const std::vector<FormulasT>& infeasibleSubsets() const` Returns one or more reasons for the unsatisfiability of the considered conjunction of formulas of this SMT-RAT composition. A reason is an infeasible subset of the sub-formulas of this conjunction.
- `const Model& model() const` Returns an assignment of the variables, which occur in the so far added formulas, to values of their domains, such that it satisfies the conjunction of these formulas. Note, that an assignment is only provided if the conjunction of so far added formulas is satisfiable. Furthermore, when solving non-linear real arithmetic formulas the assignment could contain other variables or freshly introduced variables.

- `std::vector<FormulaT> lemmas()` const Returns valid formulas, which we call lemmas. For instance the `ICPModule` might return lemmas being splitting decisions, which need to be processed in, e.g., a SAT solver. A *splitting decision* has in general the form $(c_1 \text{ and } \dots \text{ and } c_n) \rightarrow (p \leq r \text{ or } p > r)$ where c_1, \dots, c_n are constraints of the set of currently being checked constraints (forming a *premise*), p is a polynomial (in the most cases consisting only of one variable) and r being a rational number. Hence, splitting decisions always form a tautology. We recommend to use the `ICPModule` only in strategies with a preceding `SATModule`. The same holds for the `LRAModule`, `VSMModule`, and `CADModule` if used on QF_NIA formulas. Here, again, splitting decisions might be communicated.

Of course, the Manager interface contains more methods that can be found at Manager.

0.6.2.2 Syntax of formulas

The class `Formula` represents SMT formulas, which are defined according to the following abstract grammar

$$\begin{array}{lcl}
p & ::= & a \quad | \quad b \quad | \quad x \quad | \quad (p + p) \quad | \quad (p \cdot p) \quad | \quad (p^e) \\
v & ::= & u \quad | \quad x \\
s & ::= & f(v, \dots, v) \quad | \quad u \quad | \quad x \\
e & ::= & s = s \\
c & ::= & p = 0 \quad | \quad p < 0 \quad | \quad p \leq 0 \quad | \quad p > 0 \quad | \quad p \geq 0 \quad | \quad p \neq 0 \\
\varphi & ::= & c \quad | \quad (\neg\varphi) \quad | \quad (\varphi \wedge \varphi) \quad | \quad (\varphi \vee \varphi) \quad | \quad (\varphi \rightarrow \varphi) \quad | \quad (\varphi \leftrightarrow \varphi) \quad | \quad (\varphi \oplus \varphi)
\end{array}$$

where a is a rational number, e is a natural number greater one, b is a *Boolean variable* and the *arithmetic variable* x is an inherently existential quantified and either real- or integer-valued. We call p a *polynomial* and use a multivariate polynomial with rationals as coefficients to represent it. The **uninterpreted* function f is of a certain *order* $o(f)$ and each of its $o(f)$ arguments are either an arithmetic variable or an *uninterpreted variable* u , which is also inherently existential quantified, but has no domain specified. Than an *uninterpreted equation* e has either an uninterpreted function, an uninterpreted variable or an arithmetic variable as left-hand respectively right-hand side. A *constraint* c compares a polynomial to zero, using a *relation symbol*. Furthermore, we keep constraints in a normalized representation to be able to differ them better.

0.6.2.3 Boolean combinations of constraints and Boolean variables

For more information, check out the docs of [CARL](#).

A formula is stored as a directed acyclic graph, where the intermediate nodes represent the Boolean operations on the sub-formulas represented by the successors of this node. The leaves (nodes without successor) contain either a Boolean variable, a constraint or an uninterpreted equality. Equal formulas, that is formulas being leaves and containing the same element or formulas representing the same operation on the same sub-formulas, are stored only once.

The construction of formulas, which are represented by the `FormulaT` class, is mainly based on the presented abstract grammar. A formula being a leaf wraps the corresponding objects representing a Boolean variable, a constraint or an uninterpreted equality. A Boolean combination of Boolean variables, constraints and uninterpreted equalities consists of a Boolean operator and the sub-formulas it interconnects. For this purpose we either firstly create a set of formulas containing all sub-formulas and then construct the `Formula` or (if the formula shall not have more than three sub-formulas) construct the formula directly passing the operator and sub-formulas. Formulas, constraints and uninterpreted equalities are non-mutable, once they are constructed.

We give a small example constructing the formula

$$(\neg b \wedge x^2 - y < 0 \wedge 4x + y - 8y^7 = 0) \rightarrow (\neg(x^2 - y < 0) \vee b),$$

with the Boolean variable `b` and the real-valued variables `x` and `y`, for demonstration. Furthermore, we construct the UF formula

$$v = f(u, u) \oplus w \neq u$$

with `u`, `v` and `w` being uninterpreted variables of not specified domains `S` and `T`, respectively, and `f` is an uninterpreted function with not specified domain $T^{S \times S}$.

Firstly, we show how to create real valued (integer valued analogously with `VT_INT`), Boolean and uninterpreted variables:

```
carl::Variable x = smtrat::newVariable( "x", carl::VariableType::VT_REAL );
carl::Variable y = smtrat::newVariable( "y", carl::VariableType::VT_REAL );
carl::Variable b = smtrat::newVariable( "b", carl::VariableType::VT_BOOL );
carl::Variable u = smtrat::newVariable( "u", carl::VariableType::VT_UNINTERPRETED );
carl::Variable v = smtrat::newVariable( "v", carl::VariableType::VT_UNINTERPRETED );
carl::Variable w = smtrat::newVariable( "w", carl::VariableType::VT_UNINTERPRETED );
```

Uninterpreted variables, functions and function instances combined in equations or inequalities comparing them are constructed the following way.

```
carl::Sort sortS = smtrat::newSort( "S" );
carl::Sort sortT = smtrat::newSort( "T" );
carl::UVariable uu( u, sortS );
carl::UVariable uv( v, sortT );
carl::UVariable uw( w, sortS );
carl::UninterpretedFunction f = smtrat::newUF( "f", sortS, sortS, sortT );
carl::UFIInstance f1 = smtrat::newUFIInstance( f, uu, uw );
carl::UEquality ueqA( uv, f1, false );
carl::UEquality ueqB( uw, uu, true );
```

Next we see an example how to create polynomials, which form the left-hand sides of the constraints:

```
smtrat::Poly px( x );
smtrat::Poly py( y );
smtrat::Poly lhsA = px.pow(2) - py;
smtrat::Poly lhsB = smtrat::Rational(4) * px + py - smtrat::Rational(8) * py.pow(7);
```

Constraints can then be constructed as follows:

```
smtrat::ConstraintT constraintA( lhsA, carl::Relation::LESS );
smtrat::ConstraintT constraintB( lhsB, carl::Relation::EQ );
```

Now, we can construct the atoms of the Boolean formula

```
smtrat::FormulaT atomA( constraintA );
smtrat::FormulaT atomB( constraintB );
smtrat::FormulaT atomC( b );
smtrat::FormulaT atomD( ueqA );
smtrat::FormulaT atomE( ueqB );
```

and the formulas itself (either with a set of arguments or directly):

```
smtrat::FormulasT subformulasA;
subformulasA.insert( smtrat::FormulaT( carl::FormulaType::NOT, atomC ) );
subformulasA.insert( atomA );
subformulasA.insert( atomB );
smtrat::FormulaT phiA( carl::FormulaType::AND, std::move(subformulasA) );
smtrat::FormulaT phiB( carl::FormulaType::NOT, atomA );
smtrat::FormulaT phiC( carl::FormulaType::OR, phiB, atomC );
smtrat::FormulaT phiD( carl::FormulaType::IMPLIES, phiA, phiC );
smtrat::FormulaT phiE( carl::FormulaType::XOR, atomD, atomE );
```

Note, that \wedge and \vee are n -ary constructors, \neg is a unary constructor and all the other Boolean operators are binary.

0.6.2.4 Normalized constraints

A normalized constraint has the form

$$a_1 \overbrace{x_{1,1}^{e_{1,1}} \cdot \dots \cdot x_{1,k_1}^{e_{1,k_1}}}^{m_1} + \dots + a_n \overbrace{x_{n,1}^{e_{n,1}} \cdot \dots \cdot x_{n,k_n}^{e_{n,k_n}}}^{m_n} + d \sim 0$$

with $n \geq 0$, the i th coefficient a_i being an integral number ($\neq 0$), d being a integral number, x_{i,j_i} being a real- or integer-valued variable and e_{i,j_i} being a natural number greater zero (for all $1 \leq i \leq n$ and $1 \leq j_i \leq k_i$). Furthermore, it holds that $x_{i,j_i} \neq x_{i,l_i}$ if $j_i \neq l_i$ (for all $1 \leq i \leq n$ and $1 \leq j_i, l_i \leq k_i$) and $m_{i_1} \neq m_{i_2}$ if $i_1 \neq i_2$ (for all $1 \leq i_1, i_2 \leq n$). If n is 0 then d is 0 and \sim is either $=$ or $<$. In the former case we have the normalized representation of any variable-free consistent constraint, which semantically equals `true`, and in the latter case we have the normalized representation of any variable-free inconsistent constraint, which semantically equals `false`. Note that the monomials and the variables in them are ordered according the `\polynomialOrder` of `\carl`. Moreover, the first coefficient of a normalized constraint (with respect to this order) is always positive and the greatest common divisor of a_1, \dots, a_n , d is 1. If all variable are integer valued the constraint is further simplified to

$$\frac{a_1}{g} \cdot m_1 + \dots + \frac{a_n}{g} \cdot m_n + d' \sim '0,$$

where g is the greatest common divisor of a_1, \dots, a_n ,

$$\sim ' = \begin{cases} \leq, & \text{if } \sim \text{ is } < \\ \geq, & \text{if } \sim \text{ is } > \\ \sim, & \text{otherwise} \end{cases}$$

and

$$d' = \begin{cases} \lceil \frac{d}{g} \rceil & \text{if } \sim \text{ is } \leq \\ \lfloor \frac{d}{g} \rfloor & \text{if } \sim \text{ is } \geq \\ \frac{d}{g} & \text{otherwise} \end{cases}$$

If additionally $\frac{d}{g}$ is not integral and $\sim '$ is $=$, the constraint is simplified $0 < 0$, or if $\sim '$ is \neq , the constraint is simplified $0 = 0$.

We do some further simplifications, such as the elimination of multiple roots of the left-hand sides in equations and inequalities with the relation symbol \neq , e.g., $x^3 = 0$ is simplified to $x = 0$. We also simplify constraints whose left-hand sides are obviously positive (semi)/negative (semi) definite, e.g., $x^2 \leq 0$ is simplified to $x^2 = 0$, which again can be simplified to $x = 0$ according to the first simplification rule.

0.6.2.5 Linking

[Todo: example how linking works]

0.7 Other tools

0.7.1 Benchmarking

Alongside SMT-RAT, `benchmax` allows to easily run solvers on benchmarks and export the results. See [Benchmax](#) for more information.

0.7.2 Delta debugging

Delta debugging describes a generic debugging approach based on automated testing. Given a program and an input that provokes a certain behavior (for example an error) delta debugging is the process of iteratively changing the input, retaining the specific behavior. Usually, as the ultimate goal is a minimal example that triggers some bug by the application of a set of transformation rules.

0.7.2.1 SMT-RAT's own delta tool

SMT-RAT has its own tool for delta debugging, see [Delta](#) for more information.

0.7.2.2 Using ddSMT

Currently, we recommend using ddSMT as the state-of-the-art tool for delta debugging.

For a complete guide, we refer to the [documentation of ddSMT](#).

Here, we give instructions for the most common use cases when developing with SMT-RAT. There are mainly two common scenarios where we use delta debugging: If there is a failing assertion or if SMT-RAT returns a wrong result. For these scenarios, we provide wrapper scripts preparing the input to ddsmt properly.

First, install ddSMT and z3:

```
pip3 install ddsmt  
sudo apt install z3
```

In case of a *failing assertion* on `in_file.smt2`, run

```
~/src/smtrat/utilities/ddsmt/ddsmt-assertion in_file.smt2 out_file.smt2 path_to_solver
```

In case SMT-RAT returns a *wrong result* on `in_file.smt2`, run

```
~/src/smtrat/utilities/ddsmt/ddsmt-wrong in_file.smt2 out_file.smt2 path_to_solver
```

0.7.3 Analyzer

The `smtrat-analyzer` library can analyze static properties of input formulas (such as number of variables, degrees, CAD projections, ...).

To use it from the CLI, build smtrat using `CLI_ENABLE_ANALYZER=ON` and `SMTRAT_DEVOPTION_Statistics=ON`. A single input file can be analyzed by running `./smtrat --analyze.enabled --stats.print input.smt2`; properties will be printed as `statistics` object, note that the solver will not be called. For further options, see `./smtrat --help`.

To collect properties of all formulas of a benchmark sets, the analyzer can be used with `benchmax`. To do so, specify add the binary as an `smtrat-analyzer` solver; for more information, see the `benchmax` subpage.

0.7.4 Preprocessing

WIP

0.7.5 Benchmax

Benchmax is a tool for automated benchmarking. Though it was developed and is primarily used for testing SMT solvers, it aims to be agnostic of the tools and formats as good as possible.

Its fundamental model is to load a list of tools and a list of benchmarks, run every tool with every benchmark, obtain the results and output all the results. While the benchmarks are fixed to a single file, we allow to choose between different [tool interfaces](#), [execution backends](#) and output formats.

0.7.5.1 General usage

Benchmax could be called as follows:

```
./benchmax -T 1m -M 4Gi -S /path/to/smtrat-static -X out.xml -b ssh --ssh.node user@127.0.0.1@5\#9 -D /path/to/benchmark/set
```

This will run benchmax with the SMT-RAT tool at `/path/to/smtrat-static` on the `/path/to/benchmark/set` with a time limit of 1 minute and a memory limit of 4 gigabyte. The result will be written to `out.xml`. The execution is done on an SSH backend on localhost with 9 connections and executing 5 parallel jobs per connection.

It is recommended to use static builds to avoid issues with missing libraries.

For more information, run `./benchmax --help`.

0.7.5.1.1 Collecting statistics Some tools like SMT-RAT or Z3 can provide statistics about the solving process for each individual benchmark. By using the `-s` respectively `--statistics`, statistics are collected and stored in the output file.

0.7.5.1.1.1 Large output It is recommended to aggregate statistics as much as possible inside SMT-RAT. However, if the output might get large, you might want to use `--use-tmp` to prevent benchmax running out of memory.

0.7.5.1.2 Working with the results In the SMT-RAT repository, two utilities for converting the result XML file are included:

- `utilities/benchmax/xml2ods.py` for converting it to a *Flat XML LibreOffice Calc Sheet*.
- An XML filter `utilities/benchmax/OOCImporter.xsl` for converting it to a *Flat XML LibreOffice Calc Sheet*.
- `utilities/benchmax/evaluation` is a small python library for importing the results into Python (or a Jupyter notebook), inspecting the results and preparing plots. For more information, see [Benchmax python utility](#).

0.7.5.2 Tools

A tool represents a binary that can be executed on some input files. It is responsible for deciding whether it can be applied to some given file, building a command line to execute it and retrieve additional results from `stdout` or `stderr`.

The generic tool class `benchmax::Tool` can be used as a default. It will run the given binary on any input file and benchmax records the exit code as well as the runtime.

If more information is needed a new tool class can be derived that overrides or extends the default behaviour. Some premade tools are available (and new ones should be easy to create):

- [benchmax::MathSAT](#)
- [benchmax::Minisatp](#)
- [benchmax::SMTRAT](#)
- [benchmax::SMTRAT_OPB](#)
- [benchmax::Z3](#)

0.7.5.3 Backends

A **backend** offers the means to run the tasks in a specific manner. A number of different backends are implemented that allow for using benchmax in various scenarios.

0.7.5.3.1 LocalBackend The **LocalBackend** can be used to execute benchmarks on a local machine easily. It does not allow for any parallelization but simply executes all tasks sequentially.

0.7.5.3.2 SlurmBackend The **SlurmBackend** employs the Slurm workload manager to run benchmarks on a cluster. It essentially collects all tasks that shall be run in a file and creates an appropriate slurm submit file. It then submits this job, waits for it to finish and collects the results from the output files.

The Slurm backend supports starting (`--mode execute`) and collecting results (`--mode collect`) separately, thus avoiding the need for running benchmax in a screen.

0.7.5.3.3 SSHBackend The **SSHBackend** can be used if you have multiple workers that can be reached via ssh (essentially a cluster without a batch job system). It allows to configure one or more computing nodes and manually schedules all the jobs on the different computing nodes.

Using `--ssh.node`, a node is specified in the format `<user>[:<password>]@<hostname>[:<port = 22>] [<cores = 1>][#<connections = 1>]`; benchmax will then connect to the specified server with given credentials `connections` times and will run `cores` threads per connection. Thus, the number of overall parallel threads equals `connections * cores` (note that enough memory should be available on the node).

By setting the flag `--ssh.resolvedeps`, dependencies (i.e. dynamic libraries) are resolved and uploaded with the solver.

0.7.5.3.4 CondorBackend (unstable) The **CondorBackend** is aimed at the HTCondor batch system and works similar to the SlurmBackend. Note however that this backend is not well tested and we therefore consider it unstable.

0.7.5.4 Troubleshooting

- If benchmax terminates due to a segmentation fault without any message, then it probably exceeded available memory. A common error is that SMT-RAT has produced too much logging output. To fix this, simply build SMT-RAT with `LOGGING=OFF`.

0.7.5.5 Benchmax python utility

This tool allows loading XML files from Benchmax into a pandas dataframe, inspecting the results and visualizing them.

This is useful for working with the results in a Jupyter notebook.

Dependencies:

- `pandas`
- `matplotlib`
- `pillow`
- `numpy`
- `tikzplotlib`

```
pip3 install pandas matplotlib tikzplotlib numpy pillow
```

0.7.5.5.1 Loading XMLs into a pandas dataframe

First, install this directory as python library; e.g. on Ubuntu
cd ~/.local/lib/python3.8/site-packages/ # path to your python site-packages directory
ln -s ~/src/smtrat/utilities/benchmax/ # path to the benchmax utility

In your Jupyter notebook:

```
import benchmax.evaluation as ev
df = ev.xml_to_pandas("path_to/stats_file.xml", {"smtrat-static": "solver_name"}, ["statistics_name_1", "statistics_name_2"]) # second and third parameter is optional
```

or, to load multiple XMLs into one:

```
import benchmax.evaluation as ev
df = ev.xls_to_pandas({"path_to/stats_file_1.xml": {"smtrat-static": "solver_name_1"}, "path_to/stats_file_2.xml": {"smtrat-static": "solver_name_2"}}, ["statistics_name_1", "statistics_name_2"]) # second parameter is optional
```

This will create a dataframe with columns (solver_name_1, "answer"), (solver_name_1, "runtime"), (solver_name_1, "statistics_name_1") etc (as multi-index).

0.7.5.5.2 Computing a virtual best solver

A virtual best is a solver that behaves optimal on each input w.r.t. a set of solvers. It is computed by selecting for each benchmark instance the solver with shortest running time.

To compute the virtual best solver named VB w.r.t. solver1,solver2 and solver3 and considering statistics statistics_name_1.

```
df = df.join(ev.virtual_best(df, ["solver1", "solver2", "solver3"], "VB", ['statistics_name_1']))
```

0.7.5.5.3 Plotting

We provide the performance_profile and scatter_plot functions to easily generate a performance profiles and scatter plots.

0.7.5.5.4 Show a summary of an XML file

There are several methods for quickly inspecting the results of a run provided. For instance, the following script can be used to view a summary of a singel XML file and to show instances with wrong results or segmentation faults:

```
#!/usr/bin/env python3
import benchmax.evaluation as ev
import sys
df = ev.xml_to_pandas(sys.argv[1])
ev.inspect(df)
```

SMT-RAT provides a small utility script for showing a summary of one or more XML files:

```
~/Code/smtrat/utilities/benchmax/view.py result_1.xml result_2.xml
```

0.7.5.5.5 Exporting data to Latex

0.7.5.5.5.1 Pandas dataframe to latex table

```
df.to_latex(buf='file.tex')
```

0.7.5.5.5.2 matplotlib to tikz plot

see [tikzplotlib](#)

0.7.6 Delta

0.7.6.1 Delta debugging

Delta debugging describes a generic debugging approach based on automated testing. Given a program and an input that provokes a certain behavior (for example an error) delta debugging is the process of iteratively changing the input, retaining the specific behavior. Each small change to the input represents a **delta** and is the result of some transformation rule. Whenever a change was successful, it is stored and the process continues from this intermediate result. Eventually, there is no transformation left, such that the faulty behavior is retained and the debugging process terminates.

This approach only works, if the transformation rules can neither be chained to form a loop, nor continue infinitely. Usually, as the ultimate goal is a minimal example that triggers some bug, all transformation rules are designed to make the input smaller, in one way or another.

This approach has proven to be very valuable in the context of SAT and SMT solving. However, existing delta debugging tools ? needed a preprocessed input and manual restarts to achieve a fix-point, hence, we decided to include our own delta debugging tool, `delta`, in SMT-RAT. It can be used completely independent of SMT-RAT and is built to be as generic as possible, but focuses on programs operating on SMT-LIB files. It has some knowledge of the semantics of the corresponding logics, but only operates on nodes. Any SMT-LIB construct, that is either a constant or a braced expression, is a node.

The actual transformation rules are implemented in `operations.h` and are enabled in the constructor of the `Producer` class. The implemented rules are rather simple: removing a node, replacing a node by a child node, simplifying a number, replacing a symbol by a constant or eliminating a let expression. These transformations are designed such that they can be extended easily. For a given input `delta` applies each transformation to each node. Each application may produce arbitrarily many *candidate inputs* which are then tested. The first candidate that provokes the error is then adopted, the other candidates are rejected.

When analyzing the behavior, `delta` relies on the exit code of the program. It will run the program on the original input and obtain the original exit code. Whenever the program returns the same exit code, `delta` assumes that the program behaved the same.

0.7.6.1.1 Using delta `delta` is currently contained in the SMT-RAT repository and can be built using `make delta`.

Using `delta` is rather easy. It accepts the input file and the solver as its two main arguments: `./delta -i input.smt2 -s ./solver`. There are a couple of other arguments that are documented in the help: `./delta --help`.

0.7.6.1.1.1 Exit code As `delta` relies on the exit code of the program, make sure that this event results in a unique exit code:

- **Specific assertions:** Return a unique exit code by replacing the assertion with `if (!assertion_< condition) { std::exit(70); }`.
- **Faulty output:** Remove the `(set-info :status unsat)/(set-info :status sat)` line from the benchmark and use the script `utilities/result-incorrect.py` as solver. Note that you need to install z3 first.

0.8 Developers information

- [Code style](#)
- [Documentation](#)
- [Settings](#)
- [Logging](#)
- [Statistics and timing](#)
- [Testing](#)
- [Validation](#)
- [Checkpoints](#)
- [Finding and Reporting Bugs](#)
- [Tools](#)

0.8.1 Code style

Please follow the code style rules from CArL documentation.

For SMT-RAT, we follow a different rule for naming files and namespaces:

- Every file should represent a *module*.
- Every (sub-)folder has its own namespace.

0.8.2 Documentation

For SMT-RAT, there are two sources of documentation: the in-source API documentation and the more manual-like documentation (you are reading right now). While the in-source API documentation is generated based on the doxygen comments from the actual source files, the manual is generated from the markdown files in `doc/markdown/`.

0.8.2.0.1 Writing documentation Note that some of the documentation may be incomplete or rendered incorrectly, especially if you use an old version of doxygen. Here is a list of known problems:

- Comments in code blocks (see below) may not work correctly (e.g. with doxygen 1.8.1.2). See [here](#) for a workaround. This will however look ugly for newer doxygen versions, hence we do not use it.
- Files with `static_assert` statements will be incomplete. A [patch](#) is pending and will hopefully make it into doxygen 1.8.9.
- Member groups (usually used to group operators) may or may not work. There still seem to be a few cases where doxygen [messes up](#).
- Documenting unnamed parameters is not possible. A corresponding [ticket](#) exists for several years.

0.8.2.0.2 Literature references Literature references should be provided when appropriate by citing references from the bibtex database located at `doc/literature.bib` using the `@cite` command. The labels are the last name of the first author and the four-digit year. In case of duplicates, we append lowercase letters.

These references can be used with `@cite` label, for example like this:

```
/***
 * Checks whether the polynomial is unit normal
 * @see @cite GCL92, page 39
 * @return If polynomial is normal.
 */
bool is_normal() const;
```

0.8.2.1 Code comments

0.8.2.1.1 File headers

```
/***
 * @file <filename>
 * @ingroup <groupid1>
 * @ingroup <groupid2>
 * @author <author1>
 * @author <author2>
 *
 * [ Short description ]
 */
```

Descriptions may be omitted when the file contains a single class, either implementation or declaration.

0.8.2.1.2 Namespaces Namespaces are documented in a separate file, found at '`/doc/markdown/codedocs/namespaces.dox`'

0.8.2.1.3 Class headers

```
/***
 * @ingroup <groupid>
 * [ Description ]
 * @see <reference>
 * @see <OtherClass>
 */
```

0.8.2.1.4 Method headers

```
/***
 * [ Usage Description ]
 * @param <p1> [ Short description for first parameter ]
 * @param <p2> [ Short description for second parameter ]
 * @return [ Short description of return value ]
 * @see <reference>
 * @see <otherMethod>
 */
```

These method headers are written directly above the method declaration. Comments about the implementation are written above the or inside the implementation.

The `see` command is used likewise as for classes.

0.8.2.1.5 Method groups There are some cases when documenting each method is tedious and meaningless, for example operators. In this case, we use doxygen method groups.

For member operators (for example operator`+=`), this works as follows:

```
/// @name In-place addition operators
/// @{
/***
 * Add something to this polynomial and return the changed polynomial.
 * @param rhs Right hand side.
 * @return Changed polynomial.
 */
MultivariatePolynomial& operator+=(const MultivariatePolynomial& rhs);
MultivariatePolynomial& operator+=(const Term<Coeff>& rhs);
MultivariatePolynomial& operator+=(const Monomial& rhs);
MultivariatePolynomial& operator+=(Variable::Arg rhs);
MultivariatePolynomial& operator+=(const Coeff& rhs);
/// @}
```

0.8.2.2 Writing out-of-source documentation

Documentation not directly related to the source code is written in Markdown format, and is located in `/doc/markdown/`.

0.8.3 Settings

As described in sec::modules, each module has a settings template parameter.

0.8.3.0.1 Dynamic settings These settings are considered at compile time. For certain purposes, it is unhandy to recompile SMT-RAT for every parameter. For this, module parameters can be set

- via the command line using `--module.parameter key1=value1 --module.parameter key2=value2 ...` or
- via the `set-option` command of SMT-LIB: (`set-option :key "value"`) (note that you need to pass every value as a string, even if it represents a number!).

These parameters can be accessed (most appropriately in a settings object of a module) via `int my_setting = settings_module().get("my_module.my_setting", 2)` or `std::string my_setting = settings_module().get("my_module.my_setting", "default_value")`. Note that the second parameter is the default value also specifying the type of the setting to which it is parsed.

0.8.4 Logging

0.8.4.0.1 Logging frontend The frontend for logging is defined in `logging.h`.

It provides the following macros for logging:

- `SMTRAT_LOG_TRACE(channel, msg)`
- `SMTRAT_LOG_DEBUG(channel, msg)`
- `SMTRAT_LOG_INFO(channel, msg)`

- SMTRAT_LOG_WARN(channel, msg)
- SMTRAT_LOG_ERROR(channel, msg)
- SMTRAT_LOG_FATAL(channel, msg)
- SMTRAT_LOG_FUNC(channel, args)
- SMTRAT_LOG_FUNC(channel, args, msg)
- SMTRAT_LOG_ASSERT(channel, condition, msg)
- SMTRAT_LOG_NOTIMPLEMENTED()
- SMTRAT_LOG_INEFFICIENT()

Where the arguments mean the following:

- **channel**: A string describing the context. For example "smtrat.parser".
- **msg**: The actual message as an expression that can be sent to a std::stringstream. For example "foo: " << foo.
- **args**: A description of the function arguments as an expression like msg.
- **condition**: A boolean expression that can be passed to assert().

Typically, logging looks like this:

```
bool checkStuff(Object o, bool flag) {
    SMTRAT_LOG_FUNC("smtrat", o << ", " << flag);
    bool result = o.property(flag);
    SMTRAT_LOG_TRACE("smtrat", "Result: " << result);
    return result;
}
```

Logging is enabled (or disabled) by the LOGGING macro in CMake. The log levels for each channel can be configured in the configure_logging() method in cli/smtratSolver.cpp.

0.8.5 Statistics and timing

0.8.5.0.1 Statistics

SMT-RAT has the ability to collect statistics after the solving process is finished.

For enabling this feature, the SMTRAT_DEVOPTION_Statistics needs to be turned on in the CMake settings.

0.8.5.0.1.1 Collecting statistics

A statistics object can be created by inheriting from `Statistics.h`:

```
#pragma once
#include <smtrat-common/statistics/Statistics.h>
#ifndef SMTRAT_DEVOPTION_Statistics
namespace smtrat {
namespace myModule {
class MyStatistics : public Statistics {
private:
    std::size_t mCounter = 0;
public:
    void collect() { // called after the solving process to collect statistics
        Statistics::addKeyValuePair("counter", mCounter);
    }
    void count() { // user defined
        ++mCounter;
    }
};
}
#endif
```

Note that neither the key nor the value are allowed to contain spaces, (or).

This is then instantiated by calling

```
#ifdef SMTRAT_DEVOPTION_Statistics
auto& myStatistics = statistics_get<myModule::MyStatistics>("MyModuleName");
#endif
```

or, as shortcut

```
SMTRAT_STATISTICS_INIT(myModule::MyStatistics, myStatistics, "MyModuleName")
```

and statistics can be collected by calling the user defined operations (e.g. `myStatistics.count()`).

All statistics-related code should be encapsulated by the `SMTRAT_DEVOPTION_Statistics` flag. Alternatively, code can be encapsulated in `SMTRAT_STATISTICS_CALL()`.

0.8.5.0.2 Timing

The statistics framework has the ability to easily collect timings.

The following code will measure the total running time of the code block as well as the number of times the code block was executed:

```
class MyStatistics : public Statistics {
private:
    carl::statistics::timer mTimer;

public:
    void collect() {
        Statistics::addKeyValuePair("timer", mTimer);
    }
    auto& timer() {
        return mTimer;
    }
};

SMTRAT_STATISTICS_INIT(myModule::MyStatistics, myStatistics, "MyModuleName")

SMTRAT_TIME_START(start);
// expensive code
SMTRAT_TIME_FINISH(myStatistics.timer(), start);
```

The measured timings will then appear alongside the statistics.

Note that the resolution of these measurements is in 1 millisecond. Thus, be careful when interpreting results; especially, it measured code blocks should be big enough.

0.8.6 Testing

SMT-RAT and CArL use [GoogleTest](#) for unit testing. To do so, go to the `src/tests/` folder and create a test analogously to the other tests (i.e. creating a new folder, adapting the `CMakeList.txt` in the new folder and in the `tests` folder). *Note that in the SMT-RAT repository are some obsolete tests.*

0.8.6.0.1 Utilities For creating CArL data structure in unit tests, we refer to `carl-io/parser/Parser.h`.

0.8.7 Validation

For debugging purposes, it can be useful to verify intermediate results (explanations, lemmas, etc) using an external SMT solver. SMT-RAT allows to store formulas during the solving process which are written to a `smt2` file once the solving process is finished.

0.8.7.0.1 Enabling this feature For enabling this feature, the `SMTRAT_DEVOPTION_Validation` needs to be turned on in the CMake settings.

0.8.7.0.2 Logging formulas The API allows to create a *validation point* with a given channel and a name. The channel and name should identify the validation point uniquely. The channel (e.g. `smtrat.modules.vs`) can be used to turn on and off validation points (similarly to logging channels) while the name (e.g. `substitution->result`) further distinguishes validation points within a channel.

To initialize a validation point with channel and name and store its reference to a variable, use

```
SMTRAT_VALIDATION_INIT(channel, variable);
```

Hint: to put it in a static variable, use

```
SMTRAT_VALIDATION_INIT_STATIC(channel, variable);
```

To an initialized validation point stored in a variable, we can add a formula to be assumed to be satisfiable (consistent = true) or unsatisfiable (consistent = false). Each formula added to a validation point gets a unique index (given incrementally), which is also logged in the given channel with debug level.

```
SMTRAT_VALIDATION_ADD_TO(variable, name, formula, consistent);
```

To combine the two steps above, use:

```
SMTRAT_VALIDATION_ADD(channel, name, formula, consistent);
```

0.8.7.0.3 Command line usage By appending the command line parameter `--validation.export-smtlib`, the formulas are stored to an smtlib file (by default `validation.smt2`, can be customized using `--validation.smtlib-filename`).

Note that all channels of interest need to be activated explicitly with `--validation.channel channel1 --validation.channel channel2 ...`. Furthermore, `--validation.channel path.to` will activate all channels starting with `path.to`, i.e. `path.to.channel1, path.to.channel2` etc.

0.8.7.0.4 Segmentation faults Note that the formulas are only written to a file if smtrat terminates without an segmentation fault. If there is an assertion failing, set DEVELOPER=OFF in cmake.

0.8.8 Checkpoints

Checkpoints are useful for debugging a run of SMT-RAT, i.e. if an implementation of SMT-RAT behaves the same as some other implementation or some pseudocode.

To do so, we can insert checkpoints with a channel, a name, and a list of arguments of arbitrary type into the code. During a run, a sequence of checkpoints is produced which represent a run of the algorithm. We then can specify test cases which set up a reference run and then start the solver on an according input. SMT-RAT will then check during this run whether all checkpoints are hit in the correct order and will give output on that.

0.8.8.0.1 Enabling this feature You need to turn on the CMake option `SMTRAT_DEVOPTION_Checkpoints`.

0.8.8.0.2 Specyfing checkpoints Insert

```
SMTRAT_CHECKPOINT("channel_name", "checkpoint_name", parameter1, parameter2, ...);
```

into the code.

0.8.8.0.3 Setting up a reference run Create a test case in `src/test`. Include `#include <smtrat-common/smtrat-common.h>` and add checkpoints using

```
SMTRAT_ADD_CHECKPOINT("channel_name", "checkpoint_name", false, parameter1, parameter2, ...)
```

or

```
SMTRAT_ADD_CHECKPOINT("channel_name", "checkpoint_name", true, parameter1, parameter2, ...)
```

to assert that a checkpoint is reached.

Afterwards, run the respective SMT-RAT code.

You can clear all checkpoints of a channel using

```
SMTRAT_CLEAR_CHECKPOINT("channel_name");
```

to reset a channel, that is, removing all checkpoints and resetting the pointer.

0.8.9 Finding and Reporting Bugs

This page is meant as a guide for the case that you find a bug or any unexpected behaviour. We consider any of the following events a (potential) bug:

- SMT-RAT crashes.
- A library used through SMT-RAT crashes.
- SMT-RAT gives incorrect results.
- SMT-RAT does not terminate (for reasonably sized inputs).
- SMT-RAT does not provide a method or functionality that should be available according to this documentation.
- SMT-RAT does not provide a method or functionality that you consider crucial or trivial for some of the data-structures.
- Compiling SMT-RAT fails.
- Compiling your code using SMT-RAT fails and you are pretty sure that you use SMT-RAT according to this documentation.

In any of the above cases, make sure that:

- You have installed all necessary dependencies in the required versions.
- You work on something that is similar to a system listed as supported platform at [getting_started](#).
- You can (somewhat reliably) reproduce the error with a (somewhat) clean build of SMT-RAT. (i.e., you did not screw up the CMake flags, see [build_cmake](#) for more information)
- You compile either with `CMAKE_BUILD_TYPE=DEBUG` or `DEVELOPER=ON`. This will give additional warnings during compilation and enable assertions during runtime. This will slow down SMT-RAT significantly, but detect errors before an actual crash happens and give a meaningful error message in many cases.

If you are unable to solve issue yourself or you find the issue to be an actual bug in SMT-RAT, please do not hesitate to contact us. You can either contact us via email (if you suspect a configuration or usage issue on your side) or create a ticket in our bug tracker (if you suspect an error that is to be fixed by us). The bug tracker is available at <https://github.com/thc-rwth/smtrat/issues>.

When sending us a mail or creating a ticket, please provide us with:

- Your system specifications, including versions of compilers and libraries listed in the dependencies.
- The SMT-RAT version (release version or git commit id).
- A minimal working example.
- A description of what you would expect to happen.
- A description of what actually happens.

0.9 README

This is dead code.

The expressions were meant as an alternative to `carl::Formula`. Instead of having own theory constraints for each theory, here, everything is stored in a single tree structure. This would make theory combinations easier (think of a variable being interpreted both as uninterpreted and as arithmetic variable); furthermore, handling `ite` expression is easier: currently, we need to resolve `ite` expressions within the theory in the parser, leading to bad performance on some examples.

0.10 NewCoveringModule #and

Author: Philip Kroll (Philip.Kroll@rwth-aachen.de)

0.10.1 Introduction

New implementation of the CDCAC algorithm, also called the covering algorithm. The basic implementation is based on the paper [Deciding the Consistency of Non-Linear Real Arithmetic Constraints with a Conflict Driven Search Using Cylindrical Algebraic Coverings](#). In short : The algorithm is a variant of Cylindrical Algebraic Decomposition (CAD) adapted for satisfiability, where solution candidates (sample points) are constructed incrementally, either until a satisfying sample is found or sufficient samples have been sampled to conclude unsatisfiability. The choice of samples is guided by the input constraints and previous conflicts.

0.10.2 Usage

In this implementation as much code as possible from src/smtrat-cadcells. This also includes the projection operators implemented in src/smtrat-cadcells/operators and the representation heuristics implemented in src/smtrat-cadcells/representation. We also reuse the code from [src/smtrat-mcsat/variableordering/VariableOrdering.h](#) to calculate the used variable ordering. Change of the strategy to calculate the variable ordering, the used heuristics or the used projection operator, can be done by changing the respective settings in src/smtrat-modules/NewCoveringModule/NewCoveringSettings.h

0.10.3 Efficiency

The implementation also supports backtracking and incrementality, both of which are not covered in detail by the paper. The following cases are possible depending on what the previous result of the Covering Algorithm was :

- Previous result was SAT, i.e. a satisfying assignment was found and the cached coverings for all dimensions are partial
 - addConstraintSAT() is called with the new constraint and these are checked for satisfiability. The lowest level with an unsatisfied new constraints is returned. This also means that when all constraints SAT is concluded and no calculations are done.
 - removeConstraintSAT() is called with constraints that have to be removed from the cached partial coverings for all dimensions. This only makes the covering smaller, and the assignment is still satisfying.
- Previous result was UNSAT, i.e. the stored covering for level 0 is complete and thus no satisfying assignment could be found.
 - addConstraintUNSAT() is called with the new constraint. As the covering is unsatisfiable anyways these constraints are just added without further calculations.
 - removeConstraintUNSAT() is called with constraints that have to be removed from the cached complete coverings all dimensions.

0.11 Todo List

Global `smtrat::parser::QualifiedIdentifierParser::checkQualification` (`const Identifier &identifier, const carl::Sort &`) `const`

Check what can be checked here.

Global `smtrat::parser::Theories::defineFunction` (`const std::string &name, const std::vector< types::VariableType > &arguments, const carl::Sort &sort, const types::TermType &definition`)

check that definition matches the sort

0.13 Data Structure Index

0.13.1 Data Structures

Here are the data structures with brief descriptions:

<code>smrat::AbstractModuleFactory</code>	235
<code>smrat::parser::AbstractTheory</code>	
Base class for all theories	235
<code>smrat::cad::sample_compare::absvalue</code>	238
<code>smrat::analyzer::AnalysisSettings</code>	238
<code>smrat::analyzer::AnalyzerStatistics</code>	239
<code>smrat::AnnotatedBVTerm</code>	239
<code>smrat::cadcells::representation::approximation::ApxCriteria</code>	240
<code>smrat::cadcells::representation::approximation::ApxSettings</code>	241
<code>benchmax::slurm::ArchiveProperties</code>	
All properties needed to archive log files	243
<code>smrat::parser::ArithmeticTheory</code>	
Implements the theory of arithmetic, including LRA, LIA, NRA and NIA	244
<code>smrat::parser::types::ArithmeticTheory</code>	
Types of the arithmetic theory	246
<code>smrat::execution::Assertion</code>	247
<code>smrat::cad::preprocessor::AssignmentCollector</code>	247
<code>smrat::mcsat::arithmetic::AssignmentFinder</code>	248
<code>smrat::mcsat::smtaf::AssignmentFinder< Settings ></code>	249
<code>smrat::mcsat::arithmetic::AssignmentFinder_ctx</code>	249
<code>smrat::mcsat::arithmetic::AssignmentFinder_detail</code>	250
<code>smrat::mcsat::smtaf::AssignmentFinder_SMT</code>	251
<code>smrat::cadcells::datastructures::detail::AssignmentProperties</code>	251
<code>smrat::parser::Attribute</code>	
Represents an <code>Attribute</code>	252
<code>smrat::parser::AttributeParser</code>	253
<code>smrat::parser::AttributeValueParser</code>	254
<code>smrat::AxiomFactory</code>	254
<code>benchmax::Backend</code>	
Base class for all backends	255
<code>smrat::Backend< Settings ></code>	257
<code>smrat::BackendLink</code>	260
<code>smrat::BackendSynchronisation</code>	261
<code>smrat::Backtrackable< UnionFind ></code>	261
<code>smrat::cadcells::datastructures::BaseDerivation< Properties ></code>	
A <code>BaseDerivation</code> has a level and a set of properties of this level, and an underlying derivation representing the lower levels	263
<code>smrat::cad::BaseProjection< Settings ></code>	265
<code>smrat::cad::BaseSettings</code>	270
<code>smrat::expression::simplifier::BaseSimplifier</code>	271
<code>smrat::cad::Origin::BaseType</code>	273
<code>smrat::mcsat::onecell::BCApproximationSettings</code>	275
<code>smrat::mcsat::onecell::BCFilteredAllSelectiveSettings</code>	275
<code>smrat::mcsat::onecell::BCFilteredAllSettings</code>	276
<code>smrat::mcsat::onecell::BCFilteredBoundsSettings</code>	276
<code>smrat::mcsat::onecell::BCFilteredSamplesSettings</code>	276
<code>smrat::mcsat::onecell::BCFilteredSettings</code>	277
<code>smrat::mcsat::onecell::BCSettings</code>	277
<code>smrat::BEModule< Settings ></code>	278
<code>benchmax::BenchmarkResult</code>	
Results for a single benchmark run	305
<code>benchmax::BenchmarkSet</code>	
A set of benchmarks from some common base directory	307

benchmax::settings::BenchmarkSettings	308
Settings for benchmarks	308
smtrat::Bimap< Class, FirstKeyType, FirstKeyName, SecondKeyType, SecondKeyName >	
Container that stores expensive to construct objects and allows the fast lookup with respect to two independent keys within the objects	309
smtrat::expression::BinaryExpression	311
smtrat::datastructures::BinaryHeap< T >	312
smtrat::parser::BinaryParser	
Parses binaries: #b [01] +	312
smtrat::parser::BitvectorTheory	
Implements the theory of bitvectors	313
smtrat::parser::types::BitvectorTheory	
Types of the theory of bitvectors	316
smtrat::BlastedConstr	317
smtrat::BlastedPoly	318
smtrat::mcsat::Bookkeeping	
Represent the trail, i.e	319
smtrat::parser::BooleanEncodingTheory	
Implements the theory of bitvectors	320
Minisat::BoolOption	323
smtrat::BoolUEQRewriter	324
smtrat::cadcells::datastructures::Bound	
Bound type of a SymbolicInterval	325
smtrat::lra::Bound< T1, T2 >	
Stores a bound, which could be an upper " $\leq b$ " or a lower bound " $\geq b$ " for a bound value b	326
smtrat::mcsat::fm::Bound	335
smtrat::vb::Bound< T >	
Class for the bound of a variable	336
smtrat::Branching	
Stores all necessary information of an branch, which can be used to detect probable infinite loop of branchings	341
smtrat::BVAnnotation	342
smtrat::BVDirectEncoder	344
smtrat::BVModule< Settings >	344
smtrat::by_address_hasher< IterType >	
Hash an iterator by the pointed-to address	372
smtrat::cad::CAD< Settings >	372
smtrat::qe::cad::CAD< Settings >	375
smtrat::cad::CADConstraints< BT >	377
smtrat::cad::CADCore< CH >	381
smtrat::cad::CADCore< CoreHeuristic::BySample >	381
smtrat::cad::CADCore< CoreHeuristic::EnumerateAll >	381
smtrat::cad::CADCore< CoreHeuristic::Interleave >	382
smtrat::cad::CADCore< CoreHeuristic::PreferProjection >	382
smtrat::cad::CADCore< CoreHeuristic::PreferSampling >	383
smtrat::qe::cad::CADElimination	383
smtrat::cad::CADPreprocessor	383
smtrat::cad::CADPreprocessorSettings	385
smtrat::qe::cad::CADSettings	386
smtrat::CardinalityEncoder	387
smtrat::cadcells::representation::cell< H >	
Note: If connected(i) holds, then the indexed root ordering must contain an ordering between the interval bounds	388
smtrat::cadcells::representation::cell< CellHeuristic::BIGGEST_CELL >	388
smtrat::cadcells::representation::cell< CellHeuristic::BIGGEST_CELL_APPROXIMATION >	389
smtrat::cadcells::representation::cell< CellHeuristic::BIGGEST_CELL_EW >	389
smtrat::cadcells::representation::cell< CellHeuristic::CHAIN_EQ >	389
smtrat::cadcells::representation::cell< CellHeuristic::LOWEST_DEGREE_BARRIERS >	390

smrat::cadcells::representation::cell< CellHeuristic::LOWEST_DEGREE_BARRIERS_EQ >	390
smrat::cadcells::representation::cell< CellHeuristic::LOWEST_DEGREE_BARRIERS_EW >	390
smrat::cadcells::operators::properties::cell_connected	391
smrat::cadcells::representation::approximation::CellApproximator	391
smrat::cadcells::datastructures::CellRepresentation< P >	
Represents a cell	392
delta::Checker	
This class takes care of calling the actual solver	393
benchmax::slurm::ChunkedSubmitfileProperties	
All properties needed to create a submit file	394
Minisat::Clause	396
Minisat::ClauseAllocator	398
smrat::mcsat::ClauseChain	
An explanation is either a single clause or a chain of clauses, satisfying the following properties:	401
smrat::sat::detail::ClauseChecker	403
smrat::CMakeOptionPrinter	404
Minisat::CMap< T >	404
smrat::CNFerModule	405
smrat::CoCoAGBModule< Settings >	434
smrat::CollectBoolsInUEQs	461
smrat::CollectionWithOrigins< Element, Origin >	462
smrat::ICPModule< Settings >::comp	
Typedefs:	464
smrat::cadcells::datastructures::CompoundMax	
Represents the maximum function of the contained indexed root functions	464
smrat::cadcells::datastructures::CompoundMin	
Represents the minimum function of the contained indexed root functions	464
smrat::vs::Condition	465
benchmax::CondorBackend	
Backend for the HTCondor batch system	468
smrat::mcsat::fm::ConflictGenerator< Comparator >	470
smrat::cad::ConflictGraph	
Representation of a bipartite graph (C+S, E) of vertices C and S, representing the constraints and samples, respectively	470
smrat::parser::Theories::ConstantAdder	
Helper functor for <code>addConstants()</code> method	472
smrat::cad::CADConstraints< BT >::ConstraintComparator	473
smrat::cad::preprocessor::ConstraintUpdate	473
smrat::ConstrTree	474
delta::Consumer	
This class takes care of asynchronous execution of calls to the solver	475
smrat::LRAModule< Settings >::Context	
Stores a formula, being part of the received formula of this module, and the position of this formula in the passed formula	476
smrat::icp::ContractionCandidate	477
smrat::icp::contractionCandidateComp	482
smrat::icp::ContractionCandidateManager	482
smrat::parser::conversion::Converter< To >	484
smrat::parser::conversion::Converter< FormulaT >	484
smrat::parser::conversion::Converter< Poly >	485
smrat::parser::conversion::Converter< types::BVTerm >	485
benchmax::settings::CoreSettings	
Core settings	486
smrat::settings::CoreSettings	487
smrat::parser::CoreTheory	
Implements the core theory of the booleans	488
smrat::parser::types::CoreTheory	
Types of the core theory	490

<code>smrat::cadcells::representation::covering< H ></code>	491
<code>smrat::mcsat::arithmetic::Covering</code>	
Semantics: The space is divided into a number of intervals: (-oo,a][a,a](a,b][b,oo) A bit is set if the constraints refutes the corresponding interval	491
<code>smrat::cadcells::representation::covering< CoveringHeuristic::BIGGEST_CELL_COVERING ></code>	493
<code>smrat::cadcells::representation::covering< CoveringHeuristic::BIGGEST_CELL_COVERING_EW ></code>	493
<code>smrat::cadcells::representation::covering< CoveringHeuristic::CHAIN_COVERING ></code>	493
<code>smrat::cadcells::datastructures::CoveringDescription</code>	
Describes a covering of the real line by SymbolicIntervals (given an appropriate sample)	494
<code>smrat::cadcells::datastructures::CoveringRepresentation< P ></code>	
Represents a covering over a cell	494
<code>smrat::mcsat::onecellcad::recursive::CoverNullification</code>	496
<code>smrat::CSplitModule< Settings ></code>	496
<code>smrat::CubeLIAModule< Settings ></code>	523
<code>smrat::CurryModule< Settings ></code>	550
<code>smrat::CycleEnumerator< FHG, Collector ></code>	
This class encapsulates an algorithm for enumerating all cycles	576
<code>benchmax::Database</code>	
Dummy database that effectively disables storing to database. Set BENCHMAX_DATABASE to actually use a database	576
<code>benchmax::DBAL</code>	578
<code>smrat::parser::DecimalParser</code>	
Parses decimals: numeral.0*numeral	582
<code>Minisat::DeepEqual< K ></code>	582
<code>Minisat::DeepHash< K ></code>	582
<code>smrat::mcsat::fm::DefaultComparator</code>	
Does not order anything	582
<code>smrat::mcsat::fm::DefaultSettings</code>	583
<code>smrat::mcsat::smtaf::DefaultSettings</code>	583
<code>smrat::mcsat::vs::DefaultSettings</code>	583
<code>smrat::cad::projection_compare::degree</code>	584
<code>smrat::mcsat::onecellcad::recursive::DegreeAscending</code>	584
<code>smrat::analyzer::DegreeCollector</code>	584
<code>smrat::mcsat::onecellcad::recursive::DegreeDescending</code>	585
<code>smrat::cadcells::datastructures::DelineatedDerivation< Properties ></code>	
A DelineatedDerivation is a BaseDerivation with a <code>Delineation</code> and an underlying <code>SampledDerivation</code>	
585	
<code>smrat::cadcells::datastructures::Delineation</code>	
Represents the delineation of a set of polynomials (at a sample), that is	588
<code>smrat::cadcells::datastructures::DelineationInterval</code>	
An interval of a delineation	589
<code>smrat::mcsat::icp::Dependencies</code>	590
<code>smrat::cadcells::datastructures::DerivationRef< Properties ></code>	
A reference to a derivation, which is either	591
<code>smrat::mcsat::onecellcad::recursive::DontCoverNullification</code>	594
<code>smrat::cad::debug::DotSubgraph</code>	594
<code>Minisat::DoubleOption</code>	595
<code>Minisat::DoubleRange</code>	596
<code>smrat::expression::simplifier::DuplicateSimplifier</code>	597
<code>smrat::DynamicPriorityQueue< T, Compare ></code>	598
<code>smrat::dynarray< T ></code>	
Dynarray is similar to std::vector, but has only a reduced interface	600
<code>smrat::dynarray_allocator< T ></code>	604
<code>smrat::datastructures::DynHeap< KeyType, Compare, WeightType ></code>	604
<code>smrat::cad::ProjectionGlobalInformation::ECData</code>	606
<code>smrat::ForwardHyperGraph< VertexProperty, EdgeProperty, UniqueVertices >::Edge</code>	
Internal type of an edge	606

smrat::EQModule< Settings >::graph_info::edge_list_type< EdgeType >	608
Implements a list of edges	
smrat::ElementWithOrigins< Element, Origin >	610
smrat::EMModule< Settings >	611
smrat::subtropical::Encoding	639
smrat::EQGraph< VertexName >	640
smrat::EQModule< Settings >	642
smrat::EQPreprocessingModule< Settings >	668
Minisat::Equal< K >	696
delta::ErrorHandler	696
smrat::parser::ErrorHandler	696
smrat::ESModule< Settings >	697
smrat::uf_impl::estimator< IteratorType, IsRandomAccess >	
Distance estimation for a range delimited by iterators; if the given iterators are random access, returns the result of std::distance in the estimate_distance function	724
smrat::uf_impl::estimator< IteratorType, false >	725
smrat::ExactlyOneCommanderEncoder	725
smrat::execution::ExecutionState	727
smrat::Executor< Strategy >	730
smrat::mcsat::fm::Explanation< Settings >	736
smrat::mcsat::icp::Explanation	737
smrat::mcsat::nlsat::Explanation	737
smrat::mcsat::onecell::Explanation	738
smrat::mcsat::onecellcad::levelwise::Explanation< Setting1, Setting2 >	738
smrat::mcsat::onecellcad::recursive::Explanation< Setting1, Setting2 >	738
smrat::mcsat::vs::Explanation	739
smrat::mcsat::nlsat::ExplanationGenerator	739
smrat::mcsat::vs::ExplanationGenerator< Settings >	740
smrat::expression::Expression	740
smrat::expression::ExpressionContent	743
smrat::expression::ExpressionConverter	744
smrat::expression::ExpressionModifier	745
smrat::expression::ExpressionPool	747
smrat::parser::ParserState::ExpressionScope	748
smrat::expression::ExpressionTypeChecker< T >	749
smrat::expression::ExpressionVisitor	749
smrat::mcsat::FastParallelExplanation< Backends >	
This explanation executes all given explanation in parallel processes and waits for the fastest explanation, returning the fastest delivered explanation, terminating all other parallel processes	750
smrat::mcsat::variableordering::detail::FeatureCollector< Objects >	
This class manages features that are used to valuate variables on objects	751
smrat::fixedsize_allocator< T >	
An allocator meant to be used for containers that typically allocate single objects or nodes, such as sets, maps and linked lists	752
smrat::fixedsize_allocator< void >	
I do not know where an allocator for void would be of any use; but in order to mimic std::allocator (where this is explicitly mentioned) as good as possible, we do this for the void case	753
smrat::impl::fixedsize_allocator_freeLists	753
smrat::impl::fixedsize_allocator_Impl< T, SizeShift, LargeEnough, SmallEnough >	754
smrat::impl::fixedsize_allocator_Impl< T, SizeShift, true, true >	754
smrat::impl::fixedsize_allocator_size_helper< T, Size >	756
smrat::fixedsize_freelist< ChunkSizeShift >	
Implements a fixed-(at-compile-time)-size allocator based on a free list embedded in the space of currently unused objects	756
smrat::impl::fixedsize_freeLists< SizeCurrent, SizeMax, LowEnough >	
Publicly derive from all <code>fixedsize_freeList</code> types with chunk sizes between <code>SizeCurrent</code> and <code>SizeMax</code>	757
smrat::impl::fixedsize_freeLists< SizeCurrent, SizeMax, true >	757

smrat::parser::FixedWidthConstant< T >	757
Represents a constant of a fixed width	
smrat::parseformula::FormulaCollector	758
smrat::ICPModule< Settings >::formulaPtrComp	764
smrat::FormulaWithOrigins	
Stores a formula along with its origins	764
smrat::ForwardHyperGraph< VertexProperty, EdgeProperty, UniqueVertices >	
This class implements a forward hypergraph	767
smrat::FouMoModule< Settings >	
A module which applies the Fourier-Motzkin algorithm	770
smrat::qe::fm::FourierMotzkinQE	
Provides a simple implementation for Fourier Motzkin variable elimination for linear, existentially quantified constraints	796
smrat::FPPModule< Settings >	797
smrat::freelist< T >	
Implements a fixed-(at-runtime)-size allocator based on a free list embedded in the space of currently unused objects	823
smrat::mcsat::FullParallelExplanation< Backends >	
This explanation executes all given explanation parallel in multiple threads and waits until every single one has finished, returning the result of the first listed explanation	824
smrat::cad::FullSampleComparator< Iterator, Strategy >	825
smrat::cad::FullSampleComparator< Iterator, FullSampleCompareStrategy::T >	825
smrat::cad::FullSampleComparator< Iterator, FullSampleCompareStrategy::Type >	825
smrat::cad::FullSampleComparator< Iterator, FullSampleCompareStrategy::Value >	825
smrat::parser::FunctionInstantiator	825
smrat::GBModule< Settings >	
A solver module based on Groebner basis	826
smrat::GBModuleState< Settings >	
A class to save the current state of a GBModule	857
smrat::GBPPModule< Settings >	858
Minisat::Hash< K >	886
smrat::EQModule< Settings >::not_asserted_equality::hash	886
std::hash< const smrat::expression::ExpressionContent * >	886
std::hash< smrat::expression::BinaryExpression >	887
std::hash< smrat::expression::Expression >	887
std::hash< smrat::expression::ITEExpression >	887
std::hash< smrat::expression::NaryExpression >	888
std::hash< smrat::expression::QuantifierExpression >	888
std::hash< smrat::expression::UnaryExpression >	888
std::hash< smrat::lra::Variable< T1, T2 > >	
Implements std::hash for sort value	888
std::hash< smrat::vs::Substitution >	889
std::hash< std::vector< T > >	889
std::hash_combiner	889
Minisat::Heap< Comp >	890
smrat::parser::HexadecimalParser	
Parses hexadecimals: #x [0-9a-fA-F] +	892
smrat::icp::HistoryNode	893
smrat::ICEModule< Settings >	897
smrat::ICPModule< Settings >	923
smrat::icp::IcpVariable	950
smrat::icp::icpVariableComp	954
smrat::parser::Identifier	954
smrat::parser::IdentifierParser	955
smrat::cad::debug::IDSanitizer	956
smrat::mcsat::fm::IgnoreCoreSettings	956
smrat::IncWidthModule< Settings >	956
smrat::parser::IndexedFunctionInstantiator	984

smrat::cadcells::datastructures::IndexedRoot	Represents the i-th root of a multivariate polynomial at its main variable (given an appropriate sample)	984
smrat::cadcells::datastructures::IndexedRootOrdering	Describes an ordering of IndexedRoots	985
smrat::cadcells::datastructures::IndexedRootRelation	A relation between two roots	987
smrat::InequalitiesTable< Settings >	Datastructure for the GBModule	987
smrat::lra::Bound< T1, T2 >::Info	Stores some additional information for a bound	990
smrat::mcsat::InformationGetter	992
smrat::parser::Instantiator< V, T >	993
smrat::parser::InstructionHandler	995
Minisat::Int64Range	1001
smrat::IntBlastModule< Settings >	1001
smrat::IntEqModule< Settings >	A module which checks whether the equations contained in the received (linear integer) formula have a solution	1027
smrat::mcsat::icp::IntervalPropagation	1054
Minisat::IntOption	1054
Minisat::IntRange	1056
smrat::is_sample_outside< S >	1056
smrat::is_sample_outside< IsSampleOutsideAlgorithm::DEFAULT >	1057
smrat::is_variant< T >	States whether a given type is a boost::variant	1057
smrat::expression::ITEExpression	1057
benchmax::RandomizationAdaptor< T >::iterator	1058
smrat::ModuleInput::IteratorCompare	1059
benchmax::Jobs	Represents a set of jobs, constructed as the cartesian product of a set of tools and a set of benchmarks	1059
smrat::JunctorMerger	1060
smrat::parser::KeywordParser	Parses keywords::simple_symbol	1061
Minisat::Ibool	1061
smrat::mcsat::onecell::LDBFilteredAllSelectiveSettings	1062
smrat::mcsat::onecell::LDBSettings	1063
smrat::lra::Tableau< Settings, T1, T2 >::LearnedBound	1063
smrat::Module::Lemma	1065
Minisat::LessThan_default< T >	1066
smrat::cad::projection_compare::level	1066
smrat::cad::sample_compare::level	1066
smrat::cad::ProjectionLevelInformation::LevelInfo	1066
smrat::mcsat::onecellcad::levelwise::LevelwiseCAD	1068
smrat::LevelWiseInformation< Settings >	1070
smrat::cad::LiftingTree< Settings >	1072
smrat::resource::Limiter	1075
smrat::ICPModule< Settings >::linearVariable	1076
smrat::mcsat::ClauseChain::Link	1076
Minisat::Lit	1077
benchmax::LocalBackend	This backend simply runs files sequentially on the local machine	1078
smrat::LOG	1080
smrat::parser::LogicParser	1081
smrat::LongFormulaEncoder	1081
smrat::LRAModule< Settings >	A module which performs the Simplex method on the linear part of it's received formula	1082

smrat::LVEModule< Settings >	1114
smrat::Manager	
Base class for solvers	1140
Minisat::Map< K, D, H, E >	1148
benchmax::MathSAT	
Tool wrapper for MathSAT for SMT-LIB	1150
smrat::mcsat::fm::MaxSizeComparator	
This heuristic chooses the explanation excluding the largest interval	1153
smrat::MaxSMT< Solver, Strategy >	1153
smrat::maxsmt::MaxSMTBackend< Solver, Strategy >	1154
smrat::maxsmt::MaxSMTBackend< Solver, MaxSMTStrategy::FU_MALIK_INCREMENTAL >	1154
smrat::maxsmt::MaxSMTBackend< Solver, MaxSMTStrategy::LINEAR_SEARCH >	1155
smrat::maxsmt::MaxSMTBackend< Solver, MaxSMTStrategy::MSU3 >	1155
smrat::MCBModule< Settings >	1155
smrat::mcsat::MCSATBackend< Settings >	1182
smrat::mcsat::MCSATMixin< Settings >	1184
smrat::expression::simplifier::MergeSimplifier	1190
benchmax::Minisat	
Tool wrapper for a Minisat solver	1191
benchmax::Minisatp	
Tool wrapper for the Minisatp solver for pseudo-Boolean problems	1194
smrat::mcsat::fm::MinSizeComparator	
This heuristic chooses the explanation excluding the smallest interval	1196
smrat::mcsat::fm::MinVarCountComparator	
This heuristic tries to minimize the number of variables occuring in the explanation	1197
smrat::cad::MISGeneration< heuristic >	1197
smrat::MixedSignEncoder	1198
smrat::cad::ModelBasedProjection< incrementality, backtracking, Settings >	1199
smrat::cad::ModelBasedProjection< Incrementality::NONE, Backtracking::ORDERED, Settings >	
This class implements a projection that supports no incrementality and expects backtracking to be in order	1205
smrat::Module	
A base class for all kind of theory solving methods	1211
smrat::ModuleFactory< Module >	1238
smrat::ModuleInput	
The input formula a module has to consider for it's satisfiability check	1238
smrat::settings::ModuleSettings	1244
smrat::Module::ModuleStatistics	1245
smrat::ModuleWrapper< M >	1246
smrat::subtropical::Moment	
Represents the normal vector component and the sign variable assigned to a variable in an original constraint	1247
smrat::MonomialMappingByVariablePool	1247
smrat::expression::NaryExpression	1248
smrat::expression::simplifier::NegationSimplifier	1249
smrat::NewCADModule< Settings >	1251
smrat::NewCoveringModule< Settings >	1277
smrat::NNFPreparation	1305
smrat::NNFRewriter	1305
benchmax::ssh::Node	
Specification of a computation node for the SSH backend	1307
delta::Node	
This class represents a node in a SMTLIB file	1308
delta::NodePrinter< pretty >	1311
smrat::mcsat::onecellcad::recursive::NoHeuristic	1312
smrat::NRAILModule< Settings >	1312
smrat::parser::NumeralParser	
Parses numerals: (0 [1-9] [0-9]*)	1339

smrat::ira::Numeric	1339
smrat::execution::Objective	1346
Minisat::OccLists< Idx, Vec, Deleted >	1346
smrat::mcsat::onecellcad::OneCellCAD	1347
benchmax::settings::OperationSettings Operation settings	1349
smrat::Optimization< Solver >	1350
Minisat::Option	1351
Minisat::Option::OptionLt	1352
smrat::datastructures::OrderPair< T1, T2, reversed >	1353
smrat::datastructures::OrderPair< T1, T2, true >	1353
smrat::cad::Origin This class represents one or more origins of some object	1354
smrat::cad::preprocessor::Origins	1356
smrat::OrPathShortener A rewriter that checks every (X)OR that only contains ANDs and UEQs as children for equalities that hold for every alternative, and adds such equalities explicitly	1357
Minisat::OutOfMemoryException	1358
smrat::parser::OutputWrapper	1358
Minisat::Map< K, D, H, E >::Pair	1358
smrat::pairhash< F, S, FirstHasher, SecondHasher > Note that this may NOT be a specialization of std::hash for std::pair, this is not allowed by the standard as it does not involve a user-defined type	1359
smrat::mcsat::ParallelExplanation< Backends >	1359
delta::Parser This class parses a whole smtlib file into a hierarchy of Node objects	1360
smrat::parser::ParserSettings	1361
smrat::parser::ParserState	1361
smrat::PBGaussModule< Settings >	1364
smrat::PBPPModule< Settings >	1391
smrat::PersistentUnionFind	1418
smrat::PFEModule< Settings >	1420
smrat::PModule	1446
smrat::cadcells::operators::properties::poly_additional_root_outside	1472
smrat::cadcells::operators::properties::poly_irreducible_semi_sgn_inv	1473
smrat::cadcells::operators::properties::poly_irreducible_sgn_inv	1474
smrat::cadcells::operators::properties::poly_ord_inv	1474
smrat::cadcells::operators::properties::poly_ord_inv_base	1475
smrat::cadcells::operators::properties::poly_pdel	1476
smrat::cadcells::operators::properties::poly_semi_sgn_inv	1476
smrat::cadcells::operators::properties::poly_sgn_inv	1477
smrat::cadcells::representation::util::PolyDelineation	1478
smrat::cadcells::representation::util::PolyDelineations	1478
smrat::cad::ProjectionPolynomialInformation::PolyInfo	1479
smrat::cad::PolynomialComparator< PolynomialGetter >	1479
smrat::cad::PolynomialLiftingQueue< PolynomialGetter >	1479
smrat::cadcells::datastructures::PolyPool A pool for polynomials	1481
smrat::cadcells::datastructures::detail::PolyProperties	1482
smrat::cadcells::datastructures::PolyRef Refers to a polynomial	1483
smrat::PolyTree	1483
smrat::PolyTreeContent	1484
smrat::PolyTreePool	1485
smrat::cad::Preprocessor	1486
smrat::cad::PreprocessorSettings	1487
benchmax::settings::PresetSettings	1488
smrat::PriorityQueue< T, Compare >	1488

<code>delta::Producer</code>	This class iteratively applies the operators to a smtlib file until no further simplifications can be performed	1490
<code>delta::ProgressBar</code>	This class provides a simple way to show progress bars on the command line	1491
<code>smtrat::cad::Projection< incrementality, backtracking, Settings ></code>		1492
<code>smtrat::qe::cad::Projection< Settings ></code>		1497
<code>smtrat::cad::Projection< Incrementality::FULL, Backtracking::HIDE, Settings ></code>		1503
<code>smtrat::cad::Projection< Incrementality::FULL, BT, Settings ></code>		1509
<code>smtrat::cad::Projection< Incrementality::NONE, Backtracking::ORDERED, Settings ></code>		1509
<code>smtrat::cad::Projection< Incrementality::NONE, Backtracking::UNORDERED, Settings ></code>	This class implements a projection that supports no incrementality and expects backtracking to be in order	1514
<code>smtrat::cad::Projection< Incrementality::NONE, Backtracking::UNORDERED, Settings ></code>	This class implements a projection that supports no incrementality and allows backtracking to be out of order	1520
<code>smtrat::cad::Projection< Incrementality::SIMPLE, BT, Settings ></code>		1526
<code>smtrat::cad::projection_compare::ProjectionComparator< Strategy ></code>		1531
<code>smtrat::cad::projection_compare::ProjectionComparator< ProjectionCompareStrategy::D ></code>		1531
<code>smtrat::cad::projection_compare::ProjectionComparator< ProjectionCompareStrategy::LD ></code>		1532
<code>smtrat::cad::projection_compare::ProjectionComparator< ProjectionCompareStrategy::ID ></code>		1532
<code>smtrat::cad::projection_compare::ProjectionComparator< ProjectionCompareStrategy::PD ></code>		1532
<code>smtrat::cad::projection_compare::ProjectionComparator< ProjectionCompareStrategy::SD ></code>		1533
<code>smtrat::cad::projection_compare::ProjectionComparator_impl< Args ></code>		1533
<code>smtrat::cad::ProjectionGlobalInformation</code>		1533
<code>smtrat::cad::ProjectionInformation</code>		1535
<code>smtrat::cad::ProjectionLevelInformation</code>		1537
<code>smtrat::cad::ProjectionOperator</code>		1537
<code>smtrat::cad::ProjectionPolynomialInformation</code>		1538
<code>smtrat::cadcells::datastructures::Projections</code>	Encapsulates all computations on polynomials	1539
<code>smtrat::cadcells::operators::mccallum_filtered_impl::PropertiesSet</code>		1542
<code>smtrat::cadcells::operators::PropertiesSet< Op ></code>		1542
<code>smtrat::cadcells::operators::PropertiesSet< op::mccallum ></code>		1542
<code>smtrat::cadcells::datastructures::PropertiesT< Ts ></code>	Set of properties	1542
<code>smtrat::cadcells::datastructures::PropertiesT< T, Ts... ></code>		1543
<code>smtrat::cadcells::datastructures::PropertiesTContent< T, is_flag ></code>		1543
<code>smtrat::cadcells::datastructures::PropertiesTContent< T, false ></code>		1543
<code>smtrat::cadcells::datastructures::PropertiesTContent< T, true ></code>		1543
<code>smtrat::cadcells::datastructures::property_hash< T ></code>		1544
<code>smtrat::PseudoBoolEncoder</code>	Base class for a PseudoBoolean Encoder	1544
<code>smtrat::PseudoBoolNormalizer</code>		1545
<code>smtrat::parser::QEParser</code>		1546
<code>smtrat::parser::QualifiedIdentifierParser</code>		1547
<code>smtrat::expression::QuantifierExpression</code>		1547
<code>smtrat::parser::QuantifierParser</code>		1548
<code>Minisat::Queue< T ></code>		1548
<code>smtrat::mcsat::icp::QueueEntry</code>		1549
<code>benchmax::RandomizationAdaptor< T ></code>	Provides iteration over a given std::vector in a pseudo-randomized order	1550
<code>smtrat::RationalCapsule</code>		1551
<code>smtrat::parser::RationalPolicies</code>	Specialization of qi::real_policies for a Rational	1552
<code>smtrat::mcsat::onecellcad::RealAlgebraicPoint< Number ></code>	Represent a multidimensional point whose components are algebraic reals	1552
<code>smtrat::fixedsize_allocator< T >::rebind< U ></code>		1554
<code>smtrat::mcsat::onecellcad::recursive::RecursiveCAD</code>		1554

smrat::cad::projection::Reducta< Poly >	
Construct the set of reducta of the given polynomial	1558
Minisat::RegionAllocator< T >	1559
smrat::NNFRewriter::remove_xor_first_arg	1561
smrat::ReplaceVariablesRewriter	1561
delta::ErrorHandler::result< typename >	1563
smrat::parser::ErrorHandler::result< typename >	1563
smrat::cad::preprocessor::ResultantRule	1563
benchmax::Results	
Stores results for for whole benchmax run	1564
smrat::RNSEncoder	1565
smrat::cadcells::operators::properties::root_ordering_holds	1566
smrat::cadcells::operators::properties::root_well_def	1567
smrat::cadcells::datastructures::RootFunction	1568
smrat::mcsat::arithmetic::RootIndexer< RANT >	1570
smrat::cad::Sample	1570
smrat::cad::sample_compare::SampleComparator< Iterator, Strategy >	1573
smrat::cad::sample_compare::SampleComparator< Iterator, SampleCompareStrategy::LS >	1573
smrat::cad::sample_compare::SampleComparator< Iterator, SampleCompareStrategy::LT >	1573
smrat::cad::sample_compare::SampleComparator< Iterator, SampleCompareStrategy::LTA >	1573
smrat::cad::sample_compare::SampleComparator< Iterator, SampleCompareStrategy::LTS >	1574
smrat::cad::sample_compare::SampleComparator< Iterator, SampleCompareStrategy::LTSA >	1574
smrat::cad::sample_compare::SampleComparator< Iterator, SampleCompareStrategy::S >	1574
smrat::cad::sample_compare::SampleComparator< Iterator, SampleCompareStrategy::T >	1575
smrat::cad::sample_compare::SampleComparator< Iterator, SampleCompareStrategy::TLSA >	1575
smrat::cad::sample_compare::SampleComparator< Iterator, SampleCompareStrategy::TS >	1575
smrat::cad::sample_compare::SampleComparator< Iterator, SampleCompareStrategy::TSA >	1576
smrat::cad::sample_compare::SampleComparator< Iterator, SampleCompareStrategy::Type >	1576
smrat::cad::sample_compare::SampleComparator< Iterator, SampleCompareStrategy::Value >	1576
smrat::cad::sample_compare::SampleComparatorImpl< It, Args >	1577
smrat::cadcells::datastructures::SampledDerivation< Properties >	
A SampledDerivation is a DelineatedDerivation with a sample and an DelineationInterval w.r.t	1577
smrat::SampledDerivationRefCompare	1580
smrat::cad::SampleIteratorQueue< Iterator, Comparator >	1580
smrat::sampling< S >	1582
smrat::sampling< SamplingAlgorithm::LOWER_UPPER_BETWEEN_SAMPLING >	1582
smrat::SATModule< Settings >	
Implements a module performing DPLL style SAT checking	1582
smrat::parser::ScriptParser< Callee >	1614
smrat::parser::ParserState::ScriptScope	1616
smrat::mcsat::onecellcad::Section	
Represent a cell's (closed-interval-boundary) component along th k-th axis	1617
smrat::onecellcad::recursive::Section	
Represent a cell's closed-interval-boundary object along one single axis by an irreducible, multi-variate polynomial of level k	1617
smrat::mcsat::onecellcad::levelwise::SectionHeuristic1	1618
smrat::mcsat::onecellcad::levelwise::SectionHeuristic2	1618
smrat::mcsat::onecellcad::levelwise::SectionHeuristic3	1618
smrat::mcsat::onecellcad::Sector	
Represent a cell's open-interval boundary object along one single axis by two irreducible, multi-variate polynomials of level k	1619
smrat::onecellcad::recursive::Sector	
Represent a cell's open-interval boundary object along one single axis by two irreducible, multi-variate polynomials of level k	1619
smrat::mcsat::onecellcad::levelwise::SectorHeuristic1	1620
smrat::mcsat::onecellcad::levelwise::SectorHeuristic2	1620
smrat::mcsat::onecellcad::levelwise::SectorHeuristic3	1621

smrat::subtropical::Separator	
Represents the class of all original constraints with the same left hand side after a normalization	1621
smrat::mcsat::SequentialAssignment< Backends >
smrat::mcsat::SequentialExplanation< Backends >
benchmax::settings::Settings	
Generic class to manage runtime settings
delta::Settings	
This class loads and checks the command line options with help of boost::program_<options>
smrat::settings::Settings
smrat::SettingsComponents
benchmax::SettingsParser	
Generic class to manage settings parsing using boost::program_options
smrat::SettingsParser
smrat::CNFerModule::SettingsType
smrat::parser::SExpressionParser
smrat::parser::SExpressionSequence< T >
smrat::ShortFormulaEncoder
benchmax::simple_parser
smrat::parser::Theories::SimpleSortAdder	
Helper functor for addSimpleSorts() method
smrat::parser::SimpleSymbolParser	
Parses symbols: simple_symbol quoted_symbol where
smrat::expression::simplifier::Simplifier
smrat::expression::simplifier::SimplifierChainCaller< chainID >
smrat::expression::simplifier::SimplifierChainCaller< 0 >
smrat::expression::simplifier::SingletonSimplifier
smrat::cad::sample_compare::size
delta::Skipper	
This class is a boost::spirit::qi grammar that matches whitespaces and smtlib comments
smrat::parser::Skipper
benchmax::SlurmBackend	
Backend for the Slurm workload manager
benchmax::settings::SlurmBackendSettings	
Settings for the Slurm backend
smrat::parser::SMTLIBParser
benchmax::SMTRAT	
Tool wrapper for SMT-RAT for SMT-LIB
benchmax::SMTRAT_Analyzer	
Tool wrapper for SMT-RAT for SMT-LIB
benchmax::SMTRAT_OPB	
Adapts the SMTRAT solver for OPB files
smrat::execution::SoftAssertion
smrat::settings::SolverSettings
smrat::parser::SortedVariableParser
smrat::parser::SortParser
smrat::parser::SpecConstantParser
smrat::SplitSOSModule< Settings >
benchmax::SSHBackend
benchmax::settings::SSHBackendSettings	
Settings for SSH backend
benchmax::ssh::SSHConnection	
A wrapper class that manages a single SSH connection as specified in a Node object (with all its channels)
smrat::vs::State
smrat::StaticUnionFind
smrat::statistics::StatisticsSettings

smtrat::StrategyGraph	1711
delta::String	
This class can be used to create <code>std::string</code> objects using streaming operators	1712
Minisat::StringOption	1713
smtrat::parser::StringParser	
Parses strings: ".+" with escape sequences "\\" and "\\\\"	1714
smtrat::STropModule< Settings >	1715
benchmax::slurm::SubmitfileProperties	
All properties needed to create a submit file	1742
smtrat::vs::Substitution	1743
smtrat::vs::substitutionPointerEqual	1747
smtrat::vs::substitutionPointerHash	1747
smtrat::cadcells::datastructures::SymbolicInterval	
A symbolic interval whose bounds are defined by indexed root expressions	1748
delta::SymbolParser	
This class is a <code>boost::spirit::qi</code> grammar that matches all kinds of smtlib symbols, numbers etc	1749
smtrat::parser::SymbolParser	1750
smtrat::SymmetryModule< Settings >	1750
smtrat::lra::Tableau< Settings, T1, T2 >	1778
smtrat::lra::TableauEntry< T1, T2 >	1796
smtrat::cadcells::datastructures::TaggedIndexedRoot	1799
smtrat::mcsat::onecellcad::TagPoly	
Tagged Polynomials	1799
smtrat::Task	1800
delta::TempFilenameGenerator	
This class generates and reuses temporary filenames with a common prefix	1801
smtrat::parser::TermParser	1802
smtrat::mcsat::vs::helper::TestCandidate	1803
smtrat::parser::Theories	
Combines all implemented theories and provides a single interface to interact with all theories at once	1804
smtrat::parser::TheoryError	1807
smtrat::mcsat::TheoryLevel	1807
smtrat::Module::TheoryPropagation	1808
smtrat::TheoryVarSchedulerStatic< vot >	
Schedules theory variables statically	1809
smtrat::ThreadPool	1813
smtrat::cad::debug::TikzBasePrinter	1813
smtrat::cad::debug::TikzDAGPrinter	1815
smtrat::cad::debug::TikzHistoryPrinter	1816
smtrat::cad::debug::TikzTreePrinter	1817
benchmax::Tool	
Base class for any tool	1819
benchmax::settings::ToolSettings	
Tool-related settings	1822
smtrat::TotalizerEncoder	
TotalizerEncoder implements the Totalizer encoding as described in "Incremental Cardinality Constraints for MaxSAT" by Martins et al https://doi.org/10.1007/978-3-319-10428-7_39	1823
smtrat::TotalizerTree	1825
smtrat::cad::projection_compare::type	1826
smtrat::cad::sample_compare::type	1826
smtrat::uf_impl::uf_data_wrapper< T, compression >	
Wrapper around data entry and <code>uf_rank_and_class</code> ; this class contains a value of type T and both rank and class of an entry in the UF datastructure	1826
smtrat::uf_impl::uf_data_wrapper< void, compression >	
Special case of the <code>uf_data_wrapper</code> in case the data type is void	1827

<code>smtrat::uf_impl::uf_rank_and_class< compression ></code>	Wrapper class that contains the rank and parent class of some entry of the UF datastructure	1828
<code>smtrat::uf_impl::uf_rank_and_class< true ></code>	Compressed implementation of <code>uf_rank_and_class</code>	1829
<code>smtrat::UFCEgarModule< Settings ></code>		1830
<code>smtrat::UFRewriter</code>		1856
<code>smtrat::expression::UnaryExpression</code>		1857
<code>smtrat::cad::debug::UnifiedData</code>		1857
<code>smtrat::parser::types::UninterpretedTheory</code>	Types of the theory of equalities and uninterpreted functions	1858
<code>smtrat::parser::UninterpretedTheory</code>	Implements the theory of equalities and uninterpreted functions	1859
<code>smtrat::union_find< T, no_compression, MaxTracebackLength ></code>	Implements a union-find datastructure, a datastructure containing an array of entries	1862
<code>smtrat::UnionFindInterface< T, Implementation ></code>		1866
<code>smtrat::UnionFindModule< Settings ></code>		1867
<code>smtrat::SATModule< Settings >::UnorderedClauseLookup::UnorderedClauseHasher</code>		1894
<code>smtrat::UnsatCore< Solver, Strategy ></code>		1894
<code>smtrat::unsatcore::UnsatCoreBackend< Solver, Strategy ></code>		1895
<code>smtrat::unsatcore::UnsatCoreBackend< Solver, UnsatCoreStrategy::ModelExclusion ></code>	Implements an easy strategy to obtain an unsatisfiable core	1895
<code>smtrat::vs::unsignedTripleCmp</code>		1896
<code>smtrat::parser::UserFunctionInstantiator</code>		1897
<code>smtrat::validation::ValidationCollector</code>		1898
<code>smtrat::validation::ValidationPoint</code>		1898
<code>smtrat::validation::ValidationPrinter< SOF ></code>		1900
<code>smtrat::validation::ValidationSettings</code>		1900
<code>smtrat::lra::Value< T ></code>		1900
<code>smtrat::lra::Variable< T1, T2 ></code>		1908
<code>smtrat::vb::Variable< T ></code>	Class for a variable	1918
<code>smtrat::vb::VariableBounds< T ></code>	Class to manage the bounds of a variable	1921
<code>smtrat::VariableCapsule</code>		1928
<code>smtrat::mcsat::variableordering::VariableIDs</code>		1929
<code>smtrat::VariableRewriteRule</code>		1929
<code>smtrat::variant_hash_visitor</code>		1930
<code>smtrat::parser::conversion::VariantConverter< Res ></code>	Converts variants to some type using the <code>Converter</code> class	1931
<code>smtrat::VariantMap< Key, Value ></code>	This class is a specialization of <code>std::map</code> where the keys are of arbitrary type and the values are of type <code>boost::variant</code>	1932
<code>smtrat::parser::conversion::VariantVariantConverter< Res ></code>	Converts variants to another variant type not using the <code>Converter</code> class	1934
<code>smtrat::VarSchedulerBase</code>	Base class for variable schedulers	1935
<code>smtrat::VarSchedulerFixedRandom</code>		1938
<code>smtrat::VarSchedulerMcsatActivityPreferTheory< vot ></code>	Activity-based scheduler preferring initially theory variables	1941
<code>smtrat::VarSchedulerMcsatBase</code>	Base class for all MCSAT variable scheduler	1945
<code>smtrat::VarSchedulerMcsatBooleanFirst< vot ></code>	Variable scheduling that all decides Boolean variables first before deciding any theory variable	1948
<code>smtrat::VarSchedulerMcsatTheoryFirst< TheoryScheduler ></code>	Variable scheduling that all decides theory variables first before deciding any Boolean variable	1952
<code>smtrat::VarSchedulerMcsatUnivariateClausesOnly< TheoryScheduler, respectActivities ></code>	Decides only Constraints occurring in clauses that are univariate in the current theory variable while the theory ordering is static	1955

<code>smtrat::VarSchedulerMcsatUnivariateConstraintsOnly< lookahead, vot ></code>	
Decides only Constraints univariate in the current theory variable while the theory ordering is static	1959
<code>smtrat::VarSchedulerMinisat</code>	
Minisat's activity-based variable scheduling	1963
<code>smtrat::VarSchedulerRandom</code>	
Random scheduler	1966
<code>smtrat::VarSchedulerSMTTheoryGuided< theory_conflict_guided_decision_heuristic ></code>	
Scheduler for SMT, implementing theory guided heuristics	1969
<code>Minisat::vec< T ></code>	
.	1972
<code>smtrat::parser::conversion::VectorVariantConverter< Res ></code>	
Converts a vector of variants to a vector of some type using the Converter class	1975
<code>smtrat::subtropical::Vertex</code>	
Represents a term of an original constraint and assigns him a rating variable if a weak separator is searched	1976
<code>smtrat::VSMModule< Settings ></code>	
.	1977
<code>Minisat::Watcher</code>	
[Minisat related code]	2005
<code>smtrat::ICPModule< Settings >::weights</code>	
.	2006
<code>benchmax::XMLWriter</code>	
Writes results to a xml file	2006
<code>benchmax::Z3</code>	
Tool wrapper for <code>Z3</code> for SMT-LIB	2007

0.14 Namespace Documentation

0.14.1 benchmax Namespace Reference

Namespaces

- `settings`
- `slurm`
- `ssh`

Data Structures

- class `Backend`

Base class for all backends.
- class `CondorBackend`

Backend for the HTCondor batch system.
- class `RandomizationAdaptor`

Provides iteration over a given std::vector in a pseudo-randomized order.
- class `Jobs`

Represents a set of jobs, constructed as the cartesian product of a set of tools and a set of benchmarks.
- class `LocalBackend`

This backend simply runs files sequentially on the local machine.
- class `SlurmBackend`

Backend for the Slurm workload manager.
- class `SSHBackend`
- class `BenchmarkSet`

A set of benchmarks from some common base directory.
- struct `BenchmarkResult`

Results for a single benchmark run.
- class `Database`

Dummy database that effectively disables storing to database. Set BENCHMAX_DATABASE to actually use a database.

- class [DBAL](#)
- class [Results](#)
Stores results for for whole benchmax run.
- class [XMLWriter](#)
Writes results to a xml file.
- class [SettingsParser](#)
Generic class to manage settings parsing using boost::program_options.
- class [MathSAT](#)
Tool wrapper for [MathSAT](#) for SMT-LIB.
- class [Minisat](#)
Tool wrapper for a [Minisat](#) solver.
- class [Minisatp](#)
Tool wrapper for the [Minisatp](#) solver for pseudo-Boolean problems.
- class [simple_parser](#)
- class [SMTRAT](#)
Tool wrapper for SMT-RAT for SMT-LIB.
- class [SMTRAT_Analyzer](#)
Tool wrapper for SMT-RAT for SMT-LIB.
- class [SMTRAT_OPB](#)
Adapts the [SMTRAT](#) solver for OPB files.
- class [Tool](#)
Base class for any tool.
- class [Z3](#)
Tool wrapper for [Z3](#) for SMT-LIB.

TypeDefs

- using [Job](#) = std::pair< const [Tool](#) *, std::filesystem::path >
TypeDef for a job, consisting of a tool and an input file.
- using [ToolPtr](#) = std::unique_ptr< [Tool](#) >
A std::unique_ptr to a [Tool](#).
- using [Tools](#) = std::vector< [ToolPtr](#) >
A vector of ToolPtr.

Functions

- template<typename Backend >
void [execute_backend](#) (const std::string &name, const [Jobs](#) &jobs)
- void [run_backend](#) (const std::string &backend, const [Jobs](#) &jobs)
Runs a given backend on a list of tools and benchmarks.
- const auto & [settings_slurm](#) ()
Return the Slurm settings.
- const auto & [settings_ssh](#) ()
Return the SSH settings.
- [BenchmarkSet](#) [loadBenchmarks](#) ()
Loads benchmark files from directory specified in settings.
- const auto & [settings_benchmarks](#) ()
Return the benchmark settings.
- void [logging_configure](#) ()
Configure default logging for benchmax.
- void [logging_quiet](#) ()
Configure quiet logging for benchmax.

- void `logging_verbose ()`
Configure verbose logging for benchmax.
- std::ostream & `operator<< (std::ostream &os, const BenchmarkResult &results)`
Streaming operator for `BenchmarkResult`.
- const auto & `settings_preset ()`
Return the Slurm settings.
- template<typename T>
const auto & `settings_get (const std::string &name)`
Helper function to obtain settings by name and type.
- const auto & `settings_core ()`
Retrieved core settings.
- const auto & `settings_operation ()`
Retrieved operation settings.
- bool `is_system_lib (std::string path)`
- std::ostream & `operator<< (std::ostream &os, const Tool &tool)`
Streaming operator for a generic tool.
- template<typename T>
void `createTools (const std::vector< std::filesystem::path > &arguments, Tools &tools)`
Create tools of a given type `T` from a list of binaries and store them in `tools`.
- `Tools loadTools ()`
Load all tools from the tool settings.
- const auto & `settings_tools ()`
Returns the tool settings.
- int `call_program (const std::string &commandline, std::string &stdout, bool print_to_stdout=false)`
Runs an external program from some command line and records the output to `stdout`.
- std::filesystem::path `common_prefix (const std::filesystem::path &p1, const std::filesystem::path &p2)`
Computes the common prefix of two paths.
- std::filesystem::path `common_prefix (const std::vector< std::filesystem::path > &s, bool skip_last=true)`
Computes the common prefix of a list of paths.
- std::filesystem::path `common_prefix (const std::initializer_list< std::vector< std::filesystem::path > >&s, bool skip_last=true)`
Computes the common prefix of multiple lists of paths.
- std::filesystem::path `remove_prefix (const std::filesystem::path &s, const std::filesystem::path &prefix)`
Remove a prefix from a path.
- bool `is_extension (const std::filesystem::path &path, const std::string &extension)`
Checks whether the extension of the filename is as specified.
- std::size_t `parse_peak_memory (const std::string &output)`

0.14.1.1 Typedef Documentation

0.14.1.1.1 Job using `benchmax::Job = decltype (std::pair<const Tool*, std::filesystem::path>)`
Typedef for a job, consisting of a tool and an input file.

0.14.1.1.2 ToolPtr using `benchmax::ToolPtr = std::unique_ptr<Tool>`
A `std::unique_ptr` to a `Tool`.

0.14.1.1.3 Tools using `benchmax::Tools = std::vector<ToolPtr>`
A vector of `ToolPtr`.

0.14.1.2 Function Documentation

```
0.14.1.2.1 call_program() int benchmax::call_program (
    const std::string & commandline,
    std::string & stdout,
    bool print_to_stdout = false ) [inline]
```

Runs an external program from some command line and records the output to stdout.
Prints the program output and records it at the same time if *print_to_stdout* is set to true.

Parameters

<i>commandline</i>	Program to execute.
<i>stdout</i>	Standard output.
<i>print_to_stdout</i>	Also print if true.

Returns

Exit code of the program.

```
0.14.1.2.2 common_prefix() [1/3] std::filesystem::path benchmax::common_prefix (
    const std::filesystem::path & p1,
    const std::filesystem::path & p2 ) [inline]
```

Computes the common prefix of two paths.

```
0.14.1.2.3 common_prefix() [2/3] std::filesystem::path benchmax::common_prefix (
    const std::initializer_list< std::vector< std::filesystem::path >> & s,
    bool skip_last = true ) [inline]
```

Computes the common prefix of multiple lists of paths.

skip_last specifies whether the last part if the path (usually the filename) may be part of the prefix.

```
0.14.1.2.4 common_prefix() [3/3] std::filesystem::path benchmax::common_prefix (
    const std::vector< std::filesystem::path > & s,
    bool skip_last = true ) [inline]
```

Computes the common prefix of a list of paths.

skip_last specifies whether the last part if the path (usually the filename) may be part of the prefix.

```
0.14.1.2.5 createTools() template<typename T >
void benchmax::createTools (
    const std::vector< std::filesystem::path > & arguments,
    Tools & tools )
```

Create tools of a given type T from a list of binaries and store them in tools.

```
0.14.1.2.6 execute_backend() template<typename Backend >
void benchmax::execute_backend (
    const std::string & name,
    const Jobs & jobs )
```

0.14.1.2.7 `is_extension()` `bool benchmax::is_extension (`
 `const std::filesystem::path & path,`
 `const std::string & extension) [inline]`

Checks whether the extension of the filename is as specified.

0.14.1.2.8 `is_system_lib()` `bool benchmax::is_system_lib (`
 `std::string path) [inline]`

0.14.1.2.9 `loadBenchmarks()` `BenchmarkSet benchmax::loadBenchmarks ()`
Loads benchmark files from directory specified in settings.

0.14.1.2.10 `loadTools()` `Tools benchmax::loadTools ()`
Load all tools from the tool settings.

0.14.1.2.11 `logging_configure()` `void benchmax::logging_configure () [inline]`
Configure default logging for benchmax.

0.14.1.2.12 `logging_quiet()` `void benchmax::logging_quiet () [inline]`
Configure quiet logging for benchmax.

0.14.1.2.13 `logging_verbose()` `void benchmax::logging_verbose () [inline]`
Configure verbose logging for benchmax.

0.14.1.2.14 `operator<<()` [1/2] `std::ostream& benchmax::operator<< (`
 `std::ostream & os,`
 `const BenchmarkResult & results) [inline]`

Streaming operator for `BenchmarkResult`.

0.14.1.2.15 `operator<<()` [2/2] `std::ostream& benchmax::operator<< (`
 `std::ostream & os,`
 `const Tool & tool) [inline]`

Streaming operator for a generic tool.

0.14.1.2.16 `parse_peak_memory()` `std::size_t benchmax::parse_peak_memory (`
 `const std::string & output) [inline]`

0.14.1.2.17 `remove_prefix()` `std::filesystem::path benchmax::remove_prefix (`
 `const std::filesystem::path & s,`
 `const std::filesystem::path & prefix) [inline]`

Remove a prefix from a path.

```
0.14.1.2.18 run_backend() void benchmax::run_backend (
    const std::string & backend,
    const Jobs & jobs )
```

Runs a given backend on a list of tools and benchmarks.

Parameters

<i>backend</i>	Backend name.
<i>tools</i>	List of tools.
<i>benchmarks</i>	List of benchmarks.

0.14.1.2.19 settings_benchmarks() const auto& benchmax::settings_benchmarks () [inline]
Return the benchmark settings.

0.14.1.2.20 settings_core() const auto& benchmax::settings_core () [inline]
Retrieved core settings.

0.14.1.2.21 settings_get() template<typename T >
const auto& benchmax::settings_get (
 const std::string & name) [inline]
Helper function to obtain settings by name and type.

0.14.1.2.22 settings_operation() const auto& benchmax::settings_operation () [inline]
Retrieved operation settings.

0.14.1.2.23 settings_preset() const auto& benchmax::settings_preset () [inline]
Return the Slurm settings.

0.14.1.2.24 settings_slurm() const auto& benchmax::settings_slurm () [inline]
Return the Slurm settings.

0.14.1.2.25 settings_ssh() const auto& benchmax::settings_ssh () [inline]
Return the SSH settings.

0.14.1.2.26 settings_tools() const auto& benchmax::settings_tools () [inline]
Returns the tool settings.

0.14.2 benchmax::settings Namespace Reference

Data Structures

- struct [SlurmBackendSettings](#)
Settings for the Slurm backend.
- struct [SSHBackendSettings](#)
Settings for SSH backend.
- struct [BenchmarkSettings](#)
Settings for benchmarks.
- struct [PresetSettings](#)
- struct [CoreSettings](#)
Core settings.
- struct [OperationSettings](#)

- struct **Settings**
Generic class to manage runtime settings.
- struct **ToolSettings**
Tool-related settings.

Functions

- void **registerSlurmBackendSettings** (**SettingsParser** *parser)
Registers Slurm settings with the settings parser.
- void **registerSSHBackendSettings** (**SettingsParser** *parser)
Registers SSH settings with settings parser.
- bool **finalize_benchmark_settings** (**BenchmarkSettings** &s, const **boost::program_options::variables_map** &)
Postprocess benchmark settings.
- void **registerBenchmarkSettings** (**SettingsParser** *parser)
Registers benchmark settings with the settings parser.
- bool **finalize_preset_settings** (**PresetSettings** &s, **boost::program_options::variables_map** &values)
Postprocess preset settings.
- void **registerPresetSettings** (**SettingsParser** *parser)
Registers preset settings with the settings parser.
- bool **finalize_tool_settings** (**ToolSettings** &s, const **boost::program_options::variables_map** &)
Postprocess settings to compute common prefix.
- void **registerToolSettings** (**SettingsParser** *parser)
Registers tool settings with the settings parser.

0.14.2.1 Function Documentation

0.14.2.1.1 finalize_benchmark_settings() `bool benchmax::settings::finalize_benchmark_settings (`
`BenchmarkSettings & s,`
`const boost::program_options::variables_map &)`

Postprocess benchmark settings.

0.14.2.1.2 finalize_preset_settings() `bool benchmax::settings::finalize_preset_settings (`
`PresetSettings & s,`
`boost::program_options::variables_map & values)`

Postprocess preset settings.

0.14.2.1.3 finalize_tool_settings() `bool benchmax::settings::finalize_tool_settings (`
`ToolSettings & s,`
`const boost::program_options::variables_map &)`

Postprocess settings to compute common prefix.

0.14.2.1.4 registerBenchmarkSettings() `void benchmax::settings::registerBenchmarkSettings (`
`SettingsParser * parser)`

Registers benchmark settings with the settings parser.

0.14.2.1.5 registerPresetSettings() `void benchmax::settings::registerPresetSettings (`
 `SettingsParser * parser)`

Registers preset settings with the settings parser.

0.14.2.1.6 registerSlurmBackendSettings() `void benchmax::settings::registerSlurmBackendSettings (`
 `SettingsParser * parser)`

Registers Slurm settings with the settings parser.

0.14.2.1.7 registerSSHBackendSettings() `void benchmax::settings::registerSSHBackendSettings (`
 `SettingsParser * parser)`

Registers SSH settings with settings parser.

0.14.2.1.8 registerToolSettings() `void benchmax::settings::registerToolSettings (`
 `SettingsParser * parser)`

Registers tool settings with the settings parser.

0.14.3 benchmax::slurm Namespace Reference

Data Structures

- struct [ArchiveProperties](#)
All properties needed to archive log files.
- struct [SubmitfileProperties](#)
All properties needed to create a submit file.
- struct [ChunkedSubmitfileProperties](#)
All properties needed to create a submit file.

Functions

- void [archive_log_files](#) (const [ArchiveProperties](#) &p)
Put all log files into an archive.
- std::vector< fs::path > [collect_result_files](#) (const fs::path &basedir)
Collects all result files in the given base directory for this job id.
- std::string [generate_submit_file](#) (const [SubmitfileProperties](#) &p)
Generate a submit file for Slurm with the given properties.
- std::string [generate_submit_file_chunked](#) (const [ChunkedSubmitfileProperties](#) &p)
- int [parse_job_id](#) (const std::string &output)
Parses the job id from the output of sbatch.
- std::string [parse_result_info](#) (const std::string &content, const std::string &name)
Parse a single result information from the output.
- void [remove_log_files](#) (const std::vector< fs::path > &files, bool remove)
Remove the given list of files.
- void [clear_log_files](#) (const fs::path &basedir)
Clear log files from directory.
- bool [is_job_finished](#) (int jobid)
Checks if the given job is finished.
- template<typename Jobs >
void [generate_jobs_file](#) (const std::string &filename, std::pair< std::size_t, std::size_t > range, const [Jobs](#) &jobs)

0.14.3.1 Function Documentation

0.14.3.1.1 archive_log_files() `void benchmax::slurm::archive_log_files (`
 `const ArchiveProperties & p)`

Put all log files into an archive.

0.14.3.1.2 clear_log_files() `void benchmax::slurm::clear_log_files (`
 `const fs::path & basedir)`

Clear log files from directory.

Parameters

<code>basedir</code>	Base directory to search in.
----------------------	------------------------------

0.14.3.1.3 collect_result_files() `std::vector< fs::path > benchmax::slurm::collect_result_files (`
 `const fs::path & basedir)`

Collects all result files in the given base directory for this job id.

Parameters

<code>basedir</code>	Base directory to search in.
<code>jobid</code>	ID of slurm job.

Returns

List of result files.

0.14.3.1.4 generate_jobs_file() `template<typename Jobs >`
`void benchmax::slurm::generate_jobs_file (`
 `const std::string & filename,`
 `std::pair< std::size_t, std::size_t > range,`
 `const Jobs & jobs)`

0.14.3.1.5 generate_submit_file() `std::string benchmax::slurm::generate_submit_file (`
 `const SubmitfileProperties & p)`

Generate a submit file for Slurm with the given properties.

Parameters

<code>p</code>	Collection of all information needed.
----------------	---------------------------------------

Returns

The filename of the submit file.

0.14.3.1.6 generate_submit_file_chunked() `std::string benchmax::slurm::generate_submit_file_`
 `chunked (`

```
const ChunkedSubmitfileProperties & p )
```

0.14.3.1.7 `is_job_finished()` `bool benchmax::slurm::is_job_finished (int jobid)`

Checks if the given job is finished.

Parameters

<code>jobid</code>	The job id.
--------------------	-------------

Returns

True if the job is completed.

0.14.3.1.8 `parse_job_id()` `int benchmax::slurm::parse_job_id (const std::string & output)`

Parses the job id from the output of sbatch.

Parameters

<code>output</code>	Output of sbatch.
---------------------	-------------------

Returns

Slurm job id.

0.14.3.1.9 `parse_result_info()` `std::string benchmax::slurm::parse_result_info (const std::string & content, const std::string & name)`

Parse a single result information from the output.

Parameters

<code>content</code>	Result information output.
<code>name</code>	Information to be parsed.

Returns

Information specified in the output.

0.14.3.1.10 `remove_log_files()` `void benchmax::slurm::remove_log_files (const std::vector< fs::path > & files, bool remove)`

Remove the given list of files.

Parameters

<code>files</code>	List of files.
<code>remove</code>	Boolean flag whether to actually remove files.

0.14.4 `benchmax::ssh` Namespace Reference

Data Structures

- struct `Node`

Specification of a computation node for the SSH backend.
- class `SSHConnection`

A wrapper class that manages a single SSH connection as specified in a `Node` object (with all its channels).

0.14.5 `carl` Namespace Reference

0.14.6 `delta` Namespace Reference

Data Structures

- class `Checker`

This class takes care of calling the actual solver.
- class `Consumer`

This class takes care of asynchronous execution of calls to the solver.
- struct `Node`

This class represents a node in a SMTLIB file.
- struct `NodePrinter`
- struct `Skipper`

This class is a `boost::spirit::qi` grammar that matches whitespaces and smtlib comments.
- struct `SymbolParser`

This class is a `boost::spirit::qi` grammar that matches all kinds of smtlib symbols, numbers etc.
- struct `ErrorHandler`
- class `Parser`

This class parses a whole smtlib file into a hierarchy of `Node` objects.
- class `Producer`

This class iteratively applies the operators to a smtlib file until no further simplifications can be performed.
- class `Settings`

This class loads and checks the command line options with help of `boost::program_options`.
- class `TempFilenameGenerator`

This class generates and reuses temporary filenames with a common prefix.
- class `ProgressBar`

This class provides a simple way to show progress bars on the command line.
- class `String`

This class can be used to create `std::string` objects using streaming operators.

TypeDefs

- using `NodeChangeSet` = `std::vector< Node >`

Set of new nodes.
- using `NodeOperator` = `std::function< NodeChangeSet(const Node &)>`

Type of an node operator.
- typedef `boost::spirit::istream_iterator` `BaseliteratorType`
- typedef `boost::spirit::line_pos_iterator< BaseliteratorType >` `PositionIteratorType`
- typedef `PositionIteratorType` `Iterator`

Functions

- `std::ostream & operator<< (std::ostream &os, const Node &n)`
Streaming operator.
- `template<bool pretty>`
`std::ostream & operator<< (std::ostream &os, const NodePrinter< pretty > &np)`
- `NodeChangeSet children (const Node &n)`
Node operator that returns all children of a node.
- `NodeChangeSet reorderChildren (const Node &n)`
Node operator that reorders children of a node.
- `NodeChangeSet mergeChild (const Node &n)`
Node operator that merges nodes with one of its own children.
- `NodeChangeSet number (const Node &n)`
Node operator that provides meaningful replacements for numbers.
- `NodeChangeSet constant (const Node &n)`
Node operator that provides meaningful replacements for variables.
- `NodeChangeSet letExpression (const Node &n)`
Node operator that eliminated let expressions.
- `NodeChangeSet BV_zeroExtend (const Node &n)`
- `NodeChangeSet BV_mergeShift (const Node &n)`

$$(bvlshr (bvlshr x (_ bv1 8)) (_ bv1 8))$$

0.14.6.1 Typedef Documentation

0.14.6.1.1 BaselIteratorType `typedef boost::spirit::istream_iterator delta::BaseIteratorType`

0.14.6.1.2 Iterator `typedef PositionIteratorType delta::Iterator`

0.14.6.1.3 NodeChangeSet `using delta::NodeChangeSet = typedef std::vector<Node>`
Set of new nodes.

0.14.6.1.4 NodeOperator `using delta::NodeOperator = typedef std::function<NodeChangeSet (const Node &) >`

Type of an node operator.

A NodeOperator is called on a node and shall return a set of new nodes. These new nodes are supposed to be a simplifying replacement for the given node.

0.14.6.1.5 PositionIteratorType `typedef boost::spirit::line_pos_iterator<BaseIteratorType> delta::PositionIterator`

0.14.6.2 Function Documentation

0.14.6.2.1 BV_mergeShift() `NodeChangeSet delta::BV_mergeShift (`
`const Node & n)`
`(bvlshr (bvlshr x (_ bv1 8)) (_ bv1 8))`

0.14.6.2.2 `BV_zeroExtend()` `NodeChangeSet` `delta::BV_zeroExtend (`
`const Node & n)`

0.14.6.2.3 `children()` `NodeChangeSet` `delta::children (`
`const Node & n)`

`Node` operator that returns all children of a node.

Parameters

<code>n</code>	<code>Node.</code>
----------------	--------------------

Returns

A set of replacements.

0.14.6.2.4 `constant()` `NodeChangeSet` `delta::constant (`
`const Node & n)`

`Node` operator that provides meaningful replacements for variables.

Parameters

<code>n</code>	<code>Node.</code>
----------------	--------------------

Returns

A set of replacements.

0.14.6.2.5 `letExpression()` `NodeChangeSet` `delta::letExpression (`
`const Node & n)`

`Node` operator that eliminated let expressions.

Parameters

<code>n</code>	<code>Node.</code>
----------------	--------------------

Returns

A set of replacements.

0.14.6.2.6 `mergeChild()` `NodeChangeSet` `delta::mergeChild (`
`const Node & n)`

`Node` operator that merges nodes with one of its own children.

Parameters

<code>n</code>	<code>Node.</code>
----------------	--------------------

Returns

A set of replacements.

0.14.6.2.7 number() `NodeChangeSet` `delta::number (`
 `const Node & n)`

`Node` operator that provides meaningful replacements for numbers.

Parameters

<code>n</code>	<code>Node.</code>
----------------	--------------------

Returns

A set of replacements.

0.14.6.2.8 operator<<() [1/2] `std::ostream&` `delta::operator<< (`
 `std::ostream & os,`
 `const Node & n)` [inline]

Streaming operator.

This operator should output a representation that is syntactically identically to the one that was parsed.

Parameters

<code>os</code>	Output stream.
<code>n</code>	<code>Node.</code>

Returns

`os.`

0.14.6.2.9 operator<<() [2/2] `template<bool pretty>`
`std::ostream&` `delta::operator<< (`
 `std::ostream & os,`
 `const NodePrinter< pretty > & np)` [inline]

0.14.6.2.10 reorderChildren() `NodeChangeSet` `delta::reorderChildren (`
 `const Node & n)`

`Node` operator that reorders children of a node.

Parameters

<code>n</code>	<code>Node.</code>
----------------	--------------------

Returns

A set of replacements.

0.14.8 smtrat Namespace Reference

Implements a specialization of std::hash for any boost::variant.

Namespaces

- [analyzer](#)
- [cad](#)
- [cadcells](#)

A framework for sample-based CAD algorithms.

- [compile_information](#)

Compile time generated information about compiler and system version.

- [datastructures](#)
- [execution](#)
- [expression](#)
- [groebner](#)
- [helper](#)
- [icp](#)
- [impl](#)
- [lra](#)
- [lve](#)
- [maxsmt](#)

Contains strategy implementations for max SMT computations.

- [onecellcad](#)
- [options_detail](#)
- [parseformula](#)
- [parser](#)
- [preprocessor](#)
- [qe](#)
- [resource](#)
- [sat](#)
- [settings](#)
- [statistics](#)
- [subtropical](#)

Implements data structures and encodings for the subtropical method.

- [uf_impl](#)
- [unsatcore](#)

Contains strategy implementations for unsat core computations.

- [validation](#)
- [vb](#)
- [vs](#)

Data Structures

- struct [is_variant](#)

States whether a given type is a boost::variant.

- struct [is_variant< boost::variant< BOOST_VARIANT_ENUM_PARAMS\(U\) > >](#)

States that boost::variant is indeed a boost::variant.

- struct [is_variant< const boost::variant< BOOST_VARIANT_ENUM_PARAMS\(U\) > >](#)

States that const boost::variant is indeed a boost::variant.

- class [VariantMap](#)

This class is a specialization of std::map where the keys are of arbitrary type and the values are of type boost::variant.

- struct [CMakeOptionPrinter](#)

- class [Executor](#)
- class [PriorityQueue](#)
- class [DynamicPriorityQueue](#)
- class [SettingsComponents](#)
- class [SettingsParser](#)
- class [MaxSMT](#)
- class [BEModule](#)
- class [BVDirectEncoder](#)
- class [BVMODULE](#)
- class [CNFerModule](#)
- class [CoCoAGBModule](#)
- class [Bimap](#)

Container that stores expensive to construct objects and allows the fast lookup with respect to two independent keys within the objects.

- class [CSplitModule](#)
- class [CubeLIAModule](#)
- class [CurryModule](#)
- class [EMMModule](#)
- class [freelist](#)

Implements a fixed-(at-runtime)-size allocator based on a free list embedded in the space of currently unused objects.

- class [fixedsize_freelist](#)

Implements a fixed-(at-compile-time)-size allocator based on a free list embedded in the space of currently unused objects.

- class [fixedsize_allocator](#)

An allocator meant to be used for containers that typically allocate single objects or nodes, such as sets, maps and linked lists.

- class [fixedsize_allocator< void >](#)

I do not know where an allocator for void would be of any use; but in order to mimic std::allocator (where this is explicitly mentioned) as good as possible, we do this for the void case.

- class [dynarray](#)

dynarray is similar to std::vector, but has only a reduced interface.

- class [dynarray_allocator](#)
- class [union_find](#)

Implements a union-find datastructure, a datastructure containing an array of entries.

- class [EQModule](#)
- struct [by_address_hasher](#)

Hash an iterator by the pointed-to address.

- struct [pairhash](#)

Note that this may NOT be a specialization of std::hash for std::pair, this is not allowed by the standard as it does not involve a user-defined type.

- struct [variant_hash_visitor](#)
- struct [CollectBoolsInUEQs](#)
- struct [BoolUEQRewriter](#)
- class [EQPreprocessingModule](#)
- struct [UFRewriter](#)
- struct [JunctorMerger](#)
- class [ModuleWrapper](#)
- struct [NNFPreparation](#)
- class [NNFRewriter](#)
- struct [OrPathShortener](#)

A rewriter that checks every (X)OR that only contains ANDs and UEQs as children for equalities that hold for every alternative, and adds such equalities explicitly.

- struct [ReplaceVariablesRewriter](#)
- class [ESModule](#)

- class [FouMoModule](#)
A module which applies the Fourier-Motzkin algorithm.
- class [FPPModule](#)
- class [GBModule](#)
A solver module based on Groebner basis.
- class [GBModuleState](#)
A class to save the current state of a [GBModule](#).
- class [InequalitiesTable](#)
Datastructure for the [GBModule](#).
- class [VariableRewriteRule](#)
- class [GBPPModule](#)
- class [ForwardHyperGraph](#)
This class implements a forward hypergraph.
- struct [CycleEnumerator](#)
This class encapsulates an algorithm for enumerating all cycles.
- class [ICEModule](#)
- class [ICPModule](#)
- class [IncWidthModule](#)
- class [BVAnnotation](#)
- class [AnnotatedBVTerm](#)
- class [BlastedPoly](#)
- class [BlastedConstr](#)
- class [ConstrTree](#)
- class [ElementWithOrigins](#)
- class [CollectionWithOrigins](#)
- class [IntBlastModule](#)
- class [PolyTree](#)
- class [PolyTreeContent](#)
- class [PolyTreePool](#)
- class [IntEqModule](#)
A module which checks whether the equations contained in the received (linear integer) formula have a solution.
- class [LRAModule](#)
A module which performs the Simplex method on the linear part of it's received formula.
- class [LVEModule](#)
- class [MCBModule](#)
- class [NewCADModule](#)
- class [Backend](#)
- struct [SampledDerivationRefCompare](#)
- class [LevelWiseInformation](#)
- class [NewCoveringModule](#)
- struct [sampling](#)
- struct [is_sample_outside](#)
- struct [sampling< SamplingAlgorithm::LOWER_UPPER_BETWEEN_SAMPLING >](#)
- struct [is_sample_outside< IsSampleOutsideAlgorithm::DEFAULT >](#)
- class [RationalCapsule](#)
- class [VariableCapsule](#)
- class [AxiomFactory](#)
- class [LOG](#)
- class [MonomialMappingByVariablePool](#)
- class [NRAILModule](#)
- class [PBGaussModule](#)
- class [CardinalityEncoder](#)
- class [ExactlyOneCommanderEncoder](#)

- class [LongFormulaEncoder](#)
- class [MixedSignEncoder](#)
- class [PseudoBoolEncoder](#)

Base class for a PseudoBoolean Encoder.
- class [PseudoBoolNormalizer](#)
- class [RNSEncoder](#)
- class [ShortFormulaEncoder](#)
- class [TotalizerEncoder](#)

TotalizerEncoder implements the Totalizer encoding as described in "Incremental Cardinality Constraints for MaxSAT" by Martins et al https://doi.org/10.1007/978-3-319-10428-7_39.
- class [TotalizerTree](#)
- class [PBPPModule](#)
- class [PFEModule](#)
- class [VarSchedulerMcsatBase](#)

Base class for all MCSAT variable scheduler.
- class [TheoryVarSchedulerStatic](#)

Schedules theory variables statically.
- class [VarSchedulerMcsatBooleanFirst](#)

Variable scheduling that all decides Boolean variables first before deciding any theory variable.
- class [VarSchedulerMcsatTheoryFirst](#)

Variable scheduling that all decides theory variables first before deciding any Boolean variable.
- class [VarSchedulerMcsatUnivariateConstraintsOnly](#)

Decides only Constraints univariate in the current theory variable while the theory ordering is static.
- class [VarSchedulerMcsatUnivariateClausesOnly](#)

Decides only Constraints occurring in clauses that are univariate in the current theory variable while the theory ordering is static.
- class [VarSchedulerMcsatActivityPreferTheory](#)

Activity-based scheduler preferring initially theory variables.
- class [SATModule](#)

Implements a module performing DPLL style SAT checking.
- class [VarSchedulerBase](#)

Base class for variable schedulers.
- class [VarSchedulerMinisat](#)

Minisat's activity-based variable scheduling.
- class [VarSchedulerFixedRandom](#)
- class [VarSchedulerRandom](#)

Random scheduler.
- class [VarSchedulerSMTTheoryGuided](#)

Scheduler for SMT, implementing theory guided heuristics.
- class [SplitSOSModule](#)
- class [STropModule](#)
- class [SymmetryModule](#)
- class [UFCegarModule](#)
- struct [EQGraph](#)
- struct [UnionFindInterface](#)
- struct [StaticUnionFind](#)
- struct [PersistentUnionFind](#)
- struct [Backtrackable](#)
- class [UnionFindModule](#)
- class [VSModule](#)
- class [Optimization](#)
- class [Manager](#)

- **Base class for solvers.**
- struct **Branching**
Stores all necessary information of an branch, which can be used to detect probable infinite loop of branchings.
- class **Module**
A base class for all kind of theory solving methods.
- class **FormulaWithOrigins**
Stores a formula along with its origins.
- class **ModuleInput**
The input formula a module has to consider for it's satisfiability check.
- class **PModule**
- struct **AbstractModuleFactory**
- struct **ModuleFactory**
- class **BackendLink**
- class **StrategyGraph**
- class **Task**
- class **BackendSynchronisation**
- class **ThreadPool**
- class **UnsatCore**

Enumerations

- `enum LemmaLevel { NONE = 0 , NORMAL = 1 , ADVANCED = 2 }`
- `enum Answer { SAT = 0 , UNSAT = 1 , UNKNOWN = 2 , ABORTED = 3 , OPTIMAL = 4 }`

An enum with the possible answers a Module can give.
- `enum class MaxSMTStrategy { FU_MALIK_INCREMENTAL , MSU3 , LINEAR_SEARCH }`
- `enum CoveringStatus { partial = 0 , full = 1 , unknown = 2 , failed = 3 }`
- `enum SamplingAlgorithm { LOWER_UPPER_BETWEEN_SAMPLING }`
- `enum IsSampleOutsideAlgorithm { DEFAULT }`
- `enum class TheoryGuidedDecisionHeuristicLevel : unsigned { CONFLICT_FIRST , SATISFIED_FIRST , DISABLED }`
- `enum class UnsatCoreStrategy { ModelExclusion }`

Functions

- `int handle_basic_options (const SettingsParser &parser)`
- `const auto & settings_parser ()`
- `bool parseSMT2File (parser::InstructionHandler &handler, bool queueInstructions, std::istream &input)`
- `int convert_to_cnf_dimacs (const std::string &, const std::string &)`
- `int convert_to_cnf_smtlib (const std::string &, const std::string &)`
- `std::ostream & operator<< (std::ostream &os, CMakeOptionPrinter cmop)`
- `constexpr CMakeOptionPrinter CMakeOptions (bool advanced=false) noexcept`
- `template<typename Executor>`
`bool parseInput (const std::string &pathToInputFile, Executor &e, bool &queueInstructions)`
- `template<typename Executor>`
`int executeFile (const std::string &pathToInputFile, Executor &e)`

Parse the file and save it in formula.
- `int analyze_file (const std::string &)`
- `template<typename Strategy>`
`int run_dimacs_file (Strategy &, const std::string &)`
- `template<typename Strategy>`
`int run_opb_file (Strategy &, const std::string &)`
- `FormulaT parse_smtlib (const std::string &)`
- `FormulaT parse_formula (const std::string &filename)`

- Loads the smt2 file specified in filename and returns the formula.*
- int `preprocess_file` (const std::string &filename, const std::string &outfile)

Loads the smt2 file specified in filename and runs the preprocessing strategy.
 - const auto & `settings_analyzer` ()
 - `analyzer::AnalyzerStatistics & analyze_formula` (const `FormulaT` &f)

```

## Variables

- static const Model EMPTY\_MODEL = Model()
- static constexpr int COMMANDER\_GROUP\_SIZE = 4

### 0.14.8.1 Detailed Description

Implements a specialization of std::hash for any boost::variant.

Class to create a substitution object.

Class to create a state object.

Class to create a condition object.

Class to create the formulas for axioms.

This only works if the types of the variant are std::hash-enabled (have a std::hash specialization of their own).

## 0.14.8.3 Enumeration Type Documentation

**0.14.8.3.1 Answer** `enum smtrat::Answer`

An enum with the possible answers a [Module](#) can give.

Enumerator

|         |
|---------|
| SAT     |
| UNSAT   |
| UNKNOWN |
| ABORTED |
| OPTIMAL |

#### 0.14.8.3.2 CoveringStatus `enum smtrat::CoveringStatus`

Enumerator

|         |
|---------|
| partial |
| full    |
| unknown |
| failed  |

#### 0.14.8.3.3 IsSampleOutsideAlgorithm `enum smtrat::IsSampleOutsideAlgorithm`

Enumerator

|         |
|---------|
| DEFAULT |
|---------|

#### 0.14.8.3.4 LemmaLevel `enum smtrat::LemmaLevel`

Enumerator

|          |
|----------|
| NONE     |
| NORMAL   |
| ADVANCED |

#### 0.14.8.3.5 MaxSMTStrategy `enum smtrat::MaxSMTStrategy [strong]`

Enumerator

|                      |
|----------------------|
| FU_MALIK_INCREMENTAL |
| MSU3                 |
| LINEAR_SEARCH        |

#### 0.14.8.3.6 SamplingAlgorithm `enum smtrat::SamplingAlgorithm`

Enumerator

|                              |
|------------------------------|
| LOWER_UPPER_BETWEEN_SAMPLING |
|------------------------------|

**0.14.8.3.7 TheoryGuidedDecisionHeuristicLevel** enum `smtrat::TheoryGuidedDecisionHeuristicLevel`  
: unsigned [strong]

Enumerator

|                 |  |
|-----------------|--|
| CONFFLICT_FIRST |  |
| SATISFIED_FIRST |  |
| DISABLED        |  |

**0.14.8.3.8 UnsatCoreStrategy** enum `smtrat::UnsatCoreStrategy` [strong]

Enumerator

|                |  |
|----------------|--|
| ModelExclusion |  |
|----------------|--|

#### 0.14.8.4 Function Documentation

**0.14.8.4.1 abEqualcCheck()** bool `smtrat::abEqualcCheck` (  
    *VariableCapsule* *variableCapsuleOuter*,  
    *Model* *linearizedModel* )

**0.14.8.4.2 abGreatercCheck()** bool `smtrat::abGreatercCheck` (  
    *RationalCapsule* *rationalCapsule* )

**0.14.8.4.3 abLesscCheck()** bool `smtrat::abLesscCheck` (  
    *RationalCapsule* *rationalCapsule* )

**0.14.8.4.4 analyze\_file()** int `smtrat::analyze_file` (  
    const `std::string` & )

**0.14.8.4.5 analyze\_formula()** `analyzer::AnalyzerStatistics` & `smtrat::analyze_formula` (  
    const `FormulaT` & *f* )

**0.14.8.4.6 annotateFormula()** template<typename AnnotationType >  
void `smtrat::annotateFormula` (  
    const `FormulaT` & ,  
    const `std::vector< AnnotationType >` & )

**0.14.8.4.7 CMakeOptions()** constexpr `CMakeOptionPrinter` `smtrat::CMakeOptions` (  
    bool *advanced* = *false* ) [constexpr], [noexcept]

**0.14.8.4.8 convert\_to\_cnf\_dimacs()** `int smtrat::convert_to_cnf_dimacs (`  
`const std::string & ,`  
`const std::string & )`

**0.14.8.4.9 convert\_to\_cnf\_smtlib()** `int smtrat::convert_to_cnf_smtlib (`  
`const std::string & ,`  
`const std::string & )`

**0.14.8.4.10 createAbsoluteValuedModel()** `Model smtrat::createAbsoluteValuedModel (`  
`Model linearizedModel )`

**0.14.8.4.11 createAuxiliaryVariable()** `carl::Variable smtrat::createAuxiliaryVariable (`

`carl::Variable variable )`

create an auxiliary variable e.g.

`aux_<Variable Name>`

#### Parameters

|                       |                                                         |
|-----------------------|---------------------------------------------------------|
| <code>variable</code> | the variable for which auxiliary variable to be created |
|-----------------------|---------------------------------------------------------|

#### Returns

created auxiliary variable

**0.14.8.4.12 createCongruence()** `FormulaT smtrat::createCongruence (`  
`smtrat::VariableCapsule variableCapsuleOuter,`  
`smtrat::VariableCapsule variableCapsuleInner )`

**0.14.8.4.13 createEquivalentToOriginalMonotonicityOne()** `FormulaT smtrat::createEquivalentTo←`  
`OriginalMonotonicityOne (`  
`smtrat::VariableCapsule variableCapsule,`  
`smtrat::VariableCapsule variableCapsuleInner )`

**0.14.8.4.14 createEquivalentToOriginalMonotonicityThree()** `FormulaT smtrat::createEquivalentTo←`  
`OriginalMonotonicityThree (`  
`smtrat::VariableCapsule variableCapsule,`  
`smtrat::VariableCapsule variableCapsuleInner )`

**0.14.8.4.15 createEquivalentToOriginalMonotonicityTwo()** `FormulaT smtrat::createEquivalentTo←`  
`OriginalMonotonicityTwo (`  
`smtrat::VariableCapsule variableCapsule,`  
`smtrat::VariableCapsule variableCapsuleInner )`

**0.14.8.4.16 createICPGreater()** `Formulast smtrat::createICPGreater (`  
`VariableCapsule variableCapsule,`  
`RationalCapsule rationalCapsule )`

**0.14.8.4.17 `createICPGreaterOne()`** `FormulaT smtrat::createICPGreaterOne (`  
`VariableCapsule variableCapsule,`  
`RationalCapsule rationalCapsule )`

**0.14.8.4.18 `createICPGreaterTwo()`** `FormulaT smtrat::createICPGreaterTwo (`  
`VariableCapsule variableCapsule,`  
`RationalCapsule rationalCapsule )`

**0.14.8.4.19 `createICPLess()`** `FormulaT smtrat::createICPLess (`  
`VariableCapsule variableCapsule,`  
`RationalCapsule rationalCapsule )`

**0.14.8.4.20 `createMonotonicity()`** `FormulasT smtrat::createMonotonicity (`  
`VariableCapsule variableCapsuleOuter,`  
`VariableCapsule variableCapsuleInner,`  
`Model absoluteValuedModel )`

**0.14.8.4.21 `createOriginalMonotonicityOne()`** `FormulaT smtrat::createOriginalMonotonicityOne (`  
`smtrat::VariableCapsule variableCapsule,`  
`smtrat::VariableCapsule variableCapsuleInner )`

**0.14.8.4.22 `createOriginalMonotonicityThree()`** `FormulaT smtrat::createOriginalMonotonicityThree (`  
`smtrat::VariableCapsule variableCapsule,`  
`smtrat::VariableCapsule variableCapsuleInner )`

**0.14.8.4.23 `createOriginalMonotonicityTwo()`** `FormulaT smtrat::createOriginalMonotonicityTwo (`  
`smtrat::VariableCapsule variableCapsule,`  
`smtrat::VariableCapsule variableCapsuleInner )`

**0.14.8.4.24 `createTangentPlaneEQ()`** `FormulasT smtrat::createTangentPlaneEQ (`  
`VariableCapsule variableCapsule,`  
`RationalCapsule rationalCapsule )`

**0.14.8.4.25 `createTangentPlaneEQOne()`** `FormulaT smtrat::createTangentPlaneEQOne (`  
`carl::Variable xVariable,`  
`carl::Variable yVariable,`  
`carl::Variable zVariable,`  
`Rational aRational )`

**0.14.8.4.26 `createTangentPlaneEQTwo()`** `FormulaT smtrat::createTangentPlaneEQTwo (`  
`carl::Variable xVariable,`  
`carl::Variable yVariable,`  
`carl::Variable zVariable,`  
`Rational aRational )`

**0.14.8.4.27 `createTangentPlaneNEQ()`** `FormulasT smtrat::createTangentPlaneNEQ (`  
`VariableCapsule variableCapsule,`  
`RationalCapsule rationalCapsule )`

**0.14.8.4.28 `createTangentPlaneNEQFour()`** `FormulaT smtrat::createTangentPlaneNEQFour (`  
`carl::Variable xVariable,`  
`carl::Variable yVariable,`  
`carl::Variable zVariable,`  
`Rational aRational,`  
`Rational bRational )`

**0.14.8.4.29 `createTangentPlaneNEQOne()`** `FormulaT smtrat::createTangentPlaneNEQOne (`  
`carl::Variable xVariable,`  
`carl::Variable yVariable,`  
`carl::Variable zVariable,`  
`Rational aRational )`

**0.14.8.4.30 `createTangentPlaneNEQThree()`** `FormulaT smtrat::createTangentPlaneNEQThree (`  
`carl::Variable xVariable,`  
`carl::Variable yVariable,`  
`carl::Variable zVariable,`  
`Rational aRational,`  
`Rational bRational )`

**0.14.8.4.31 `createTangentPlaneNEQTwo()`** `FormulaT smtrat::createTangentPlaneNEQTwo (`  
`carl::Variable xVariable,`  
`carl::Variable yVariable,`  
`carl::Variable zVariable,`  
`Rational bRational )`

**0.14.8.4.32 `createZero()`** `FormulasT smtrat::createZero (`  
`smtrat::VariableCapsule variableCapsule )`

**0.14.8.4.33 `createZeroOne()`** `FormulaT smtrat::createZeroOne (`  
`carl::Variable xVariable,`  
`carl::Variable yVariable,`  
`carl::Variable zVariable )`

**0.14.8.4.34 `createZeroThree()`** `FormulaT smtrat::createZeroThree (`  
`carl::Variable xVariable,`  
`carl::Variable yVariable,`  
`carl::Variable zVariable )`

**0.14.8.4.35 `createZeroTwo()`** `FormulaT smtrat::createZeroTwo (`  
`carl::Variable xVariable,`  
`carl::Variable yVariable,`  
`carl::Variable zVariable )`

```
0.14.8.4.36 executeFile() template<typename Executor>
int smtrat::executeFile (
 const std::string & pathToInputFile,
 Executor & e)
```

Parse the file and save it in formula.

#### Parameters

|                        |                                                                          |
|------------------------|--------------------------------------------------------------------------|
| <i>pathToInputFile</i> | The path to the input smt2 file.                                         |
| <i>formula</i>         | A pointer to the formula object which holds the parsed input afterwards. |
| <i>options</i>         | Save options from the smt2 file here.                                    |

```
0.14.8.4.37 extractRationalCapsule() RationalCapsule smtrat::extractRationalCapsule (
 VariableCapsule variableCapsule,
 Model linearizedModel)
```

```
0.14.8.4.38 extractVariables() const smtrat::VariableCapsule smtrat::extractVariables (
 MonomialMapIterator monomialIterator)
```

```
0.14.8.4.39 factorial() [1/2] Rational smtrat::factorial (
 Rational n)
```

```
0.14.8.4.40 factorial() [2/2] Rational smtrat::factorial (
 std::size_t n)
```

```
0.14.8.4.41 generateAbcPrimeForICP() RationalCapsule smtrat::generateAbcPrimeForICP (
 RationalCapsule rationalCapsule,
 bool isGreater)
```

```
0.14.8.4.42 generateAbsFormula() [1/2] FormulaT smtrat::generateAbsFormula (
 carl::Variable variable,
 carl::Variable aux_variable)
| x1 | = (and (=> (x1 >= 0) (y1 = x1)) (=> (x1 < 0) (y1 = -x1)))
```

#### Parameters

|                 |  |
|-----------------|--|
| <i>variable</i> |  |
|-----------------|--|

#### Returns

```
0.14.8.4.43 generateAbsFormula() [2/2] FormulaT smtrat::generateAbsFormula (
 carl::Variable variableLeft,
 carl::Variable variableRight,
 carl::Relation relation)
| x1 | <= | x1 | = (and (=> (x1 >= 0) (y1 = x1)) (=> (x1 < 0) (y1 = -x1)) (=> (x2 >= 0) (y2 = x2)) (=> (x2 < 0) (y2 = -x2)) (y1 <= y2))
```

**Parameters**

|                            |  |
|----------------------------|--|
| <code>variableLeft</code>  |  |
| <code>variableRight</code> |  |
| <code>relation</code>      |  |

**Returns**

**0.14.8.4.44 `get_name()` [1/2]** `std::string smtrat::get_name (`  
`IsSampleOutsideAlgorithm samplingAlgorithm )` [inline]

**0.14.8.4.45 `get_name()` [2/2]** `std::string smtrat::get_name (`  
`SamplingAlgorithm samplingAlgorithm )` [inline]

**0.14.8.4.46 `handle_basic_options()`** `int smtrat::handle_basic_options (`  
`const SettingsParser & parser )`

**0.14.8.4.47 `hash_combine()`** `static void smtrat::hash_combine (`  
`std::size_t & seed,`  
`std::size_t hash_value )` [inline], [static], [noexcept]

**0.14.8.4.48 `is_sat()`** `bool smtrat::is_sat (`  
`Answer a )` [inline]

**0.14.8.4.49 `isAnyRationalIsZero()`** `bool smtrat::isAnyRationalIsZero (`  
`RationalCapsule rationalCapsule )`

**0.14.8.4.50 `isCondition()`** `bool smtrat::isCondition (`  
`carl::Condition _condition )`

**0.14.8.4.51 `operator<<()` [1/10]** `std::ostream& smtrat::operator<< (`  
`std::ostream & os,`  
`Answer a )` [inline]

**0.14.8.4.52 `operator<<()` [2/10]** `std::ostream & smtrat::operator<< (`  
`std::ostream & os,`  
`CMakeOptionPrinter cmop )`

**0.14.8.4.53 `operator<<()` [3/10]** `std::ostream& smtrat::operator<< (`  
`std::ostream & os,`  
`const CoveringStatus & status )` [inline]

**0.14.8.4.54 operator<<()** [4/10] template<typename Settings >  
std::ostream& smtrat::operator<< (  
 std::ostream & os,  
 const LevelWiseInformation< Settings > & levelWiseInformation ) [inline]

**0.14.8.4.55 operator<<()** [5/10] template<typename Module >  
std::ostream& smtrat::operator<< (

 const ModuleInput & mi ) [inline]

**0.14.8.4.57 operator<<()** [7/10] template<typename TT , typename C >  
std::ostream& smtrat::operator<< (  
 std::ostream & os,  
 const PriorityQueue< TT, C > & pq )

**0.14.8.4.58 operator<<()** [8/10] std::ostream& smtrat::operator<< (  
 std::ostream & os,  
 MaxSMTStrategy ucs ) [inline]

**0.14.8.4.59 operator<<()** [9/10] std::ostream& smtrat::operator<< (  
 std::ostream & os,  
 Module::LemmaType lt ) [inline]

**0.14.8.4.60 operator<<()** [10/10] std::ostream& smtrat::operator<< (  
 std::ostream & os,  
 UnsatCoreStrategy ucs ) [inline]

**0.14.8.4.61 parse\_formula()** FormulaT smtrat::parse\_formula (  
 const std::string & filename )

Loads the smt2 file specified in filename and returns the formula.

This function ignores most SMT-LIB commands but simply accumulated all asserted formulas.

**0.14.8.4.62 parse\_smtlib()** FormulaT smtrat::parse\_smtlib (  
 const std::string & )

**0.14.8.4.63 parseInput()** template<typename Executor >  
bool smtrat::parseInput (  
 const std::string & pathToInputFile,  
 Executor & e,  
 bool & queueInstructions )

```
0.14.8.4.64 parseSMT2File() bool smtrat::parseSMT2File (
 parser::InstructionHandler & handler,
 bool queueInstructions,
 std::istream & input)
```

```
0.14.8.4.65 preprocess_file() int smtrat::preprocess_file (
 const std::string & filename,
 const std::string & outfile)
```

Loads the smt2 file specified in filename and runs the preprocessing strategy.  
The resulting (simplified) problem is written to outfile (or stdout if outfile is empty).

```
0.14.8.4.66 run_dimacs_file() template<typename Strategy >
int smtrat::run_dimacs_file (
 Strategy & ,
 const std::string &)
```

```
0.14.8.4.67 run_opb_file() template<typename Strategy >

#### 0.14.15.1 Function Documentation

**0.14.15.1.1 canBeForwarded()** bool smtrat::cad::projection::canBeForwarded ( std::size\_t , const UPoly & p ) [inline]

Checks whether a polynomial can safely be forwarded to the next level.

**0.14.15.1.2 canBeRemoved()** bool smtrat::cad::projection::canBeRemoved ( const UPoly & p ) [inline]

Checks whether a polynomial can safely be ignored.

**0.14.15.1.3 discriminant()** template<typename Poly >  
**Poly** smtrat::cad::projection::discriminant ( carl::Variable variable, const Poly & p )

Computes the discriminant of a polynomial.

The polynomial is assumed to be univariate and thus knows its main variable. The given variable instead indicates the main variable of the resulting polynomial.

##### Parameters

|                 |                                            |
|-----------------|--------------------------------------------|
| <i>variable</i> | Main variable of the resulting polynomial. |
| <i>p</i>        | Input polynomial.                          |

##### Returns

Discriminant of p in main variable variable.

**0.14.15.1.4 doesNotVanish()** template<typename Poly >  
bool smtrat::cad::projection::doesNotVanish ( const Poly & p )

Tries to determine whether the given Poly vanishes for some assignment.

Returns true if the Poly is guaranteed not to vanish. Returns false otherwise.

```
0.14.15.1.5 normalize() template<typename Poly >
Poly smtrat::cad::projection::normalize (
 const Poly & p)
```

Normalizes the given Poly by removing constant and duplicate factors.

```
0.14.15.1.6 PSC() template<typename Poly >
std::vector<Poly> smtrat::cad::projection::PSC (
 const Poly & p,
 const Poly & q)
```

Computes the Principal Subresultant Coefficients of two polynomials.

```
0.14.15.1.7 resultant() template<typename Poly >
Poly smtrat::cad::projection::resultant (
 carl::Variable variable,
 const Poly & p,
 const Poly & q)
```

Computes the resultant of two polynomials.

The polynomials are assumed to be univariate polynomials and thus know their respective main variables. The given variable instead indicates the main variable of the resulting polynomial.

#### Parameters

|                 |                                            |
|-----------------|--------------------------------------------|
| <i>variable</i> | Main variable of the resulting polynomial. |
| <i>p</i>        | First input polynomial.                    |
| <i>q</i>        | Second input polynomial.                   |

#### Returns

Resultant of p and q in main variable variable.

```
0.14.15.1.8 returnPoly() template<typename Poly , typename Callback >
void smtrat::cad::projection::returnPoly (
 const Poly & p,
 Callback && cb)
```

## 0.14.16 smtrat::cad::projection::brown Namespace Reference

Contains the implementation of Browns projection operator as specified in ? after Theorem 3.1.

#### Functions

- template<typename Poly , typename Callback >  
void **single** (const Poly &p, carl::Variable variable, Callback &&cb)  
*Implements the part of Browns projection operator from ? that deals with a single polynomial  $p \leftarrow : \{leading\text{coeff}(p), discriminant(p)\}$ .*
- template<typename Poly , typename Callback >  
void **paired** (const Poly &p, const UPoly &q, carl::Variable variable, Callback &&cb)  
*Implements the part of Browns projection operator from ? that deals with two polynomials  $p$  and  $q$  which is just the respective part of McCallums projection operator [mccallum::paired](#).*

### 0.14.16.1 Detailed Description

Contains the implementation of Browns projection operator as specified in ? after Theorem 3.1.

### 0.14.16.2 Function Documentation

```
0.14.16.2.1 paired() template<typename Poly , typename Callback >
void smtrat::cad::projection::brown::paired (
 const Poly & p,
 const UPoly & q,
 carl::Variable variable,
 Callback && cb)
```

Implements the part of Browns projection operator from ? that deals with two polynomials  $p$  and  $q$  which is just the respective part of McCallums projection operator [mccallum::paired](#).

```
0.14.16.2.2 single() template<typename Poly , typename Callback >
void smtrat::cad::projection::brown::single (
 const Poly & p,
 carl::Variable variable,
 Callback && cb)
```

Implements the part of Browns projection operator from ? that deals with a single polynomial  $p \leftarrow : \{leadingcoeff(p), discriminant(p)\}$ .

## 0.14.17 smtrat::cad::projection::collins Namespace Reference

Contains the implementation of Collins projection operator as specified in ? below Theorem 4.

### Functions

- template<typename Poly , typename Callback >  
void **single** (const Poly &p, carl::Variable variable, Callback &&cb)  
*Implements the part of Collins projection operator from ? that deals with a single polynomial  $p \leftarrow : \bigcup_{B \in RED(p)} \{Idcf(B)\} \cup PSC(B, B')$ .*
- template<typename Poly , typename Callback >  
void **paired** (const Poly &p, const UPoly &q, carl::Variable variable, Callback &&cb)  
*Implements the part of Collins projection operator from ? that deals with two polynomials  $p$  and  $q \leftarrow : \bigcup_{B_1 \in RED(p), B_2 \in RED(q)} PSC(B_1, B_2)$ .*

### 0.14.17.1 Detailed Description

Contains the implementation of Collins projection operator as specified in ? below Theorem 4.

### 0.14.17.2 Function Documentation

```
0.14.17.2.1 paired() template<typename Poly , typename Callback >
void smtrat::cad::projection::collins::paired (
 const Poly & p,
 const UPoly & q,
 carl::Variable variable,
 Callback && cb)
```

Implements the part of Collins projection operator from ? that deals with two polynomials  $p$  and  $q \leftarrow : \bigcup_{B_1 \in RED(p), B_2 \in RED(q)} PSC(B_1, B_2)$ .

```
0.14.17.2.2 single() template<typename Poly , typename Callback >
void smtrat::cad::projection::collins::single (
 const Poly & p,
 carl::Variable variable,
 Callback && cb)
```

Implements the part of Collins projection operator from ? that deals with a single polynomial  $p \leftarrow \bigcup_{B \in RED(p)} \{ldcf(B)\} \cup PSC(B, B')$ .

## 0.14.18 smtrat::cad::projection::hong Namespace Reference

Contains the implementation of Hongs projection operator as specified in ? in Section 2.2.

### Functions

- template<typename Poly , typename Callback >  
void **single** (const Poly &p, carl::Variable variable, Callback &&cb)  
*Implements the part of Hongs projection operator from ? that deals with a single polynomial  $p$  which is just the respective part of Collins' projection operator collins::single.*
- template<typename Poly , typename Callback >  
void **paired** (const Poly &p, const UPoly &q, carl::Variable variable, Callback &&cb)  
*Implements the part of Hongs projection operator from ? that deals with two polynomials  $p$  and  $q \leftarrow \bigcup_{F \in RED(p)} PSC(F, q)$ .*

### 0.14.18.1 Detailed Description

Contains the implementation of Hongs projection operator as specified in ? in Section 2.2.

### 0.14.18.2 Function Documentation

```
0.14.18.2.1 paired() template<typename Poly , typename Callback >
void smtrat::cad::projection::hong::paired (
 const Poly & p,
 const UPoly & q,
 carl::Variable variable,
 Callback && cb)
```

Implements the part of Hongs projection operator from ? that deals with two polynomials  $p$  and  $q \leftarrow \bigcup_{F \in RED(p)} PSC(F, q)$ .

```
0.14.18.2.2 single() template<typename Poly , typename Callback >
void smtrat::cad::projection::hong::single (
 const Poly & p,
 carl::Variable variable,
 Callback && cb)
```

Implements the part of Hongs projection operator from ? that deals with a single polynomial  $p$  which is just the respective part of Collins' projection operator collins::single.

## 0.14.19 smtrat::cad::projection::lazard Namespace Reference

Contains the implementation of Lazards projection operator as specified in [Lauard1994].

### Functions

- template<typename Poly , typename Callback >  
void **single** (const Poly &p, carl::Variable variable, Callback &&cb)

Implements the part of Lazards projection operator from ? that deals with a single polynomial  $p \leftarrow : \{leading_{coeff}(p), trailing_{coeff}(p), discriminant(p)\}$ .

- template<typename Poly , typename Callback >  
void **paired** (const Poly &p, const UPoly &q, carl::Variable variable, Callback &&cb)  
*Implements the part of Lazard projection operator from ? that deals with two polynomials p and q which is just the respective part of McCallums projection operator [mccallum::paired](#).*

#### 0.14.19.1 Detailed Description

Contains the implementation of Lazards projection operator as specified in [\[Lauard1994\]](#).

#### 0.14.19.2 Function Documentation

**0.14.19.2.1 paired()** template<typename Poly , typename Callback >  
void smtrat::cad::projection::lazard::paired (  
    const Poly & p,  
    const UPoly & q,  
    carl::Variable variable,  
    Callback && cb )

Implements the part of Lazard projection operator from ? that deals with two polynomials p and q which is just the respective part of McCallums projection operator [mccallum::paired](#).

**0.14.19.2.2 single()** template<typename Poly , typename Callback >  
void smtrat::cad::projection::lazard::single (  
    const Poly & p,  
    carl::Variable variable,  
    Callback && cb )

Implements the part of Lazards projection operator from ? that deals with a single polynomial  $p \leftarrow : \{leading_{coeff}(p), trailing_{coeff}(p), discriminant(p)\}$ .

### 0.14.20 smtrat::cad::projection::mccallum Namespace Reference

Contains the implementation of McCallums projection operator as specified in ?.

#### Functions

- template<typename Poly , typename Callback >  
void **single** (const Poly &p, carl::Variable variable, Callback &&cb)  
*Implements the part of McCallums projection operator from ? that deals with a single polynomial  $p \leftarrow : coefficients(p) \cup \{discriminant(p)\}$ .*
- template<typename Poly , typename Callback >  
void **paired** (const Poly &p, const UPoly &q, carl::Variable variable, Callback &&cb)  
*Implements the part of McCallums projection operator from ? that deals with two polynomials p and q  $\leftarrow : \{resultant(p, q)\}$ .*

#### 0.14.20.1 Detailed Description

Contains the implementation of McCallums projection operator as specified in ?.

#### 0.14.20.2 Function Documentation

```
0.14.20.2.1 paired() template<typename Poly , typename Callback >
void smtrat::cad::projection::mccallum::paired (
 const Poly & p,
 const UPoly & q,
 carl::Variable variable,
 Callback && cb)
```

Implements the part of McCallums projection operator from ? that deals with two polynomials  $p$  and  $q \leftarrow : \{resultant(p, q)\}$ .

```
0.14.20.2.2 single() template<typename Poly , typename Callback >
void smtrat::cad::projection::mccallum::single (
 const Poly & p,
 carl::Variable variable,
 Callback && cb)
```

Implements the part of McCallums projection operator from ? that deals with a single polynomial  $p \leftarrow : coefficients(p) \cup \{discriminant(p)\}$ .

## 0.14.21 smtrat::cad::projection::mccallum\_partial Namespace Reference

Contains the implementation of an optimized version McCallums projection operator.

### Functions

- template<typename Poly , typename Callback >  
void **single** (const Poly &p, carl::Variable variable, Callback &&cb)
- template<typename Poly , typename Callback >  
void **paired** (const Poly &p, const UPoly &q, carl::Variable variable, Callback &&cb)

### 0.14.21.1 Detailed Description

Contains the implementation of an optimized version McCallums projection operator.

It is based on the observation by Brown that if some coefficient does not vanish only the leading coefficient is required.

### 0.14.21.2 Function Documentation

```
0.14.21.2.1 paired() template<typename Poly , typename Callback >
void smtrat::cad::projection::mccallum_partial::paired (
 const Poly & p,
 const UPoly & q,
 carl::Variable variable,
 Callback && cb)
```

```
0.14.21.2.2 single() template<typename Poly , typename Callback >
void smtrat::cad::projection::mccallum_partial::single (
 const Poly & p,
 carl::Variable variable,
 Callback && cb)
```

### 0.14.25.1 Detailed Description

A framework for sample-based CAD algorithms.

This is a highly modular framework for sample-based CAD algorithms, i.e. single cell construction and coverings. The basic idea is to have properties (of some polynomials or real root functions); each property has a level w.r.t. to a variable ordering (i.e. the index of the main variable of a polynomial) and rules operating on them, each replacing a property by a "simpler" set of properties (eventually reducing the level). At some stage, we delineate properties (that is, ordering the root under a partial sample), determine an ordering and cell boundaries (called representation) to continue proving properties. For more details on the general framework, we refer to the paper.

The structure of this implementation is as follows:

- [cadcells::datastructures](#) contains the main datastructures. Read here for more details on the general structure of the framework.
- [cadcells::operators](#) defines the properties, the rules and methods to delineate properties. These are used by operators which provide an interface for performing projections on certain steps.
- [cadcells::representation](#) provides heuristics for computing the representations for cells, coverings and delineations.
- [cadcells::algorithms](#) contains helper methods, building blocks for algorithms as well as algorithms themselves. Go here for usage of the framework and high-level interfaces.

#### 0.14.25.1.1 Quick start

For an introduction, we refer to the code of `algorithms::oncell`.

### 0.14.25.2 Typedef Documentation

#### 0.14.25.2.1 Assignment

- template<`cadcells::operators::op op>`  
`std::vector< datastructures::SampledDerivationRef< typename operators::PropertiesSet< op >::type > > get_unsat_intervals (const VariableComparison &c, datastructures::Projections &proj, const Assignment &sample)`
- template<`cadcells::operators::op op>`  
`std::vector< datastructures::SampledDerivationRef< typename operators::PropertiesSet< op >::type > > get_unsat_intervals (const Atom &c, datastructures::Projections &proj, const Assignment &sample)`  
*Returns the unsat intervals of the given atom w.r.t.*

### 0.14.26.1 Detailed Description

Various algorithms as well as helper functions for developing new algorithms.

### 0.14.26.2 Function Documentation

**0.14.26.2.1 get\_interval()** template<cadcells::operators::op op, representation::CellHeuristic cell\_heuristic>  
`std::optional<std::pair<carl::Variable, datastructures::SymbolicInterval> > smrat::cadcells->`  
`::algorithms::get_interval (`  
 `datastructures::SampledDerivationRef< typename operators::PropertiesSet< op >>->`  
`::type > & cell_deriv )`  
Single cell construction algorithm.

#### Template Parameters

|                       |                     |
|-----------------------|---------------------|
| <i>op</i>             | The operator.       |
| <i>cell_heuristic</i> | The cell heuristic. |

#### Parameters

|                   |                                                 |
|-------------------|-------------------------------------------------|
| <i>cell_deriv</i> | A derivation object to construct the cell from. |
|-------------------|-------------------------------------------------|

#### Returns

A vector of pairs of variables and their symbolic intervals on success or std::nullopt otherwise.

**0.14.26.2.2 get\_level\_covering()** template<cadcells::operators::op op, representation::Covering->  
Heuristic covering\_heuristic>  
`std::optional<datastructures::SampledDerivationRef<typename operators::PropertiesSet<op>>->`  
`::type > smrat::cadcells::algorithms::get_level_covering (`  
 `datastructures::Projections & proj,`  
 `const std::vector< Atom > & constraints,`  
 `const Assignment & sample )`

Computes an unsat covering w.r.t.  
a set of constraints.

If a constraint is univariate under a sample, for the unassigned variables, the constraint induces intervals in which the constraint will be conflicting. If multiple such intervals from a set of constraints cover the real line, then the partial sample cannot be extended without making a conflict. This conflict is generalized.

#### Parameters

|                    |                                                                                                                                                             |
|--------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <i>constraints</i> | Atoms of the same level such that sample cannot be extended for the highest variable without making one atom false. Note that this property is not checked. |
| <i>sample</i>      | A sample such that all but the highest variable in constraints are assigned.                                                                                |

#### Returns

A sampled derivation which contains the information to reproduce the conflict.

**0.14.26.2.3 get\_unsat\_intervals()** [1/3] template<cadcells::operators::op op>

```
std::vector<datastructures::SampledDerivationRef<typename operators::PropertiesSet<op>><
::type> > smtrat::cadcells::algorithms::get_unsat_intervals (
 const Atom & c,
 datastructures::Projections & proj,
 const Assignment & sample)
```

Returns the unsat intervals of the given atom w.r.t.  
an underlying sample.

#### Parameters

|               |                                                                                                                                        |
|---------------|----------------------------------------------------------------------------------------------------------------------------------------|
| <i>c</i>      | A constraint or a variable comparison.                                                                                                 |
| <i>sample</i> | A sample point such that the highest variable in <i>c</i> w.r.t. the variable ordering in <i>proj</i> is the only unassigned variable. |

#### Returns

A list of sampled derivations with the same delineated derivations. The samples for the unassigned variables are sampled from the respective interval.

#### 0.14.26.2.4 `get_unsat_intervals()` [2/3] template<cadcells::operators::op op>

```
std::vector<datastructures::SampledDerivationRef<typename operators::PropertiesSet<op>><
::type> > smtrat::cadcells::algorithms::get_unsat_intervals (
 const Constraint & c,
 datastructures::Projections & proj,
 const Assignment & sample)
```

#### 0.14.26.2.5 `get_unsat_intervals()` [3/3] template<cadcells::operators::op op>

```
std::vector<datastructures::SampledDerivationRef<typename operators::PropertiesSet<op>><
::type> > smtrat::cadcells::algorithms::get_unsat_intervals (
 const VariableComparison & c,
 datastructures::Projections & proj,
 const Assignment & sample)
```

### Data Structures

- struct [TaggedIndexedRoot](#)
- class [DelineationInterval](#)

*An interval of a delineation.*

- class [Delineation](#)

*Represents the delineation of a set of polynomials (at a sample), that is.*

- class [BaseDerivation](#)

*A [BaseDerivation](#) has a level and a set of properties of this level, and an underlying derivation representing the lower levels.*

- class [DelineatedDerivation](#)

*A [DelineatedDerivation](#) is a [BaseDerivation](#) with a [Delineation](#) and an underlying [SampledDerivation](#).*

- class [SampledDerivation](#)

A [SampledDerivation](#) is a [DelineatedDerivation](#) with a sample and an [DelineationInterval](#) w.r.t.

- class [DerivationRef](#)  
*A reference to a derivation, which is either.*
- struct [PolyRef](#)  
*Refers to a polynomial.*
- class [PolyPool](#)  
*A pool for polynomials.*
- class [Projections](#)  
*Encapsulates all computations on polynomials.*
- struct [property\\_hash](#)
- struct [PropertiesTContent](#)
- struct [PropertiesTContent< T, true >](#)
- struct [PropertiesTContent< T, false >](#)
- struct [PropertiesT](#)  
*Set of properties.*
- struct [PropertiesT< T, Ts... >](#)
- struct [CellRepresentation](#)  
*Represents a cell.*
- struct [CoveringRepresentation](#)  
*Represents a covering over a cell.*
- struct [IndexedRoot](#)  
*Represents the i-th root of a multivariate polynomial at its main variable (given an appropriate sample).*
- struct [CompoundMin](#)  
*Represents the minimum function of the contained indexed root functions.*
- struct [CompoundMax](#)  
*Represents the maximum function of the contained indexed root functions.*
- class [RootFunction](#)
- class [Bound](#)  
*Bound type of a [SymbolicInterval](#).*
- class [SymbolicInterval](#)  
*A symbolic intreal whose bounds are defined by indexed root expressions.*
- class [CoveringDescription](#)  
*Describes a covering of the real line by [SymbolicIntervals](#) (given an appropriate sample).*
- struct [IndexedRootRelation](#)  
*A relation between two roots.*
- class [IndexedRootOrdering](#)  
*Describes an ordering of [IndexedRoots](#).*

#### 0.14.27.1 Detailed Description

Main datastructures.

**0.14.27.1.1 Polynomials and projection results** We assume a fixed variable ordering `VariableOrdering`. All polynomials are pooled in `PolyPool` w.r.t. this ordering, that is, they are identified by a `PolyRef` (a pair of the polynomial's level and an ID on this level). Projection results are cached in `Projections`. The latter holds a reference to a `PolyPool`. An instance `Projections` will be required for all kinds of operations and passed during various function calls. Thus, we initialize these data structures as follows:

```
VariableOrdering vars; // a variable ordering of all variables that will occur.
datastructures::PolyPool pool(vars);
datastructures::Projections proj(pool);
```

Note that `PolyPool` and `Projections` do not do reference counting; the cache needs to be cleared explicitly, see `Projections::clear_cache` and `Projections::clear_assignment_cache`.

**0.14.27.1.2 Basic datastructures** The basic datastructures for representing mathematical objects are `datastructures::IndexedRoot`, `datastructures::SymbolicInterval`, `datastructures::CoveringDescription`, and `datastructures::IndexedRootOrdering`.

**0.14.27.1.3 Properties** `datastructures::PropertiesT` is the datastructure for storing properties on a single level. If you work on an algorithm using this framework, you don't need to know this datastructure. If you need to implement a new property, then you find the interfaces a property needs to implement there.

**0.14.27.1.4 Delineations** `datastructures::Delineation` is the datastructure for storing the delineation of the indexed roots that stem from properties.

If you work on an algorithm using this framework, you don't need to know this datastructure. If you need to implement a new property or a heuristic for describing a cell (i.e. compute a representation), then you might be interested in this.

**0.14.27.1.5 Derivations** In the derivation datastructures, all data regarding the derivation is stored - that is the current sample points, the set of properties, the delineation of roots and the possible cell boundaries.

This datastructure is recursive, that is, each derivation object handles only a single level and holds a pointer to a derivation object of the next lower level (the underlying derivation). All operations are forwarded to lower levels whenever necessary.

Furthermore, there are three types of derivations:

- `datastructures::BaseDerivation` assumes no sample point or whatever. It simply stores properties.

- `datastructures::DelineatedDerivation` extends the `datastructures::BaseDerivation`; it requires that the underlying derivation is a `datastructures::SampledDerivation`, thus a sample for all lower levels is present under which the properties of the current level can be delineated (i.e. their zeros can be isolated and sorted).
- `datastructures::SampledDerivation` extends the `datastructures::DelineatedDerivation`, thus a full sample point is available for which a cell can be isolated. The derivation datastructures are thus two-dimensional recursive. Note that multiple derivation objects can have common underlying cells or even share the same base or delineated derivation.

`datastructures::DerivationRef` allows to reference a derivation independent of its type.

For initializing derivations properly, use `datastructures::make_derivation`. To create a sampled derivation from a delineated derivation and a sample, use `datastructures::make_sampled_derivation`. For merging underlying derivations, use `datastructures::merge_underlying`.

For more information on memory management read `datastructures::DerivationRef`.

**0.14.27.1.6 Representations** The derivation objects do not store heuristic decisions, they just describe the current state. At some point, a representation of this state needs to be determined that is passed to the operator. This heuristic decision is stored in `datastructures::CellRepresentation` or `datastructures::CoveringRepresentation`. The heuristics for computing representations are in `representation`.

**0.14.27.1.7 Operators** The `operators` work on derivations and representations.

## 0.14.27.2 Typedef Documentation

### 0.14.27.2.1 BaseDerivationRef template<typename Properties >

```
using smtrat::cadcells::datastructures::BaseDerivationRef = typedef std::shared_ptr<BaseDerivation<Properties>>
```

### 0.14.27.2.2 DelineatedDerivationRef template<typename Properties >

```
using smtrat::cadcells::datastructures::DelineatedDerivationRef = typedef std::shared_ptr<DelineatedDerivation<Properties>>
```

### 0.14.27.2.3 PropertiesTSet template<typename T >

```
using smtrat::cadcells::datastructures::PropertiesTSet = typedef boost::container::flat_set<T>
```

### 0.14.27.2.4 RootMap using smtrat::cadcells::datastructures::RootMap = typedef std::map<RAN, std::vector<TaggedIndexedRoot>>

### 0.14.27.2.5 RootMapPlain using smtrat::cadcells::datastructures::RootMapPlain = typedef std::map<RAN, std::vector<IndexedRoot>>

### 0.14.27.2.6 SampledDerivationRef template<typename Properties >

```
using smtrat::cadcells::datastructures::SampledDerivationRef = typedef std::shared_ptr<SampledDerivation<Properties>>
```

## 0.14.27.3 Function Documentation

**0.14.27.3.1 `lower_eq_lower()`** `bool smtrat::cadcells::datastructures::lower_eq_lower (`  
    `const DelineationInterval & del1,`  
    `const DelineationInterval & del2 ) [inline]`

Compares the lower bounds of two DelineationIntervals.

It respects whether the interval is a section or sector.

**0.14.27.3.2 `lower_lt_lower()`** `bool smtrat::cadcells::datastructures::lower_lt_lower (`  
    `const DelineationInterval & del1,`  
    `const DelineationInterval & del2 ) [inline]`

Compares the lower bounds of two DelineationIntervals.

It respects whether the interval is a section or sector.

**0.14.27.3.3 `make_derivation()`** `template<typename Properties >`  
`DerivationRef<Properties> smtrat::cadcells::datastructures::make_derivation (`  
    `Projections & proj,`  
    `const Assignment & assignment,`  
    `size_t level )`

Initializes a derivation according the the given assignment and level.

**0.14.27.3.4 `make_sampled_derivation()`** `template<typename Properties >`  
`SampledDerivationRef<Properties> smtrat::cadcells::datastructures::make_sampled_derivation (`  
    `DelineatedDerivationRef<Properties> delineated,`  
    `const RAN & main_sample )`

Initializes a sampled derivation w.r.t.

the delineated derivation and sample.

**0.14.27.3.5 `merge()`** `template<class T , class... Ts>`  
`void smtrat::cadcells::datastructures::merge (`  
    `PropertiesT< T, Ts... > & sets_a,`  
    `const PropertiesT< T, Ts... > & sets_b )`

**0.14.27.3.6 `merge_underlying()`** `template<typename Properties >`

`void smtrat::cadcells::datastructures::merge_underlying (`  
    `std::vector< SampledDerivationRef<Properties>> & derivations )`

Merges the underlying derivations of a set of sampled derivations.

After the operation, all sampled derivations point to the same underlying derivation.

**0.14.27.3.7 `operator"!=() [1/5]`** `bool smtrat::cadcells::datastructures::operator!= (`  
    `const CompoundMax & lhs,`  
    `const CompoundMax & rhs ) [inline]`

**0.14.27.3.8 `operator"!=() [2/5]`** `bool smtrat::cadcells::datastructures::operator!= (`  
    `const CompoundMin & lhs,`  
    `const CompoundMin & rhs ) [inline]`

**0.14.27.3.9 `operator"!=() [3/5]`** `bool smtrat::cadcells::datastructures::operator!= (`  
    `const IndexedRoot & lhs,`  
    `const IndexedRoot & rhs ) [inline]`

**0.14.27.3.10 operator"!=() [4/5]** bool smtrat::cadcells::datastructures::operator!= ( const PolyRef & lhs, const PolyRef & rhs ) [inline]

**0.14.27.3.11 operator"!=() [5/5]** bool smtrat::cadcells::datastructures::operator!= ( const RootFunction & lhs, const RootFunction & rhs ) [inline]

**0.14.27.3.12 operator<() [1/8]** bool smtrat::cadcells::datastructures::operator< ( const CompoundMax & lhs, const CompoundMax & rhs ) [inline]

**0.14.27.3.13 operator<() [2/8]** bool smtrat::cadcells::datastructures::operator< ( const CompoundMin & lhs, const CompoundMin & rhs ) [inline]

**0.14.27.3.14 operator<() [3/8]** template<typename P> bool smtrat::cadcells::datastructures::operator< ( const DerivationRef< P > & lhs, const DerivationRef< P > & rhs )

**0.14.27.3.15 operator<() [4/8]** bool smtrat::cadcells::datastructures::operator< ( const IndexedRoot & lhs, const IndexedRoot & rhs ) [inline]

**0.14.27.3.16 operator<() [5/8]** bool smtrat::cadcells::datastructures::operator< ( const IndexedRootRelation & lhs, const IndexedRootRelation & rhs ) [inline]

**0.14.27.3.17 operator<() [6/8]** bool smtrat::cadcells::datastructures::operator< ( const PolyRef & lhs, const PolyRef & rhs ) [inline]

**0.14.27.3.18 operator<() [7/8]** bool smtrat::cadcells::datastructures::operator< ( const RootFunction & lhs, const RootFunction & rhs ) [inline]

**0.14.27.3.19 operator<() [8/8]** bool smtrat::cadcells::datastructures::operator< ( const TaggedIndexedRoot & lhs, const TaggedIndexedRoot & rhs ) [inline]

**0.14.27.3.20 operator<<() [1/14]** template<typename P> std::ostream& smtrat::cadcells::datastructures::operator<< ( std::ostream & os, const CellRepresentation< P > & data ) [inline]

- 0.14.27.3.21** `operator<<()` [2/14] `std::ostream& smtrat::cadcells::datastructures::operator<< ( std::ostream & os, const CompoundMax & data ) [inline]`
- 0.14.27.3.22** `operator<<()` [3/14] `std::ostream& smtrat::cadcells::datastructures::operator<< ( std::ostream & os, const CompoundMin & data ) [inline]`
- 0.14.27.3.23** `operator<<()` [4/14] `std::ostream& smtrat::cadcells::datastructures::operator<< ( std::ostream & os, const CoveringDescription & data ) [inline]`
- 0.14.27.3.24** `operator<<()` [5/14] `template<typename P > std::ostream& smtrat::cadcells::datastructures::operator<< ( std::ostream & os, const CoveringRepresentation< P > & data )`
- 0.14.27.3.25** `operator<<()` [6/14] `std::ostream& smtrat::cadcells::datastructures::operator<< ( std::ostream & os, const Delineation & data ) [inline]`
- 0.14.27.3.26** `operator<<()` [7/14] `std::ostream& smtrat::cadcells::datastructures::operator<< ( std::ostream & os, const DelineationInterval & data ) [inline]`
- 0.14.27.3.27** `operator<<()` [8/14] `std::ostream& smtrat::cadcells::datastructures::operator<< ( std::ostream & os, const IndexedRoot & data ) [inline]`
- 0.14.27.3.28** `operator<<()` [9/14] `std::ostream& smtrat::cadcells::datastructures::operator<< ( std::ostream & os, const IndexedRootOrdering & data ) [inline]`
- 0.14.27.3.29** `operator<<()` [10/14] `std::ostream& smtrat::cadcells::datastructures::operator<< ( std::ostream & os, const IndexedRootRelation & data ) [inline]`
- 0.14.27.3.30** `operator<<()` [11/14] `std::ostream& smtrat::cadcells::datastructures::operator<< ( std::ostream & os, const PolyRef & data ) [inline]`
- 0.14.27.3.31** `operator<<()` [12/14] `std::ostream& smtrat::cadcells::datastructures::operator<< ( std::ostream & os, const RootFunction & data ) [inline]`

**0.14.27.3.32 operator<<()** [13/14] std::ostream& smtrat::cadcells::datastructures::operator<< ( std::ostream & os, const SymbolicInterval & data ) [inline]

**0.14.27.3.33 operator<<()** [14/14] std::ostream& smtrat::cadcells::datastructures::operator<< ( std::ostream & os, const TaggedIndexedRoot & data ) [inline]

**0.14.27.3.34 operator==()** [1/8] bool smtrat::cadcells::datastructures::operator== ( const CompoundMax & lhs, const CompoundMax & rhs ) [inline]

**0.14.27.3.35 operator==()** [2/8] bool smtrat::cadcells::datastructures::operator== ( const CompoundMin & lhs, const CompoundMin & rhs ) [inline]

**0.14.27.3.36 operator==()** [3/8] template<typename P> bool smtrat::cadcells::datastructures::operator== ( const DerivationRef< P > & lhs, const DerivationRef< P > & rhs )

**0.14.27.3.37 operator==()** [4/8] bool smtrat::cadcells::datastructures::operator== ( const IndexedRoot & lhs, const IndexedRoot & rhs ) [inline]

**0.14.27.3.38 operator==()** [5/8] bool smtrat::cadcells::datastructures::operator== ( const IndexedRootRelation & lhs, const IndexedRootRelation & rhs ) [inline]

**0.14.27.3.39 operator==()** [6/8] bool smtrat::cadcells::datastructures::operator== ( const PolyRef & lhs, const PolyRef & rhs ) [inline]

**0.14.27.3.40 operator==()** [7/8] bool smtrat::cadcells::datastructures::operator== ( const RootFunction & lhs, const RootFunction & rhs ) [inline]

**0.14.27.3.41 operator==()** [8/8] bool smtrat::cadcells::datastructures::operator== ( const TaggedIndexedRoot & lhs, const TaggedIndexedRoot & rhs ) [inline]

**0.14.27.3.42 prop\_get()** [1/2] template<class T, class... Ts> const auto& smtrat::cadcells::datastructures::prop\_get ( const Propertiest< T, Ts... > & sets )

**0.14.27.3.43 prop\_get() [2/2]** template<class S , class T , class... Ts, typename std::enable\_if<!std::is\_same< S, T >::value>::type>  
const auto& smtrat::cadcells::datastructures::prop\_get (  
 const PropertiesT< T, Ts... > & sets )

**0.14.27.3.44 prop\_has() [1/2]** template<class S , class T , class... Ts, typename std::enable\_if<!std::is\_same< S, T >::value>::type>  
bool smtrat::cadcells::datastructures::prop\_has (  
 const PropertiesT< T, Ts... > & sets,  
 const S & element )

**0.14.27.3.45 prop\_has() [2/2]** template<class T , class... Ts>  
bool smtrat::cadcells::datastructures::prop\_has (  
 const PropertiesT< T, Ts... > & sets,  
 const T & element )

**0.14.27.3.46 prop\_insert() [1/2]** template<class S , class T , class... Ts, typename std::enable\_if<!std::is\_same< S, T >::value>::type>  
void smtrat::cadcells::datastructures::prop\_insert (  
 PropertiesT< T, Ts... > & sets,  
 const S & element )

**0.14.27.3.47 prop\_insert() [2/2]** template<class T , class... Ts>  
void smtrat::cadcells::datastructures::prop\_insert (  
 PropertiesT< T, Ts... > & sets,  
 const T & element )

**0.14.27.3.48 upper\_lt\_lower()** bool smtrat::cadcells::datastructures::upper\_lt\_lower (  
 const DelineationInterval & del1,  
 const DelineationInterval & del2 ) [inline]

Compares an upper bound with a lower bound of DelineationIntervals.

It respects whether the interval is a section or sector.

**0.14.27.3.49 upper\_lt\_upper()** bool smtrat::cadcells::datastructures::upper\_lt\_upper (  
 const DelineationInterval & del1,  
 const DelineationInterval & del2 ) [inline]

Compares the upper bounds of two DelineationIntervals.

It respects whether the interval is a section or sector.

## Variables

- static const char \* OpStrings [] = { "mccallum", "mccallum\_filtered", "mccallum\_filtered\_all", "mccallum\_filtered\_bounds", "mccallum\_filtered\_samples", "mccallum\_filtered\_all\_selective" }

### 0.14.30.1 Detailed Description

Projection operators.

Currently, only the McCallum based operator is implemented.

#### 0.14.30.1.1 Relevant projection functions

We refer to [algorithms](#) for usage examples.

##### 0.14.30.1.1.1 Cells

- project\_cell\_properties
- project\_basic\_properties
- delineate\_properties
- project\_delineated\_cell\_properties

### 0.14.30.1.1.2 Coverings

- project\_cell\_properties (on each cell individually)
- project\_basic\_properties (on each cell individually)
- delineate\_properties (on each cell individually)
- project\_covering\_properties

### 0.14.30.1.1.3 Delineation

- project\_basic\_properties
- delineate\_properties
- project\_delineation\_properties

## 0.14.30.2 Enumeration Type Documentation

### 0.14.30.2.1 op enum smtrat::cadcells::operators::op

Enumerator

|                                 |  |
|---------------------------------|--|
| mccallum                        |  |
| mccallum_filtered               |  |
| mccallum_filtered_all           |  |
| mccallum_filtered_bounds        |  |
| mccallum_filtered_samples       |  |
| mccallum_filtered_all_selective |  |

## 0.14.30.3 Function Documentation

### 0.14.30.3.1 delineate\_properties() [1/2] template<op Op>

```
void smtrat::cadcells::operators::delineate_properties (
 datastructures::DelineatedDerivation< typename PropertiesSet< Op >::type > &
deriv) [inline]
Delineate properties.
```

### 0.14.30.3.2 delineate\_properties() [2/2] template<op Op>

```
void smtrat::cadcells::operators::delineate_properties (
 datastructures::SampledDerivation< typename PropertiesSet< Op >::type > & deriv
) [inline]
Delineate properties.
```

### 0.14.30.3.3 delineate\_properties< op::mccallum >() [1/2] template<>

```
void smtrat::cadcells::operators::delineate_properties< op::mccallum > (
 datastructures::DelineatedDerivation< PropertiesSet< op::mccallum >::type > &
deriv) [inline]
```

**0.14.30.3.4 delineate\_properties< op::mccallum >()** [2/2] template<>  
void smtrat::cadcells::operators::delineate\_properties< op::mccallum > ( datastructures::SampledDerivation< PropertiesSet< op::mccallum >::type > & deriv ) [inline]

**0.14.30.3.5 delineate\_properties< op::mccallum\_filtered >()** template<>

**0.14.30.3.11 project\_basic\_properties()** template<op Op>  
bool smtrat::cadcells::operators::project\_basic\_properties ( datastructures::DelineatedDerivation< typename PropertiesSet< Op >::type > & deriv ) [inline]

Project basic properties, i.e.  
independent from any sample or delineation.

**0.14.30.3.12 project\_basic\_properties< op::mccallum >()** template<>  
bool smtrat::cadcells::operators::project\_basic\_properties< op::mccallum > ( datastructures::DelineatedDerivation< PropertiesSet< op::mccallum >::type > & deriv ) [inline]

**0.14.30.3.13 `project_cell_properties()`** template<op Op>  
`bool smtrat::cadcells::operators::project_cell_properties (`  
 `datastructures::SampledDerivation< typename PropertiesSet< Op >::type > & deriv`  
`) [inline]`  
 Project cell properties.  
 Returns false iff the given operator is incomplete and cannot cover the given case (i.e. on nullification with McCallum).

**0.14.30.3.14 `project_cell_properties< op::mccallum >()`** template<>  
`bool smtrat::cadcells::operators::project_cell_properties< op::mccallum > (`  
 `datastructures::SampledDerivation< PropertiesSet< op::mccallum >::type > & deriv`  
`) [inline]`

**0.14.30.3.15 `project_covering_properties()`** template<op Op>  
`bool smtrat::cadcells::operators::project_covering_properties (`  
 `datastructures::CoveringRepresentation< typename PropertiesSet< Op >::type > &`  
`repr ) [inline]`  
 Project covering properties.

**0.14.30.3.16 `project_covering_properties< op::mccallum >()`** template<>  
`bool smtrat::cadcells::operators::project_covering_properties< op::mccallum > (`  
 `datastructures::CoveringRepresentation< PropertiesSet< op::mccallum >::type > &`  
`repr ) [inline]`

**0.14.30.3.17 `project_delineated_cell_properties()`** template<op Op>  
`bool smtrat::cadcells::operators::project_delineated_cell_properties (`  
 `datastructures::CellRepresentation< typename PropertiesSet< Op >::type > & deriv,`  
 `bool cell_represents = true ) [inline]`  
 Project cell properties that depend on a delineation.

**0.14.30.3.18 `project_delineated_cell_properties< op::mccallum >()`** template<>  
`bool smtrat::cadcells::operators::project_delineated_cell_properties< op::mccallum > (`  
 `datastructures::CellRepresentation< PropertiesSet< op::mccallum >::type > &`  
`repr,`  
 `bool cell_represents ) [inline]`

### 0.14.32.1 Detailed Description

Contains all properties that are stored in a derivation.

Note that not all properties have a representation here as not all of them are stored but resolved directly in the derivation rules.

### 0.14.32.2 Function Documentation

#### 0.14.33.1 Detailed Description

Implementation of derivation rules.

Each rule is realized by a function which works on a derivation object. The parameters of the respective properties are passed as function parameter. The function realizing a derivation rule might either call other derivation rules or add properties to the given derivation.

#### 0.14.33.2 Function Documentation

### Enumerations

- enum class [Updated](#) { [LEFT](#) , [RIGHT](#) , [BOTH](#) , [NONE](#) }

### Functions

- std::vector< Poly > [getNonlinearMonomials](#) (const Poly &\_expr)  
*Obtains the non-linear monomials of the given polynomial.*
- std::pair< ConstraintT, ConstraintT > [intervalToConstraint](#) (const Poly &\_lhs, const smtrat::DoubleInterval \_interval)  
*Creates a new constraint from an existing interval.*
- bool [intervalBoxContainsEmptyInterval](#) (const EvalDoubleIntervalMap &\_intervals)  
*Checks mIntervals if it contains an empty interval.*
- const LRAVariable \* [getOriginalLraVar](#) (carl::Variable::Arg \_var, const LRAVariable< LRASettings1 > &\_lra)

### 0.14.47.1 Typedef Documentation

**0.14.47.1.1 Contractor** template<template< typename > class Operator>  
using [smtrat::icp::Contractor](#) = typedef carl::Contraction<Operator, Poly>

**0.14.47.1.2 LRAVariable** typedef [LRAVariable](#)< LRASettings1 >::[LRAVariable](#) [smtrat::icp::LRAVariable](#)

**0.14.47.1.3 set\_icpVariable** typedef std::set<const [IcpVariable](#)\*, [icpVariableComp](#)> [smtrat::icp::set\\_icpVariable](#)

### 0.14.47.2 Enumeration Type Documentation

**0.14.47.2.1 Updated** enum [smtrat::icp::Updated](#) [strong]

#### Enumerator

|       |  |
|-------|--|
| LEFT  |  |
| RIGHT |  |
| BOTH  |  |
| NONE  |  |

### 0.14.47.3 Function Documentation

**0.14.47.3.1 getNonlinearMonomials()** `std::vector< Poly > smtrat::icp::getNonlinearMonomials ( const Poly & _expr )`

Obtains the non-linear monomials of the given polynomial.

#### Parameters

|                    |                                                        |
|--------------------|--------------------------------------------------------|
| <code>_expr</code> | The polynomial to obtain the non-linear monomials for. |
|--------------------|--------------------------------------------------------|

#### Returns

The non-linear monomials.

**0.14.47.3.2 getOriginalLraVar()** `const LRAModule< LRASettings1 >::LRAVariable * smtrat::icp::getOriginalLraVar (`

`carl::Variable::Arg _var,`  
`const LRAModule< LRASettings1 > & _lra )`

**0.14.47.3.3 intervalBoxContainsEmptyInterval()** `bool smtrat::icp::intervalBoxContainsEmptyInterval (`

`const EvalDoubleIntervalMap & _intervals )`

Checks mIntervals if it contains an empty interval.

#### Returns

**0.14.47.3.4 intervalToConstraint()** `std::pair< ConstraintT, ConstraintT > smtrat::icp::intervalToConstraint (`

`const Poly & _lhs,`  
`const smtrat::DoubleInterval _interval )`

Creates a new constraint from an existing interval.

#### Parameters

|                        |  |
|------------------------|--|
| <code>_interval</code> |  |
|------------------------|--|

#### Returns

`pair <lowerBoundConstraint*, upperBoundConstraint*>`

## 0.14.48 smtrat::impl Namespace Reference

### Data Structures

- class `fixedsize_allocator_impl`
- class `fixedsize_freelists`

*Publicly derive from all `fixedsize_freelist` types with chunk sizes between `SizeCurrent` and `SizeMax`.*

- class `fixedsize_freelists< SizeCurrent, SizeMax, true >`
- class `fixedsize_allocator_freelists`

- class [fixedsize\\_allocator\\_impl< T, SizeShift, true, true >](#)
- class [fixedsize\\_allocator\\_size\\_helper](#)

## Functions

- template<typename T >  
static CONSTEXPR std::size\_t [roundup\\_log2](#) (T)
- Used to find ceil(log2(n)) (the shift distance in the freelist allocator).*

## Variables

- static CONSTEXPR std::size\_t [LOWER\\_SIZE\\_BOUND](#) = sizeof(void\*)

### 0.14.49.1 Typedef Documentation

#### 0.14.49.1.1 **EntryID** **typedef size\_t smtrat::lra::EntryID**

### 0.14.49.2 Function Documentation

#### 0.14.49.2.1 **abs()** **Numeric smtrat::lra::abs (const Numeric & \_value )**

Calculates the absolute value of the given **Numeric**.

#### Parameters

|               |                                                         |
|---------------|---------------------------------------------------------|
| <b>_value</b> | The <b>Numeric</b> to calculate the <b>Numeric</b> for. |
|---------------|---------------------------------------------------------|

**Returns**

The absolute value of the given [Numeric](#).

**0.14.49.2.2 gcd()** [Numeric](#) smtrat::lra::gcd (

```
const Numeric & _valueA,
const Numeric & _valueB)
```

Calculates the greatest common divisor of the two arguments.

Note, that this method can only be applied to integers.

**Parameters**

|                      |             |
|----------------------|-------------|
| <code>_valueA</code> | An integer. |
| <code>_valueB</code> | An integer. |

**Returns**

The least common divisor of the two arguments.

**0.14.49.2.3 lcm()** [Numeric](#) smtrat::lra::lcm (

```
const Numeric & _valueA,
const Numeric & _valueB)
```

Calculates the least common multiple of the two arguments.

Note, that this method can only be applied to integers.

**Parameters**

|                      |             |
|----------------------|-------------|
| <code>_valueA</code> | An integer. |
| <code>_valueB</code> | An integer. |

**Returns**

The least common multiple of the two arguments.

**0.14.49.2.4 mod()** [Numeric](#) smtrat::lra::mod (

```
const Numeric & _valueA,
const Numeric & _valueB)
```

Calculates the result of the first argument modulo the second argument.

Note, that this method can only be applied to integers.

**Parameters**

|                      |                  |
|----------------------|------------------|
| <code>_valueA</code> | An integer.      |
| <code>_valueB</code> | An integer != 0. |

**Returns**

The first argument modulo the second argument.

**0.14.49.2.5 operator\*()** [Numeric](#) smtrat::lra::operator\* (

```
 const Numeric & _valueA,
 const Numeric & _valueB)
```

Calculates the product of the two given Numerics.

#### Parameters

|         |                    |
|---------|--------------------|
| _valueA | The first factor.  |
| _valueB | The second factor. |

#### Returns

The product of the two given Numerics.

**0.14.49.2.6 operator\*=( )** `Numeric & smtrat::lra::operator*=(`  
 `Numeric & _valueA,`  
 `const Numeric & _valueB )`

Multiplies the second given [Numeric](#) to the first given [Numeric](#).

#### Parameters

|         |                                             |
|---------|---------------------------------------------|
| _valueA | The <a href="#">Numeric</a> to multiply.    |
| _valueB | The <a href="#">Numeric</a> to multiply by. |

#### Returns

The first given [Numeric](#) multiplied by the second given [Numeric](#).

**0.14.49.2.7 operator+()** `Numeric smtrat::lra::operator+ (`  
 `const Numeric & _valueA,`  
 `const Numeric & _valueB )`

Calculates the sum of the two given Numerics.

#### Parameters

|         |                     |
|---------|---------------------|
| _valueA | The first summand.  |
| _valueB | The second summand. |

#### Returns

The sum of the two given Numerics.

**0.14.49.2.8 operator++()** `Numeric & smtrat::lra::operator++ (`  
 `Numeric & _value )`

Increments the given [Numeric](#) by one.

#### Parameters

|        |                                           |
|--------|-------------------------------------------|
| _value | The <a href="#">Numeric</a> to increment. |
|--------|-------------------------------------------|

**Returns**

The given [Numeric](#) incremented by one.

**0.14.49.2.9 operator+=() [Numeric](#) & smtrat::lra::operator+= (**

```
 Numeric & _valueA,
 const Numeric & _valueB)
```

Adds the value of the second given [Numeric](#) to the second given [Numeric](#).

**Parameters**

|                         |                                        |
|-------------------------|----------------------------------------|
| <a href="#">_valueA</a> | The <a href="#">Numeric</a> to add to. |
| <a href="#">_valueB</a> | The <a href="#">Numeric</a> to add.    |

**Returns**

The first given [Numeric](#) increased by the second given [Numeric](#).

**0.14.49.2.10 operator-() [1/2] [Numeric](#) smtrat::lra::operator- (**

```
 const Numeric & _value)
```

Calculates the additive inverse of the given [Numeric](#).

**Parameters**

|                        |                                                                    |
|------------------------|--------------------------------------------------------------------|
| <a href="#">_value</a> | The <a href="#">Numeric</a> to calculate the additive inverse for. |
|------------------------|--------------------------------------------------------------------|

**Returns**

The additive inverse of the given [Numeric](#).

**0.14.49.2.11 operator-() [2/2] [Numeric](#) smtrat::lra::operator- (**

```
 const Numeric & _valueA,
 const Numeric & _valueB)
```

Calculates the difference between the two given Numerics.

**Parameters**

|                         |                 |
|-------------------------|-----------------|
| <a href="#">_valueA</a> | The minuend.    |
| <a href="#">_valueB</a> | The subtrahend. |

**Returns**

The difference between the two given Numerics.

**0.14.49.2.12 operator--() [Numeric](#) & smtrat::lra::operator-- (**

```
 Numeric & _value)
```

Decrements the given [Numeric](#) by one.

**Parameters**

|                        |                                           |
|------------------------|-------------------------------------------|
| <a href="#">_value</a> | The <a href="#">Numeric</a> to decrement. |
|------------------------|-------------------------------------------|

**Returns**

The given [Numeric](#) decremented by one.

**0.14.49.2.13 operator=( )** [Numeric](#) & smtrat::lra::operator== (

```
 Numeric & _valueA,
 const Numeric & _valueB)
```

Subtracts the second given [Numeric](#) to the first given [Numeric](#).

**Parameters**

|                         |                                               |
|-------------------------|-----------------------------------------------|
| <a href="#">_valueA</a> | The <a href="#">Numeric</a> to subtract from. |
| <a href="#">_valueB</a> | The <a href="#">Numeric</a> to subtract.      |

**Returns**

The first given [Numeric](#) subtracted by the second given [Numeric](#).

**0.14.49.2.14 operator/()** [Numeric](#) smtrat::lra::operator/ (

```
 const Numeric & _valueA,
 const Numeric & _valueB)
```

Calculates the division of the two given Numerics.

**Parameters**

|                         |               |
|-------------------------|---------------|
| <a href="#">_valueA</a> | The dividend. |
| <a href="#">_valueB</a> | The divisor.  |

**Returns**

The difference of the two given Numerics.

**0.14.49.2.15 operator/=( )** [Numeric](#) & smtrat::lra::operator/= (

```
 Numeric & _valueA,
 const Numeric & _valueB)
```

Divides the first given [Numeric](#) by the second given [Numeric](#).

**Parameters**

|                         |                                           |
|-------------------------|-------------------------------------------|
| <a href="#">_valueA</a> | The <a href="#">Numeric</a> to divide.    |
| <a href="#">_valueB</a> | The <a href="#">Numeric</a> to divide by. |

**Returns**

The first given [Numeric](#) divided by the second given [Numeric](#).

**0.14.49.2.16 operator<<()** [1/2] std::ostream & smtrat::lra::operator<< (

```
 std::ostream & _out,
 const Numeric & _value)
```

Prints the given Numerics representation on the given output stream.

**Parameters**

|                     |                                       |
|---------------------|---------------------------------------|
| <code>_out</code>   | The output stream to print on.        |
| <code>_value</code> | The <a href="#">Numeric</a> to print. |

**Returns**

The output stream after printing the given Numerics representation on it.

```
0.14.49.2.17 operator<<() [2/2] template<typename T1>
std::ostream& smtrat::lra::operator<<(
 std::ostream & _out,
 const Value< T1 > & _value)
```

### 0.14.52.2 Enumeration Type Documentation

#### 0.14.52.2.1 ConstraintType enum `smtrat::mcsat::ConstraintType` [strong]

This type categorizes constraints with respect to a given (partial) model and the next variable to be assigned. Note that Constant implies Assigned.

##### Enumerator

|            |                                                                                                                                         |
|------------|-----------------------------------------------------------------------------------------------------------------------------------------|
| Constant   |                                                                                                                                         |
| Assigned   | The constraint contains no variables.                                                                                                   |
| Univariate | The constraint is fully assigned.                                                                                                       |
| Unassigned | The constraint has a single unassigned variable being the next one. The constraint has an unassigned variable that is not the next one. |

#### 0.14.52.2.2 VariableOrdering enum `smtrat::mcsat::VariableOrdering` [strong]

#### 0.14.55.1 Detailed Description

A Fourier-Motzkin based backend.

Preprocessing of constraints:

The input is a constraint  $c: p*x \sim q$  which can be used as a bound on  $x$  with  $p,q$  multivariate polynomials. If  $x$  only occurs linearly in  $c$ , this decomposition is possible. If  $p$  is zero, then  $c$  is conflicting iff  $!(0 \sim q)$ . If this is the case, we can return  $(c \&& p=0) \rightarrow 0 \sim q$  as explanation. Otherwise, we evaluate  $c$  over the partial model and obtain  $x \sim r$ , where  $r$  is a rational. To properly perform the elimination step detailed below, we additionally store whether  $p$  is negative over the current assignment as a Boolean.

We store  $(c,p,q,r,n)$  for each bound.

FM elimination:

Given a lower bound  $l$  and an upper bound  $u$ , the elimination is as follows: Conflict if  $l.r \geq u.r$  (or strict, if both relations from  $c$  are weak)  $l.q * u.p < u.q * l.p$

If exactly one of  $u.p$  and  $l.p$  was found to be negative, the relation has to be inverted. If  $u.p$  or  $l.p$  are not constants, we additionally have to add a literal stating that their sign does not change.

For all bounds involved, we add  $b.p < 0$  resp.  $b.p > 0$  as side condition to the explanation.

Handling of "not equal":

For linear arithmetic, a bound  $i$  belonging to a constraint with relation  $\neq$  can be in conflict with

- a bound e for a constraint with = iff  $i.r == e.r$ , then we return  $i.c \&& e.c \rightarrow i.q * e.p != e.q * i.p$
- two bounds l, u with  $\geq$  resp.  $\leq$  as relation and  $i.r == l.r == u.r$ , then we return  $i.c \&& l.c \&& u.c \&& (l.q * u.p = u.q * l.p) \rightarrow l.q * i.p != i.q * l.p$

For all bounds b involved, we add  $b.p != 0$  as side condition to the explanation.

### 0.14.59.1 Typedef Documentation

**0.14.59.1.1 Settings** using `smtrat::mcsat::oncell::Settings` = `typedef LDBFilteredAllSelectiveSettings`

### 0.14.59.2 Function Documentation

**0.14.59.2.1 oncell()** template<typename Settings >  
std::optional<std::vector<cadcells::Atom>> smtrat::mcsat::oncell::oncell (  
    const std::vector< cadcells::Atom > & constraints,  
    const cadcells::Polynomial::ContextType & context,  
    const cadcells::Assignment & sample )

An MCSAT-style single cell explanation function.

A set of constraints is called infeasible w.r.t. an assignment if the defining polynomials are univariate under the sample and there does not exist a value for the unassigned variable that satisfies all constraints.

This method eliminates the unassigned variable using `get_level_covering` or `get_delineation` and then constructs a single cell in the assigned variables level by level.

#### Parameters

|                          |                                                                                                                                                             |
|--------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>constraints</code> | Atoms of the same level such that sample cannot be extended for the highest variable without making one atom false. Note that this property is not checked. |
| <code>sample</code>      | A sample such that all but the highest variable in constraints are assigned.                                                                                |

#### Returns

A set of constraints whose conjunction describes an unsatisfying cell that can be concluded from the input constraints.

`std::size_t cellComponentCount )` [inline]

**0.14.60.3.14 `getDegree()`** `std::size_t smtrat::mcsat::oncellcad::getDegree (`  
`TagPoly p,`  
`carl::Variable v )` [inline]

#### Parameters

|                |                               |
|----------------|-------------------------------|
| <code>p</code> | Polynomial to get degree from |
| <code>v</code> | Rootvariable for degree calc  |

#### Returns

**0.14.60.3.15 `hasOnlyNonConstIrreducibles()`** `template<typename PolyType >`  
`bool smtrat::mcsat::oncellcad::hasOnlyNonConstIrreducibles (`  
`const std::vector< PolyType > & polys )`

**0.14.60.3.16 `hasUniqElems()`** `template<typename T >`  
`bool smtrat::mcsat::oncellcad::hasUniqElems (`  
`const std::vector< T > & container )`

**0.14.60.3.17 `isNonConstIrreducible()`** `template<typename PolyType >`  
`bool smtrat::mcsat::oncellcad::isNonConstIrreducible (`  
`const PolyType & poly )`

---

**0.14.60.3.18 `isSubset()`** template<typename T>  
`bool smtrat::mcsat::onecellcad::isSubset (`  
 `const std::vector< T > & c1,`  
 `const std::vector< T > & c2 )`

**0.14.60.3.19 `leadcoefficient()`** `Poly smtrat::mcsat::onecellcad::leadcoefficient (`  
 `const carl::Variable & mainVariable,`  
 `const Poly & p ) [inline]`

**0.14.60.3.20 `levelOf()`** `std::optional<std::size_t> smtrat::mcsat::onecellcad::levelOf (`  
 `const std::vector< carl::Variable > & variableOrder,`  
 `const Poly & poly ) [inline]`

Find the index of the highest variable (wrt.

the ordering in 'variableOrder') that occurs with positive degree in 'poly'. Although 'level' is a math concept that starts counting at 1 we start counting at 0 and represent "no level/variable" as `std::nullopt` because it simplifies using the level directly as an index into arrays or vectors. Examples:

- `polyLevel(2) == nullopt` wrt. any variable order
  - `polyLevel(0*x+2) == nullopt` wrt. any variable order
  - `polyLevel(x+2) == 0` wrt.  $[x < y < z]$
  - `polyLevel(x+2) == 1` wrt.  $[y < x < z]$
  - `polyLevel(x+2) == 2` wrt.  $[y < z < x]$
  - `polyLevel(x*y+2) == 1` wrt.  $[x < y < z]$  because of y
  - `polyLevel(x*y+2) == 1` wrt.  $[y < x < z]$  because of x
  - `polyLevel(x*y+2) == 2` wrt.  $[x < z < y]$  because of y
- Preconditions:
- 'variables(poly)' must be a subset of 'variableOrder'.

**0.14.60.3.21 `nonConstIrreducibleFactors()`** `std::vector<TagPoly> smtrat::mcsat::onecellcad::nonConstIrreducibleFactors (`  
 `std::vector< carl::Variable > variableOrder,`  
 `Poly poly,`  
 `InvarianceType tag ) [inline]`

**0.14.60.3.22 `operator<()`** `bool smtrat::mcsat::onecellcad::operator< (`  
 `const InvarianceType & l,`  
 `const InvarianceType & r ) [inline]`

**0.14.60.3.23 `operator<<()` [1/8]** `std::ostream& smtrat::mcsat::onecellcad::operator<< (`  
 `std::ostream & os,`  
 `const CADCell & cell ) [inline]`

**0.14.60.3.24 `operator<<()` [2/8]** `std::ostream& smtrat::mcsat::onecellcad::operator<< (`  
 `std::ostream & os,`  
 `const InvarianceType & inv ) [inline]`

```
0.14.60.3.25 operator<<() [3/8] template<typename Number >
std::ostream& smtrat::mcsat::oncellcad::operator<< (
 std::ostream & os,
 const RealAlgebraicPoint< Number > & r)
```

Streaming operator for a [RealAlgebraicPoint](#).

```
0.14.60.3.26 operator<<() [4/8] std::ostream& smtrat::mcsat::oncellcad::operator<< (
 std::ostream & os,
 const Section & s) [inline]
```

```

### 0.14.62.1 Detailed Description

OneCell [Explanation](#).

**0.14.62.1.1 Rationale** To better understand the CAD implementation this document concisely explains important CAD terminology from the literature and high-level implementation design decisions. Low-level design decisions for structs and classes are found in the implementation files themselves.

**0.14.62.1.2 Universe** The n-dimensional space in which a CADCell exists. The universe has n axes (=std basis vectors), numbered 0 to n-1, and each axis is associated with one variable.

**0.14.62.1.3 Variables order** A variable order like x,y,z tell us that the universe is 3-dimensional, gives a name to the each coordinate axis (thus also defines an axis ordering), tells us how to interpret a point like (5,2,1), and allows us to define properties like "level" for points and polynomials and "cylindrical" for CADCells.

**0.14.62.1.4 Level of a point** Number of components that a point has but interpreted with respect to the first variables in a variable ordering. E.g., if the universe has 3 axes/variables like x,y,z in that (increasing) order, then a point of level 2 has exactly 2 components representing the coordinates for the first two variables, x and y.

**0.14.62.1.5 Level of a polynomial** The number/index of the highest variable, with respect to a variable ordering, that appears with a positive degree in a polynomial. E.g., if the universe has 3 axes/variables like x,y,z in that (increasing) order, then a polynomial of level 2 at most mentions the first 2 variables, x and y, and definitely mentions second variable y but no "higher" variable like z .

**0.14.62.1.6 CADCell** A "cylindric algebraic cell" exists in an n-dimensional vector space called a "universe". A cell is a subspace of that universe with a possibly lower dimension and is "cylindric" only with respect to a specific variable ordering, numbered 0 to n-1. A cell is "algebraic", because its boundaries are represented by polynomials. Along each axis a cell is bound by either an non-empty open interval, called a "sector" and represented by two polynomials, or by a closed point-interval, called a "section" and represented by one polynomial. E.g. a section along axis k, said to be of "level k", requires a polynomial instead of a fixed number, because the fixed number can vary depending on the position along the (lower dimensional) axes 0 to k-1. This is why a section of level k is represented by a multivariate polynomial of "level k" (uses only the first k variables in the variable ordering). If we replace the first k-1 variables in that polynomial by specific numbers, we are left with a univariate polynomial whose root is then the fixed boundary number along axis k (if that polynomial has multiple roots, we also need to specify precisely which one of those represents the fixed boundary number). A different position, i.e., a different variable replacement, yields a possibly different univariate polynomial with a different root.

**0.14.62.1.7 Level of a sector/section** The number of the axis (with respect to some variable ordering that defines the same axis ordering) for which a sector/section defines the bounds. This number is also the level of the polynomial(s) inside the sector/section.

**0.14.62.1.8 Open CADCell** A cell is "open" if it only consists of sectors, i.e., it is open along all axes and is therefore a subspace with the same dimension as its universe.

### 0.14.62.2 Enumeration Type Documentation

#### 0.14.62.2.1 ShrinkResult enum `smtrat::mcsat::onecellcad::recursive::ShrinkResult` [strong]

Enumerator

*Substitutes the variable var in constr by term.*

#### 0.14.67.1 Function Documentation

**0.14.67.1.1 `addOrMergeTestCandidate()`** static bool smtrat::mcsat::vs::helper::addOrMergeTestCandidate (
 std::vector< `TestCandidate` > & results,
 const `TestCandidate` & newSubstitution ) [static]

Adds a new substitution to the given list of substitutions or merges it to an existing one.

Returns true if a new substitution was created.

**0.14.67.1.2 `generateTestCandidates()`** static bool smtrat::mcsat::vs::helper::generateTestCandidates (
 std::vector< `TestCandidate` > & results,
 const `carl::Variable` & eliminationVar,
 const `FormulaSetT` & constraints ) [static]

Generate all test candidates according to "vanilla" virtual substitution.

Returns false iff VS is not applicable.

**0.14.67.1.3 `generateZeros()`** static bool smtrat::mcsat::vs::helper::generateZeros (
 const `FormulaT` & formula,
 const `carl::Variable` & eliminationVar,
 std::function< void(`SqrtEx` &&`sqrteXpression`, `ConstraintsT` &&`sideConditions`)>
 yield\_result ) [static]

Get zeros with side conditions of the given constraint.

Kind of a generator function. Passes generated zeros to a callback function to avoid copying.

**0.14.67.1.4 `getFormulaAtoms()`** void smtrat::mcsat::vs::helper::getFormulaAtoms (
 const `FormulaT` & f,
 `FormulaSetT` & result ) [inline]

**0.14.67.1.5 `substitute()`** bool smtrat::mcsat::vs::helper::substitute (
 const `FormulaT` & constr,
 const `carl::Variable` var,
 const `carl::vs::Term`< `Poly` > & term,
 `FormulaT` & result ) [inline]

**0.14.67.1.6 `to_formula()`** `FormulaT` smtrat::mcsat::vs::helper::to\_formula (
 const `carl::vs::CaseDistinction`< `Poly` > & docc ) [inline]

Converts a DisjunctionOfConstraintConjunctions to a regular Formula.

### 0.14.69.1 Typedef Documentation

**0.14.69.1.1 MultiCoeffUniPoly** using [smtrat::onecellcad::recursive::MultiCoeffUniPoly](#) = [typedef](#)  
carl::UnivariatePolynomial<[MultiPoly](#)>

**0.14.69.1.2 MultiPoly** using [smtrat::onecellcad::recursive::MultiPoly](#) = [typedef](#) carl::MultivariatePolynomial<[smtrat::Rational](#)>

**0.14.69.1.3 OpenCADCell** using `smtrat::onecellcad::recursive::OpenCADCell` = `typedef std::vector<Sector>`

Represent a single open cell [1].

A cell is a collection of boundary objects along each axis. In case of an open cell, the boundary objects are all sectors.

**0.14.69.1.4 RANMap** using `smtrat::onecellcad::recursive::RANMap` = `typedef std::map<carl::Variable, RAN>`

**0.14.69.1.5 RANPoint** using `smtrat::onecellcad::recursive::RANPoint` = `typedef RealAlgebraic::Point<smtrat::Rational>`

**0.14.69.1.6 UniPoly** using `smtrat::onecellcad::recursive::UniPoly` = `typedef carl::Univariate<Polynomial<smtrat::Rational>>`

## 0.14.69.2 Function Documentation

**0.14.69.2.1 createFullspaceCoveringCell()** `OpenCADCell smtrat::onecellcad::recursive::createFullspaceCoveringCell ( size_t level )`

**0.14.69.2.2 createOpenCADCell()** `std::optional<OpenCADCell> smtrat::onecellcad::recursive::createOpenCADCell ( const std::vector< MultiPoly > polySet, const RANPoint & point, const std::vector< carl::Variable > & variableOrder )`

Construct a OpenCADCell for the given set of polynomials 'polySet' that contains the given 'point'.

The returned cell represents the largest region that is sign-invariant on all polynomials in the 'polySet' and is cylindrical with respect to the variables ordering given in 'variableOrder'. Note that this construction is only correct if plugging in the 'point' into any polynomial of the 'polySet' yields a non-zero value, i.e. 'point' is not a root of any polynomial in 'polySet', otherwise no OpenCADCell is returned. Note that the dimension (number of components) of the 'point' == the number of variables in 'variableOrder' and that any polynomial of the 'polySet' must be irreducible and mention only variables from 'variableOrder'.

**0.14.69.2.3 levelOf()** `size_t smtrat::onecellcad::recursive::levelOf ( const MultiPoly & poly, const std::vector< carl::Variable > & variableOrder )`

Find the index of the highest variable (wrt.

the ordering in 'variableOrder') that occurs with positive degree in 'poly'. Since levelOf is a math concept it starts counting at 1! Examples:

- `levelOf(2) == 0` wrt. any variable order
- `levelOf(0*x+2) == 0` wrt. any variable order
- `levelOf(x+2) == 1` wrt.  $[x < y < z]$
- `levelOf(x+2) == 2` wrt.  $[y < x < z]$
- `levelOf(x+2) == 3` wrt.  $[y < z < x]$
- `levelOf(x*y+2) == 2` wrt.  $[x < y < z]$  because of y
- `levelOf(x*y+2) == 2` wrt.  $[y < x < z]$  because of x

- `levelOf(x*y+2) == 3` wrt.  $[x < z < y]$  because of y Preconditions:
- 'variables(poly)' must be a subset of 'variableOrder'.

#### 0.14.69.2.4 `mergeCellWithPoly()` `std::optional<OpenCADCell> smtrat::oncellcad::recursive::mergeCellWithPoly (`

```
 OpenCADCell & cell,
 const RANPoint & point,
 const std::vector< carl::Variable > & variableOrder,
 const MultiPoly poly)
```

Merge the given open OpenCADCell 'cell' that contains the given 'point' (called "alpha" in [1]) with a polynomial 'poly'.

Before the merge 'cell' represents a region that is sign-invariant on other (previously merged) polynomials (all signs are non-zero). The returned cell represents a region that is additionally sign-invariant on 'poly' (also with non-zero sign).

##### Returns

either an OpenCADCell or nothing (representing a failed construction)

#### 0.14.69.2.5 `operator<<()` [1/3] `std::ostream& smtrat::oncellcad::recursive::operator<< (`

```
 std::ostream & o,
 const OpenCADCell & c)
```

#### 0.14.69.2.6 `operator<<()` [2/3] `std::ostream& smtrat::oncellcad::recursive::operator<< (`

```
 std::ostream & o,
 const Section & s)
```

#### 0.14.69.2.7 `operator<<()` [3/3] `std::ostream& smtrat::oncellcad::recursive::operator<< (`

```
 std::ostream & o,
 const Sector & s)
```

#### 0.14.69.2.8 `toStdMap()` `std::map<carl::Variable, RAN> smtrat::oncellcad::recursive::toStdMap (`

```
 const RANPoint & point,
 size_t count,
 const std::vector< carl::Variable > & variableOrder)
```

Create a mapping from the first 'count'-many variables in the given 'variableOrder' to the first 'count'-many components of the given 'point'.

- [FormulaT](#) [encode\\_as\\_formula](#) (const [FormulaT](#) &formula, [Encoding](#) &encoding, [SeparatorType](#) separator\_type)  
*Requires a quantifier-free real arithmetic formula with no negations.*

### 0.14.87.1 Detailed Description

Implements data structures and encodings for the subtropical method.

### 0.14.87.2 Enumeration Type Documentation

**Enumerator**

**0.14.87.2.1 Direction** enum `smtrat::subtropical::Direction` [strong]  
 Subdivides the relations into classes with the same linearization result.

**Enumerator**

|          |  |
|----------|--|
| BOTH     |  |
| NEGATIVE |  |
| POSITIVE |  |

**0.14.87.2.2 SeparatorType** enum `smtrat::subtropical::SeparatorType` [strong]

**Enumerator**

|        |  |
|--------|--|
| STRICT |  |
| WEAK   |  |

**0.14.87.3 Function Documentation**

**0.14.87.3.1 direction()** std::optional<`Direction`> `smtrat::subtropical::direction` (  
`carl::Relation r`) [inline]

**0.14.87.3.2 direction\_for\_equality()** std::optional<`Direction`> `smtrat::subtropical::direction_<=for_equality` (  
`const Separator & s`) [inline]

**0.14.87.3.3 encode\_as\_formula()** `FormulaT` `smtrat::subtropical::encode_as_formula` (  
`const FormulaT & formula,`  
`Encoding & encoding,`  
`SeparatorType separator_type`) [inline]

Requires a quantifier-free real arithmetic formula with no negations.

**Parameters**

|                      |                          |
|----------------------|--------------------------|
| <code>formula</code> | The formula to translate |
|----------------------|--------------------------|

**Returns**

linear formula

**0.14.87.3.4 normalize()** `carl::BasicConstraint<Poly>` `smtrat::subtropical::normalize` (  
`const carl::BasicConstraint< Poly > & c`) [inline]

**0.14.87.3.5 transform\_to\_equation()** `FormulaT` `smtrat::subtropical::transform_to_equation` (  
`const FormulaT & formula`) [inline]

Requires a quantifier-free real arithmetic formula with no negations.

#### Parameters

|                      |                          |
|----------------------|--------------------------|
| <code>formula</code> | The formula to transform |
|----------------------|--------------------------|

#### Returns

an equisatisfiable equation

## 0.14.88 smtrat::uf\_impl Namespace Reference

#### Data Structures

- class [uf\\_rank\\_and\\_class](#)  
*Wrapper class that contains the rank and parent class of some entry of the UF datastructure.*
- class [uf\\_rank\\_and\\_class< true >](#)  
*Compressed implementation of [uf\\_rank\\_and\\_class](#).*
- class [uf\\_data\\_wrapper](#)  
*Wrapper around data entry and [uf\\_rank\\_and\\_class](#); this class contains a value of type T and both rank and class of an entry in the UF datastructure.*
- class [uf\\_data\\_wrapper< void, compression >](#)  
*Special case of the [uf\\_data\\_wrapper](#) in case the data type is void.*
- struct [estimator](#)  
*Distance estimation for a range delimited by iterators; if the given iterators are random access, returns the result of std::distance in the estimate\_distance function.*
- struct [estimator< IteratorType, false >](#)

## 0.14.89 smtrat::unsatcore Namespace Reference

Contains strategy implementations for unsat core computations.

#### Data Structures

- class [UnsatCoreBackend](#)
- class [UnsatCoreBackend< Solver, UnsatCoreStrategy::ModelExclusion >](#)  
*Implements an easy strategy to obtain an unsatisfiable core.*

### 0.14.89.1 Detailed Description

Contains strategy implementations for unsat core computations.

## 0.14.90 smtrat::validation Namespace Reference

#### Data Structures

- class [ValidationCollector](#)
- class [ValidationPoint](#)
- struct [ValidationPrinter](#)
- struct [ValidationSettings](#)

#### Enumerations

- enum class [ValidationOutputFormat { SMTLIB }](#)

## Functions

- auto & `get` (const std::string &channel, const std::string &file, int line)
- template<ValidationOutputFormat SOF>  
std::ostream & `operator<<` (std::ostream &os, ValidationPrinter< SOF >)
- template<> std::ostream & `operator<<` (std::ostream &os, ValidationPrinter< ValidationOutputFormat::SMTLIB >)
- auto `validation_formulas_as_smtlib` ()
- void `validation_formulas_to_smtlib_file` (const std::string &filename)
- template<typename T >  
void `registerValidationSettings` (T &parser)

### 0.14.90.1 Enumeration Type Documentation

#### 0.14.90.1.1 ValidationOutputFormat enum smtrat::validation::ValidationOutputFormat [strong]

Enumerator

SMTLIB

### 0.14.90.2 Function Documentation

**0.14.90.2.1 get()** auto& smtrat::validation::get (  
const std::string & channel,  
const std::string & file,  
int line ) [inline]

**0.14.90.2.2 operator<<()** [1/2] template<ValidationOutputFormat SOF>  
std::ostream& smtrat::validation::operator<< (  
std::ostream & os,  
ValidationPrinter< SOF > )

**0.14.90.2.3 operator<<()** [2/2] template<>  
std::ostream& smtrat::validation::operator<< (  
std::ostream & os,  
ValidationPrinter< ValidationOutputFormat::SMTLIB > )

**0.14.90.2.4 registerValidationSettings()** template<typename T >  
void smtrat::validation::registerValidationSettings (  
T & parser )

**0.14.90.2.5 validation\_formulas\_as\_smtlib()** auto smtrat::validation::validation\_formulas\_as\_<→  
smtlib ( )

**0.14.90.2.6 validation\_formulas\_to\_smtlib\_file()** void smtrat::validation::validation\_formulas\_to\_<→  
smtlib\_file (   
const std::string & filename )

## 0.14.91 smtrat::vb Namespace Reference

### Data Structures

- class [Variable](#)  
*Class for a variable.*
- class [Bound](#)  
*Class for the bound of a variable.*
- class [VariableBounds](#)  
*Class to manage the bounds of a variable.*

### Functions

- template<typename Type >  
std::ostream & [operator<<](#) (std::ostream &\_os, const [VariableBounds< Type >](#) &\_vs)  
*Prints the contents of the given variable bounds manager to the given stream.*

#### 0.14.91.1 Function Documentation

**0.14.91.1.1 [operator<<\(\)](#)** template<typename Type >  
std::ostream& smtrat::vb::operator<< (  
    std::ostream & \_os,  
    const [VariableBounds< Type >](#) & \_vs ) [inline]

Prints the contents of the given variable bounds manager to the given stream.

#### Parameters

|                  |                                       |
|------------------|---------------------------------------|
| <code>_os</code> | The stream to print on.               |
| <code>_vs</code> | The variable bounds manager to print. |

#### Returns

The stream after printing on it.

## 0.14.92 smtrat::vs Namespace Reference

*Applies a substitution of a variable to a term, which is not minus infinity nor a to an square root expression plus an infinitesimal.*
- bool `substitutePlusEps` (const `smrat::ConstraintT` &`_cons`, const `Substitution` &`_subs`, `DisjunctionOfConstraintConjunctions` &`_result`, bool `_accordingPaper`, `carl::Variables` &`_conflictingVariables`, const `smrat::EvalDoubleIntervalMap` &`_solutionSpace`)  
*Applies the given substitution to the given constraint, where the substitution is of the form [x -> t+epsilon] with x as the variable and c and b polynomials in the real theory excluding x.*
- bool `substituteEpsGradients` (const `smrat::ConstraintT` &`_cons`, const `Substitution` &`_subs`, const `carl::Relation` &`_relation`, `DisjunctionOfConstraintConjunctions` &, bool `_accordingPaper`, `carl::Variables` &`_conflictingVariables`, const `smrat::EvalDoubleIntervalMap` &`_solutionSpace`)  
*Sub-method of `substituteEps`, where one of the gradients in the point represented by the substitution must be negative if the given relation is less or positive if the given relation is greater.*
- void `substituteInf` (const `smrat::ConstraintT` &`_cons`, const `Substitution` &`_subs`, `DisjunctionOfConstraintConjunctions` &`_result`, `carl::Variables` &`_conflictingVariables`, const `smrat::EvalDoubleIntervalMap` &`_solutionSpace`)  
*Applies the given substitution to the given constraint, where the substitution is of the form [x -> -infinity] with x as the variable and c and b polynomials in the real theory excluding x.*
- `std::ostream` & `operator<<` (`std::ostream` &`os`, const `Substitution` &`s`)  
*Prints the given substitution on the given output stream.*

### 0.14.92.1 Typedef Documentation

**0.14.92.1.1 ConditionList** `typedef std::list< const Condition* > smtrat::vs::ConditionList`

**0.14.92.1.2 ConditionSetSet** `typedef std::set< carl::PointerSet<Condition> > smtrat::vs::ConditionSetSet`

**0.14.92.1.3 ConditionSetSetSet** `typedef std::set< ConditionSetSet > smtrat::vs::ConditionSetSetSet`

**0.14.92.1.4 ConstraintVector** `typedef std::vector<smtrat::ConstraintT> smtrat::vs::ConstraintVector`  
a vector of constraints

**0.14.92.1.5 DisjunctionOfConditionConjunctions** `typedef std::vector< ConditionList > smtrat::vs::DisjunctionOfConditionConjunctions`

**0.14.92.1.6 DisjunctionOfConstraintConjunctions** `typedef std::vector<ConstraintVector> smtrat::vs::DisjunctionOfConstraintConjunctions`  
a vector of vectors of constraints

```
0.14.92.1.7 SubstitutionFastPointerMap template<typename T >
using smtrat::vs::SubstitutionFastPointerMap = typedef std::unordered_map<const smtrat::Poly*, T, substitutionPointerHash, substitutionPointerEqual>
```

**0.14.92.1.8 UnsignedTriple** `typedef std::pair<size_t, std::pair<size_t, size_t> > smtrat::vs::UnsignedTriple`

**0.14.92.1.9 ValStatePair** `typedef std::pair<UnsignedTriple, vs::State*> smtrat::vs::ValStatePair`

**0.14.92.1.10 ValuationMap** `typedef std::map<UnsignedTriple, vs::State*, unsignedTripleCmp> smtrat::vs::ValuationMap`

### 0.14.92.2 Function Documentation

```
0.14.92.2.1 combine() template<class combineType >
bool smtrat::vs::combine (
 const std::vector< std::vector< std::vector< combineType > > > & _toCombine,
 std::vector< std::vector< combineType > > & _combination)
```

Combines vectors.

#### Parameters

|                           |                            |
|---------------------------|----------------------------|
| <code>_toCombine</code>   | The vectors to combine.    |
| <code>_combination</code> | The resulting combination. |

**Returns**

false, if the upper limit in the number of combinations resulting by this method is exceeded. Note, that this hinders a combinatorial blow up. true, otherwise.

**0.14.92.2.2 getEvenBitStrings() [1/2]** void smtrat::vs::getEvenBitStrings ( size\_t \_length,  
std::vector< std::bitset< MAX\_PRODUCT\_SPLIT\_NUMBER > > & \_strings )

**Parameters**

|          |                                                                            |
|----------|----------------------------------------------------------------------------|
| _length  | The maximal length of the bit strings with even parity to compute.         |
| _strings | All bit strings of length less or equal the given length with even parity. |

**0.14.92.2.3 getEvenBitStrings() [2/2]** void smtrat::vs::getEvenBitStrings ( std::size\_t \_length,  
std::vector< std::bitset< MAX\_PRODUCT\_SPLIT\_NUMBER > > & \_strings )

**0.14.92.2.4 getOddBitStrings() [1/2]** void smtrat::vs::getOddBitStrings ( size\_t \_length,  
std::vector< std::bitset< MAX\_PRODUCT\_SPLIT\_NUMBER > > & \_strings )

**Parameters**

|          |                                                                           |
|----------|---------------------------------------------------------------------------|
| _length  | The maximal length of the bit strings with odd parity to compute.         |
| _strings | All bit strings of length less or equal the given length with odd parity. |

**0.14.92.2.5 getOddBitStrings() [2/2]** void smtrat::vs::getOddBitStrings ( std::size\_t \_length,  
std::vector< std::bitset< MAX\_PRODUCT\_SPLIT\_NUMBER > > & \_strings )

**0.14.92.2.6 getSignCombinations()** *DisjunctionOfConstraintConjunctions* smtrat::vs::getSign← Combinations ( const smtrat::ConstraintT & )

For a given constraint  $f_1 \sim \dots \sim f_n \sim 0$  this method computes all combinations of constraints  $f_1 \sim_1 0 \dots f_n \sim_n 0$  such that

$f_1 \sim_1 0 \text{ and } \dots \text{ and } f_n \sim_n 0 \quad \text{iff} \quad f_1 \sim \dots \sim f_n \sim 0$

holds.

**Parameters**

|             |                                                |
|-------------|------------------------------------------------|
| _constraint | A pointer to the constraint to split this way. |
|-------------|------------------------------------------------|

**Returns**

The resulting combinations.

**0.14.92.2.7 operator<<()** [1/2] `std::ostream& smtrat::vs::operator<< ( std::ostream & _out, const Condition & _condition )`

**0.14.92.2.8 operator<<()** [2/2] `std::ostream & smtrat::vs::operator<< ( std::ostream & os, const Substitution & s )`

Prints the given substitution on the given output stream.

#### Parameters

|                            |                                       |
|----------------------------|---------------------------------------|
| <code>_out</code>          | The output stream, on which to write. |
| <code>_substitution</code> | The substitution to print.            |

#### Returns

The output stream after printing the substitution on it.

**0.14.92.2.9 print()** `void smtrat::vs::print ( DisjunctionOfConstraintConjunctions & _substitutionResults )`

Prints the given disjunction of conjunction of constraints.

#### Parameters

|                                   |                                                         |
|-----------------------------------|---------------------------------------------------------|
| <code>_substitutionResults</code> | The disjunction of conjunction of constraints to print. |
|-----------------------------------|---------------------------------------------------------|

**0.14.92.2.10 simplify()** [1/3] `void smtrat::vs::simplify ( DisjunctionOfConstraintConjunctions & )`

Simplifies a disjunction of conjunctions of constraints by deleting consistent constraint and inconsistent conjunctions of constraints.

If a conjunction of only consistent constraints exists, the simplified disjunction contains one empty conjunction.

#### Parameters

|                          |                                              |
|--------------------------|----------------------------------------------|
| <code>_toSimplify</code> | The disjunction of conjunctions to simplify. |
|--------------------------|----------------------------------------------|

**0.14.92.2.11 simplify()** [2/3] `void smtrat::vs::simplify ( DisjunctionOfConstraintConjunctions & , carl::Variables & , const smtrat::EvalDoubleIntervalMap & )`

Simplifies a disjunction of conjunctions of constraints by deleting consistent constraint and inconsistent conjunctions of constraints.

If a conjunction of only consistent constraints exists, the simplified disjunction contains one empty conjunction.

#### Parameters

|                               |                                              |
|-------------------------------|----------------------------------------------|
| <code>_toSimplify</code>      | The disjunction of conjunctions to simplify. |
| <code>_conflictingVars</code> |                                              |
| <code>_solutionSpace</code>   |                                              |

---

**0.14.92.2.12** `simplify()` [3/3] `void smtrat::vs::simplify (`  
`DisjunctionOfConstraintConjunctions & _toSimplify,`  
`Variables & _conflictingVars,`  
`const smtrat::EvalDoubleIntervalMap & _solutionSpace )`

**0.14.92.2.13** `splitProducts()` [1/3] `bool smtrat::vs::splitProducts (`  
`const ConstraintVector & ,`  
`DisjunctionOfConstraintConjunctions & ,`  
`bool = false )`

Splits all constraints in the given conjunction of constraints having a non-trivial factorization into a set of constraints which compare the factors instead.

#### Parameters

|                          |                                                                                |
|--------------------------|--------------------------------------------------------------------------------|
| <code>_toSimplify</code> | The conjunction of the constraints to split.                                   |
| <code>_result</code>     | The result, being a disjunction of conjunctions of constraints.                |
| <code>_onlyNeq</code>    | A flag indicating that only constraints with the relation symbol != are split. |

#### Returns

false, if the upper limit in the number of combinations resulting by this method is exceeded. Note, that this hinders a combinatorial blow up. true, otherwise.

**0.14.92.2.14** `splitProducts()` [2/3] `DisjunctionOfConstraintConjunctions smtrat::vs::splitProducts (`  
`const smtrat::ConstraintT & ,`  
`bool = false )`

Splits the given constraint into a set of constraints which compare the factors of the factorization of the constraints considered polynomial.

#### Parameters

|                          |                                                                                |
|--------------------------|--------------------------------------------------------------------------------|
| <code>_constraint</code> | A pointer to the constraint to split.                                          |
| <code>_onlyNeq</code>    | A flag indicating that only constraints with the relation symbol != are split. |

#### Returns

The resulting disjunction of conjunctions of constraints, which is semantically equivalent to the given constraint.

**0.14.92.2.15** `splitProducts()` [3/3] `bool smtrat::vs::splitProducts (`  
`DisjunctionOfConstraintConjunctions & ,`  
`bool = false )`

Splits all constraints in the given disjunction of conjunctions of constraints having a non-trivial factorization into a set of constraints which compare the factors instead.

#### Parameters

|                          |                                                                                |
|--------------------------|--------------------------------------------------------------------------------|
| <code>_toSimplify</code> | The disjunction of conjunctions of the constraints to split.                   |
| <code>_onlyNeq</code>    | A flag indicating that only constraints with the relation symbol != are split. |

**Returns**

false, if the upper limit in the number of combinations resulting by this method is exceeded. Note, that this hinders a combinatorial blow up. true, otherwise.

**0.14.92.2.16 `splitSosDecompositions()`** void smrat::vs::splitSosDecompositions (   
`DisjunctionOfConstraintConjunctions` & `_toSimplify` )

**0.14.92.2.17 `substitute()` [1/2]** bool smrat::vs::substitute (   
 const `smrat::ConstraintT` & ,   
 const `Substitution` & ,   
`DisjunctionOfConstraintConjunctions` & ,   
 bool `_accordingPaper`,   
`carl::Variables` & ,   
 const `smrat::EvalDoubleIntervalMap` & )

Applies a substitution to a constraint and stores the results in the given vector.

**Parameters**

|                      |                                                                 |
|----------------------|-----------------------------------------------------------------|
| <code>_cons</code>   | The constraint to substitute in.                                |
| <code>_subs</code>   | The substitution to apply.                                      |
| <code>_result</code> | The vector, in which to store the results of this substitution. |

**Returns**

false, if the upper limit in the number of combinations in the result of the substitution is exceeded. Note, that this hinders a combinatorial blow up. true, otherwise.

**0.14.92.2.18 `substitute()` [2/2]** bool smrat::vs::substitute (   
 const `smrat::ConstraintT` & `_cons`,   
 const `Substitution` & `_subs`,   
`DisjunctionOfConstraintConjunctions` & `_result`,   
 bool `_accordingPaper`,   
`Variables` & `_conflictingVariables`,   
 const `smrat::EvalDoubleIntervalMap` & `_solutionSpace` )

**0.14.92.2.19 `substituteEpsGradients()` [1/2]** bool smrat::vs::substituteEpsGradients (   
 const `smrat::ConstraintT` & `_cons`,   
 const `Substitution` & `_subs`,   
 const `carl::Relation` `_relation`,   
`DisjunctionOfConstraintConjunctions` & ,   
 bool `_accordingPaper`,   
`carl::Variables` & `_conflictingVariables`,   
 const `smrat::EvalDoubleIntervalMap` & `_solutionSpace` )

Sub-method of `substituteEps`, where one of the gradients in the point represented by the substitution must be negative if the given relation is less or positive if the given relation is greater.

**Parameters**

|                    |                                  |
|--------------------|----------------------------------|
| <code>_cons</code> | The constraint to substitute in. |
| <code>_subs</code> | The substitution to apply.       |

**Parameters**

|                                    |                                                                                                                                                                                                                                                                                                                     |
|------------------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>_relation</code>             | The relation symbol, deciding whether the substitution result must be negative or positive.                                                                                                                                                                                                                         |
| <code>_result</code>               | The vector, in which to store the results of this substitution. It is semantically a disjunction of conjunctions of constraints.                                                                                                                                                                                    |
| <code>_accordingPaper</code>       | A flag that indicates whether to apply the virtual substitution rules according to the paper "Quantifier elimination for real algebra - the quadratic case and beyond." by Volker Weispfenning (true) or in an adapted way which omits a higher degree in the result by splitting the result in more cases (false). |
| <code>_conflictingVariables</code> | If a conflict with the given solution space occurs, the variables being part of this conflict are stored in this container.                                                                                                                                                                                         |
| <code>_solutionSpace</code>        | The solution space in form of double intervals of the variables occurring in the given constraint.                                                                                                                                                                                                                  |

```
0.14.92.2.20 substituteEpsGradients() [2/2] bool smtrat::vs::substituteEpsGradients (
 const smtrat::ConstraintT & _cons,
 const Substitution & _subs,
 const Relation _relation,
 DisjunctionOfConstraintConjunctions & _result,
 bool _accordingPaper,
 Variables & _conflictingVariables,
 const smtrat::EvalDoubleIntervalMap & _solutionSpace)
```

```
0.14.92.2.21 substituteInf() [1/2] void smtrat::vs::substituteInf (
 const smtrat::ConstraintT & _cons,
 const Substitution & _subs,
 DisjunctionOfConstraintConjunctions & _result,
 carl::Variables & _conflictingVariables,
 const smtrat::EvalDoubleIntervalMap & _solutionSpace)
```

Applies the given substitution to the given constraint, where the substitution is of the form  $[x \rightarrow -\infty]$  with  $x$  as the variable and  $c$  and  $b$  polynomials in the real theory excluding  $x$ .

The constraint is of the form " $f(x) \rho 0$ " with  $\rho$  element of  $\{=, !=, <, >, \leq, \geq\}$  and  $k$  as the maximum degree of  $x$  in  $f$ .

**Parameters**

|                                    |                                                                                                                                  |
|------------------------------------|----------------------------------------------------------------------------------------------------------------------------------|
| <code>_cons</code>                 | The constraint to substitute in.                                                                                                 |
| <code>_subs</code>                 | The substitution to apply.                                                                                                       |
| <code>_result</code>               | The vector, in which to store the results of this substitution. It is semantically a disjunction of conjunctions of constraints. |
| <code>_conflictingVariables</code> | If a conflict with the given solution space occurs, the variables being part of this conflict are stored in this container.      |
| <code>_solutionSpace</code>        | The solution space in form of double intervals of the variables occurring in the given constraint.                               |

```
0.14.92.2.22 substituteInf() [2/2] void smtrat::vs::substituteInf (
 const smtrat::ConstraintT & _cons,
 const Substitution & _subs,
 DisjunctionOfConstraintConjunctions & _result,
 Variables & _conflictingVariables,
```

```
const smtrat::EvalDoubleIntervalMap & _solutionSpace)
```

**0.14.92.2.23 substituteInfLessGreater()** void smtrat::vs::substituteInfLessGreater (

```
const smtrat::ConstraintT & _cons,
const Substitution & _subs,
DisjunctionOfConstraintConjunctions & _result)
```

Applies the given substitution to the given constraint, where the substitution is of the form  $[x \rightarrow +/-\infty]$  with x as the variable and c and b polynomials in the real theory excluding x.

The constraint is of the form " $a*x^2+bx+c \rho 0$ ", where  $\rho$  is less or greater.

#### Parameters

|                |                                                                                                                                  |
|----------------|----------------------------------------------------------------------------------------------------------------------------------|
| <i>_cons</i>   | The constraint to substitute in.                                                                                                 |
| <i>_subs</i>   | The substitution to apply.                                                                                                       |
| <i>_result</i> | The vector, in which to store the results of this substitution. It is semantically a disjunction of conjunctions of constraints. |

**0.14.92.2.24 substituteNormal() [1/2]** bool smtrat::vs::substituteNormal (

```
const smtrat::ConstraintT & _cons,
const Substitution & _subs,
DisjunctionOfConstraintConjunctions & _result,
bool _accordingPaper,
carl::Variables & _conflictingVariables,
const smtrat::EvalDoubleIntervalMap & _solutionSpace)
```

Applies a substitution of a variable to a term, which is not minus infinity nor a to an square root expression plus an infinitesimal.

#### Parameters

|                              |                                                                                                                                                                                                                                                                                                                     |
|------------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <i>_cons</i>                 | The constraint to substitute in.                                                                                                                                                                                                                                                                                    |
| <i>_subs</i>                 | The substitution to apply.                                                                                                                                                                                                                                                                                          |
| <i>_result</i>               | The vector, in which to store the results of this substitution. It is semantically a disjunction of conjunctions of constraints.                                                                                                                                                                                    |
| <i>_accordingPaper</i>       | A flag that indicates whether to apply the virtual substitution rules according to the paper "Quantifier elimination for real algebra - the quadratic case and beyond." by Volker Weispfenning (true) or in an adapted way which omits a higher degree in the result by splitting the result in more cases (false). |
| <i>_conflictingVariables</i> | If a conflict with the given solution space occurs, the variables being part of this conflict are stored in this container.                                                                                                                                                                                         |
| <i>_solutionSpace</i>        | The solution space in form of double intervals of the variables occurring in the given constraint.                                                                                                                                                                                                                  |

**0.14.92.2.25 substituteNormal() [2/2]** bool smtrat::vs::substituteNormal (

```
const smtrat::ConstraintT & _cons,
const Substitution & _subs,
DisjunctionOfConstraintConjunctions & _result,
bool _accordingPaper,
Variables & _conflictingVariables,
const smtrat::EvalDoubleIntervalMap & _solutionSpace)
```

---

```
0.14.92.2.26 substituteNormalSqrtEq() bool smtrat::vs::substituteNormalSqrtEq (
 const smtrat::Poly & _radicand,
 const smtrat::Poly & _q,
 const smtrat::Poly & _r,
 DisjunctionOfConstraintConjunctions & _result,
 bool _accordingPaper)
```

Sub-method of substituteNormalSqrt, where applying the substitution led to a term containing a square root.  
The relation symbol of the constraint to substitute is "=".

$$(_q + _r * \sqrt{(_radicand)})$$

The term then looks like: ----- \_s

#### Parameters

|                        |                                                                                                                                                                                                                                                                                                                     |
|------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <i>_radicand</i>       | The radicand of the square root.                                                                                                                                                                                                                                                                                    |
| <i>_q</i>              | The summand not containing the square root.                                                                                                                                                                                                                                                                         |
| <i>_r</i>              | The coefficient of the radicand.                                                                                                                                                                                                                                                                                    |
| <i>_result</i>         | The vector, in which to store the results of this substitution. It is semantically a disjunction of conjunctions of constraints.                                                                                                                                                                                    |
| <i>_accordingPaper</i> | A flag that indicates whether to apply the virtual substitution rules according to the paper "Quantifier elimination for real algebra - the quadratic case and beyond." by Volker Weispfenning (true) or in an adapted way which omits a higher degree in the result by splitting the result in more cases (false). |

```

Sub-method of substituteNormalSqrt, where applying the substitution led to a term containing a square root.  
The relation symbol of the constraint to substitute is less or equal.

$$(_q + _r * \sqrt{(_radicand)})$$

The term then looks like: ----- \_s

#### Parameters

|                        |                                                                                                                                                                                                                                                                                                                     |
|------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <i>_radicand</i>       | The radicand of the square root.                                                                                                                                                                                                                                                                                    |
| <i>_q</i>              | The summand not containing the square root.                                                                                                                                                                                                                                                                         |
| <i>_r</i>              | The coefficient of the radicand.                                                                                                                                                                                                                                                                                    |
| <i>_s</i>              | The denominator of the expression containing the square root.                                                                                                                                                                                                                                                       |
| <i>_result</i>         | The vector, in which to store the results of this substitution. It is semantically a disjunction of conjunctions of constraints.                                                                                                                                                                                    |
| <i>_accordingPaper</i> | A flag that indicates whether to apply the virtual substitution rules according to the paper "Quantifier elimination for real algebra - the quadratic case and beyond." by Volker Weispfenning (true) or in an adapted way which omits a higher degree in the result by splitting the result in more cases (false). |

---

```
0.14.92.2.28 substituteNormalSqrtLess() bool smtrat::vs::substituteNormalSqrtLess (
 const smtrat::Poly & _radicand,
```

```

const smtrat::Poly & _q,
const smtrat::Poly & _r,
const smtrat::Poly & _s,
DisjunctionOfConstraintConjunctions & _result,
bool _accordingPaper)

```

Sub-method of `substituteNormalSqrt`, where applying the substitution led to a term containing a square root.  
The relation symbol of the constraint to substitute is less.

$$(\_q + \_r * \sqrt{(\_radicand)})$$

The term then looks like: -----  $\_s$

#### Parameters

|                              |                                                                                                                                                                                                                                                                                                                     |
|------------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>_radicand</code>       | The radicand of the square root.                                                                                                                                                                                                                                                                                    |
| <code>_q</code>              | The summand not containing the square root.                                                                                                                                                                                                                                                                         |
| <code>_r</code>              | The coefficient of the radicand.                                                                                                                                                                                                                                                                                    |
| <code>_s</code>              | The denominator of the expression containing the square root.                                                                                                                                                                                                                                                       |
| <code>_result</code>         | The vector, in which to store the results of this substitution. It is semantically a disjunction of conjunctions of constraints.                                                                                                                                                                                    |
| <code>_accordingPaper</code> | A flag that indicates whether to apply the virtual substitution rules according to the paper "Quantifier elimination for real algebra - the quadratic case and beyond." by Volker Weispfenning (true) or in an adapted way which omits a higher degree in the result by splitting the result in more cases (false). |

**0.14.92.2.29 `substituteNormalSqrtNeq()`** `bool smtrat::vs::substituteNormalSqrtNeq (`

```

const smtrat::Poly & _radicand,
const smtrat::Poly & _q,
const smtrat::Poly & _r,
DisjunctionOfConstraintConjunctions & _result,
bool _accordingPaper)

```

Sub-method of `substituteNormalSqrt`, where applying the substitution led to a term containing a square root.  
The relation symbol of the constraint to substitute is " $!=$ ".

$$(\_q + \_r * \sqrt{(\_radicand)})$$

The term then looks like: -----  $\_s$

#### Parameters

|                              |                                                                                                                                                                                                                                                                                                                     |
|------------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>_radicand</code>       | The radicand of the square root.                                                                                                                                                                                                                                                                                    |
| <code>_q</code>              | The summand not containing the square root.                                                                                                                                                                                                                                                                         |
| <code>_r</code>              | The coefficient of the radicand.                                                                                                                                                                                                                                                                                    |
| <code>_result</code>         | The vector, in which to store the results of this substitution. It is semantically a disjunction of conjunctions of constraints.                                                                                                                                                                                    |
| <code>_accordingPaper</code> | A flag that indicates whether to apply the virtual substitution rules according to the paper "Quantifier elimination for real algebra - the quadratic case and beyond." by Volker Weispfenning (true) or in an adapted way which omits a higher degree in the result by splitting the result in more cases (false). |

**0.14.92.2.30 `substituteNotTrivialCase()`** `void smtrat::vs::substituteNotTrivialCase (`

```

const smtrat::ConstraintT & ,
const Substitution & ,
DisjunctionOfConstraintConjunctions &)

```

Deals with the case, that the left hand side of the constraint to substitute is not a trivial polynomial in the variable to substitute.

The constraints left hand side then should looks like:  $ax^2+bx+c$

#### Parameters

|                      |                                                                                                                                  |
|----------------------|----------------------------------------------------------------------------------------------------------------------------------|
| <code>_cons</code>   | The constraint to substitute in.                                                                                                 |
| <code>_subs</code>   | The substitution to apply.                                                                                                       |
| <code>_result</code> | The vector, in which to store the results of this substitution. It is semantically a disjunction of conjunctions of constraints. |

```
0.14.92.2.31 substitutePlusEps() [1/2] bool smtrat::vs::substitutePlusEps (
 const smtrat::ConstraintT & _cons,
 const Substitution & _subs,
 DisjunctionOfConstraintConjunctions & _result,
 bool _accordingPaper,
 carl::Variables & _conflictingVariables,
 const smtrat::EvalDoubleIntervalMap & _solutionSpace)
```

Applies the given substitution to the given constraint, where the substitution is of the form  $[x \rightarrow t+\epsilon]$  with  $x$  as the variable and  $c$  and  $b$  polynomials in the real theory excluding  $x$ .

The constraint is of the form " $f(x) \rho 0$ " with  $\rho$  element of  $\{=, !=, <, >, \leq, \geq\}$  and  $k$  as the maximum degree of  $x$  in  $f$ .

#### Parameters

|                                    |                                                                                                                                                                                                                                                                                                                     |
|------------------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>_cons</code>                 | The constraint to substitute in.                                                                                                                                                                                                                                                                                    |
| <code>_subs</code>                 | The substitution to apply.                                                                                                                                                                                                                                                                                          |
| <code>_result</code>               | The vector, in which to store the results of this substitution. It is semantically a disjunction of conjunctions of constraints.                                                                                                                                                                                    |
| <code>_accordingPaper</code>       | A flag that indicates whether to apply the virtual substitution rules according to the paper "Quantifier elimination for real algebra - the quadratic case and beyond." by Volker Weispfenning (true) or in an adapted way which omits a higher degree in the result by splitting the result in more cases (false). |
| <code>_conflictingVariables</code> | If a conflict with the given solution space occurs, the variables being part of this conflict are stored in this container.                                                                                                                                                                                         |
| <code>_solutionSpace</code>        | The solution space in form of double intervals of the variables occurring in the given constraint.                                                                                                                                                                                                                  |

```
0.14.92.2.32 substitutePlusEps() [2/2] bool smtrat::vs::substitutePlusEps (
 const smtrat::ConstraintT & _cons,
 const Substitution & _subs,
 DisjunctionOfConstraintConjunctions & _result,
 bool _accordingPaper,
 Variables & _conflictingVariables,
 const smtrat::EvalDoubleIntervalMap & _solutionSpace)
```

```
0.14.92.2.33 substituteTrivialCase() void smtrat::vs::substituteTrivialCase (
 const smtrat::ConstraintT & _cons,
 const Substitution & _subs,
 DisjunctionOfConstraintConjunctions & _result)
```

Deals with the case, that the left hand side of the constraint to substitute is a trivial polynomial in the variable to substitute.

The constraints left hand side then should look like:  $ax^2+bx+c$

#### Parameters

|                      |                                                                                                                                  |
|----------------------|----------------------------------------------------------------------------------------------------------------------------------|
| <code>_cons</code>   | The constraint to substitute in.                                                                                                 |
| <code>_subs</code>   | The substitution to apply.                                                                                                       |
| <code>_result</code> | The vector, in which to store the results of this substitution. It is semantically a disjunction of conjunctions of constraints. |

## Data Fields

- ParserState \* state

### 0.15.2.1 Detailed Description

Base class for all theories.

A theory represents one or multiple SMT-LIB theories and takes care of converting smtlib constructs into our data-structures.

A theory has two kinds of functions:

- Initializer are static functions that initialize global datastructures. These are for example the set of constants.
- Handlers are member functions that implement a certain SMT-LIB functionality. Handlers always return a boolean that indicates if the theory could complete the request. Oftentimes, a theory will return false because the request should be handled by another theory. Handlers are used, whenever the parser can not easily decide which theory to use and thus tries to call every theory. The result of a handler is always a term that is returned through a reference argument.

A theory may override any of the following methods.

### 0.15.2.2 Constructor & Destructor Documentation

#### 0.15.2.2.1 AbstractTheory()

```
smtrat::parser::AbstractTheory::AbstractTheory (
 ParserState * state) [inline]
```

#### 0.15.2.2.2 ~AbstractTheory()

```
virtual smtrat::parser::AbstractTheory::~AbstractTheory () [inline], [virtual]
```

### 0.15.2.3 Member Function Documentation

**0.15.2.3.1 addConstants()** static void smtrat::parser::AbstractTheory::addConstants (qi::symbols< char, types::ConstType > & ) [inline], [static]

Initialize the global symbol table for constants.

**0.15.2.3.2 addSimpleSorts()** static void smtrat::parser::AbstractTheory::addSimpleSorts (qi::symbols< char, carl::Sort > & ) [inline], [static]

Initialize the global symbol table for simple sorts.

**0.15.2.3.3 declareVariable()** virtual bool smtrat::parser::AbstractTheory::declareVariable (const std::string & , const carl::Sort & , types::VariableType & , TheoryError & errors ) [inline], [virtual]

Declare a new variable with the given name and the given sort.

Reimplemented in [smtrat::parser::UninterpretedTheory](#), [smtrat::parser::CoreTheory](#), [smtrat::parser::BitvectorTheory](#), and [smtrat::parser::ArithmeticTheory](#).

**0.15.2.3.4 expandDistinct()** template<typename T , typename Builder > FormulaT smtrat::parser::AbstractTheory::expandDistinct (const std::vector< T > & values, const Builder & negBuilder ) [inline]

**0.15.2.3.5 functionCall()** virtual bool smtrat::parser::AbstractTheory::functionCall (const Identifier & , const std::vector< types::TermType > & , types::TermType & , TheoryError & errors ) [inline], [virtual]

Resolve another unknown function call.

Reimplemented in [smtrat::parser::UninterpretedTheory](#), [smtrat::parser::CoreTheory](#), [smtrat::parser::BitvectorTheory](#), and [smtrat::parser::ArithmeticTheory](#).

**0.15.2.3.6 handleDistinct()** virtual bool smtrat::parser::AbstractTheory::handleDistinct (const std::vector< types::TermType > & , types::TermType & , TheoryError & errors ) [inline], [virtual]

Resolve a distinct operator.

Reimplemented in [smtrat::parser::CoreTheory](#), [smtrat::parser::BitvectorTheory](#), [smtrat::parser::ArithmeticTheory](#), and [smtrat::parser::UninterpretedTheory](#).

**0.15.2.3.7 handleITE()** virtual bool smtrat::parser::AbstractTheory::handleITE (const FormulaT & , const types::TermType & , const types::TermType & , types::TermType & , TheoryError & errors ) [inline], [virtual]

Resolve an if-then-else operator.

Reimplemented in [smtrat::parser::UninterpretedTheory](#), [smtrat::parser::CoreTheory](#), [smtrat::parser::BitvectorTheory](#), and [smtrat::parser::ArithmeticTheory](#).

**0.15.2.3.8 `instantiate()`** `virtual bool smtrat::parser::AbstractTheory::instantiate (`  
    `const types::VariableType &,`  
    `const types::TermType &,`  
    `types::TermType &,`  
    `TheoryError & errors ) [inline], [virtual]`

Instantiate a variable within a term.

Reimplemented in [smtrat::parser::BitvectorTheory](#), and [smtrat::parser::ArithmeticTheory](#).

**0.15.2.3.9 `refreshVariable()`** `virtual bool smtrat::parser::AbstractTheory::refreshVariable (`  
    `const types::VariableType &,`  
    `types::VariableType &,`  
    `TheoryError & errors ) [inline], [virtual]`

Reimplemented in [smtrat::parser::BitvectorTheory](#).

**0.15.2.3.10 `resolveSymbol()`** `virtual bool smtrat::parser::AbstractTheory::resolveSymbol (`  
    `const Identifier &,`  
    `types::TermType &,`  
    `TheoryError & errors ) [inline], [virtual]`

Resolve a symbol that was not declared within the [ParserState](#).

This might be a symbol that actually uses indices, for example bitvector constants.

Reimplemented in [smtrat::parser::BitvectorTheory](#).

#### 0.15.2.4 Field Documentation

**0.15.2.4.1 `state`** `ParserState* smtrat::parser::AbstractTheory::state`

### 0.15.3 [smtrat::cad::sample\\_compare::absvalue Struct Reference](#)

### 0.15.10.1 Detailed Description

Implements the theory of arithmetic, including LRA, LIA, NRA and NIA.

### 0.15.10.2 Constructor & Destructor Documentation

**0.15.10.2.1 ArithmeticTheory()** smtrat::parser::ArithmeticTheory::ArithmeticTheory (  
    ParserState \* state )

### 0.15.10.3 Member Function Documentation

**0.15.10.3.1 `addConstants()`** static void smtrat::parser::AbstractTheory::addConstants (qi::symbols< char, types::ConstType > & ) [inline], [static], [inherited]  
Initialize the global symbol table for constants.

**0.15.10.3.2 `addSimpleSorts()`** void smtrat::parser::ArithmeticTheory::addSimpleSorts (qi::symbols< char, carl::Sort > & sorts ) [static]

**0.15.10.3.3 `declareVariable()`** bool smtrat::parser::ArithmeticTheory::declareVariable (const std::string &, const carl::Sort &, types::VariableType &, TheoryError & errors ) [virtual]

Declare a new variable with the given name and the given sort.

Reimplemented from [smtrat::parser::AbstractTheory](#).

**0.15.10.3.4 `expandDistinct()`** template<typename T , typename Builder > FormulaT smtrat::parser::AbstractTheory::expandDistinct (const std::vector< T > & values, const Builder & negBuilder ) [inline], [inherited]

**0.15.10.3.5 `functionCall()`** bool smtrat::parser::ArithmeticTheory::functionCall (const Identifier &, const std::vector< types::TermType > &, types::TermType &, TheoryError & errors ) [virtual]

Resolve another unknown function call.

Reimplemented from [smtrat::parser::AbstractTheory](#).

**0.15.10.3.6 `handleDistinct()`** bool smtrat::parser::ArithmeticTheory::handleDistinct (const std::vector< types::TermType > &, types::TermType &, TheoryError & errors ) [virtual]

Resolve a distinct operator.

Reimplemented from [smtrat::parser::AbstractTheory](#).

**0.15.10.3.7 `handleITE()`** bool smtrat::parser::ArithmeticTheory::handleITE (const FormulaT &, const types::TermType &, const types::TermType &, types::TermType &, TheoryError & errors ) [virtual]

Resolve an if-then-else operator.

Reimplemented from [smtrat::parser::AbstractTheory](#).

```
0.15.10.3.8 instantiate() bool smtrat::parser::ArithmeticTheory::instantiate (
 const types::VariableType & ,
 const types::TermType & ,
 types::TermType & ,
 TheoryError & errors) [virtual]
```

Instantiate a variable within a term.

Reimplemented from [smtrat::parser::AbstractTheory](#).

```
0.15.10.3.9 refreshVariable() virtual bool smtrat::parser::AbstractTheory::refreshVariable (
 const types::VariableType & ,
 types::VariableType & ,
 TheoryError & errors) [inline], [virtual], [inherited]
```

Reimplemented in [smtrat::parser::BitvectorTheory](#).

```
0.15.10.3.10 resolveSymbol() virtual bool smtrat::parser::AbstractTheory::resolveSymbol (
 const Identifier & ,
 types::TermType & ,
 TheoryError & errors) [inline], [virtual], [inherited]
```

Resolve a symbol that was not declared within the [ParserState](#).

This might be a symbol that actually uses indices, for example bitvector constants.

Reimplemented in [smtrat::parser::BitvectorTheory](#).

## 0.15.10.4 Field Documentation

```
0.15.10.4.1 mITES std::map<carl::Variable, std::tuple<FormulaT, Poly, Poly>> smtrat::parser<-

 Theory::ops
```

```
0.15.10.4.3 state ParserState* smtrat::parser::AbstractTheory::state [inherited]
```

## 0.15.11 smtrat::parser::types::ArithmeticTheory Struct Reference

Types of the arithmetic theory.

```
#include <TheoryTypes.h>
```

### Public Types

- `typedef mpl::vector< Rational, FixedWidthConstant< Integer > > ConstTypes`
- `typedef mpl::vector< carl::Variable > VariableTypes`
- `typedef mpl::vector< carl::Variable, Rational, FixedWidthConstant< Integer >, Poly, carl::MultivariateRoot< Poly > > ExpressionTypes`
- `typedef mpl::vector< carl::Variable, Rational, FixedWidthConstant< Integer >, Poly, carl::MultivariateRoot< Poly > > TermTypes`
- `typedef carl::mpl_variant_of< TermTypes >::type TermType`

### 0.15.11.1 Detailed Description

Types of the arithmetic theory.

### 0.15.11.2 Member Typedef Documentation

**0.15.11.2.1 ConstTypes** `typedef mpl::vector<Rational, FixedWidthConstant<Integer> > smtrat::parser::types::ConstTypes`

**0.15.11.2.2 ExpressionTypes** `typedef mpl::vector<carl::Variable, Rational, FixedWidthConstant<Integer>, Poly, carl::MultivariateRoot<Poly> > smtrat::parser::types::ArithmeticTheory::ExpressionTypes`

**0.15.11.2.3 TermType** `typedef carl::mpl_variant_of<TermTypes>::type smtrat::parser::types::ArithmeticTheory::TermType`

**0.15.11.2.4 TermTypes** `typedef mpl::vector<carl::Variable, Rational, FixedWidthConstant<Integer>, Poly, carl::MultivariateRoot<Poly> > smtrat::parser::types::ArithmeticTheory::TermTypes`

**0.15.11.2.5 VariableTypes** `typedef mpl::vector<carl::Variable> smtrat::parser::types::ArithmeticTheory::VariableTypes`

## 0.15.12 smtrat::execution::Assertion Struct Reference

```
#include <ExecutionState.h>
```

### Data Fields

- `FormulaT formula`

### 0.15.12.1 Field Documentation

**0.15.12.1.1 formula** `FormulaT smtrat::execution::Assertion::formula`

## 0.15.13 smtrat::cad::preprocessor::AssignmentCollector Class Reference

```
#include <CADPreprocessor.h>
```

### Public Types

- using `CollectionResult = std::variant< bool, ConstraintT >`  
*Result of an assignment collection.*

### Public Member Functions

- `AssignmentCollector (Model &model)`
- `const auto & reasons () const`
- `auto & reasons ()`
- `const auto & constraints () const`
- `auto & constraints ()`
- `CollectionResult collect (std::map< ConstraintT, ConstraintT > &constraints)`

### 0.15.13.1 Member Typedef Documentation

**0.15.13.1.1 CollectionResult** using `smtrat::cad::preprocessor::AssignmentCollector::CollectionResult`  
= `std::variant<bool, ConstraintT>`  
Result of an assignment collection.  
true: new assignments were found false: no new assignments were found constraint: found direct conflict

## 0.15.13.2 Constructor & Destructor Documentation

**0.15.13.2.1 AssignmentCollector()** `smtrat::cad::preprocessor::AssignmentCollector::AssignmentCollector(`  
`Model & model ) [inline]`

## 0.15.24 benchmax::Backend Class Reference

Base class for all backends.

```
#include <Backend.h>
```

## Public Member Functions

- bool `suspendable () const`
- void `process_results (const Jobs &jobs, bool check_finished)`
- void `addResult (const Tool *tool, const fs::path &file, BenchmarkResult &&result)`

*Add a result.*
- void `run (const Jobs &jobs, bool wait_for_termination)`

*Run the list of tools against the list of benchmarks.*

## Protected Member Functions

- `Backend ()`
- virtual void `startTool (const Tool *)`

*Hook for every tool at the beginning.*
- virtual void `finalize ()`

*Hook to allow for asynchronous backends to wait for jobs to terminate.*
- virtual void `execute (const Tool *, const fs::path &)`

- Execute a single pair of tool and benchmark.*
- void [madeProgress](#) (std::size\_t files=1)  
*Can be called to give information about the current progress, if available.*
  - virtual bool [collect\\_results](#) (const [Jobs](#) &, bool)
  - void [sanitize\\_results](#) (const [Jobs](#) &jobs) const
  - void [write\\_results](#) (const [Jobs](#) &jobs) const

## Protected Attributes

- std::size\_t [mExpectedJobs](#)  
*Number of jobs that should be run.*
- std::atomic< std::size\_t > [mFinishedJobs](#)  
*Number of jobs that are finished.*
- std::atomic< std::size\_t > [mLastPercent](#)  
*Percentage of finished jobs when [madeProgress\(\)](#) was last called.*

### 0.15.24.1 Detailed Description

Base class for all backends.

Offers appropriate hooks to model the whole workflow for backends where each job is executed individually. The [run\(\)](#) method is called from outside which first calls [startTool\(\)](#) for every tool and then runs [execute\(\)](#) for every pair of tool and benchmark. It also offers [addResult\(\)](#) to store results and [madeProgress\(\)](#) to provide a progress indication to the user. If a benchmark requires a completely different workflow, for example for a batch job, it should override the [run\(\)](#) method.

### 0.15.24.2 Constructor & Destructor Documentation

#### 0.15.24.2.1 [Backend\(\)](#) `benchmax::Backend::Backend( ) [inline], [protected]`

### 0.15.24.3 Member Function Documentation

#### 0.15.24.3.1 [addResult\(\)](#) `void benchmax::Backend::addResult( const Tool * tool, const fs::path & file, BenchmarkResult && result ) [inline]`

Add a result.

#### 0.15.24.3.2 [collect\\_results\(\)](#) `virtual bool benchmax::Backend::collect_results( const Jobs &, bool ) [inline], [protected], [virtual]`

#### 0.15.24.3.3 [execute\(\)](#) `virtual void benchmax::Backend::execute( const Tool *, const fs::path & ) [inline], [protected], [virtual]`

Execute a single pair of tool and benchmark.

Reimplemented in [benchmax::LocalBackend](#), and [benchmax::CondorBackend](#).

#### 0.15.24.3.4 [finalize\(\)](#) `virtual void benchmax::Backend::finalize( ) [inline], [protected], [virtual]`

Hook to allow for asynchronous backends to wait for jobs to terminate.

**0.15.24.3.5 madeProgress()** void benchmax::Backend::madeProgress (

std::size\_t files = 1 ) [inline], [protected]

Can be called to give information about the current progress, if available.

**0.15.24.3.6 process\_results()** void benchmax::Backend::process\_results (

const Jobs &amp; jobs,

bool check\_finished ) [inline]

**0.15.24.3.7 run()** void benchmax::Backend::run (

const Jobs &amp; jobs,

bool wait\_for\_termination ) [inline]

Run the list of tools against the list of benchmarks.

**0.15.24.3.8 sanitize\_results()** void benchmax::Backend::sanitize\_results (

const Jobs &amp; jobs ) const [inline], [protected]

**0.15.24.3.9 startTool()** virtual void benchmax::Backend::startTool (

const Tool \* ) [inline], [protected], [virtual]

Hook for every tool at the beginning.

Can be used to upload the tool to some remote system.

**0.15.24.3.10 suspendable()** bool benchmax::Backend::suspendable ( ) const [inline]**0.15.24.3.11 write\_results()** void benchmax::Backend::write\_results (

const Jobs &amp; jobs ) const [inline], [protected]

```

### 0.15.30.3 Member Function Documentation

**0.15.30.3.1 addEqConstraint() [1/2]** template<typename Settings >  
 carl::Bitset smtrat::cad::BaseProjection< Settings >::addEqConstraint ( const Poly & p, std::size\_t cid, bool isBound ) [inline]

Adds the given polynomial of an equational constraint to the projection. Converts to a UPoly and calls the appropriate overload.

**0.15.30.3.2 addEqConstraint() [2/2]** template<typename Settings >  
 virtual carl::Bitset smtrat::cad::BaseProjection< Settings >::addEqConstraint ( const UPoly & p, std::size\_t cid, bool isBound ) [inline], [virtual]

Adds the given polynomial of an equational constraint to the projection.

Reimplemented in [smtrat::cad::Projection< Incrementality::FULL, Backtracking::HIDE, Settings >](#).

**0.15.30.3.3 addPolynomial() [1/2]** template<typename Settings >  
 carl::Bitset smtrat::cad::BaseProjection< Settings >::addPolynomial ( const Poly & p, std::size\_t cid, bool isBound ) [inline]

Adds the given polynomial to the projection. Converts to a UPoly and calls the appropriate overload.

**0.15.30.3.4 addPolynomial() [2/2]** template<typename Settings >  
 virtual carl::Bitset smtrat::cad::BaseProjection< Settings >::addPolynomial ( const UPoly & p, std::size\_t cid, bool isBound ) [pure virtual]

Adds the given polynomial to the projection.

Implemented in [smtrat::cad::Projection< Incrementality::NONE, Backtracking::UNORDERED, Settings >](#), [smtrat::cad::Projection< Incrementality::NONE, Backtracking::ORDERED, Settings >](#), [smtrat::cad::Projection< Incrementality::INCREMENTAL, Backtracking::HIDE, Settings >](#), [smtrat::cad::Projection< Incrementality::FULL, Backtracking::HIDE, Settings >](#), and [smtrat::cad::Projection< Incrementality::SIMPLE, Backtracking::HIDE, Settings >](#).

**0.15.30.3.5 callRemoveCallback()** template<typename Settings >  
 void smtrat::cad::BaseProjection< Settings >::callRemoveCallback ( std::size\_t level, const SampleLiftedWith & slw ) const [inline], [protected]

**0.15.30.3.6 canBePurgedByBounds()** template<typename Settings >  
 bool smtrat::cad::BaseProjection< Settings >::canBePurgedByBounds ( const UPoly & p ) const [inline], [protected]

Checks whether a polynomial can safely be ignored due to the bounds.

**0.15.30.3.7 dim()** template<typename Settings >  
 std::size\_t smtrat::cad::BaseProjection< Settings >::dim ( ) const [inline]

Returns the dimension of the projection.

**0.15.30.3.8 empty() [1/2]** template<typename Settings >  
virtual bool smtrat::cad::BaseProjection< Settings >::empty ( ) [inline], [virtual]

**0.15.30.3.9 empty() [2/2]** template<typename Settings >  
virtual bool smtrat::cad::BaseProjection< Settings >::empty ( std::size\_t level ) const [pure virtual]

Implemented in [smtrat::qe::cad::Projection< Settings >](#), [smtrat::cad::Projection< Incrementality::NONE, Backtracking::UNORDERED, smtrat::cad::Projection< Incrementality::NONE, Backtracking::ORDERED, Settings >](#), [smtrat::cad::ModelBasedProjection< Incrementality::NONE, smtrat::cad::Projection< Incrementality::FULL, BT, Settings >](#), and [smtrat::cad::Projection< Incrementality::FULL, Backtracking::HIDDEN >](#).

**0.15.30.3.10 exportAsDot()** template<typename Settings >  
virtual void smtrat::cad::BaseProjection< Settings >::exportAsDot ( std::ostream & ) const [inline], [virtual]

Reimplemented in [smtrat::cad::Projection< Incrementality::FULL, BT, Settings >](#), and [smtrat::cad::Projection< Incrementality::FULL, Backtracking::HIDDEN >](#).

**0.15.30.3.11 freeID()** template<typename Settings >  
void smtrat::cad::BaseProjection< Settings >::freeID ( std::size\_t level, std::size\_t id ) [inline], [protected]

Frees a currently used polynomial id for the given level.

**0.15.30.3.12 getID()** template<typename Settings >  
std::size\_t smtrat::cad::BaseProjection< Settings >::getID ( std::size\_t level ) [inline], [protected]

Returns a fresh polynomial id for the given level.

**0.15.30.3.13 getOrigin()** template<typename Settings >  
virtual Origin smtrat::cad::BaseProjection< Settings >::getOrigin ( std::size\_t level, std::size\_t id ) const [inline], [virtual]

Reimplemented in [smtrat::cad::Projection< Incrementality::FULL, BT, Settings >](#).

**0.15.30.3.14 getPolyForLifting()** template<typename Settings >  
OptionalID smtrat::cad::BaseProjection< Settings >::getPolyForLifting ( std::size\_t level, SampleLiftedWith & slw ) [inline]

Get a polynomial from this level suited for lifting.

**0.15.30.3.15 getPolynomialById()** template<typename Settings >  
virtual const UPoly& smtrat::cad::BaseProjection< Settings >::getPolynomialById ( std::size\_t level, std::size\_t id ) const [pure virtual]

Retrieves a polynomial from its id.

Implemented in [smtrat::qe::cad::Projection< Settings >](#), [smtrat::cad::Projection< Incrementality::NONE, Backtracking::UNORDERED, smtrat::cad::Projection< Incrementality::NONE, Backtracking::ORDERED, Settings >](#), [smtrat::cad::ModelBasedProjection< Incrementality::NONE, smtrat::cad::Projection< Incrementality::FULL, BT, Settings >](#), and [smtrat::cad::Projection< Incrementality::FULL, Backtracking::HIDDEN >](#).

```
0.15.30.3.16 hasPolynomialById() template<typename Settings >
virtual bool smtrat::cad::BaseProjection< Settings >::hasPolynomialById (
 std::size_t level,
 std::size_t id) const [pure virtual]
```

Implemented in `smtrat::qe::cad::Projection< Settings >`, `smtrat::cad::Projection< Incrementality::NONE, Backtracking::UNORDERED, Settings >`, `smtrat::cad::Projection< Incrementality::NONE, Backtracking::ORDERED, Settings >`, `smtrat::cad::ModelBasedProjection< Incrementality::NONE, Backtracking::HIDE, Settings >`, `smtrat::cad::Projection< Incrementality::FULL, BT, Settings >`, and `smtrat::cad::Projection< Incrementality::FULL, Backtracking::HIDE, Settings >`

```
0.15.30.3.17 isPurged() template<typename Settings >
bool smtrat::cad::BaseProjection< Settings >::isPurged (
 std::size_t level,
 std::size_t id) [inline], [protected]
```

```
0.15.30.3.18 removePolynomial() [1/2] template<typename Settings >
void smtrat::cad::BaseProjection< Settings >::removePolynomial (
 const Poly & p,
 std::size_t cid,
 bool isBound) [inline]
```

Removes the given polynomial from the projection. Converts to a UPoly and calls the appropriate overload.

```
0.15.30.3.19 removePolynomial() [2/2] template<typename Settings >
virtual void smtrat::cad::BaseProjection< Settings >::removePolynomial (
 const UPoly & p,
 std::size_t cid,
 bool isBound) [pure virtual]
```

Removes the given polynomial from the projection.

Implemented in `smtrat::cad::Projection< Incrementality::NONE, Backtracking::ORDERED, Settings >`, `smtrat::cad::ModelBasedProjection< Incrementality::NONE, Backtracking::HIDE, Settings >`, `smtrat::cad::Projection< Incrementality::FULL, BT, Settings >`, `smtrat::cad::Projection< Incrementality::FULL, Backtracking::HIDE, Settings >`, `smtrat::cad::Projection< Incrementality::SIMPLE, BT, Settings >`, and `smtrat::cad::Projection< Incrementality::NONE, Backtracking::HIDE, Settings >`

```
0.15.30.3.20 reset() template<typename Settings >
void smtrat::cad::BaseProjection< Settings >::reset () [inline]
```

Resets all datastructures, use the given variables from now on.

```
0.15.30.3.21 setRemoveCallback() template<typename Settings >
template<typename F >
void smtrat::cad::BaseProjection< Settings >::setRemoveCallback (
 F && f) [inline]
```

Sets a callback that is called whenever polynomials are removed.

```
0.15.30.3.22 size() [1/2] template<typename Settings >
std::size_t smtrat::cad::BaseProjection< Settings >::size () const [inline]
```

```
0.15.30.3.23 size() [2/2] template<typename Settings >
virtual std::size_t smtrat::cad::BaseProjection< Settings >::size (
 std::size_t level) const [pure virtual]
```

Implemented in `smtrat::qe::cad::Projection< Settings >`, `smtrat::cad::Projection< Incrementality::NONE, Backtracking::UNORDERED, Settings >`, `smtrat::cad::Projection< Incrementality::NONE, Backtracking::ORDERED, Settings >`, `smtrat::cad::ModelBasedProjection< Incrementality::NONE, Backtracking::HIDE, Settings >`, `smtrat::cad::Projection< Incrementality::FULL, BT, Settings >`, and `smtrat::cad::Projection< Incrementality::FULL, Backtracking::HIDE, Settings >`

```
0.15.30.3.24 var() template<typename Settings >
carl::Variable smtrat::cad::BaseProjection< Settings >::var (
 std::size_t level) const [inline], [protected]
```

Returns the variable that corresponds to the given level, that is the variable eliminated in this level.

```
0.15.30.3.25 vars() template<typename Settings >
const auto& smtrat::cad::BaseProjection< Settings >::vars () const [inline]
```

Returns the variables used for projection.

#### 0.15.30.4 Field Documentation

```
0.15.30.4.1 mConstraints template<typename Settings >
const Constraints& smtrat::cad::BaseProjection< Settings >::mConstraints [protected]
```

```
0.15.30.4.2 mInfo template<typename Settings >
ProjectionInformation smtrat::cad::BaseProjection< Settings >::mInfo [protected]
```

Additional info on projection, projection levels and projection polynomials.

```
0.15.30.4.3 mLiftingQueues template<typename Settings >
std::vector<PolynomialLiftingQueue<BaseProjection> > smtrat::cad::BaseProjection< Settings
>::mLiftingQueues [protected]
```

List of lifting queues that can be used for incremental projection.

```
0.15.30.4.4 mOperator template<typename Settings >
ProjectionOperator smtrat::cad::BaseProjection< Settings >::mOperator [protected]
```

The projection operator.

```
0.15.30.4.5 mRemoveCallback template<typename Settings >
std::function<void(std::size_t, const SampleLiftedWith&)> smtrat::cad::BaseProjection< Settings
>::mRemoveCallback [protected]
```

Callback to be called when polynomials are removed. The arguments are the projection level and a bitset that indicate which polynomials were removed in this level.

### 0.15.31 smtrat::cad::BaseSettings Struct Reference

## 0.15.41 `smtrat::BEModule< Settings >` Class Template Reference

```
#include <BEModule.h>
```

### Public Types

- `typedef Settings SettingsType`
- `enum class LemmaType : unsigned { NORMAL = 0 , PERMANENT = 1 }`

### Public Member Functions

- `std::string moduleName () const`
- `BEModule (const ModuleInput *_formula, Conditionals &_conditionals, Manager *_manager=NULL)`
- `~BEModule ()`
- `Answer checkCore ()`

*Checks the received formula for consistency.*
- `bool isPreprocessor () const`
- `bool appliedPreprocessing () const`
- `bool add (ModuleInput::const_iterator _subformula)`

*The module has to take the given sub-formula of the received formula into account.*
- `void remove (ModuleInput::const_iterator _subformula)`

*Removes everything related to the given sub-formula of the received formula.*
- `Answer check (bool _final=false, bool _full=true, carl::Variable _objective=carl::Variable::NO_VARIABLE)`

*Checks the received formula for consistency.*
- `Answer runBackends (bool _final, bool _full, carl::Variable _objective)`

*Runs the backend solvers on the passed formula.*
- `virtual Answer runBackends ()`
- `std::pair< bool, FormulaT > getReceivedFormulaSimplified ()`
- `void updateModel () const`

*Updates the current assignment into the model.*
- `bool inform (const FormulaT &_constraint)`

*Informs the module about the given constraint.*
- `void deinform (const FormulaT &_constraint)`

*The inverse of informing about a constraint.*
- `virtual void init ()`

*Informs all backends about the so far encountered constraints, which have not yet been communicated.*
- `virtual void updateAllModels ()`

*Updates all satisfying models, if the solver has detected the consistency of the received formula, beforehand.*
- `virtual std::list< std::vector< carl::Variable > > getModelEqualities () const`

*Partition the variables from the current model into equivalence classes according to their assigned value.*

- `unsigned currentlySatisfiedByBackend (const FormulaT &_formula) const`
- `virtual unsigned currentlySatisfied (const FormulaT &) const`
- `bool receivedVariable (carl::Variable::Arg _var) const`
- `Answer solverState () const`
- `std::size_t id () const`
- `void setId (std::size_t _id)`

*Sets this modules unique ID to identify itself.*

- `thread_priority threadPriority () const`
- `void setThreadPriority (thread_priority _threadPriority)`

*Sets the priority of this module to get a thread for running its check procedure.*

- `const ModuleInput * pReceivedFormula () const`
- `const ModuleInput & rReceivedFormula () const`
- `const ModuleInput * pPassedFormula () const`
- `const ModuleInput & rPassedFormula () const`
- `const Model & model () const`
- `const std::vector< Model > & allModels () const`
- `const std::vector< FormulaSetT > & infeasibleSubsets () const`
- `const std::vector< Module * > & usedBackends () const`
- `const carl::FastSet< FormulaT > & constraintsToInform () const`
- `const carl::FastSet< FormulaT > & informedConstraints () const`
- `void addLemma (const FormulaT &_lemma, const LemmaType &_lt=LemmaType::NORMAL, const FormulaT &_preferredFormula=FormulaT(carl::FormulaType::TRUE))`

*Stores a lemma being a valid formula.*

- `bool hasLemmas ()`

*Checks whether this module or any of its backends provides any lemmas.*

- `void clearLemmas ()`

*Deletes all yet found lemmas.*

- `const std::vector< Lemma > & lemmas () const`
- `ModuleInput::const_iterator firstUncheckedReceivedSubformula () const`
- `ModuleInput::const_iterator firstSubformulaToPass () const`
- `void receivedFormulaChecked ()`

*Notifies that the received formulas has been checked.*

- `const smrat::Conditionals & answerFound () const`
- `carl::Variable objective () const`
- `bool is_minimizing () const`
- `void excludeNotReceivedVariablesFromModel () const`

*Excludes all variables from the current model, which do not occur in the received formula.*

- `void updateLemmas ()`

*Stores all lemmas of any backend of this module in its own lemma vector.*

- `void collectTheoryPropagations ()`
- `void collectOrigins (const FormulaT &_formula, FormulasT &_origins) const`

*Collects the formulas in the given formula, which are part of the received formula.*

- `void collectOrigins (const FormulaT &_formula, FormulaSetT &_origins) const`
- `bool hasValidInfeasibleSubset () const`
- `void checkInfSubsetForMinimality (std::vector< FormulaSetT >::const_iterator _infsSubset, const std::string &_filename="smaller_muses", unsigned _maxSizeDifference=1) const`

*Checks the given infeasible subset for minimality by storing all subsets of it, which have a smaller size which differs from the size of the infeasible subset not more than the given threshold.*

- `void print (const std::string &_initiation="***") const`

*Prints everything relevant of the solver.*

- `void printReceivedFormula (const std::string &_initiation="***") const`

*Prints the vector of the received formula.*

- void `printPassedFormula` (const std::string &\_initiation="\*\*\*") const  
*Prints the vector of passed formula.*
- void `printInfeasibleSubsets` (const std::string &\_initiation="\*\*\*") const  
*Prints the infeasible subsets.*
- void `printModel` (std::ostream &\_out=std::cout) const  
*Prints the assignment of this module satisfying its received formula if it satisfiable and this module could find an assignment.*
- void `printAllModels` (std::ostream &\_out=std::cout)  
*Prints all assignments of this module satisfying its received formula if it satisfiable and this module could find an assignment.*

### Static Public Member Functions

- static void `freeSplittingVariable` (const `FormulaT` &\_splittingVariable)

### Static Public Attributes

- static size\_t `mNumOfBranchVarsToStore` = 5  
*The number of different variables to consider for a probable infinite loop of branchings.*
- static std::vector< `Branching` > `mLastBranches` = std::vector<`Branching`>(mNumOfBranchVarsToStore, `Branching`(typename Poly::PolyType(), 0))  
*Stores the last branches in a cycle buffer.*
- static size\_t `mFirstPosInLastBranches` = 0  
*The beginning of the cyclic buffer storing the last branches.*
- static std::vector< `FormulaT` > `mOldSplittingVariables`  
*Reusable splitting variables.*

### Protected Member Functions

- virtual bool `informCore` (const `FormulaT` &\_constraint)  
*Informs the module about the given constraint.*
- virtual void `deinformCore` (const `FormulaT` &\_constraint)  
*The inverse of informing about a constraint.*
- virtual bool `addCore` (`ModuleInput`::const\_iterator formula)  
*The module has to take the given sub-formula of the received formula into account.*
- virtual void `removeCore` (`ModuleInput`::const\_iterator formula)  
*Removes everything related to the given sub-formula of the received formula.*
- bool `anAnswerFound` () const  
*Checks for all antecedent modules and those which run in parallel with the same antecedent modules, whether one of them has determined a result.*
- void `clearModel` () const  
*Clears the assignment, if any was found.*
- void `clearModels` () const  
*Clears all assignments, if any was found.*
- void `cleanModel` () const  
*Substitutes variable occurrences by its model value in the model values of other variables.*
- `ModuleInput`::iterator `passedFormulaBegin` ()
- `ModuleInput`::iterator `passedFormulaEnd` ()
- void `addOrigin` (`ModuleInput`::iterator \_formula, const `FormulaT` &\_origin)  
*Adds the given set of formulas in the received formula to the origins of the given passed formula.*
- const `FormulaT` & `getOrigins` (`ModuleInput`::const\_iterator \_formula) const  
*Gets the origins of the passed formula at the given position.*
- void `getOrigins` (const `FormulaT` &\_formula, `FormulasT` &\_origins) const

- void `getOrigins` (const `FormulaT` &\_formula, `FormulaSetT` &\_origins) const
  - std::pair< `ModuleInput::iterator`, bool > `removeOrigin` (`ModuleInput::iterator` \_formula, const `FormulaT` &\_origin)
    - std::pair< `ModuleInput::iterator`, bool > `removeOrigins` (`ModuleInput::iterator` \_formula, const std::shared\_ptr< std::vector< `FormulaT` >> &\_origins)
  - void `informBackends` (const `FormulaT` &\_constraint)
    - Informs all backends of this module about the given constraint.*
- virtual void `addConstraintToInform` (const `FormulaT` &\_constraint)
  - Adds a constraint to the collection of constraints of this module, which are informed to a freshly generated backend.*
- std::pair< `ModuleInput::iterator`, bool > `addReceivedSubformulaToPassedFormula` (`ModuleInput::const_iterator` \_subformula)
  - Copies the given sub-formula of the received formula to the passed formula.*
- bool `originInReceivedFormula` (const `FormulaT` &\_origin) const
  - std::pair< `ModuleInput::iterator`, bool > `addSubformulaToPassedFormula` (const `FormulaT` &\_formula)
    - Adds the given formula to the passed formula with no origin.*
  - std::pair< `ModuleInput::iterator`, bool > `addSubformulaToPassedFormula` (const `FormulaT` &\_formula, const std::shared\_ptr< std::vector< `FormulaT` >> &\_origins)
    - Adds the given formula to the passed formula.*
  - std::pair< `ModuleInput::iterator`, bool > `addSubformulaToPassedFormula` (const `FormulaT` &\_formula, const `FormulaT` &\_origin)
    - Adds the given formula to the passed formula.*
- void `generateTrivialInfeasibleSubset` ()
  - Stores the trivial infeasible subset being the set of received formulas.*
- void `receivedFormulasAsInfeasibleSubset` (`ModuleInput::const_iterator` \_subformula)
  - Stores an infeasible subset consisting only of the given received formula.*
- std::vector< `FormulaT` >::const\_iterator `findBestOrigin` (const std::vector< `FormulaT` > &\_origins) const
  - void `getInfeasibleSubsets` ()
    - Copies the infeasible subsets of the passed formula.*
  - std::vector< `FormulaSetT` > `getInfeasibleSubsets` (const `Module` &\_backend) const
    - Get the infeasible subsets the given backend provides.*
  - const `Model` & `backendsModel` () const
    - Stores the model of a backend which determined satisfiability of the passed formula in the model of this module.*
  - void `getBackendsModel` () const
    - Stores all models of a backend in the list of all models of this module.*
  - void `getBackendsAllModels` () const
    - Removes everything related to the sub-formula to remove from the passed formula in the backends of this module.*
  - void `clearPassedFormula` ()
    - Merges the two vectors of sets into the first one.*
  - size\_t `determine_smallest_origin` (const std::vector< `FormulaT` > &origins) const
    - bool `probablyLooping` (const typename `Poly::PolyType` &\_branchingPolynomial, const `Rational` &\_branchingValue) const
      - Checks whether given the current branching value and branching variable/polynomial it is (highly) probable that this branching is part of an infinite loop of branchings.*
    - bool `branchAt` (const `Poly` &\_polynomial, bool \_integral, const `Rational` &\_value, std::vector< `FormulaT` > &&\_premise, bool \_leftCaseWeak=true, bool \_preferLeftCase=true, bool \_useReceivedFormulaAsPremise=false)
      - Adds a lemmas which provoke a branching for the given variable at the given value, if this module returns Unknown and there exists a preceding `SATModule`.*

- bool `branchAt` (const `Poly` &\_polynomial, bool \_integral, const `Rational` &\_value, bool \_leftCaseWeak=true, bool \_preferLeftCase=true, bool \_useReceivedFormulaAsPremise=false, const std::vector<`FormulaT`> &\_premise=std::vector<`FormulaT`>())
- bool `branchAt` (carl::Variable::Arg \_var, const `Rational` &\_value, std::vector<`FormulaT`> &&\_premise, bool \_leftCaseWeak=true, bool \_preferLeftCase=true, bool \_useReceivedFormulaAsPremise=false)
- bool `branchAt` (carl::Variable::Arg \_var, const `Rational` &\_value, bool \_leftCaseWeak=true, bool \_preferLeftCase=true, bool \_useReceivedFormulaAsPremise=false, const std::vector<`FormulaT`> &\_premise=std::vector<`FormulaT`>())
- void `splitUnequalConstraint` (const `FormulaT` &)
 

*Adds the following lemmas for the given constraint p!=0.*
- unsigned `checkModel` () const
- void `addInformationRelevantFormula` (const `FormulaT` &formula)
 

*Adds a formula to the InformationRelevantFormula.*
- const std::set<`FormulaT`> & `getInformationRelevantFormulas` ()
 

*Gets all InformationRelevantFormulas.*
- bool `isLemmaLevel` (`LemmaLevel` level)
 

*Checks if current lemma level is greater or equal to given level.*

### Static Protected Member Functions

- static bool `modelsDisjoint` (const `Model` &\_modelA, const `Model` &\_modelB)
 

*Checks whether there is no variable assigned by both models.*

### Protected Attributes

- std::vector<`FormulaSetT`> `mInfeasibleSubsets`

*Stores the infeasible subsets.*
- `Manager` \*const `mpManager`

*A reference to the manager.*
- `Model` `mModel`

*Stores the assignment of the current satisfiable result, if existent.*
- std::vector<`Model`> `mAllModels`

*Stores all satisfying assignments.*
- bool `mModelComputed`

*True, if the model has already been computed.*
- bool `mFinalCheck`

*true, if the check procedure should perform a final check which especially means not to postpone splitting decisions*
- bool `mFullCheck`

*false, if this module should avoid too expensive procedures and rather return unknown instead.*
- carl::Variable `mObjectiveVariable`

*Objective variable to be minimized. If set to NO\_VARIABLE, a normal sat check should be performed.*
- std::vector<`TheoryPropagation`> `mTheoryPropagations`
- std::atomic<`Answer`> `mSolverState`

*States whether the received formula is known to be satisfiable or unsatisfiable otherwise it is set to unknown.*
- std::atomic\_bool \* `mBackendsFoundAnswer`

*This flag is passed to any backend and if it determines an answer to a prior check call, this flag is fired.*
- `Conditionals` `mFoundAnswer`

*Vector of Booleans: If any of them is true, we have to terminate a running check procedure.*
- std::vector<`Module` \*> `mUsedBackends`

*The backends of this module which are currently used (conditions to use this module are fulfilled for the passed formula).*
- std::vector<`Module` \*> `mAllBackends`

*The backends of this module which have been used.*

- `std::vector< Lemma > mLemmas`  
*Stores the lemmas being valid formulas this module or its backends made.*
- `ModuleInput::iterator mFirstSubformulaToPass`  
*Stores the position of the first sub-formula in the passed formula, which has not yet been considered for a consistency check of the backends.*
- `carl::FastSet< FormulaT > mConstraintsToInform`  
*Stores the constraints which the backends must be informed about.*
- `carl::FastSet< FormulaT > mInformedConstraints`  
*Stores the position of the first constraint of which no backend has been informed about.*
- `ModuleInput::const_iterator mFirstUncheckedReceivedSubformula`  
*Stores the position of the first (by this module) unchecked sub-formula of the received formula.*
- `unsigned mSmallerMusesCheckCounter`  
*Counter used for the generation of the smt2 files to check for smaller muses.*
- `std::vector< std::size_t > mVariableCounters`  
*Maps variables to the number of their occurrences.*

#### 0.15.41.1 Member Typedef Documentation

**0.15.41.1.1 SettingsType** `template<typename Settings >`  
`typedef Settings smtrat::BEModule< Settings >::SettingsType`

#### 0.15.41.2 Member Enumeration Documentation

**0.15.41.2.1 LemmaType** `enum smtrat::Module::LemmaType : unsigned [strong], [inherited]`

Enumerator

|           |  |

| NORMAL    |  |
| PERMANENT |  |

#### 0.15.41.3 Constructor & Destructor Documentation

**0.15.41.3.1 BEModule()** `template<typename Settings >`  
`smtrat::BEModule< Settings >::BEModule (`  
 `const ModuleInput * _formula,`  
 `Conditionals & _conditionals,`  
 `Manager * _manager = NULL )`

**0.15.41.3.2 ~BEModule()** `template<typename Settings >`  
`smtrat::BEModule< Settings >::~BEModule ( )`

#### 0.15.41.4 Member Function Documentation

**0.15.41.4.1 add()** `bool smtrat::PModule::add (`  
 `ModuleInput::const_iterator _subformula ) [inherited]`

The module has to take the given sub-formula of the received formula into account.

**Parameters**

|                          |                                                    |
|--------------------------|----------------------------------------------------|
| <code>_subformula</code> | The sub-formula to take additionally into account. |
|--------------------------|----------------------------------------------------|

**Returns**

false, if it can be easily decided that this sub-formula causes a conflict with the already considered sub-formulas; true, otherwise.

#### **0.15.41.4.2 `addConstraintToInform()`** `void smtrat::Module::addConstraintToInform ( const FormulaT & _constraint )` [protected], [virtual], [inherited]

Adds a constraint to the collection of constraints of this module, which are informed to a freshly generated backend.

**Parameters**

|                          |                        |
|--------------------------|------------------------|
| <code>_constraint</code> | The constraint to add. |
|--------------------------|------------------------|

Reimplemented in [smtrat::SATModule< Settings >](#).

#### **0.15.41.4.3 `addCore()`** `virtual bool smtrat::Module::addCore ( ModuleInput::const_iterator formula )` [inline], [protected], [virtual], [inherited]

The module has to take the given sub-formula of the received formula into account.

**Parameters**

|                      |                                                    |
|----------------------|----------------------------------------------------|
| <code>formula</code> | The sub-formula to take additionally into account. |
|----------------------|----------------------------------------------------|

**Returns**

false, if it can be easily decided that this sub-formula causes a conflict with the already considered sub-formulas; true, otherwise.

Reimplemented in [smtrat::VSModule< Settings >](#), [smtrat::SATModule< Settings >](#), [smtrat::PFEModule< Settings >](#), [smtrat::ICPModule< Settings >](#), [smtrat::ICPModule< ICPSettings4 >](#), [smtrat::ICPModule< ICPSettings1 >](#), [smtrat::UnionFindModule< Settings >](#), [smtrat::UFCegarModule< Settings >](#), [smtrat::STropModule< Settings >](#), [smtrat::PBPPModule< Settings >](#), [smtrat::PBGaussModule< Settings >](#), [smtrat::NRAILModule< Settings >](#), [smtrat::NewCoveringModule< Settings >](#), [smtrat::NewCADModule< Settings >](#), [smtrat::LRAModule< Settings >](#), [smtrat::LRAModule< LRASettingsICP >](#), [smtrat::LRAModule< LRASettings1 >](#), [smtrat::IntEqModule< Settings >](#), [smtrat::IntBlastModule< Settings >](#), [smtrat::IncWidthModule< Settings >](#), [smtrat::ICEModule< Settings >](#), [smtrat::FPPModule< Settings >](#), [smtrat::FouMoModule< Settings >](#), [smtrat::EQModule< Settings >](#), [smtrat::CurryModule< Settings >](#), [smtrat::CubeLIAModule< Settings >](#), [smtrat::CSplitModule< Settings >](#), [smtrat::BVMModule< Settings >](#), and [smtrat::GBModule< Settings >](#).

#### **0.15.41.4.4 `addInformationRelevantFormula()`** `void smtrat::Module::addInformationRelevantFormula ( const FormulaT & formula )` [protected], [inherited]

Adds a formula to the InformationRelevantFormula.

**Parameters**

|                      |                |
|----------------------|----------------|
| <code>formula</code> | Formula to add |
|----------------------|----------------|

---

**0.15.41.4.5 addLemma()** void smtrat::Module::addLemma (

```
const FormulaT & _lemma,
const LemmaType & _lt = LemmaType::NORMAL,
const FormulaT & _preferredFormula = FormulaT(carl::FormulaType::TRUE)) [inline],
[inherited]
```

Stores a lemma being a valid formula.

#### Parameters

|                   |                                                                       |
|-------------------|-----------------------------------------------------------------------|
| _lemma            | The eduction/lemma to store.                                          |
| _lt               | The type of the lemma.                                                |
| _preferredFormula | Hint for the next decision, which formula should be assigned to true. |

**0.15.41.4.6 addOrigin()** void smtrat::Module::addOrigin (

```
ModuleInput::iterator _formula,
const FormulaT & _origin) [inline], [protected], [inherited]
```

Adds the given set of formulas in the received formula to the origins of the given passed formula.

#### Parameters

|          |                                                           |
|----------|-----------------------------------------------------------|
| _formula | The passed formula to set the origins for.                |
| _origin  | A set of formulas in the received formula of this module. |

**0.15.41.4.7 addReceivedSubformulaToPassedFormula()** std::pair<ModuleInput::iterator,bool>

```
smtrat::Module::addReceivedSubformulaToPassedFormula (
```

```
ModuleInput::const_iterator _subformula) [inline], [protected], [inherited]
```

Copies the given sub-formula of the received formula to the passed formula.

Note, that there is always a link between sub-formulas of the passed formulas to sub-formulas of the received formulas, which are responsible for its occurrence.

#### Parameters

|             |                                                  |
|-------------|--------------------------------------------------|
| _subformula | The sub-formula of the received formula to copy. |
|-------------|--------------------------------------------------|

**0.15.41.4.8 addSubformulaToPassedFormula()** [1/3] std::pair<ModuleInput::iterator,bool> smtrat::Module::addSubformulaToPassedFormula (

```
const FormulaT & _formula) [inline], [protected], [inherited]
```

Adds the given formula to the passed formula with no origin.

Note that in the next call of this module's removeSubformula, all formulas in the passed formula without origins will be removed.

#### Parameters

|          |                                           |
|----------|-------------------------------------------|
| _formula | The formula to add to the passed formula. |
|----------|-------------------------------------------|

#### Returns

A pair to the position where the formula to add has been inserted (or its first sub-formula which has not yet been in the passed formula, in case the formula to add is a conjunction), and a Boolean stating whether anything has been added to the passed formula.

```
0.15.41.4.9 addSubformulaToPassedFormula() [2/3] std::pair<ModuleInput::iterator,bool> smtrat→
::Module::addSubformulaToPassedFormula (
 const FormulaT & _formula,
 const FormulaT & _origin) [inline], [protected], [inherited]
```

Adds the given formula to the passed formula.

#### Parameters

|                 |                                                                                                                           |
|-----------------|---------------------------------------------------------------------------------------------------------------------------|
| <i>_formula</i> | The formula to add to the passed formula.                                                                                 |
| <i>_origin</i>  | The sub-formula of the received formula being responsible for the occurrence of the formula to add to the passed formula. |

#### Returns

A pair to the position where the formula to add has been inserted (or its first sub-formula which has not yet been in the passed formula, in case the formula to add is a conjunction), and a Boolean stating whether anything has been added to the passed formula.

```
0.15.41.4.10 addSubformulaToPassedFormula() [3/3] std::pair<ModuleInput::iterator,bool> smtrat→
::Module::addSubformulaToPassedFormula (
 const FormulaT & _formula,
 const std::shared_ptr< std::vector<FormulaT> >& _origins) [inline], [protected],
[inherited]
```

Adds the given formula to the passed formula.

#### Parameters

|                 |                                                                                                                                         |
|-----------------|-----------------------------------------------------------------------------------------------------------------------------------------|
| <i>_formula</i> | The formula to add to the passed formula.                                                                                               |
| <i>_origins</i> | The link of the formula to add to the passed formula to sub-formulas of the received formulas, which are responsible for its occurrence |

#### Returns

A pair to the position where the formula to add has been inserted (or its first sub-formula which has not yet been in the passed formula, in case the formula to add is a conjunction), and a Boolean stating whether anything has been added to the passed formula.

```
0.15.41.4.11 allModels() const std::vector<Model>& smtrat::Module::allModels () const [inline],
[inherited]
```

#### Returns

All satisfying assignments, if existent.

```
0.15.41.4.12 anAnswerFound() bool smtrat::Module::anAnswerFound () const [inline], [protected],
[inherited]
```

Checks for all antecedent modules and those which run in parallel with the same antecedent modules, whether one of them has determined a result.

#### Returns

True, if one of them has determined a result.

**0.15.41.4.13 answerFound()** const `smtrat::Conditionals`& `smtrat::Module::answerFound` ( ) const [inline], [inherited]

**Returns**

A vector of Booleans: If any of them is true, we have to terminate a running check procedure.

**0.15.41.4.14 appliedPreprocessing()** bool `smtrat::PModule::appliedPreprocessing` ( ) const [inline], [inherited]

**Returns**

true, if the current received formula has been simplified and the result of this simplification is stored in the passed formula.

**0.15.41.4.15 backendsModel()** const `Model` & `smtrat::Module::backendsModel` ( ) const [protected], [inherited]

Stores the model of a backend which determined satisfiability of the passed formula in the model of this module.

**0.15.41.4.16 branchAt() [1/4]** bool `smtrat::Module::branchAt` (

```
 carl::Variable::Arg _var,
 const Rational & _value,
 bool _leftCaseWeak = true,
 bool _preferLeftCase = true,
 bool _useReceivedFormulaAsPremise = false,
 const std::vector< FormulaT > & _premise = std::vector<FormulaT>()) [inline],
[protected], [inherited]
```

**0.15.41.4.17 branchAt() [2/4]** bool `smtrat::Module::branchAt` (

```
 carl::Variable::Arg _var,
 const Rational & _value,
 std::vector< FormulaT > && _premise,
 bool _leftCaseWeak = true,
 bool _preferLeftCase = true,
 bool _useReceivedFormulaAsPremise = false) [inline], [protected], [inherited]
```

**0.15.41.4.18 branchAt() [3/4]** bool `smtrat::Module::branchAt` (

```
 const Poly & _polynomial,
 bool _integral,
 const Rational & _value,
 bool _leftCaseWeak = true,
 bool _preferLeftCase = true,
 bool _useReceivedFormulaAsPremise = false,
 const std::vector< FormulaT > & _premise = std::vector<FormulaT>()) [inline],
[protected], [inherited]
```

**0.15.41.4.19 branchAt() [4/4]** bool `smtrat::Module::branchAt` (

```
 const Poly & _polynomial,
 bool _integral,
 const Rational & _value,
 std::vector< FormulaT > && _premise,
```

```

 bool _leftCaseWeak = true,
 bool _preferLeftCase = true,
 bool _useReceivedFormulaAsPremise = false) [protected], [inherited]

```

Adds a lemmas which provoke a branching for the given variable at the given value, if this module returns Unknown and there exists a preceding [SATModule](#).

Note that the given value is rounded down and up, if the given variable is integer-valued.

#### Parameters

|                                           |                                                                                                                                                                                                                |
|-------------------------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>_polynomial</code>                  | The variable to branch for.                                                                                                                                                                                    |
| <code>_integral</code>                    | A flag being true, if all variables in the polynomial to branch for are integral.                                                                                                                              |
| <code>_value</code>                       | The value to branch at.                                                                                                                                                                                        |
| <code>_premise</code>                     | The sub-formulas of the received formula from which the branch is followed. Note, that a premise is not necessary, as every branch is a valid formula. But a premise can prevent from branching unnecessarily. |
| <code>_leftCaseWeak</code>                | true, if a branching in the form of (or ( $\leq p b$ ) ( $> p b$ )) is desired. false, if a branching in the form of (or ( $< p b$ ) ( $\geq p b$ )) is desired.                                               |
| <code>_preferLeftCase</code>              | true, if the left case (polynomial less(or equal) 0 shall be chosen first. false, otherwise.                                                                                                                   |
| <code>_useReceivedFormulaAsPremise</code> | true, if the whole received formula should be used as premise                                                                                                                                                  |

#### 0.15.41.4.20 `check()`

```

 Answer smtrat::PModule::check (
 bool _final = false,
 bool _full = true,
 carl::Variable _objective = carl::Variable::NO_VARIABLE) [virtual], [inherited]

```

Checks the received formula for consistency.

Note, that this is an implementation of the satisfiability check of the conjunction of the so far received formulas, which does actually nothing but passing the problem to its backends. This implementation is only used internally and must be overwritten by any derived module.

#### Parameters

|                         |                                                                                                                                       |
|-------------------------|---------------------------------------------------------------------------------------------------------------------------------------|
| <code>_final</code>     | true, if this satisfiability check will be the last one (for a global sat-check), if its result is SAT                                |
| <code>_full</code>      | false, if this module should avoid too expensive procedures and rather return unknown instead.                                        |
| <code>_objective</code> | if not set to NO_VARIABLE, the module should find an assignment minimizing this objective variable; otherwise any assignment is good. |

#### Returns

True, if the received formula is satisfiable; False, if the received formula is not satisfiable; Unknown, otherwise.

Reimplemented from [smtrat::Module](#).

#### 0.15.41.4.21 `checkCore()`

```

 template<typename Settings >
 Answer smtrat::BEModule< Settings >::checkCore () [virtual]

```

Checks the received formula for consistency.

#### Returns

SAT, if the received formula is satisfiable; UNSAT, if the received formula is not satisfiable; Unknown, otherwise.

Reimplemented from [smtrat::Module](#).

```
0.15.41.4.22 checkInfSubsetForMinimality() void smtrat::Module::checkInfSubsetForMinimality (
 std::vector< FormulaSetT >::const_iterator _infssubset,
 const std::string & _filename = "smaller_muses",
 unsigned _maxSizeDifference = 1) const [inherited]
```

Checks the given infeasible subset for minimality by storing all subsets of it, which have a smaller size which differs from the size of the infeasible subset not more than the given threshold.

#### Parameters

|                                 |                                                                                                        |
|---------------------------------|--------------------------------------------------------------------------------------------------------|
| <code>_infssubset</code>        | The infeasible subset to check for minimality.                                                         |
| <code>_filename</code>          | The name of the file to store the infeasible subsets in order to be able to check their infeasibility. |
| <code>_maxSizeDifference</code> | The maximal difference between the sizes of the subsets compared to the size of the infeasible subset. |

```
0.15.41.4.23 checkModel() unsigned smtrat::Module::checkModel () const [protected], [inherited]
```

#### Returns

false, if the current model of this module does not satisfy the current given formula; true, if it cannot be said whether the model satisfies the given formula.

```
0.15.41.4.24 cleanModel() void smtrat::Module::cleanModel () const [inline], [protected], [inherited]
```

Substitutes variable occurrences by its model value in the model values of other variables.

```
0.15.41.4.25 clearLemmas() void smtrat::Module::clearLemmas () [inline], [inherited]
```

Deletes all yet found lemmas.

```
0.15.41.4.26 clearModel() void smtrat::Module::clearModel () const [inline], [protected], [inherited]
```

Clears the assignment, if any was found.

```
0.15.41.4.27 clearModels() void smtrat::Module::clearModels () const [inline], [protected], [inherited]
```

Clears all assignments, if any was found.

```
0.15.41.4.28 clearPassedFormula() void smtrat::Module::clearPassedFormula () [protected], [inherited]
```

```
0.15.41.4.29 collectOrigins() [1/2] void smtrat::Module::collectOrigins (
 const FormulaT & _formula,
 FormulaSetT & _origins) const [inherited]
```

```
0.15.41.4.30 collectOrigins() [2/2] void smtrat::Module::collectOrigins (
 const FormulaT & _formula,
 FormulasT & _origins) const [inherited]
```

Collects the formulas in the given formula, which are part of the received formula.

If the given formula directly occurs in the received formula, it is inserted into the given set. Otherwise, the given formula must be of type AND and all its sub-formulas part of the received formula. Hence, they will be added to the given set.

#### Parameters

|                 |                                                                                                      |
|-----------------|------------------------------------------------------------------------------------------------------|
| <i>_formula</i> | The formula from which to collect the formulas being sub-formulas of the received formula (origins). |
| <i>_origins</i> | The set in which to store the origins.                                                               |

```
0.15.41.4.31 collectTheoryPropagations() void smtrat::Module::collectTheoryPropagations ()
[inherited]
```

```
0.15.41.4.32 constraintsToInform() const carl::FastSet<FormulaT>& smtrat::Module::constraints←
ToInform () const [inline], [inherited]
```

#### Returns

The constraints which the backends must be informed about.

```
0.15.41.4.33 currentlySatisfied() virtual unsigned smtrat::Module::currentlySatisfied (
 const FormulaT &) const [inline], [virtual], [inherited]
```

#### Returns

0, if the given formula is conflicted by the current model; 1, if the given formula is satisfied by the current model; 2, otherwise; 3, if we do not know anything (default)

Reimplemented in [smtrat::LRAModule< Settings >](#), [smtrat::LRAModule< LRASettingsICP >](#), and [smtrat::LRAModule< LRASettings >](#)

```
0.15.41.4.34 currentlySatisfiedByBackend() unsigned smtrat::Module::currentlySatisfiedByBackend (
 const FormulaT & _formula) const [inherited]
```

#### Returns

0, if the given formula is conflicted by the current model; 1, if the given formula is satisfied by the current model; 2, otherwise 3, if we do not know anything (default)

```
0.15.41.4.35 deinform() void smtrat::Module::deinform (
 const FormulaT & _constraint) [inherited]
```

The inverse of informing about a constraint.

All data structures which were kept regarding this constraint are going to be removed. Note, that this makes only sense if it is not likely enough that a formula with this constraint must be solved again.

#### Parameters

|                    |                                                         |
|--------------------|---------------------------------------------------------|
| <i>_constraint</i> | The constraint to remove from internal data structures. |
|--------------------|---------------------------------------------------------|

**0.15.41.4.36 `deinformCore()`** `virtual void smtrat::Module::deinformCore (`  
    `const FormulaT & _constraint )` [inline], [protected], [virtual], [inherited]

The inverse of informing about a constraint.

All data structures which were kept regarding this constraint are going to be removed. Note, that this makes only sense if it is not likely enough that a formula with this constraint must be solved again.

#### Parameters

|                          |                                                         |
|--------------------------|---------------------------------------------------------|
| <code>_constraint</code> | The constraint to remove from internal data structures. |
|--------------------------|---------------------------------------------------------|

Reimplemented in [smtrat::LRAModule< Settings >](#), [smtrat::LRAModule< LRASettingsICP >](#), and [smtrat::LRAModule< LRASettings1 >](#).

**0.15.41.4.37 `determine_smallest_origin()`** `size_t smtrat::Module::determine_smallest_origin (`  
    `const std::vector< FormulaT > & origins ) const` [protected], [inherited]

#### Parameters

|                      |                              |
|----------------------|------------------------------|
| <code>origins</code> | A vector of sets of origins. |
|----------------------|------------------------------|

#### Returns

The index of the smallest (regarding the size of the sets) element of origins

**0.15.41.4.38 `eraseSubformulaFromPassedFormula()`** `ModuleInput::iterator smtrat::Module::eraseSubformulaFromPassedFormula (`  
    `ModuleInput::iterator _subformula,`  
    `bool _ignoreOrigins = false )` [protected], [virtual], [inherited]

Removes everything related to the sub-formula to remove from the passed formula in the backends of this module.  
Afterwards the sub-formula is removed from the passed formula.

#### Parameters

|                             |                                                                                                              |
|-----------------------------|--------------------------------------------------------------------------------------------------------------|
| <code>_subformula</code>    | The sub-formula to remove from the passed formula.                                                           |
| <code>_ignoreOrigins</code> | True, if the sub-formula shall be removed regardless of its origins (should only be applied with expertise). |

#### Returns

Reimplemented in [smtrat::ICPModule< Settings >](#), [smtrat::ICPModule< ICPSettings4 >](#), and [smtrat::ICPModule< ICPSettings1 >](#).

**0.15.41.4.39 `excludeNotReceivedVariablesFromModel()`** `void smtrat::Module::excludeNotReceivedVariablesFromModel ( ) const` [inherited]

Excludes all variables from the current model, which do not occur in the received formula.

**0.15.41.4.40 `findBestOrigin()`** `std::vector< FormulaT >::const_iterator smtrat::Module::findBestOrigin (`  
    `const std::vector< FormulaT > & _origins ) const` [protected], [inherited]

## Parameters

|                 |  |
|-----------------|--|
| <i>_origins</i> |  |
|-----------------|--|

## Returns

**0.15.41.4.41 `firstSubformulaToPass()`** `ModuleInput::const_iterator smtrat::Module::firstSubformulaToPass () const [inline], [inherited]`

## Returns

The position of the first sub-formula in the passed formula, which has not yet been considered for a consistency check of the backends.

**0.15.41.4.42 `firstUncheckedReceivedSubformula()`** `ModuleInput::const_iterator smtrat::Module::firstUncheckedReceivedSubformula () const [inline], [inherited]`

## Returns

The position of the first (by this module) unchecked sub-formula of the received formula.

**0.15.41.4.43 `freeSplittingVariable()`** `static void smtrat::Module::freeSplittingVariable (const FormulaT & _splittingVariable ) [inline], [static], [inherited]`

**0.15.41.4.44 `generateTrivialInfeasibleSubset()`** `void smtrat::Module::generateTrivialInfeasibleSubset () [inline], [protected], [inherited]`

Stores the trivial infeasible subset being the set of received formulas.

**0.15.41.4.45 `getBackendsAllModels()`** `void smtrat::Module::getBackendsAllModels () const [protected], [inherited]`

Stores all models of a backend in the list of all models of this module.

**0.15.41.4.46 `getBackendsModel()`** `void smtrat::Module::getBackendsModel () const [protected], [inherited]`

**0.15.41.4.47 `getInfeasibleSubsets()` [1/2]** `void smtrat::Module::getInfeasibleSubsets () [protected], [inherited]`

Copies the infeasible subsets of the passed formula.

**0.15.41.4.48 `getInfeasibleSubsets()` [2/2]** `std::vector< FormulaSetT > smtrat::Module::getInfeasibleSubsets (const Module & _backend ) const [protected], [inherited]`

Get the infeasible subsets the given backend provides.

Note, that an infeasible subset in a backend contains sub formulas of the passed formula and an infeasible subset of this module contains sub formulas of the received formula. In this method the LATTER is returned.

**Parameters**

|                       |                                                          |
|-----------------------|----------------------------------------------------------|
| <code>_backend</code> | The backend from which to obtain the infeasible subsets. |
|-----------------------|----------------------------------------------------------|

**Returns**

The infeasible subsets the given backend provides.

**0.15.41.4.49 `getInformationRelevantFormulas()`** `const std::set< FormulaT > & smtrat::Module::getInformationRelevantFormulas ( ) [protected], [inherited]`  
Gets all InformationRelevantFormulas.

**Returns**

Set of all formulas

**0.15.41.4.50 `getModelEqualities()`** `std::list< std::vector< carl::Variable > > smtrat::Module::getModelEqualities ( ) const [virtual], [inherited]`  
Partition the variables from the current model into equivalence classes according to their assigned value.  
The result is a set of equivalence classes of variables where all variables within one class are assigned the same value. Note that the number of classes may not be minimal, i.e. two classes may actually be equivalent.

**Returns**

Equivalence classes.

**0.15.41.4.51 `getOrigins() [1/3]`** `void smtrat::Module::getOrigins ( const FormulaT & _formula, FormulaSetT & _origins ) const [inline], [protected], [inherited]`

**Parameters**

|                       |  |
|-----------------------|--|
| <code>_formula</code> |  |
| <code>_origins</code> |  |

**0.15.41.4.52 `getOrigins() [2/3]`** `void smtrat::Module::getOrigins ( const FormulaT & _formula, FormulasT & _origins ) const [inline], [protected], [inherited]`

**Parameters**

|                       |  |
|-----------------------|--|
| <code>_formula</code> |  |
| <code>_origins</code> |  |

**0.15.41.4.53 `getOrigins() [3/3]`** `const FormulaT& smtrat::Module::getOrigins ( ModuleInput::const_iterator _formula ) const [inline], [protected], [inherited]`  
Gets the origins of the passed formula at the given position.

**Parameters**

|                 |                                                   |
|-----------------|---------------------------------------------------|
| <i>_formula</i> | The position of a formula in the passed formulas. |
|-----------------|---------------------------------------------------|

**Returns**

The origins of the passed formula at the given position.

**0.15.41.4.54 `getReceivedFormulaSimplified()`** `std::pair< bool, FormulaT > smtrat::PModule::getReceivedFormulaSimplified( ) [virtual], [inherited]`

**Returns**

A pair of a Boolean and a formula, where the Boolean is true, if the received formula could be simplified to an equisatisfiable formula. The formula is equisatisfiable to this module's received formula, if the Boolean is true.

Reimplemented from [smtrat::Module](#).

**0.15.41.4.55 `hasLemmas()`** `bool smtrat::Module::hasLemmas( ) [inline], [inherited]`

Checks whether this module or any of its backends provides any lemmas.

**0.15.41.4.56 `isValidInfeasibleSubset()`** `bool smtrat::Module::isValidInfeasibleSubset( ) const [inherited]`

**Returns**

true, if the module has at least one valid infeasible subset, that is all its elements are sub-formulas of the received formula (pointer must be equal).

**0.15.41.4.57 `id()`** `std::size_t smtrat::Module::id( ) const [inline], [inherited]`

**Returns**

A unique ID to identify this module instance.

**0.15.41.4.58 `infeasibleSubsets()`** `const std::vector<FormulaSetT>& smtrat::Module::infeasibleSubsets( ) const [inline], [inherited]`

**Returns**

The infeasible subsets of the set of received formulas (empty, if this module has not detected unsatisfiability of the conjunction of received formulas).

**0.15.41.4.59 `inform()`** `bool smtrat::Module::inform( const FormulaT & _constraint ) [inherited]`

Informs the module about the given constraint.

It should be tried to inform this module about any constraint it could receive eventually before assertSubformula is called (preferably for the first time, but at least before adding a formula containing that constraint).

**Parameters**

|                    |                                 |
|--------------------|---------------------------------|
| <i>_constraint</i> | The constraint to inform about. |
|--------------------|---------------------------------|

**Returns**

false, if it can be easily decided whether the given constraint is inconsistent; true, otherwise.

**0.15.41.4.60 informBackends()** void smrat::Module::informBackends ( const FormulaT & \_constraint ) [inline], [protected], [inherited]

Informs all backends of this module about the given constraint.

**Parameters**

|                          |                                 |
|--------------------------|---------------------------------|
| <code>_constraint</code> | The constraint to inform about. |
|--------------------------|---------------------------------|

**0.15.41.4.61 informCore()** virtual bool smrat::Module::informCore (

const FormulaT & \_constraint ) [inline], [protected], [virtual], [inherited]

Informs the module about the given constraint.

It should be tried to inform this module about any constraint it could receive eventually before assertSubformula is called (preferably for the first time, but at least before adding a formula containing that constraint).

**Parameters**

|                          |                                 |
|--------------------------|---------------------------------|
| <code>_constraint</code> | The constraint to inform about. |
|--------------------------|---------------------------------|

**Returns**

false, if it can be easily decided whether the given constraint is inconsistent; true, otherwise.

Reimplemented in [smrat::UnionFindModule< Settings >](#), [smrat::PBPPModule< Settings >](#), [smrat::PBGaussModule< Settings >](#), [smrat::NRAILModule< Settings >](#), [smrat::NewCoveringModule< Settings >](#), [smrat::NewCADModule< Settings >](#), [smrat::LRAModule< Settings >](#), [smrat::LRAModule< LRASettingsICP >](#), [smrat::LRAModule< LRASettings1 >](#), [smrat::IntBlastModule< Settings >](#), [smrat::FPPModule< Settings >](#), [smrat::EQModule< Settings >](#), [smrat::CurryModule< Settings >](#), [smrat::BVMModule< Settings >](#), [smrat::ICPModule< Settings >](#), [smrat::ICPModule< ICPSettings4 >](#), and [smrat::ICPModule< ICPSettings1 >](#).

**0.15.41.4.62 informedConstraints()** const carl::FastSet<FormulaT>& smrat::Module::informedConstraints ( ) const [inline], [inherited]

**Returns**

The position of the first constraint of which no backend has been informed about.

**0.15.41.4.63 init()** void smrat::Module::init ( ) [virtual], [inherited]

Informs all backends about the so far encountered constraints, which have not yet been communicated.

This method must not be called twice and only before the first runBackends call.

Reimplemented in [smrat::PBPPModule< Settings >](#), [smrat::PBGaussModule< Settings >](#), [smrat::NRAILModule< Settings >](#), [smrat::NewCoveringModule< Settings >](#), [smrat::NewCADModule< Settings >](#), [smrat::LRAModule< Settings >](#), [smrat::LRAModule< LRASettingsICP >](#), [smrat::LRAModule< LRASettings1 >](#), [smrat::IntBlastModule< Settings >](#), [smrat::FPPModule< Settings >](#), [smrat::EQModule< Settings >](#), [smrat::CurryModule< Settings >](#), and [smrat::BVMModule< Settings >](#).

**0.15.41.4.64 is\_minimizing()** bool smrat::Module::is\_minimizing ( ) const [inline], [inherited]

**0.15.41.4.65 isLemmaLevel()** `bool smtrat::Module::isLemmaLevel (``LemmaLevel level ) [protected], [inherited]`

Checks if current lemma level is greater or equal to given level.

**Parameters**

|              |                 |
|--------------|-----------------|
| <i>level</i> | Level to check. |
|--------------|-----------------|

**0.15.41.4.66 isPreprocessor()** `bool smtrat::PModule::isPreprocessor ( ) const [inline], [inherited]`**Returns**

true, if this module is a preprocessor that is a module, which simplifies its received formula to an equisatisfiable formula being passed to its backends. The simplified formula can be obtained with [getReceivedFormulaSimplified\(\)](#).

**0.15.41.4.67 lemmas()** `const std::vector<Lemma>& smtrat::Module::lemmas ( ) const [inline], [inherited]`**Returns**

A constant reference to the lemmas being valid formulas this module or its backends made.

**0.15.41.4.68 merge()** `std::vector< FormulaT > smtrat::Module::merge (``const std::vector< FormulaT > & _vecSetA,``const std::vector< FormulaT > & _vecSetB ) const [protected], [inherited]`

Merges the two vectors of sets into the first one.

({a,b},{a,c}) and ({b,d},{b}) -> ({a,b,d},{a,b},{a,b,c,d},{a,b,c})

**Parameters**

|                 |                                  |
|-----------------|----------------------------------|
| <i>_vecSetA</i> | A vector of sets of constraints. |
| <i>_vecSetB</i> | A vector of sets of constraints. |

**Returns**

The vector being the two given vectors merged.

**0.15.41.4.69 model()** `const Model& smtrat::Module::model ( ) const [inline], [inherited]`**Returns**

The assignment of the current satisfiable result, if existent.

**0.15.41.4.70 modelsDisjoint()** `bool smtrat::Module::modelsDisjoint (``const Model & _modelA,``const Model & _modelB ) [static], [protected], [inherited]`

Checks whether there is no variable assigned by both models.

**Parameters**

|                      |                                |
|----------------------|--------------------------------|
| <code>_modelA</code> | The first model to check for.  |
| <code>_modelB</code> | The second model to check for. |

**Returns**

true, if there is no variable assigned by both models; false, otherwise.

**0.15.41.4.71 `moduleName()`** template<typename Settings >  
std::string smtrat::BEModule< Settings >::moduleName ( ) const [inline], [virtual]

**Returns**

The name of the given module type as name.

Reimplemented from [smtrat::Module](#).

**0.15.41.4.72 `objective()`** carl::Variable smtrat::Module::objective ( ) const [inline], [inherited]

**0.15.41.4.73 `originInReceivedFormula()`** bool smtrat::Module::originInReceivedFormula ( const FormulaT & \_origin ) const [protected], [inherited]

**0.15.41.4.74 `passedFormulaBegin()`** ModuleInput::iterator smtrat::Module::passedFormulaBegin ( ) [inline], [protected], [inherited]

**Returns**

An iterator to the end of the passed formula. TODO: disable this method

**0.15.41.4.75 `passedFormulaEnd()`** ModuleInput::iterator smtrat::Module::passedFormulaEnd ( ) [inline], [protected], [inherited]

**Returns**

An iterator to the end of the passed formula.

**0.15.41.4.76 `pPassedFormula()`** const ModuleInput\* smtrat::Module::pPassedFormula ( ) const [inline], [inherited]

**Returns**

A pointer to the formula passed to the backends of this module.

**0.15.41.4.77 `pReceivedFormula()`** const ModuleInput\* smtrat::Module::pReceivedFormula ( ) const [inline], [inherited]

**Returns**

A pointer to the formula passed to this module.

**0.15.41.4.78 `print()`** void smtrat::Module::print ( const std::string & \_initiation = "\*\*\*" ) const [inherited]

Prints everything relevant of the solver.

**Parameters**

|                    |                      |
|--------------------|----------------------|
| <i>_initiation</i> | The line initiation. |
|--------------------|----------------------|

**0.15.41.4.79 `printAllModels()`** void smtrat::Module::printAllModels ( std::ostream & *\_out* = std::cout ) [inherited]

Prints all assignments of this module satisfying its received formula if it satisfiable and this module could find an assignment.

**Parameters**

|             |                                        |
|-------------|----------------------------------------|
| <i>_out</i> | The stream to print the assignment on. |
|-------------|----------------------------------------|

**0.15.41.4.80 `printInfeasibleSubsets()`** void smtrat::Module::printInfeasibleSubsets ( const std::string & *\_initiation* = "\*\*\*" ) const [inherited]

Prints the infeasible subsets.

**Parameters**

|                    |                      |
|--------------------|----------------------|
| <i>_initiation</i> | The line initiation. |
|--------------------|----------------------|

**0.15.41.4.81 `printModel()`** void smtrat::Module::printModel ( std::ostream & *\_out* = std::cout ) const [inherited]

Prints the assignment of this module satisfying its received formula if it satisfiable and this module could find an assignment.

**Parameters**

|             |                                        |
|-------------|----------------------------------------|
| <i>_out</i> | The stream to print the assignment on. |
|-------------|----------------------------------------|

**0.15.41.4.82 `printPassedFormula()`** void smtrat::Module::printPassedFormula ( const std::string & *\_initiation* = "\*\*\*" ) const [inherited]

Prints the vector of passed formula.

**Parameters**

|                    |                      |
|--------------------|----------------------|
| <i>_initiation</i> | The line initiation. |
|--------------------|----------------------|

**0.15.41.4.83 `printReceivedFormula()`** void smtrat::Module::printReceivedFormula ( const std::string & *\_initiation* = "\*\*\*" ) const [inherited]

Prints the vector of the received formula.

**Parameters**

|                    |                      |
|--------------------|----------------------|
| <i>_initiation</i> | The line initiation. |
|--------------------|----------------------|

**0.15.41.4.84 `probablyLooping()`** `bool smrat::Module::probablyLooping (`  
    `const typename Poly::PolyType & _branchingPolynomial,`  
    `const Rational & _branchingValue ) const [protected], [inherited]`

Checks whether given the current branching value and branching variable/polynomial it is (highly) probable that this branching is part of an infinite loop of branchings.

#### Parameters

|                                   |                                                                                     |
|-----------------------------------|-------------------------------------------------------------------------------------|
| <code>_branchingPolynomial</code> | The polynomial to branch at (in most branching strategies this is just a variable). |
| <code>_branchingValue</code>      | The value to branch at.                                                             |

#### Returns

true, if this branching is probably part of an infinite loop of branchings; false, otherwise.

**0.15.41.4.85 `receivedFormulaChecked()`** `void smrat::Module::receivedFormulaChecked ( ) [inline], [inherited]`

Notifies that the received formulas has been checked.

**0.15.41.4.86 `receivedFormulasAsInfeasibleSubset()`** `void smrat::Module::receivedFormulasAsInfeasibleSubset (`  
    `ModuleInput::const_iterator _subformula ) [inline], [protected], [inherited]`

Stores an infeasible subset consisting only of the given received formula.

**0.15.41.4.87 `receivedVariable()`** `bool smrat::Module::receivedVariable (`  
    `carl::Variable::Arg _var ) const [inline], [inherited]`

**0.15.41.4.88 `remove()`** `void smrat::PModule::remove (`  
    `ModuleInput::const_iterator _subformula ) [virtual], [inherited]`

Removes everything related to the given sub-formula of the received formula.

However, it is desired not to lose track of search spaces where no satisfying assignment can be found for the remaining sub-formulas.

#### Parameters

|                          |                                                    |
|--------------------------|----------------------------------------------------|
| <code>_subformula</code> | The sub formula of the received formula to remove. |
|--------------------------|----------------------------------------------------|

Reimplemented from [smrat::Module](#).

**0.15.41.4.89 `removeCore()`** `virtual void smrat::Module::removeCore (`  
    `ModuleInput::const_iterator formula ) [inline], [protected], [virtual], [inherited]`

Removes everything related to the given sub-formula of the received formula.

However, it is desired not to lose track of search spaces where no satisfying assignment can be found for the remaining sub-formulas.

#### Parameters

|                      |                                                    |
|----------------------|----------------------------------------------------|
| <code>formula</code> | The sub formula of the received formula to remove. |
|----------------------|----------------------------------------------------|

Reimplemented in [smrat::VSModule< Settings >](#), [smrat::SATModule< Settings >](#), [smrat::PFEModule< Settings >](#), [smrat::ICPModule< Settings >](#), [smrat::ICPModule< ICPSettings4 >](#), [smrat::ICPModule< ICPSettings1 >](#), [smrat::UnionFindModule< Settings >](#), [smrat::UFCegarModule< Settings >](#), [smrat::STropModule< Settings >](#), [smrat::PBPPModule< Settings >](#), [smrat::PBGaussModule< Settings >](#), [smrat::NRAILModule< Settings >](#), [smrat::NewCoveringModule< Settings >](#), [smrat::NewCADModule< Settings >](#), [smrat::LRAModule< Settings >](#), [smrat::LRAModule< LRASettingsICP >](#), [smrat::LRAModule< LRASettings1 >](#), [smrat::IntEqModule< Settings >](#), [smrat::IntBlastModule< Settings >](#), [smrat::IncWidthModule< Settings >](#), [smrat::ICEModule< Settings >](#), [smrat::FPPModule< Settings >](#), [smrat::FouMoModule< Settings >](#), [smrat::EQModule< Settings >](#), [smrat::CurryModule< Settings >](#), [smrat::CubeLIAModule< Settings >](#), [smrat::CSplitModule< Settings >](#), [smrat::BVMModule< Settings >](#), and [smrat::GBModule< Settings >](#).

**0.15.41.4.90 removeOrigin()** `std::pair<ModuleInput::iterator,bool> smrat::Module::removeOrigin(`

```
 ModuleInput::iterator _formula,
 const FormulaT & _origin) [inline], [protected], [inherited]
```

**0.15.41.4.91 removeOrigins()** `std::pair<ModuleInput::iterator,bool> smrat::Module::removeOrigins(`

```
 ModuleInput::iterator _formula,
 const std::shared_ptr< std::vector<FormulaT>> & _origins) [inline], [protected],
[inherited]
```

**0.15.41.4.92 rPassedFormula()** `const ModuleInput& smrat::Module::rPassedFormula( ) const`

[inline], [inherited]

#### Returns

A reference to the formula passed to the backends of this module.

**0.15.41.4.93 rReceivedFormula()** `const ModuleInput& smrat::Module::rReceivedFormula( ) const`

[inline], [inherited]

#### Returns

A reference to the formula passed to this module.

**0.15.41.4.94 runBackends() [1/2]** `virtual Answer smrat::PModule::runBackends( ) [inline], [virtual], [inherited]`

Reimplemented from [smrat::Module](#).

**0.15.41.4.95 runBackends() [2/2]** `Answer smrat::PModule::runBackends(`

```
 bool _final,
 bool _full,
 carl::Variable _objective) [virtual], [inherited]
```

Runs the backend solvers on the passed formula.

#### Parameters

|                         |                                                                                                                                       |
|-------------------------|---------------------------------------------------------------------------------------------------------------------------------------|
| <code>_final</code>     | true, if this satisfiability check will be the last one (for a global sat-check), if its result is SAT.                               |
| <code>_full</code>      | false, if this module should avoid too expensive procedures and rather return unknown instead.                                        |
| <code>_objective</code> | if not set to NO_VARIABLE, the module should find an assignment minimizing this objective variable; otherwise any assignment is good. |

**Returns**

True, if the passed formula is consistent; False, if the passed formula is inconsistent; Unknown, otherwise.

Reimplemented from [smrat::Module](#).

**0.15.41.4.96 setId()** `void smrat::Module::setId ( std::size_t _id ) [inline], [inherited]`  
Sets this modules unique ID to identify itself.

**Parameters**

|              |                                    |
|--------------|------------------------------------|
| $\leftarrow$ | The id to set this module's id to. |
| $\_id$       |                                    |

**0.15.41.4.97 setThreadPriority()** `void smrat::Module::setThreadPriority ( thread_priority _threadPriority ) [inline], [inherited]`  
Sets the priority of this module to get a thread for running its check procedure.

**Parameters**

|                    |                                                       |
|--------------------|-------------------------------------------------------|
| $\_threadPriority$ | The priority to set this module's thread priority to. |
|--------------------|-------------------------------------------------------|

**0.15.41.4.98 solverState()** `Answer smrat::Module::solverState ( ) const [inline], [inherited]`

**Returns**

True, if this module is in a state, such that it has found a solution for its received formula; False, if this module is in a state, such that it has determined that there is no solution for its received formula; Unknown, otherwise.

**0.15.41.4.99 splitUnequalConstraint()** `void smrat::Module::splitUnequalConstraint ( const FormulaT & _unequalConstraint ) [protected], [inherited]`

Adds the following lemmas for the given constraint  $p \neq 0$ .

$(p \neq 0 \leftrightarrow (p < 0 \text{ or } p > 0))$

and  $\neg(p < 0 \text{ and } p > 0)$

**Parameters**

|                       |                                                  |
|-----------------------|--------------------------------------------------|
| $\_unequalConstraint$ | A constraint having the relation symbol $\neq$ . |
|-----------------------|--------------------------------------------------|

**0.15.41.4.100 threadPriority()** `thread_priority smrat::Module::threadPriority ( ) const [inline], [inherited]`

**Returns**

The priority of this module to get a thread for running its check procedure.

**0.15.41.4.101 updateAllModels()** void smrat::Module::updateAllModels () [virtual], [inherited]  
Updates all satisfying models, if the solver has detected the consistency of the received formula, beforehand.  
Reimplemented in [smrat::SATModule< Settings >](#).

**0.15.41.4.102 updateLemmas()** void smrat::Module::updateLemmas () [inherited]  
Stores all lemmas of any backend of this module in its own lemma vector.

**0.15.41.4.103 updateModel()** void smrat::PModule::updateModel () const [virtual], [inherited]  
Updates the current assignment into the model.  
Note, that this is a unique but possibly symbolic assignment maybe containing newly introduced variables.  
Reimplemented from [smrat::Module](#).

**0.15.41.4.104 usedBackends()** const std::vector<[Module](#)\*>& smrat::Module::usedBackends ()  
const [inline], [inherited]

Returns

The backends of this module which are currently used (conditions to use this module are fulfilled for the passed formula).

## 0.15.41.5 Field Documentation

**0.15.41.5.1 mAllBackends** std::vector<[Module](#)\*> smrat::Module::mAllBackends [protected], [inherited]  
The backends of this module which have been used.

**0.15.41.5.2 mAllModels** std::vector<[Model](#)> smrat::Module::mAllModels [mutable], [protected], [inherited]  
Stores all satisfying assignments.

**0.15.41.5.3 mBackendsFoundAnswer** std::atomic\_bool\* smrat::Module::mBackendsFoundAnswer [protected], [inherited]  
This flag is passed to any backend and if it determines an answer to a prior check call, this flag is fired.

**0.15.41.5.4 mConstraintsToInform** carl::FastSet<[FormulaT](#)> smrat::Module::mConstraintsToInform [protected], [inherited]  
Stores the constraints which the backends must be informed about.

**0.15.41.5.5 mFinalCheck** bool smrat::Module::mFinalCheck [protected], [inherited]  
true, if the check procedure should perform a final check which especially means not to postpone splitting decisions

**0.15.41.5.6 mFirstPosInLastBranches** std::size\_t smrat::Module::mFirstPosInLastBranches = 0 [static], [inherited]  
The beginning of the cyclic buffer storing the last branches.

**0.15.41.5.7 mFirstSubformulaToPass** `ModuleInput::iterator smrat::Module::mFirstSubformulaToPass` [protected], [inherited]

Stores the position of the first sub-formula in the passed formula, which has not yet been considered for a consistency check of the backends.

**0.15.41.5.8 mFirstUncheckedReceivedSubformula** `ModuleInput::const_iterator smrat::Module::mFirstUncheckedReceivedSubformula` [protected], [inherited]

Stores the position of the first (by this module) unchecked sub-formula of the received formula.

**0.15.41.5.9 mFoundAnswer** `Conditionals smrat::Module::mFoundAnswer` [protected], [inherited]

Vector of Booleans: If any of them is true, we have to terminate a running check procedure.

**0.15.41.5.10 mFullCheck** `bool smrat::Module::mFullCheck` [protected], [inherited]

false, if this module should avoid too expensive procedures and rather return unknown instead.

**0.15.41.5.11 mInfeasibleSubsets** `std::vector<FormulaSetT> smrat::Module::mInfeasibleSubsets`

[protected], [inherited]

Stores the infeasible subsets.

**0.15.41.5.12 mInformedConstraints** `carl::FastSet<FormulaT> smrat::Module::mInformedConstraints`

[protected], [inherited]

Stores the position of the first constraint of which no backend has been informed about.

**0.15.41.5.13 mLastBranches** `std::vector< Branching > smrat::Module::mLastBranches = std::vector<Branching> (mNumOfBranchVarsToStore, Branching(typename Poly::PolyType(), 0))` [static], [inherited]

Stores the last branches in a cycle buffer.

**0.15.41.5.14 mLemmas** `std::vector<Lemma> smrat::Module::mLemmas` [protected], [inherited]

Stores the lemmas being valid formulas this module or its backends made.

**0.15.41.5.15 mModel** `Model smrat::Module::mModel` [mutable], [protected], [inherited]

Stores the assignment of the current satisfiable result, if existent.

**0.15.41.5.16 mModelComputed** `bool smrat::Module::mModelComputed` [mutable], [protected], [inherited]

True, if the model has already been computed.

**0.15.41.5.17 mNumOfBranchVarsToStore** `std::size_t smrat::Module::mNumOfBranchVarsToStore = 5` [static], [inherited]

The number of different variables to consider for a probable infinite loop of branchings.

**0.15.41.5.18 mObjectiveVariable** `carl::Variable smtrat::Module::mObjectiveVariable [protected], [inherited]`  
 Objective variable to be minimized. If set to NO\_VARIABLE, a normal sat check should be performed.

**0.15.41.5.19 mOldSplittingVariables** `std::vector< FormulaT > smtrat::Module::mOldSplittingVariables [static], [inherited]`  
 Reusable splitting variables.

**0.15.41.5.20 mpManager** `Manager* const smtrat::Module::mpManager [protected], [inherited]`  
 A reference to the manager.

**0.15.41.5.21 mSmallerMusesCheckCounter** `unsigned smtrat::Module::mSmallerMusesCheckCounter [mutable], [protected], [inherited]`  
 Counter used for the generation of the smt2 files to check for smaller muses.

**0.15.41.5.22 mSolverState** `std::atomic<Answer> smtrat::Module::mSolverState [protected], [inherited]`  
 States whether the received formula is known to be satisfiable or unsatisfiable otherwise it is set to unknown.

**0.15.41.5.23 mTheoryPropagations** `std::vector<TheoryPropagation> smtrat::Module::mTheoryPropagations [protected], [inherited]`

**0.15.41.5.24 mUsedBackends** `std::vector<Module*> smtrat::Module::mUsedBackends [protected], [inherited]`  
 The backends of this module which are currently used (conditions to use this module are fulfilled for the passed formula).

**0.15.41.5.25 mVariableCounters** `std::vector<std::size_t> smtrat::Module::mVariableCounters [protected], [inherited]`  
 Maps variables to the number of their occurrences.

## 0.15.42 benchmax::BenchmarkResult Struct Reference

Results for a single benchmark run.

```
#include <BenchmarkResult.h>
```

### Public Member Functions

- template<typename TimeLimit >  
`void cleanup (const TimeLimit &limit)`  
*Properly detect timeouts.*
- auto `get_path () const`
- void `store (size_t id) const`
- void `store () const`
- void `restore () const`
- void `forget () const`

## Data Fields

- int `exitCode`  
*Shell exit code.*
- std::chrono::milliseconds `time`  
*Runtime in milliseconds.*
- std::string `answer`  
*Answer string.*
- std::size\_t `peak_memory_kbytes`  
*Peak memory usage.*
- std::string `stdout`  
*Standard output (mostly for parsing the answer and additional information).*
- std::string `stderr`  
*Error output (mostly for parsing the answer and additional information).*
- std::map< std::string, std::string > `additional`  
*Arbitrary additional information that can be provided by the tool class.*
- size\_t `stored_id` = 0  
*Identifier for temporary file.*

### 0.15.42.1 Detailed Description

[Results](#) for a single benchmark run.

### 0.15.42.2 Member Function Documentation

**0.15.42.2.1 `cleanup()`** template<typename TimeLimit >  
void benchmax::BenchmarkResult::cleanup (  
 const TimeLimit & limit ) [inline]

Properly detect timeouts.

Most backends give processes a bit more time to avoid having race-condition-like situations.

**0.15.42.2.2 `forget()`** void benchmax::BenchmarkResult::forget ( ) const [inline]

**0.15.42.2.3 `get_path()`** auto benchmax::BenchmarkResult::get\_path ( ) const [inline]

**0.15.42.2.4 `restore()`** void benchmax::BenchmarkResult::restore ( ) const [inline]

**0.15.42.2.5 `store()` [1/2]** void benchmax::BenchmarkResult::store ( ) const [inline]

**0.15.42.2.6 `store()` [2/2]** void benchmax::BenchmarkResult::store (  
 size\_t id ) const [inline]

### 0.15.42.3 Field Documentation

**0.15.42.3.1 `additional`** std::map<std::string, std::string> benchmax::BenchmarkResult::additional  
[mutable]

Arbitrary additional information that can be provided by the tool class.

**0.15.42.3.2 answer** std::string benchmax::BenchmarkResult::answer  
Answer string.

**0.15.42.3.3 exitCode** int benchmax::BenchmarkResult::exitCode  
Shell exit code.

**0.15.42.3.4 peak\_memory\_kbytes** std::size\_t benchmax::BenchmarkResult::peak\_memory\_kbytes  
Peak memory usage.

**0.15.42.3.5 stderr** std::string benchmax::BenchmarkResult::stderr  
Error output (mostly for parsing the answer and additional information).

**0.15.42.3.6 stdout** std::string benchmax::BenchmarkResult::stdout  
Standard output (mostly for parsing the answer and additional information).

**0.15.42.3.7 stored\_id** size\_t benchmax::BenchmarkResult::stored\_id = 0 [mutable]  
Identifier for temporary file.

**0.15.42.3.8 time** std::chrono::milliseconds benchmax::BenchmarkResult::time  
Runtime in milliseconds.

## 0.15.43 benchmax::BenchmarkSet Class Reference

A set of benchmarks from some common base directory.

```
#include <BenchmarkSet.h>
```

### Public Member Functions

- void **add\_directory** (const std::filesystem::path &dir)  
*Recursively find all benchmarks from this directory.*
- std::size\_t **size** () const  
*Number of files.*
- auto **begin** () const  
*Begin iterator.*
- auto **end** () const  
*End iterator.*

### 0.15.43.1 Detailed Description

A set of benchmarks from some common base directory.

### 0.15.43.2 Member Function Documentation

**0.15.43.2.1 add\_directory()** void benchmax::BenchmarkSet::add\_directory (  
    const std::filesystem::path & dir )  
Recursively find all benchmarks from this directory.

**0.15.43.2.2 `begin()`** `auto benchmax::BenchmarkSet::begin() const [inline]`  
Begin iterator.

**0.15.43.2.3 `end()`** `auto benchmax::BenchmarkSet::end() const [inline]`  
End iterator.

**0.15.43.2.4 `size()`** `std::size_t benchmax::BenchmarkSet::size() const [inline]`  
Number of files.

## 0.15.44 `benchmax::settings::BenchmarkSettings` Struct Reference

[Settings](#) for benchmarks.

```
#include <benchmarks.h>
```

### Data Fields

- `carl::settings::binary_quantity limit_memory`  
*Memory limit in megabytes.*
- `carl::settings::duration limit_time`  
*Time limit in seconds.*
- `carl::settings::duration grace_time`  
*Grace time in seconds.*
- `std::vector< std::filesystem::path > input_directories`  
*Lift of input directories.*
- `std::filesystem::path input_directories_common_prefix`  
*Common prefix of input directories (to shorten filenames in output).*
- `std::filesystem::path output_dir`  
*Output directory.*
- `std::filesystem::path output_file_xml`  
*Filename of xml file.*

### 0.15.44.1 Detailed Description

[Settings](#) for benchmarks.

### 0.15.44.2 Field Documentation

**0.15.44.2.1 `grace_time`** `carl::settings::duration benchmax::settings::BenchmarkSettings::grace_time`  
Grace time in seconds.

**0.15.44.2.2 `input_directories`** `std::vector<std::filesystem::path> benchmax::settings::BenchmarkSettings::input_directories`  
Lift of input directories.

**0.15.44.2.3 `input_directories_common_prefix`** `std::filesystem::path benchmax::settings::BenchmarkSettings::input_directories_common_prefix`  
Common prefix of input directories (to shorten filenames in output).

**0.15.44.2.4 limit\_memory** carl::settings::binary\_quantity benchmax::settings::BenchmarkSettings::limit\_memory  
Memory limit in megabytes.

**0.15.44.2.5 limit\_time** carl::settings::duration benchmax::settings::BenchmarkSettings::limit\_time  
Time limit in seconds.

**0.15.44.2.6 output\_dir** std::filesystem::path benchmax::settings::BenchmarkSettings::output\_dir  
Output directory.

**0.15.44.2.7 output\_file\_xml** std::filesystem::path benchmax::settings::BenchmarkSettings::output\_file\_xml  
Filename of xml file.

## 0.15.45 smtrat::Bimap< Class, FirstKeyType, FirstKeyName, SecondKeyType, SecondKeyName > Class Template Reference

Container that stores expensive to construct objects and allows the fast lookup with respect to two independent keys within the objects.

```
#include <Bimap.h>
```

### Public Types

- `typedef std::forward_list< Class > Data`
- `typedef Data::iterator Iterator`
- `typedef Data::const_iterator ConstIterator`

### Public Member Functions

- `Iterator begin () noexcept`
- `ConstIterator begin () const noexcept`
- `Iterator end () noexcept`
- `ConstIterator end () const noexcept`
- `Class & firstAt (const FirstKeyType &firstKey)`
- `Class & secondAt (const SecondKeyType &secondKey)`
- `Iterator firstFind (const FirstKeyType &firstKey)`
- `Iterator secondFind (const SecondKeyType &secondKey)`
- `template<typename... Args> Iterator emplace (Args &&... args)`

### 0.15.45.1 Detailed Description

```
template<class Class, typename FirstKeyType, FirstKeyType Class::* FirstKeyName, typename SecondKeyType, SecondKeyType Class::* SecondKeyName>
```

```
class smtrat::Bimap< Class, FirstKeyType, FirstKeyName, SecondKeyType, SecondKeyName >
```

Container that stores expensive to construct objects and allows the fast lookup with respect to two independent keys within the objects.

### 0.15.45.2 Member Typedef Documentation

**0.15.45.2.1 ConstIterator** template<class Class , typename FirstKeyType , FirstKeyType Class::\* FirstKeyName, typename SecondKeyType , SecondKeyType Class::\* SecondKeyName>

- `conversion::VariantConverter< types::BVTerm > termConverter`
- `ParserState * state`

### 0.15.49.1 Detailed Description

Implements the theory of bitvectors.

### 0.15.49.2 Member Typedef Documentation

#### 0.15.49.2.1 OperatorType using `smtrat::parser::BitvectorTheory::OperatorType` = `carl::BVTermType`

### 0.15.49.3 Constructor & Destructor Documentation

**0.15.49.3.1 BitvectorTheory()** smtrat::parser::BitvectorTheory::BitvectorTheory ( ParserState \* state )

#### 0.15.49.4 Member Function Documentation

**0.15.49.4.1 addConstants()** static void smtrat::parser::AbstractTheory::addConstants ( qi::symbols< char, types::ConstType > & ) [inline], [static], [inherited]  
Initialize the global symbol table for constants.

**0.15.49.4.2 addSimpleSorts()** void smtrat::parser::BitvectorTheory::addSimpleSorts ( qi::symbols< char, carl::Sort > & sorts ) [static]

**0.15.49.4.3 declareVariable()** bool smtrat::parser::BitvectorTheory::declareVariable ( const std::string & , const carl::Sort & , types::VariableType & , TheoryError & errors ) [virtual]

Declare a new variable with the given name and the given sort.

Reimplemented from [smtrat::parser::AbstractTheory](#).

**0.15.49.4.4 expandDistinct()** template<typename T , typename Builder > FormulaT smtrat::parser::AbstractTheory::expandDistinct ( const std::vector< T > & values, const Builder & neqBuilder ) [inline], [inherited]

**0.15.49.4.5 functionCall()** bool smtrat::parser::BitvectorTheory::functionCall ( const Identifier & , const std::vector< types::TermType > & , types::TermType & , TheoryError & errors ) [virtual]

Resolve another unknown function call.

Reimplemented from [smtrat::parser::AbstractTheory](#).

**0.15.49.4.6 handleDistinct()** bool smtrat::parser::BitvectorTheory::handleDistinct ( const std::vector< types::TermType > & , types::TermType & , TheoryError & errors ) [virtual]

Resolve a distinct operator.

Reimplemented from [smtrat::parser::AbstractTheory](#).

**0.15.49.4.7 handleITE()** bool smtrat::parser::BitvectorTheory::handleITE ( const FormulaT & , const types::TermType & , const types::TermType & , types::TermType & , TheoryError & errors ) [virtual]

Resolve an if-then-else operator.

Reimplemented from [smtrat::parser::AbstractTheory](#).

```
0.15.49.4.8 instantiate() bool smtrat::parser::BitvectorTheory::instantiate (
 const types::VariableType & ,
 const types::TermType & ,
 types::TermType & ,
 TheoryError & errors) [virtual]
```

Instantiate a variable within a term.

Reimplemented from [smtrat::parser::AbstractTheory](#).

```
0.15.49.4.9 refreshVariable() bool smtrat::parser::BitvectorTheory::refreshVariable (
 const types::VariableType & var,
 types::VariableType & subject,
 TheoryError & errors) [virtual]
```

Reimplemented from [smtrat::parser::AbstractTheory](#).

```
0.15.49.4.10 resolveSymbol() bool smtrat::parser::BitvectorTheory::resolveSymbol (
 const Identifier & ,
 types::TermType & ,
 TheoryError & errors) [virtual]
```

Resolve a symbol that was not declared within the [ParserState](#).

This might be a symbol that actually uses indices, for example bitvector constants.

Reimplemented from [smtrat::parser::AbstractTheory](#).

## 0.15.49.5 Field Documentation

**0.15.49.5.1 bvSort** carl::Sort smtrat::parser::BitvectorTheory::bvSort

**0.15.49.5.2 state** ParserState\* smtrat::parser::AbstractTheory::state [inherited]

**0.15.49.5.3 termConverter** conversion::VariantConverter<types::BVTerm> smtrat::parser::BitvectorTheory::termConverter

**0.15.49.5.4 vectorConverter** conversion::VectorVariantConverter<types::BVTerm> smtrat::parser::BitvectorTheory::vectorConverter

## 0.15.50 smtrat::parser::types::BitvectorTheory Struct Reference

Types of the theory of bitvectors.

```
#include <TheoryTypes.h>
```

### Public Types

- `typedef mpl::vector< BVVariable, FixedWidthConstant< Integer >, BVTerm > ConstTypes`
- `typedef mpl::vector< BVVariable > VariableTypes`
- `typedef mpl::vector< BVVariable, FixedWidthConstant< Integer >, BVTerm, BVConstraint > ExpressionTypes`
- `typedef mpl::vector< BVVariable, FixedWidthConstant< Integer >, BVTerm, BVConstraint > TermTypes`
- `typedef carl::mpl_variant_of< TermTypes >::type TermType`

### 0.15.50.1 Detailed Description

Types of the theory of bitvectors.

### 0.15.50.2 Member Typedef Documentation

**0.15.50.2.1 ConstTypes** `typedef mpl::vector<BVVariable, FixedWidthConstant<Integer>, BVTerm> smtrat::parser::types::BitvectorTheory::ConstTypes`

**0.15.50.2.2 ExpressionTypes** `typedef mpl::vector<BVVariable, FixedWidthConstant<Integer>, BVTerm, BVConstraint> smtrat::parser::types::BitvectorTheory::ExpressionTypes`

**0.15.50.2.3 TermType** `typedef carl::mpl_variant_of<TermTypes>::type smtrat::parser::types::BitvectorTheory::TermType`

**0.15.50.2.4 TermTypes** `typedef mpl::vector<BVVariable, FixedWidthConstant<Integer>, BVTerm, BVConstraint> smtrat::parser::types::BitvectorTheory::TermTypes`

**0.15.50.2.5 VariableTypes** `typedef mpl::vector<BVVariable> smtrat::parser::types::BitvectorTheory::VariableTypes`

### 0.15.51 smtrat::BlastedConstr Class Reference

```
#include <IntBlastModule.h>
```

#### Public Member Functions

- `BlastedConstr()`
- `BlastedConstr(const FormulaT &_formula, const FormulasT &_constraints)`

**0.15.52.3.1 operator<<** std::ostream& operator<< ( std::ostream & \_out, const BlastedPoly & \_poly ) [friend]

## 0.15.53 smtrat::mcsat::Bookkeeping Class Reference

Represent the trail, i.e.

```
#include <Bookkeeping.h>
```

### Public Member Functions

- const auto & **model** () const
- const auto & **assignedVariables** () const
- const auto & **assignments** () const
- const auto & **constraints** () const
- const auto & **mvBounds** () const
- const auto & **variables** () const
- void **updateVariables** (const carl::Variables &**variables**)
- void **pushConstraint** (const FormulaT &f)
 

*Assert a constraint/literal.*
- void **popConstraint** (const FormulaT &f)
- void **pushAssignment** (carl::Variable v, const ModelValue &mv, const FormulaT &f)
- void **popAssignment** (carl::Variable v)

### 0.15.53.1 Detailed Description

Represent the trail, i.e.

the assignment/model state, of a MCSAT run in different representations (kept in sync) for a fast access. Most notably, we store literals, i.e. a polynomial (in)equality-atom or its negation, which we assert to be true. Since the negation can be represented by an atom by flipping the (in)equality, it suffices to store only atoms. Here we call atomic formulas over the theory of real arithmetic "constraints".

### 0.15.53.2 Member Function Documentation

**0.15.53.2.1 assignedVariables()** const auto& smtrat::mcsat::Bookkeeping::assignedVariables ( )  
const [inline]

**0.15.53.2.2 assignments()** const auto& smtrat::mcsat::Bookkeeping::assignments ( ) const [inline]

**0.15.53.2.3 constraints()** const auto& smtrat::mcsat::Bookkeeping::constraints ( ) const [inline]

**0.15.53.2.4 model()** const auto& smtrat::mcsat::Bookkeeping::model ( ) const [inline]

**0.15.53.2.5 mvBounds()** const auto& smtrat::mcsat::Bookkeeping::mvBounds ( ) const [inline]

**0.15.53.2.6 popAssignment()** void smtrat::mcsat::Bookkeeping::popAssignment ( carl::Variable v ) [inline]

**0.15.53.2.7 popConstraint()** void smtrat::mcsat::Bookkeeping::popConstraint ( const FormulaT & f ) [inline]

**0.15.53.2.8 pushAssignment()** void smtrat::mcsat::Bookkeeping::pushAssignment ( carl::Variable v, const ModelValue & mv, const FormulaT & f ) [inline]

**0.15.53.2.9 pushConstraint()** void smtrat::mcsat::Bookkeeping::pushConstraint ( const FormulaT & f ) [inline]

Assert a constraint/literal.

**0.15.53.2.10 updateVariables()** void smtrat::mcsat::Bookkeeping::updateVariables ( const carl::Variables & variables ) [inline]

**0.15.53.2.11 variables()** const auto& smtrat::mcsat::Bookkeeping::variables ( ) const [inline]

## 0.15.54 smtrat::parser::BooleanEncodingTheory Struct Reference

Implements the theory of bitvectors.

```
#include <BooleanEncoding.h>
```

## Public Member Functions

## Data Fields

- `ParserState * state`

### 0.15.54.1 Detailed Description

Implements the theory of bitvectors.

### 0.15.54.2 Constructor & Destructor Documentation

```
0.15.54.2.1 BooleanEncodingTheory() smtrat::parser::BooleanEncodingTheory::BooleanEncoding<→
Theory (
 ParserState * state)
```

### 0.15.54.3 Member Function Documentation

```
0.15.54.3.1 addConstants() static void smtrat::parser::AbstractTheory::addConstants (
 qi::symbols< char, types::ConstType > &) [inline], [static], [inherited]
Initialize the global symbol table for constants.
```

**0.15.54.3.2 addSimpleSorts()** static void smtrat::parser::AbstractTheory::addSimpleSorts ( qi::symbols< char, carl::Sort > & ) [inline], [static], [inherited]  
Initialize the global symbol table for simple sorts.

**0.15.54.3.3 declareVariable()** virtual bool smtrat::parser::AbstractTheory::declareVariable ( const std::string & , const carl::Sort & , types::VariableType & , TheoryError & errors ) [inline], [virtual], [inherited]

Declare a new variable with the given name and the given sort.

Reimplemented in [smtrat::parser::UninterpretedTheory](#), [smtrat::parser::CoreTheory](#), [smtrat::parser::BitvectorTheory](#), and [smtrat::parser::ArithmeticTheory](#).

**0.15.54.3.4 expandDistinct()** template<typename T , typename Builder > FormulaT smtrat::parser::AbstractTheory::expandDistinct ( const std::vector< T > & values, const Builder & negBuilder ) [inline], [inherited]

**0.15.54.3.5 functionCall()** virtual bool smtrat::parser::AbstractTheory::functionCall ( const Identifier & , const std::vector< types::TermType > & , types::TermType & , TheoryError & errors ) [inline], [virtual], [inherited]

Resolve another unknown function call.

Reimplemented in [smtrat::parser::UninterpretedTheory](#), [smtrat::parser::CoreTheory](#), [smtrat::parser::BitvectorTheory](#), and [smtrat::parser::ArithmeticTheory](#).

**0.15.54.3.6 handleDistinct()** virtual bool smtrat::parser::AbstractTheory::handleDistinct ( const std::vector< types::TermType > & , types::TermType & , TheoryError & errors ) [inline], [virtual], [inherited]

Resolve a distinct operator.

Reimplemented in [smtrat::parser::CoreTheory](#), [smtrat::parser::BitvectorTheory](#), [smtrat::parser::ArithmeticTheory](#), and [smtrat::parser::UninterpretedTheory](#).

**0.15.54.3.7 handleITE()** virtual bool smtrat::parser::AbstractTheory::handleITE ( const FormulaT & , const types::TermType & , const types::TermType & , types::TermType & , TheoryError & errors ) [inline], [virtual], [inherited]

Resolve an if-then-else operator.

Reimplemented in [smtrat::parser::UninterpretedTheory](#), [smtrat::parser::CoreTheory](#), [smtrat::parser::BitvectorTheory](#), and [smtrat::parser::ArithmeticTheory](#).

**0.15.54.3.8 instantiate()** virtual bool smtrat::parser::AbstractTheory::instantiate ( const types::VariableType & , const types::TermType & , types::TermType & , TheoryError & errors ) [inline], [virtual], [inherited]

Instantiate a variable within a term.

Reimplemented in [smtrat::parser::BitvectorTheory](#), and [smtrat::parser::ArithmeticTheory](#).

```
0.15.54.3.9 refreshVariable() virtual bool smtrat::parser::AbstractTheory::refreshVariable (
 const types::VariableType & ,
 types::VariableType & ,
 TheoryError & errors) [inline], [virtual], [inherited]
```

Reimplemented in [smtrat::parser::BitvectorTheory](#).

```
0.15.54.3.10 resolveSymbol() virtual bool smtrat::parser::AbstractTheory::resolveSymbol (
 const Identifier & ,
 types::TermType & ,
 TheoryError & errors) [inline], [virtual], [inherited]
```

Resolve a symbol that was not declared within the [ParserState](#).

This might be a symbol that actually uses indices, for example bitvector constants.

Reimplemented in [smtrat::parser::BitvectorTheory](#).

#### 0.15.54.4 Field Documentation

**0.15.57.2.10 `weak()`** `static Bound smtrat::cadcells::datastructures::Bound::weak (RootFunction value) [inline], [static]`

## 0.15.58 `smtrat::lra::Bound< T1, T2 >` Class Template Reference

Stores a bound, which could be an upper " $\leq b$ " or a lower bound " $\geq b$ " for a bound value  $b$ .

#include <Bound.h>

### Data Structures

- struct `Info`

*Stores some additional information for a bound.*

### Public Types

- enum `Type` { `LOWER` , `UPPER` , `EQUAL` }  
*The type of the bound: `LOWER` = " $\geq$ ", `UPPER` = " $\leq$ ", `EQUAL` = " $=$ ".*
- typedef `carl::PointerSet< Bound< T1, T2 > > BoundSet`  
*A set of pointer to bounds.*

### Public Member Functions

### 0.15.58.1 Detailed Description

```
template<typename T1, typename T2>
class smrat::ira::Bound< T1, T2 >
```

Stores a bound, which could be an upper " $\leq b$ " or a lower bound " $\geq b$ " for a bound value  $b$ .  
 In the case that " $\leq b$ " and " $\geq b$ " hold this bound is a so called equal bound represented by " $\equiv b$ ".

### 0.15.58.2 Member Typedef Documentation

**0.15.58.2.1 BoundSet** template<typename T1 , typename T2 >  
typedef carl::PointerSet<Bound<T1, T2> > smtrat::lra::Bound< T1, T2 >::BoundSet  
A set of pointer to bounds.

### 0.15.58.3 Member Enumeration Documentation

**0.15.58.3.1 Type** template<typename T1 , typename T2 >  
enum smtrat::lra::Bound::Type  
The type of the bound: LOWER = ">=", UPPER = "<=", EQUAL "==".

#### Enumerator

|       |  |
|-------|--|
| LOWER |  |
| UPPER |  |
| EQUAL |  |

### 0.15.58.4 Constructor & Destructor Documentation

**0.15.58.4.1 Bound() [1/2]** template<typename T1 , typename T2 >  
smtrat::lra::Bound< T1, T2 >::Bound ( ) [delete]

**0.15.58.4.2 Bound() [2/2]** template<typename T1 , typename T2 >  
smtrat::lra::Bound< T1, T2 >::Bound (   
    const Value< T1 > \*const \_limit,  
    Variable< T1, T2 > \*const \_var,  
    Type \_type,  
    const FormulaT & \_constraint,  
    Bound< T1, T2 >::Info \* \_boundInfo = NULL,  
    bool \_deduced = false )

#### Parameters

|             |  |
|-------------|--|
| _limit      |  |
| _var        |  |
| _type       |  |
| _constraint |  |
| _boundInfo  |  |
| _deduced    |  |

**0.15.58.4.3 ~Bound()** template<typename T1 , typename T2 >  
smtrat::lra::Bound< T1, T2 >::~Bound ( )

### 0.15.58.5 Member Function Documentation

**0.15.58.5.1 asConstraint()** template<typename T1 , typename T2 >  
const FormulaT& smtrat::lra::Bound< T1, T2 >::asConstraint ( ) const [inline]

Returns

**0.15.58.5.2 boundExists()** template<typename T1 , typename T2 >  
void **smtrat::lra::Bound**< T1, T2 >::boundExists ( ) const [inline]

**0.15.58.5.3 deduced()** template<typename T1 , typename T2 >  
bool **smtrat::lra::Bound**< T1, T2 >::deduced ( ) const [inline]

Returns

**0.15.58.5.4 exists()** template<typename T1 , typename T2 >  
bool **smtrat::lra::Bound**< T1, T2 >::exists ( ) const [inline]

**0.15.58.5.5 hasNeqRepresentation()** template<typename T1 , typename T2 >  
bool **smtrat::lra::Bound**< T1, T2 >::hasNeqRepresentation ( ) const [inline]

Returns

**0.15.58.5.6 isActive()** template<typename T1 , typename T2 >  
bool **smtrat::lra::Bound**< T1, T2 >::isActive ( ) const [inline]

Returns

**0.15.58.5.7 isComplementActive()** template<typename T1 , typename T2 >  
bool **smtrat::lra::Bound**< T1, T2 >::isComplementActive ( ) const [inline]

Returns

**0.15.58.5.8 isInfinite()** template<typename T1 , typename T2 >  
bool **smtrat::lra::Bound**< T1, T2 >::isInfinite ( ) const [inline]

Returns

**0.15.58.5.9 isLowerBound()** template<typename T1 , typename T2 >  
bool **smtrat::lra::Bound**< T1, T2 >::isLowerBound ( ) const [inline]

Returns

**0.15.58.5.10 `isSatisfied()`** template<typename T1 , typename T2 >  
bool smtrat::lra::Bound< T1, T2 >::isSatisfied ( const T1 & \_delta ) const [inline]

**0.15.58.5.11 `isUnassigned()`** template<typename T1 , typename T2 >  
bool smtrat::lra::Bound< T1, T2 >::isUnassigned ( ) const [inline]

**0.15.58.5.12 `isUpperBound()`** template<typename T1 , typename T2 >  
bool smtrat::lra::Bound< T1, T2 >::isUpperBound ( ) const [inline]

**Returns**

**0.15.58.5.13 `isWeak()`** template<typename T1 , typename T2 >  
bool smtrat::lra::Bound< T1, T2 >::isWeak ( ) const [inline]

**Returns**

**0.15.58.5.14 `limit()`** template<typename T1 , typename T2 >  
const Value<T1>& smtrat::lra::Bound< T1, T2 >::limit ( ) const [inline]

**Returns**

**0.15.58.5.15 `markAsDeleted()`** template<typename T1 , typename T2 >  
void smtrat::lra::Bound< T1, T2 >::markAsDeleted ( ) const [inline]

**Returns**

**0.15.58.5.16 `markedAsDeleted()`** template<typename T1 , typename T2 >  
bool smtrat::lra::Bound< T1, T2 >::markedAsDeleted ( ) const [inline]

**Returns**

**0.15.58.5.17 `neqRepresentation()`** template<typename T1 , typename T2 >  
const FormulaT& smtrat::lra::Bound< T1, T2 >::neqRepresentation ( ) const [inline]

**Returns**

**0.15.58.5.18 `operator<()` [1/3]** template<typename T1 , typename T2 >  
bool smtrat::lra::Bound< T1, T2 >::operator< ( const Bound< T1, T2 > & \_bound ) const

**Parameters**

|               |  |
|---------------|--|
| <i>_bound</i> |  |
|---------------|--|

**Returns**

**0.15.58.5.19 operator<() [2/3]** template<typename T1 , typename T2 >  
bool **smtrat::lra::Bound<** T1, T2 **>::operator<** (  
    const T1 & *\_a* ) const

**Parameters**

|                      |  |
|----------------------|--|
| $\leftrightarrow$    |  |
| $\_ \leftrightarrow$ |  |
| <i>a</i>             |  |

**Returns**

**0.15.58.5.20 operator<() [3/3]** template<typename T1 , typename T2 >  
bool **smtrat::lra::Bound<** T1, T2 **>::operator<** (  
    const Value< T1 > & *\_value* ) const

**Parameters**

|               |  |
|---------------|--|
| <i>_value</i> |  |
|---------------|--|

**Returns**

**0.15.58.5.21 operator<=()** [1/2] template<typename T1 , typename T2 >  
bool **smtrat::lra::Bound<** T1, T2 **>::operator<=** (  
    const T1 & *\_a* ) const

**Parameters**

|                      |  |
|----------------------|--|
| $\leftrightarrow$    |  |
| $\_ \leftrightarrow$ |  |
| <i>a</i>             |  |

**Returns**

**0.15.58.5.22 operator<=()** [2/2] template<typename T1 , typename T2 >  
bool **smtrat::lra::Bound<** T1, T2 **>::operator<=** (  
    const Value< T1 > & *v* ) const [inline]

Returns

**0.15.58.5.23 operator==( ) [1/2]** template<typename T1 , typename T2 >  
bool smtrat::lra::Bound< T1, T2 >::operator== (  
    const T1 & \_a ) const

Parameters

|                      |  |
|----------------------|--|
| $\leftrightarrow$    |  |
| $\_ \leftrightarrow$ |  |
| <i>a</i>             |  |

Returns

**0.15.58.5.24 operator==( ) [2/2]** template<typename T1 , typename T2 >  
bool smtrat::lra::Bound< T1, T2 >::operator== (  
    const Value< T1 > & \_value ) const

Parameters

|               |  |
|---------------|--|
| <i>_value</i> |  |
|---------------|--|

Returns

**0.15.58.5.25 operator>() [1/3]** template<typename T1 , typename T2 >  
bool smtrat::lra::Bound< T1, T2 >::operator> (  
    const Bound< T1, T2 > & \_bound ) const

Parameters

|               |  |
|---------------|--|
| <i>_bound</i> |  |
|---------------|--|

Returns

**0.15.58.5.26 operator>() [2/3]** template<typename T1 , typename T2 >  
bool smtrat::lra::Bound< T1, T2 >::operator> (  
    const T1 & \_a ) const

Parameters

|                      |  |
|----------------------|--|
| $\leftrightarrow$    |  |
| $\_ \leftrightarrow$ |  |
| <i>a</i>             |  |

Returns

```
0.15.58.5.27 operator>() [3/3] template<typename T1 , typename T2 >
bool smtrat::lra::Bound< T1, T2 >::operator> (
 const Value< T1 > & _value) const
```

Parameters

|                     |  |
|---------------------|--|
| <code>_value</code> |  |
|---------------------|--|

Returns

```
0.15.58.5.28 operator>=() [1/2] template<typename T1 , typename T2 >
bool smtrat::lra::Bound< T1, T2 >::operator>= (
 const T1 & _a) const
```

Parameters

|                      |  |
|----------------------|--|
| $\leftrightarrow$    |  |
| $\_ \leftrightarrow$ |  |
| <code>a</code>       |  |

Returns

```
0.15.58.5.29 operator>=() [2/2] template<typename T1 , typename T2 >
bool smtrat::lra::Bound< T1, T2 >::operator>= (
 const Value< T1 > & v) const [inline]
```

Returns

```
0.15.58.5.30 origins() template<typename T1 , typename T2 >
const std::vector<FormulaT>& smtrat::lra::Bound< T1, T2 >::origins () const [inline]
```

Returns

```
0.15.58.5.31 pInfo() template<typename T1 , typename T2 >
Info* smtrat::lra::Bound< T1, T2 >::pInfo () const [inline]
```

Returns

**0.15.58.5.32 pLimit()** template<typename T1 , typename T2 >  
const `Value<T1>*` `smtrat::lra::Bound< T1, T2 >::pLimit` ( ) const [inline]

Returns

**0.15.58.5.33 pOrigins()** template<typename T1 , typename T2 >  
const `std::shared_ptr<std::vector<FormulaT> >&` `smtrat::lra::Bound< T1, T2 >::pOrigins` ( )  
const [inline]

Returns

**0.15.58.5.34 print()** template<typename T1 , typename T2 >  
void `smtrat::lra::Bound< T1, T2 >::print` (  
    bool `_withOrigins` = `false`,  
    `std::ostream & _out` = `std::cout`,  
    bool `_printTypebool` = `false` ) const

Parameters

|                             |  |
|-----------------------------|--|
| <code>_withOrigins</code>   |  |
| <code>_out</code>           |  |
| <code>_printTypebool</code> |  |

**0.15.58.5.35 pVariable()** template<typename T1 , typename T2 >  
`Variable<T1, T2>*` `smtrat::lra::Bound< T1, T2 >::pVariable` ( ) const [inline]

Returns

**0.15.58.5.36 resetNeqRepresentation()** template<typename T1 , typename T2 >  
void `smtrat::lra::Bound< T1, T2 >::resetNeqRepresentation` ( ) const [inline]

**0.15.58.5.37 setComplement()** template<typename T1 , typename T2 >  
void `smtrat::lra::Bound< T1, T2 >::setComplement` (  
    const `Bound< T1, T2 > *` `_complement` ) const [inline]

**0.15.58.5.38 setNeqRepresentation()** template<typename T1 , typename T2 >  
void `smtrat::lra::Bound< T1, T2 >::setNeqRepresentation` (  
    const `FormulaT &` `_constraint` ) const [inline]

Parameters

|                          |  |
|--------------------------|--|
| <code>_constraint</code> |  |
|--------------------------|--|

```
0.15.58.5.39 toString() template<typename T1 , typename T2 >
const std::string smtrat::lra::Bound< T1, T2 >::toString () const
```

Returns

```
0.15.58.5.40 type() template<typename T1 , typename T2 >
Type smtrat::lra::Bound< T1, T2 >::type () const [inline]
```

Returns

```
0.15.58.5.41 unmarkAsDeleted() template<typename T1 , typename T2 >
void smtrat::lra::Bound< T1, T2 >::unmarkAsDeleted () const [inline]
```

Returns

```
0.15.58.5.42 variable() template<typename T1 , typename T2 >
const Variable<T1, T2>& smtrat::lra::Bound< T1, T2 >::variable () const [inline]
```

Returns

## 0.15.58.6 Friends And Related Function Documentation

```
0.15.58.6.1 operator<< template<typename T1 , typename T2 >
template<typename T3 , typename T4 >
std::ostream& operator<< (
 std::ostream & _ostream,
 const Bound< T3, T4 > & _bound) [friend]
```

Parameters

|                             |  |
|-----------------------------|--|
| <code>_withOrigins</code>   |  |
| <code>_out</code>           |  |
| <code>_printTypebool</code> |  |

### 0.15.60.1 Detailed Description

```
template<typename T>
class smrat::vb::Bound< T >
```

Class for the bound of a variable.

### 0.15.60.2 Member Enumeration Documentation

**Enumerator**

**0.15.60.2.1 Type** template<typename T >  
enum **smtrat::vb::Bound::Type**  
The type of a bounds.

**Enumerator**

|                    |
|--------------------|
| STRICT_LOWER_BOUND |
| WEAK_LOWER_BOUND   |
| EQUAL_BOUND        |
| WEAK_UPPER_BOUND   |
| STRICT_UPPER_BOUND |

**0.15.60.3 Constructor & Destructor Documentation**

**0.15.60.3.1 Bound()** template<typename T >  
**smtrat::vb::Bound< T >::Bound** (  
    **Rational** \*const *\_limit*,  
    **Variable**< T > \*const *\_variable*,  
    **Type** *\_type* )

Constructs this bound.

**Parameters**

|                  |                                                                                                      |
|------------------|------------------------------------------------------------------------------------------------------|
| <i>_limit</i>    | A pointer to the limit (rational) of the bound. It is NULL, if the limit is not finite.              |
| <i>_variable</i> | The variable to which this bound belongs.                                                            |
| <i>_type</i>     | The type of the bound (either it is an equal bound or it is weak resp. strict and upper resp. lower) |

**0.15.60.3.2 ~Bound()** template<typename T >  
**smtrat::vb::Bound< T >::~Bound** ( )

Destructs this bound.

**0.15.60.4 Member Function Documentation**

**0.15.60.4.1 activate()** template<typename T >  
bool **smtrat::vb::Bound< T >::activate** (  
    const T & *\_origin* ) const [inline]

Adds an origin to this bound.

**Parameters**

|                |                    |
|----------------|--------------------|
| <i>_origin</i> | The origin to add. |
|----------------|--------------------|

**Returns**

true, if this has activated this bound; false, if the bound was already active before.

```
0.15.60.4.2 deactivate() template<typename T >
bool smtrat::vb::Bound< T >::deactivate (
 const T & _origin) const [inline]
Removes an origin from this bound.
```

**Parameters**

|                |                    |
|----------------|--------------------|
| <i>_origin</i> | The origin to add. |
|----------------|--------------------|

**Returns**

true, if this has deactivated this bound; false, if the bound was already inactive before.

```
0.15.60.4.3 isActive() template<typename T >
bool smtrat::vb::Bound< T >::isActive () const [inline]
```

**Returns**

true, if this bound is active, which means that there is at least one origin for it left. Note, that origins can be removed belatedly. false, otherwise.

```
0.15.60.4.4 isInfinite() template<typename T >
bool smtrat::vb::Bound< T >::isInfinite () const [inline]
```

**Returns**

true, if the bound infinite; false, otherwise.

```
0.15.60.4.5 isLowerBound() template<typename T >
bool smtrat::vb::Bound< T >::isLowerBound () const [inline]
```

**Returns**

true, if the bound is a lower bound; false, otherwise.

```
0.15.60.4.6 isUpperBound() template<typename T >
bool smtrat::vb::Bound< T >::isUpperBound () const [inline]
```

**Returns**

true, if the bound is an upper bound; false, otherwise.

```
0.15.60.4.7 limit() template<typename T >
const Rational& smtrat::vb::Bound< T >::limit () const [inline]
```

**Returns**

A constant reference to the value of the limit. Note, that it must be ensured that the bound is finite before calling this method.

```
0.15.60.4.8 operator<() template<typename T >
bool smtrat::vb::Bound< T >::operator< (
 const Bound< T > & _bound) const
```

Checks whether the this bound is smaller than the given one.

**Parameters**

|               |                            |
|---------------|----------------------------|
| <i>_bound</i> | The bound to compare with. |
|---------------|----------------------------|

**Returns**

true, if for this bound (A) and the given bound (B) it holds that: A is not inf and B is inf, A smaller than B, where A and B are rationals, A equals B, where A and B are rationals, but A is an equal bound but B is not; false, otherwise.

**0.15.60.4.9 `origins()`** `template<typename T >`

```
const std::set<T, carl::less<T, false> >& smtrat::vb::Bound< T >::origins () const [inline]
```

**Returns**

A constant reference to the set of origins of this bound.

**0.15.60.4.10 `pLimit()`** `template<typename T >`

```
const Rational* smtrat::vb::Bound< T >::pLimit () const [inline]
```

**Returns**

A pointer to the limit of this bound.

**0.15.60.4.11 `print()`** `template<typename T >`

```
void smtrat::vb::Bound< T >::print (
 std::ostream & _out,
 bool _withRelation = false) const
```

Prints this bound on the given stream.

**Parameters**

|                      |                                                                                        |
|----------------------|----------------------------------------------------------------------------------------|
| <i>_out</i>          | The stream to print on.                                                                |
| <i>_withRelation</i> | A flag indicating whether to print also a relation symbol in front of the bound value. |

**0.15.60.4.12 `pVariable()`** `template<typename T >`

```
Variable<T>* smtrat::vb::Bound< T >::pVariable () const [inline]
```

**Returns**

A pointer to the variable wrapper considered by this bound.

**0.15.60.4.13 `type()`** `template<typename T >`

```
Type smtrat::vb::Bound< T >::type () const [inline]
```

**Returns**

The type of this bound.

```
0.15.60.4.14 variable() template<typename T >
const Variable<T>& smrat::vb::Bound< T >::variable () const [inline]
```

**Returns**

A constant reference to the variable wrapper considered by this bound.

**0.15.60.5 Friends And Related Function Documentation**

```
0.15.60.5.1 operator<< template<typename T >
template<typename T1 >
std::ostream& operator<< (
 std::ostream & _out,
 const Bound< T1 > & _bound) [friend]
```

Prints the bound on the given output stream.

**Parameters**

|                     |                                |
|---------------------|--------------------------------|
| <code>_out</code>   | The output stream to print on. |
| <code>_bound</code> | The bound to print.            |

**Returns**

The output stream after printing the bound on it.

**0.15.61 smrat::Branching Struct Reference**

Stores all necessary information of an branch, which can be used to detect probable infinite loop of branchings.

```
#include <Module.h>
```

**Public Member Functions**

- **Branching** (const typename Poly::PolyType &`_polynomial`, const Rational &`_value`)  
*Constructor.*

**Data Fields**

- Poly::PolyType **mPolynomial**  
*The polynomial to branch at.*
- Rational **mValue**  
*The value to branch the polynomial at.*
- size\_t **mRepetitions**  
*The number of repetitions of the branching.*
- int **mIncreasing**  
*Stores whether this the branching of the polynomial has been on an increasing sequence of values ( $>0$ ), or on a decreasing sequence of values ( $<0$ ).*

**0.15.61.1 Detailed Description**

Stores all necessary information of an branch, which can be used to detect probable infinite loop of branchings.

**0.15.61.2 Constructor & Destructor Documentation**

```
0.15.61.2.1 Branching() smtrat::Branching::Branching (
 const typename Poly::PolyType & _polynomial,
 const Rational & _value) [inline]
```

Constructor.

#### Parameters

|                          |                                        |
|--------------------------|----------------------------------------|
| <code>_polynomial</code> | The polynomial to branch at.           |
| <code>_value</code>      | The value to branch the polynomial at. |

### 0.15.61.3 Field Documentation

#### 0.15.61.3.1 mIncreasing int smtrat::Branching::mIncreasing

Stores whether this the branching of the polynomial has been on an increasing sequence of values ( $>0$ ), or on a decreasing sequence of values ( $<0$ ).

It is initially zero.

#### 0.15.61.3.2 mPolynomial Poly::PolyType smtrat::Branching::mPolynomial

The polynomial to branch at.

#### 0.15.61.3.3 mRepetitions size\_t smtrat::Branching::mRepetitions

The number of repetitions of the branching.

#### 0.15.61.3.4 mValue Rational smtrat::Branching::mValue

The value to branch the polynomial at.

*Adds the given set of formulas in the received formula to the origins of the given passed formula.*
- const FormulaT & `getOrigins` (ModuleInput::const\_iterator \_formula) const  
*Gets the origins of the passed formula at the given position.*
- void `getOrigins` (const FormulaT &\_formula, FormulasT &\_origins) const
- void `getOrigins` (const FormulaT &\_formula, FormulaSetT &\_origins) const
- std::pair< ModuleInput::iterator, bool > `removeOrigin` (ModuleInput::iterator \_formula, const FormulaT &\_origin)
- std::pair< ModuleInput::iterator, bool > `removeOrigins` (ModuleInput::iterator \_formula, const std::shared\_ptr< std::vector< FormulaT >> &\_origins)
- void `informBackends` (const FormulaT &\_constraint)  
*Informs all backends of this module about the given constraint.*
- virtual void `addConstraintToInform` (const FormulaT &\_constraint)  
*Adds a constraint to the collection of constraints of this module, which are informed to a freshly generated backend.*
- std::pair< ModuleInput::iterator, bool > `addReceivedSubformulaToPassedFormula` (ModuleInput::const\_iterator \_subformula)  
*Copies the given sub-formula of the received formula to the passed formula.*
- bool `originInReceivedFormula` (const FormulaT &\_origin) const
- std::pair< ModuleInput::iterator, bool > `addSubformulaToPassedFormula` (const FormulaT &\_formula)  
*Adds the given formula to the passed formula with no origin.*
- std::pair< ModuleInput::iterator, bool > `addSubformulaToPassedFormula` (const FormulaT &\_formula, const std::shared\_ptr< std::vector< FormulaT >> &\_origins)  
*Adds the given formula to the passed formula.*
- std::pair< ModuleInput::iterator, bool > `addSubformulaToPassedFormula` (const FormulaT &\_formula, const FormulaT &\_origin)  
*Adds the given formula to the passed formula.*

- Adds the given formula to the passed formula.
- void `generateTrivialInfeasibleSubset ()`

Stores the trivial infeasible subset being the set of received formulas.
- void `receivedFormulasAsInfeasibleSubset (ModuleInput::const_iterator _subformula)`

Stores an infeasible subset consisting only of the given received formula.
- std::vector< `FormulaT` >::const\_iterator `findBestOrigin (const std::vector< FormulaT > &_origins) const`
- void `getInfeasibleSubsets ()`

Copies the infeasible subsets of the passed formula.
- std::vector< `FormulaSetT` > `getInfeasibleSubsets (const Module &_backend) const`

Get the infeasible subsets the given backend provides.
- const `Model & backendsModel () const`

Stores the model of a backend which determined satisfiability of the passed formula in the model of this module.
- void `getBackendsModel () const`
- void `getBackendsAllModels () const`

Stores all models of a backend in the list of all models of this module.
- virtual `Answer runBackends (bool _final, bool _full, carl::Variable _objective)`

Runs the backend solvers on the passed formula.
- virtual `Answer runBackends ()`
- virtual `ModuleInput::iterator eraseSubformulaFromPassedFormula (ModuleInput::iterator _subformula, bool _ignoreOrigins=false)`

Removes everything related to the sub-formula to remove from the passed formula in the backends of this module.
- void `clearPassedFormula ()`
- std::vector< `FormulaT` > `merge (const std::vector< FormulaT > &, const std::vector< FormulaT > &) const`

Merges the two vectors of sets into the first one.
- size\_t `determine_smallest_origin (const std::vector< FormulaT > &origins) const`
- bool `probablyLooping (const typename Poly::PolyType &_branchingPolynomial, const Rational &_branchingValue) const`

Checks whether given the current branching value and branching variable/polynomial it is (highly) probable that this branching is part of an infinite loop of branchings.
- bool `branchAt (const Poly &_polynomial, bool _integral, const Rational &_value, std::vector< FormulaT > &&_premise, bool _leftCaseWeak=true, bool _preferLeftCase=true, bool _useReceivedFormulaAsPremise=false)`

Adds a lemmas which provoke a branching for the given variable at the given value, if this module returns Unknown and there exists a preceding SATModule.
- bool `branchAt (const Poly &_polynomial, bool _integral, const Rational &_value, bool _leftCaseWeak=true, bool _preferLeftCase=true, bool _useReceivedFormulaAsPremise=false, const std::vector< FormulaT > &_premise=std::vector< FormulaT >())`
- bool `branchAt (carl::Variable::Arg _var, const Rational &_value, std::vector< FormulaT > &&_premise, bool _leftCaseWeak=true, bool _preferLeftCase=true, bool _useReceivedFormulaAsPremise=false)`
- bool `branchAt (carl::Variable::Arg _var, const Rational &_value, bool _leftCaseWeak=true, bool _preferLeftCase=true, bool _useReceivedFormulaAsPremise=false, const std::vector< FormulaT > &_premise=std::vector< FormulaT >())`
- void `splitUnequalConstraint (const FormulaT &)`

Adds the following lemmas for the given constraint  $p \neq 0$ .
- unsigned `checkModel () const`
- void `addInformationRelevantFormula (const FormulaT &formula)`

Adds a formula to the InformationRelevantFormula.
- const std::set< `FormulaT` > & `getInformationRelevantFormulas ()`

Gets all InformationRelevantFormulas.
- bool `isLemmaLevel (LemmaLevel level)`

Checks if current lemma level is greater or equal to given level.

## Static Protected Member Functions

- static bool `modelsDisjoint` (const `Model` &\_modelA, const `Model` &\_modelB)

*Checks whether there is no variable assigned by both models.*

## Protected Attributes

- `std::vector<FormulaSetT> mInfeasibleSubsets`

*Stores the infeasible subsets.*

- `Manager *const mpManager`

*A reference to the manager.*

- `Model mModel`

*Stores the assignment of the current satisfiable result, if existent.*

- `std::vector<Model> mAllModels`

*Stores all satisfying assignments.*

- `bool mFinalCheck`

*true, if the check procedure should perform a final check which especially means not to postpone splitting decisions*

- `bool mFullCheck`

*false, if this module should avoid too expensive procedures and rather return unknown instead.*

- `carl::Variable mObjectiveVariable`

*Objective variable to be minimized. If set to NO\_VARIABLE, a normal sat check should be performed.*

- `std::vector<TheoryPropagation> mTheoryPropagations`

- `std::atomic<Answer> mSolverState`

*States whether the received formula is known to be satisfiable or unsatisfiable otherwise it is set to unknown.*

- `std::atomic_bool * mBackendsFoundAnswer`

*This flag is passed to any backend and if it determines an answer to a prior check call, this flag is fired.*

- `Conditionals mFoundAnswer`

*Vector of Booleans: If any of them is true, we have to terminate a running check procedure.*

- `std::vector<Module*> mUsedBackends`

*The backends of this module which are currently used (conditions to use this module are fulfilled for the passed formula).*

- `std::vector<Module*> mAllBackends`

*The backends of this module which have been used.*

- `std::vector<Lemma> mLemmas`

*Stores the lemmas being valid formulas this module or its backends made.*

- `ModuleInput::iterator mFirstSubformulaToPass`

*Stores the position of the first sub-formula in the passed formula, which has not yet been considered for a consistency check of the backends.*

- `carl::FastSet<FormulaT> mConstraintsToInform`

*Stores the constraints which the backends must be informed about.*

- `carl::FastSet<FormulaT> mInformedConstraints`

*Stores the position of the first constraint of which no backend has been informed about.*

- `ModuleInput::const_iterator mFirstUncheckedReceivedSubformula`

*Stores the position of the first (by this module) unchecked sub-formula of the received formula.*

- `unsigned mSmallerMusesCheckCounter`

*Counter used for the generation of the smt2 files to check for smaller muses.*

- `std::vector<std::size_t> mVariableCounters`

*Maps variables to the number of their occurrences.*

```

### 0.15.64.4 Member Function Documentation

**0.15.64.4.1 add()** bool [smtrat::Module::add](#) (  
 [ModuleInput::const\\_iterator](#) *\_subformula* ) [inherited]

The module has to take the given sub-formula of the received formula into account.

Parameters

|                    |                                                    |
|--------------------|----------------------------------------------------|
| <i>_subformula</i> | The sub-formula to take additionally into account. |
|--------------------|----------------------------------------------------|

Returns

false, if it can be easily decided that this sub-formula causes a conflict with the already considered sub-formulas; true, otherwise.

```
0.15.64.4.2 addConstraintToInform() void smtrat::Module::addConstraintToInform (
 const FormulaT & _constraint) [protected], [virtual], [inherited]
```

Adds a constraint to the collection of constraints of this module, which are informed to a freshly generated backend.

Parameters

|                    |                        |
|--------------------|------------------------|
| <i>_constraint</i> | The constraint to add. |
|--------------------|------------------------|

Reimplemented in [smtrat::SATModule< Settings >](#).

```
0.15.64.4.3 addCore() template<typename Settings >
bool smtrat::BVModule< Settings >::addCore (
 ModuleInput::const_iterator _subformula) [virtual]
```

The module has to take the given sub-formula of the received formula into account.

**Parameters**

|                          |                                                    |
|--------------------------|----------------------------------------------------|
| <code>_subformula</code> | The sub-formula to take additionally into account. |
|--------------------------|----------------------------------------------------|

**Returns**

false, if it can be easily decided that this sub-formula causes a conflict with the already considered sub-formulas; true, otherwise.

Reimplemented from [smtrat::Module](#).

```
0.15.64.4.4 addInformationRelevantFormula() void smtrat::Module::addInformationRelevantFormula (
 const FormulaT & formula) [protected], [inherited]
```

Adds a formula to the InformationRelevantFormula.

**Parameters**

|                      |                |
|----------------------|----------------|
| <code>formula</code> | Formula to add |
|----------------------|----------------|

```
0.15.64.4.5 addLemma() void smtrat::Module::addLemma (
 const FormulaT & _lemma,
 const LemmaType & _lt = LemmaType::NORMAL,
 const FormulaT & _preferredFormula = FormulaT(carl::FormulaType::TRUE)) [inline],
[inherited]
```

Stores a lemma being a valid formula.

**Parameters**

|                                |                                                                       |
|--------------------------------|-----------------------------------------------------------------------|
| <code>_lemma</code>            | The eduction/lemma to store.                                          |
| <code>_lt</code>               | The type of the lemma.                                                |
| <code>_preferredFormula</code> | Hint for the next decision, which formula should be assigned to true. |

```
0.15.64.4.6 addOrigin() void smtrat::Module::addOrigin (
 ModuleInput::iterator _formula,
 const FormulaT & _origin) [inline], [protected], [inherited]
```

Adds the given set of formulas in the received formula to the origins of the given passed formula.

**Parameters**

|                       |                                                           |
|-----------------------|-----------------------------------------------------------|
| <code>_formula</code> | The passed formula to set the origins for.                |
| <code>_origin</code>  | A set of formulas in the received formula of this module. |

**0.15.64.4.7 addReceivedSubformulaToPassedFormula()** std::pair<ModuleInput::iterator,bool>  
smtrat::Module::addReceivedSubformulaToPassedFormula (

    ModuleInput::const\_iterator \_subformula ) [inline], [protected], [inherited]

Copies the given sub-formula of the received formula to the passed formula.

Note, that there is always a link between sub-formulas of the passed formulas to sub-formulas of the received formulas, which are responsible for its occurrence.

#### Parameters

|             |                                                  |
|-------------|--------------------------------------------------|
| _subformula | The sub-formula of the received formula to copy. |
|-------------|--------------------------------------------------|

**0.15.64.4.8 addSubformulaToPassedFormula() [1/3]** std::pair<ModuleInput::iterator,bool> smtrat<->  
::Module::addSubformulaToPassedFormula (

    const FormulaT & \_formula ) [inline], [protected], [inherited]

Adds the given formula to the passed formula with no origin.

Note that in the next call of this module's removeSubformula, all formulas in the passed formula without origins will be removed.

#### Parameters

|          |                                           |
|----------|-------------------------------------------|
| _formula | The formula to add to the passed formula. |
|----------|-------------------------------------------|

#### Returns

A pair to the position where the formula to add has been inserted (or its first sub-formula which has not yet been in the passed formula, in case the formula to add is a conjunction), and a Boolean stating whether anything has been added to the passed formula.

**0.15.64.4.9 addSubformulaToPassedFormula() [2/3]** std::pair<ModuleInput::iterator,bool> smtrat<->  
::Module::addSubformulaToPassedFormula (

    const FormulaT & \_formula,

    const FormulaT & \_origin ) [inline], [protected], [inherited]

Adds the given formula to the passed formula.

#### Parameters

|          |                                           |
|----------|-------------------------------------------|
| _formula | The formula to add to the passed formula. |
|----------|-------------------------------------------|

|         |                                                                                                                           |
|---------|---------------------------------------------------------------------------------------------------------------------------|
| _origin | The sub-formula of the received formula being responsible for the occurrence of the formula to add to the passed formula. |
|---------|---------------------------------------------------------------------------------------------------------------------------|

#### Returns

A pair to the position where the formula to add has been inserted (or its first sub-formula which has not yet been in the passed formula, in case the formula to add is a conjunction), and a Boolean stating whether anything has been added to the passed formula.

**0.15.64.4.10 addSubformulaToPassedFormula() [3/3]** std::pair<ModuleInput::iterator,bool> smtrat<->  
::Module::addSubformulaToPassedFormula (

    const FormulaT & \_formula,

    const std::shared\_ptr< std::vector< FormulaT >> & \_origins ) [inline], [protected],

[inherited]

Adds the given formula to the passed formula.

**Parameters**

|                       |                                                                                                                                         |
|-----------------------|-----------------------------------------------------------------------------------------------------------------------------------------|
| <code>_formula</code> | The formula to add to the passed formula.                                                                                               |
| <code>_origins</code> | The link of the formula to add to the passed formula to sub-formulas of the received formulas, which are responsible for its occurrence |

**Returns**

A pair to the position where the formula to add has been inserted (or its first sub-formula which has not yet been in the passed formula, in case the formula to add is a conjunction), and a Boolean stating whether anything has been added to the passed formula.

**0.15.64.4.11 `allModels()`** `const std::vector<Model>& smtrat::Module::allModels () const [inline], [inherited]`

**Returns**

All satisfying assignments, if existent.

**0.15.64.4.12 `anAnswerFound()`** `bool smtrat::Module::anAnswerFound () const [inline], [protected], [inherited]`

Checks for all antecedent modules and those which run in parallel with the same antecedent modules, whether one of them has determined a result.

**Returns**

True, if one of them has determined a result.

**0.15.64.4.13 `answerFound()`** `const smtrat::Conditionals& smtrat::Module::answerFound () const [inline], [inherited]`

**Returns**

A vector of Booleans: If any of them is true, we have to terminate a running check procedure.

**0.15.64.4.14 `backendsModel()`** `const Model & smtrat::Module::backendsModel () const [protected], [inherited]`

Stores the model of a backend which determined satisfiability of the passed formula in the model of this module.

**0.15.64.4.15 `branchAt()` [1/4]** `bool smtrat::Module::branchAt ( carl::Variable::Arg _var, const Rational & _value, bool _leftCaseWeak = true, bool _preferLeftCase = true, bool _useReceivedFormulaAsPremise = false, const std::vector< FormulaT > & _premise = std::vector< FormulaT > () ) [inline], [protected], [inherited]`

```
0.15.64.4.16 branchAt() [2/4] bool smrat::Module::branchAt (
 carl::Variable::Arg _var,
 const Rational & _value,
 std::vector< FormulaT > && _premise,
 bool _leftCaseWeak = true,
 bool _preferLeftCase = true,
 bool _useReceivedFormulaAsPremise = false) [inline], [protected], [inherited]
```

```
0.15.64.4.17 branchAt() [3/4] bool smrat::Module::branchAt (
 const Poly & _polynomial,
 bool _integral,
 const Rational & _value,
 bool _leftCaseWeak = true,
 bool _preferLeftCase = true,
 bool _useReceivedFormulaAsPremise = false,
 const std::vector< FormulaT > & _premise = std::vector<FormulaT>()) [inline],
[protected], [inherited]
```

```
0.15.64.4.18 branchAt() [4/4] bool smrat::Module::branchAt (
 const Poly & _polynomial,
 bool _integral,
 const Rational & _value,
 std::vector< FormulaT > && _premise,
 bool _leftCaseWeak = true,
 bool _preferLeftCase = true,
 bool _useReceivedFormulaAsPremise = false) [protected], [inherited]
```

Adds a lemmas which provoke a branching for the given variable at the given value, if this module returns Unknown and there exists a preceding [SATModule](#).

Note that the given value is rounded down and up, if the given variable is integer-valued.

#### Parameters

|                                           |                                                                                                                                                                                                                |
|-------------------------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>_polynomial</code>                  | The variable to branch for.                                                                                                                                                                                    |
| <code>_integral</code>                    | A flag being true, if all variables in the polynomial to branch for are integral.                                                                                                                              |
| <code>_value</code>                       | The value to branch at.                                                                                                                                                                                        |
| <code>_premise</code>                     | The sub-formulas of the received formula from which the branch is followed. Note, that a premise is not necessary, as every branch is a valid formula. But a premise can prevent from branching unnecessarily. |
| <code>_leftCaseWeak</code>                | true, if a branching in the form of (or ( $\leq p b$ ) ( $> p b$ )) is desired. false, if a branching in the form of (or ( $< p b$ ) ( $\geq p b$ )) is desired.                                               |
| <code>_preferLeftCase</code>              | true, if the left case (polynomial less(or equal) 0 shall be chosen first. false, otherwise.                                                                                                                   |
| <code>_useReceivedFormulaAsPremise</code> | true, if the whole received formula should be used as premise                                                                                                                                                  |

```
0.15.64.4.19 check() Answer smrat::Module::check (
 bool _final = false,
 bool _full = true,
 carl::Variable _objective = carl::Variable::NO_VARIABLE) [virtual], [inherited]
```

Checks the received formula for consistency.

Note, that this is an implementation of the satisfiability check of the conjunction of the so far received formulas, which does actually nothing but passing the problem to its backends. This implementation is only used internally and must be overwritten by any derived module.

**Parameters**

|                         |                                                                                                                                       |
|-------------------------|---------------------------------------------------------------------------------------------------------------------------------------|
| <code>_final</code>     | true, if this satisfiability check will be the last one (for a global sat-check), if its result is SAT                                |
| <code>_full</code>      | false, if this module should avoid too expensive procedures and rather return unknown instead.                                        |
| <code>_objective</code> | if not set to NO_VARIABLE, the module should find an assignment minimizing this objective variable; otherwise any assignment is good. |

**Returns**

True, if the received formula is satisfiable; False, if the received formula is not satisfiable; Unknown, otherwise.

Reimplemented in [smtrat::PModule](#).

**0.15.64.4.20 `checkCore()`** `template<typename Settings >`  
`Answer smtrat::BVModule< Settings >::checkCore ( ) [virtual]`  
 Checks the received formula for consistency.

**Returns**

SAT, if the received formula is satisfiable; UNSAT, if the received formula is not satisfiable; Unknown, otherwise.

Reimplemented from [smtrat::Module](#).

**0.15.64.4.21 `checkInfeasibleSubsetForMinimality()`** `void smtrat::Module::checkInfeasibleSubsetForMinimality (`  
`std::vector< FormulaSetT >::const_iterator _infsSubset,`  
`const std::string & _filename = "smaller_muses",`  
`unsigned _maxSizeDifference = 1 ) const [inherited]`

Checks the given infeasible subset for minimality by storing all subsets of it, which have a smaller size which differs from the size of the infeasible subset not more than the given threshold.

**Parameters**

|                                 |                                                                                                        |
|---------------------------------|--------------------------------------------------------------------------------------------------------|
| <code>_infsSubset</code>        | The infeasible subset to check for minimality.                                                         |
| <code>_filename</code>          | The name of the file to store the infeasible subsets in order to be able to check their infeasibility. |
| <code>_maxSizeDifference</code> | The maximal difference between the sizes of the subsets compared to the size of the infeasible subset. |

**0.15.64.4.22 `checkModel()`** `unsigned smtrat::Module::checkModel ( ) const [protected], [inherited]`

**Returns**

false, if the current model of this module does not satisfy the current given formula; true, if it cannot be said whether the model satisfies the given formula.

**0.15.64.4.23 `cleanModel()`** `void smtrat::Module::cleanModel ( ) const [inline], [protected], [inherited]`

Substitutes variable occurrences by its model value in the model values of other variables.

**0.15.64.4.24 `clearLemmas()`** `void smtrat::Module::clearLemmas ( ) [inline], [inherited]`

Deletes all yet found lemmas.

**0.15.64.4.25 `clearModel()`** `void smtrat::Module::clearModel () const [inline], [protected], [inherited]`  
 Clears the assignment, if any was found.

**0.15.64.4.26 `clearModels()`** `void smtrat::Module::clearModels () const [inline], [protected], [inherited]`  
 Clears all assignments, if any was found.

**0.15.64.4.27 `clearPassedFormula()`** `void smtrat::Module::clearPassedFormula () [protected], [inherited]`

**0.15.64.4.28 `collectOrigins() [1/2]`** `void smtrat::Module::collectOrigins (const FormulaT & _formula, FormulaSetT & _origins ) const [inherited]`

**0.15.64.4.29 `collectOrigins() [2/2]`** `void smtrat::Module::collectOrigins (const FormulaT & _formula, FormulasT & _origins ) const [inherited]`

Collects the formulas in the given formula, which are part of the received formula.

If the given formula directly occurs in the received formula, it is inserted into the given set. Otherwise, the given formula must be of type AND and all its sub-formulas part of the received formula. Hence, they will be added to the given set.

#### Parameters

|                       |                                                                                                      |
|-----------------------|------------------------------------------------------------------------------------------------------|
| <code>_formula</code> | The formula from which to collect the formulas being sub-formulas of the received formula (origins). |
| <code>_origins</code> | The set in which to store the origins.                                                               |

**0.15.64.4.30 `collectTheoryPropagations()`** `void smtrat::Module::collectTheoryPropagations () [inherited]`

**0.15.64.4.31 `constraintsToInform()`** `const carl::FastSet<FormulaT>& smtrat::Module::constraintsToInform () const [inline], [inherited]`

#### Returns

The constraints which the backends must be informed about.

**0.15.64.4.32 `currentlySatisfied()`** `virtual unsigned smtrat::Module::currentlySatisfied (const FormulaT & ) const [inline], [virtual], [inherited]`

#### Returns

0, if the given formula is conflicted by the current model; 1, if the given formula is satisfied by the current model; 2, otherwise; 3, if we do not know anything (default)

Reimplemented in [smtrat::LRAModule< Settings >](#), [smtrat::LRAModule< LRASettingsICP >](#), and [smtrat::LRAModule< LRASettings >](#)

```
0.15.64.4.33 currentlySatisfiedByBackend() unsigned smrat::Module::currentlySatisfiedByBackend
(
 const FormulaT & _formula) const [inherited]
```

#### Returns

0, if the given formula is conflicted by the current model; 1, if the given formula is satisfied by the current model; 2, otherwise 3, if we do not know anything (default)

```
0.15.64.4.34 deinform() void smrat::Module::deinform (
 const FormulaT & _constraint) [inherited]
```

The inverse of informing about a constraint.

All data structures which were kept regarding this constraint are going to be removed. Note, that this makes only sense if it is not likely enough that a formula with this constraint must be solved again.

#### Parameters

|                          |                                                         |
|--------------------------|---------------------------------------------------------|
| <code>_constraint</code> | The constraint to remove from internal data structures. |
|--------------------------|---------------------------------------------------------|

```
0.15.64.4.35 deinformCore() virtual void smrat::Module::deinformCore (
 const FormulaT & _constraint) [inline], [protected], [virtual], [inherited]
```

The inverse of informing about a constraint.

All data structures which were kept regarding this constraint are going to be removed. Note, that this makes only sense if it is not likely enough that a formula with this constraint must be solved again.

#### Parameters

|                          |                                                         |
|--------------------------|---------------------------------------------------------|
| <code>_constraint</code> | The constraint to remove from internal data structures. |
|--------------------------|---------------------------------------------------------|

Reimplemented in [smrat::LRAModule< Settings >](#), [smrat::LRAModule< LRASettingsICP >](#), and [smrat::LRAModule< LRASetting >](#).

```
0.15.64.4.36 determine_smallest_origin() size_t smrat::Module::determine_smallest_origin (
 const std::vector< FormulaT > & origins) const [protected], [inherited]
```

#### Parameters

|                      |                              |
|----------------------|------------------------------|
| <code>origins</code> | A vector of sets of origins. |
|----------------------|------------------------------|

#### Returns

The index of the smallest (regarding the size of the sets) element of origins

```
0.15.64.4.37 eraseSubformulaFromPassedFormula() ModuleInput::iterator smrat::Module::erase←
SubformulaFromPassedFormula (
 ModuleInput::iterator _subformula,
 bool _ignoreOrigins = false) [protected], [virtual], [inherited]
```

Removes everything related to the sub-formula to remove from the passed formula in the backends of this module. Afterwards the sub-formula is removed from the passed formula.

#### Parameters

|                          |                                                    |
|--------------------------|----------------------------------------------------|
| <code>_subformula</code> | The sub-formula to remove from the passed formula. |
|--------------------------|----------------------------------------------------|

## Parameters

|                             |                                                                                                              |
|-----------------------------|--------------------------------------------------------------------------------------------------------------|
| <code>_ignoreOrigins</code> | True, if the sub-formula shall be removed regardless of its origins (should only be applied with expertise). |
|-----------------------------|--------------------------------------------------------------------------------------------------------------|

## Returns

Reimplemented in `smtrat::ICPModule< Settings >`, `smtrat::ICPModule< ICPSettings4 >`, and `smtrat::ICPModule< ICPSettings1 >`.

**0.15.64.4.38 `evaluateBVFormula()`** `template<typename Settings >`  
`size_t smtrat::BVModule< Settings >::evaluateBVFormula (`  
`const FormulaT & formula ) [protected]`

**0.15.64.4.39 `excludeNotReceivedVariablesFromModel()`** `void smtrat::Module::excludeNotReceivedVariablesFromModel ( ) const [inherited]`  
Excludes all variables from the current model, which do not occur in the received formula.

**0.15.64.4.40 `findBestOrigin()`** `std::vector< FormulaT >::const_iterator smtrat::Module::findBestOrigin (`  
`const std::vector< FormulaT > & _origins ) const [protected], [inherited]`

## Parameters

|                      |  |
|----------------------|--|
| <code>origins</code> |  |
|----------------------|--|

## Returns

**0.15.64.4.41 `firstSubformulaToPass()`** `ModuleInput::const_iterator smtrat::Module::firstSubformulaToPass ( ) const [inline], [inherited]`

## Returns

The position of the first sub-formula in the passed formula, which has not yet been considered for a consistency check of the backends.

**0.15.64.4.42 `firstUncheckedReceivedSubformula()`** `ModuleInput::const_iterator smtrat::Module::firstUncheckedReceivedSubformula ( ) const [inline], [inherited]`

## Returns

The position of the first (by this module) unchecked sub-formula of the received formula.

**0.15.64.4.43 `freeSplittingVariable()`** `static void smtrat::Module::freeSplittingVariable (`  
`const FormulaT & _splittingVariable ) [inline], [static], [inherited]`

**0.15.64.4.44 generateTrivialInfeasibleSubset()** void smtrat::Module::generateTrivialInfeasibleSubset ( ) [inline], [protected], [inherited]  
Stores the trivial infeasible subset being the set of received formulas.

**0.15.64.4.45 getBackendsAllModels()** void smtrat::Module::getBackendsAllModels ( ) const [protected], [inherited]  
Stores all models of a backend in the list of all models of this module.

**0.15.64.4.46 getBackendsModel()** void smtrat::Module::getBackendsModel ( ) const [protected], [inherited]

**0.15.64.4.47 getInfeasibleSubsets() [1/2]** void smtrat::Module::getInfeasibleSubsets ( ) [protected], [inherited]  
Copies the infeasible subsets of the passed formula.

**0.15.64.4.48 getInfeasibleSubsets() [2/2]** std::vector< [FormulaSetT](#) > smtrat::Module::getInfeasibleSubsets ( )  
const [Module](#) & \_backend ) const [protected], [inherited]

Get the infeasible subsets the given backend provides.

Note, that an infeasible subset in a backend contains sub formulas of the passed formula and an infeasible subset of this module contains sub formulas of the received formula. In this method the LATTER is returned.

#### Parameters

|                       |                                                          |
|-----------------------|----------------------------------------------------------|
| <code>_backend</code> | The backend from which to obtain the infeasible subsets. |
|-----------------------|----------------------------------------------------------|

#### Returns

The infeasible subsets the given backend provides.

**0.15.64.4.49 getInformationRelevantFormulas()** const std::set< [FormulaT](#) > & smtrat::Module::getInformationRelevantFormulas ( ) [protected], [inherited]  
Gets all InformationRelevantFormulas.

#### Returns

Set of all formulas

**0.15.64.4.50 getModelEqualities()** std::list< std::vector< [carl::Variable](#) > > smtrat::Module::getModelEqualities ( ) const [virtual], [inherited]  
Partition the variables from the current model into equivalence classes according to their assigned value.  
The result is a set of equivalence classes of variables where all variables within one class are assigned the same value. Note that the number of classes may not be minimal, i.e. two classes may actually be equivalent.

#### Returns

Equivalence classes.

**0.15.64.4.51 getOrigins() [1/3]** void smtrat::Module::getOrigins ( )  
const [FormulaT](#) & \_formula,  
[FormulaSetT](#) & \_origins ) const [inline], [protected], [inherited]

## Parameters

|                       |  |
|-----------------------|--|
| <code>_formula</code> |  |
| <code>_origins</code> |  |

**0.15.64.4.52 `getOrigins()` [2/3]** `void smtrat::Module::getOrigins (`  
`const FormulaT & _formula,`  
`FormulasT & _origins ) const [inline], [protected], [inherited]`

## Parameters

|                       |  |
|-----------------------|--|
| <code>_formula</code> |  |
| <code>_origins</code> |  |

**0.15.64.4.53 `getOrigins()` [3/3]** `const FormulaT& smtrat::Module::getOrigins (`  
`ModuleInput::const_iterator _formula ) const [inline], [protected], [inherited]`  
Gets the origins of the passed formula at the given position.

## Parameters

|                       |                                                   |
|-----------------------|---------------------------------------------------|
| <code>_formula</code> | The position of a formula in the passed formulas. |
|-----------------------|---------------------------------------------------|

## Returns

The origins of the passed formula at the given position.

**0.15.64.4.54 `getReceivedFormulaSimplified()`** `std::pair< bool, FormulaT > smtrat::Module::get←`  
`ReceivedFormulaSimplified ( ) [virtual], [inherited]`

## Returns

A pair of a Boolean and a formula, where the Boolean is true, if the received formula could be simplified to an equisatisfiable formula. The formula is equisatisfiable to this module's received formula, if the Boolean is true.

Reimplemented in [smtrat::PModule](#).

**0.15.64.4.55 `hasLemmas()`** `bool smtrat::Module::hasLemmas ( ) [inline], [inherited]`  
Checks whether this module or any of its backends provides any lemmas.

**0.15.64.4.56 `hasValidInfeasibleSubset()`** `bool smtrat::Module::hasValidInfeasibleSubset ( ) const`  
`[inherited]`

## Returns

true, if the module has at least one valid infeasible subset, that is all its elements are sub-formulas of the received formula (pointer must be equal).

**0.15.64.4.57 `id()`** `std::size_t smrat::Module::id( ) const [inline], [inherited]`

**Returns**

A unique ID to identify this module instance.

**0.15.64.4.58 `infeasibleSubsets()`** `const std::vector<FormulaSetT>& smrat::Module::infeasibleSubsets( ) const [inline], [inherited]`

**Returns**

The infeasible subsets of the set of received formulas (empty, if this module has not detected unsatisfiability of the conjunction of received formulas).

**0.15.64.4.59 `inform()`** `bool smrat::Module::inform( const FormulaT & _constraint ) [inherited]`

Informs the module about the given constraint.

It should be tried to inform this module about any constraint it could receive eventually before assertSubformula is called (preferably for the first time, but at least before adding a formula containing that constraint).

**Parameters**

|                          |                                 |
|--------------------------|---------------------------------|
| <code>_constraint</code> | The constraint to inform about. |
|--------------------------|---------------------------------|

**Returns**

false, if it can be easily decided whether the given constraint is inconsistent; true, otherwise.

**0.15.64.4.60 `informBackends()`** `void smrat::Module::informBackends( const FormulaT & _constraint ) [inline], [protected], [inherited]`

Informs all backends of this module about the given constraint.

**Parameters**

|                          |                                 |
|--------------------------|---------------------------------|
| <code>_constraint</code> | The constraint to inform about. |
|--------------------------|---------------------------------|

**0.15.64.4.61 `informCore()`** `template<typename Settings > bool smrat::BVModule< Settings >::informCore( const FormulaT & _constraint ) [virtual]`

Informs the module about the given constraint.

It should be tried to inform this module about any constraint it could receive eventually before assertSubformula is called (preferably for the first time, but at least before adding a formula containing that constraint).

**Parameters**

|                          |                                 |
|--------------------------|---------------------------------|
| <code>_constraint</code> | The constraint to inform about. |
|--------------------------|---------------------------------|

**Returns**

false, if it can be easily decided whether the given constraint is inconsistent; true, otherwise.

Reimplemented from [smrat::Module](#).

**0.15.64.4.62 informedConstraints()** const carl::FastSet<[FormulaT](#)>& smrat::Module::informedConstraints ( ) const [inline], [inherited]

**Returns**

The position of the first constraint of which no backend has been informed about.

**0.15.64.4.63 init()** template<typename Settings >  
void smrat::BVModule< Settings >::init ( ) [virtual]

Informs all backends about the so far encountered constraints, which have not yet been communicated.  
This method must not and will not be called more than once and only before the first runBackends call.  
Reimplemented from [smrat::Module](#).

**0.15.64.4.64 is\_minimizing()** bool smrat::Module::is\_minimizing ( ) const [inline], [inherited]

**0.15.64.4.65 isLemmaLevel()** bool smrat::Module::isLemmaLevel ( [LemmaLevel](#) level ) [protected], [inherited]

Checks if current lemma level is greater or equal to given level.

**Parameters**

|              |                 |
|--------------|-----------------|
| <i>level</i> | Level to check. |
|--------------|-----------------|

**0.15.64.4.66 isPreprocessor()** bool smrat::Module::isPreprocessor ( ) const [inline], [inherited]

**Returns**

true, if this module is a preprocessor that is a module, which simplifies its received formula to an equisatisfiable formula being passed to its backends. The simplified formula can be obtained with [getReceivedFormulaSimplified\(\)](#).

**0.15.64.4.67 lemmas()** const std::vector<[Lemma](#)>& smrat::Module::lemmas ( ) const [inline], [inherited]

**Returns**

A constant reference to the lemmas being valid formulas this module or its backends made.

**0.15.64.4.68 merge()** std::vector< [FormulaT](#) > smrat::Module::merge ( const std::vector< [FormulaT](#) > & \_vecSetA, const std::vector< [FormulaT](#) > & \_vecSetB ) const [protected], [inherited]

Merges the two vectors of sets into the first one.

({a,b},{a,c}) and ({b,d},{b}) -> ({a,b,d},{a,b},{a,b,c,d},{a,b,c})

**Parameters**

|                       |                                  |
|-----------------------|----------------------------------|
| <code>_vecSetA</code> | A vector of sets of constraints. |
| <code>_vecSetB</code> | A vector of sets of constraints. |

**Returns**

The vector being the two given vectors merged.

**0.15.64.4.69 `model()`** `const Model& smtrat::Module::model () const [inline], [inherited]`**Returns**

The assignment of the current satisfiable result, if existent.

**0.15.64.4.70 `modelsDisjoint()`** `bool smtrat::Module::modelsDisjoint (`

```
 const Model & _modelA,
 const Model & _modelB) [static], [protected], [inherited]
```

Checks whether there is no variable assigned by both models.

**Parameters**

|                      |                                |
|----------------------|--------------------------------|
| <code>_modelA</code> | The first model to check for.  |
| <code>_modelB</code> | The second model to check for. |

**Returns**

true, if there is no variable assigned by both models; false, otherwise.

**0.15.64.4.71 `moduleName()`** `template<typename Settings >  
std::string smtrat::BVMModule< Settings >::moduleName () const [inline], [virtual]`**Returns**

The name of the given module type as name.

Reimplemented from [smtrat::Module](#).

**0.15.64.4.72 `objective()`** `carl::Variable smtrat::Module::objective () const [inline], [inherited]`**0.15.64.4.73 `originInReceivedFormula()`** `bool smtrat::Module::originInReceivedFormula (`

```
 const FormulaT & _origin) const [protected], [inherited]
```

**0.15.64.4.74 `passedFormulaBegin()`** `ModuleInput::iterator smtrat::Module::passedFormulaBegin () [inline], [protected], [inherited]`**Returns**

An iterator to the end of the passed formula. TODO: disable this method

**0.15.64.4.75 passedFormulaEnd()** `ModuleInput::iterator smtrat::Module::passedFormulaEnd ( )`  
[inline], [protected], [inherited]

**Returns**

An iterator to the end of the passed formula.

**0.15.64.4.76 pPassedFormula()** `const ModuleInput* smtrat::Module::pPassedFormula ( ) const`  
[inline], [inherited]

**Returns**

A pointer to the formula passed to the backends of this module.

**0.15.64.4.77 pReceivedFormula()** `const ModuleInput* smtrat::Module::pReceivedFormula ( ) const`  
[inline], [inherited]

**Returns**

A pointer to the formula passed to this module.

**0.15.64.4.78 print()** `void smtrat::Module::print (`  
`const std::string & _initiation = "***" ) const [inherited]`  
Prints everything relevant of the solver.

**Parameters**

|                          |                      |
|--------------------------|----------------------|
| <code>_initiation</code> | The line initiation. |
|--------------------------|----------------------|

**0.15.64.4.79 printAllModels()** `void smtrat::Module::printAllModels (`  
`std::ostream & _out = std::cout ) [inherited]`

Prints all assignments of this module satisfying its received formula if it satisfiable and this module could find an assignment.

**Parameters**

|                   |                                        |
|-------------------|----------------------------------------|
| <code>_out</code> | The stream to print the assignment on. |
|-------------------|----------------------------------------|

**0.15.64.4.80 printInfeasibleSubsets()** `void smtrat::Module::printInfeasibleSubsets (`  
`const std::string & _initiation = "***" ) const [inherited]`

Prints the infeasible subsets.

**Parameters**

|                          |                      |
|--------------------------|----------------------|
| <code>_initiation</code> | The line initiation. |
|--------------------------|----------------------|

**0.15.64.4.81 printModel()** `void smtrat::Module::printModel (`  
`std::ostream & _out = std::cout ) const [inherited]`

Prints the assignment of this module satisfying its received formula if it satisfiable and this module could find an assignment.

Parameters

|                   |                                        |
|-------------------|----------------------------------------|
| <code>_out</code> | The stream to print the assignment on. |
|-------------------|----------------------------------------|

**0.15.64.4.82 `printPassedFormula()`** `void smtrat::Module::printPassedFormula ( const std::string & _initiation = "***" ) const [inherited]`

Prints the vector of passed formula.

Parameters

|                          |                      |
|--------------------------|----------------------|
| <code>_initiation</code> | The line initiation. |
|--------------------------|----------------------|

**0.15.64.4.83 `printReceivedFormula()`** `void smtrat::Module::printReceivedFormula ( const std::string & _initiation = "***" ) const [inherited]`

Prints the vector of the received formula.

Parameters

|                          |                      |
|--------------------------|----------------------|
| <code>_initiation</code> | The line initiation. |
|--------------------------|----------------------|

**0.15.64.4.84 `probablyLooping()`** `bool smtrat::Module::probablyLooping ( const typename Poly::PolyType & _branchingPolynomial, const Rational & _branchingValue ) const [protected], [inherited]`

Checks whether given the current branching value and branching variable/polynomial it is (highly) probable that this branching is part of an infinite loop of branchings.

Parameters

|                                   |                                                                                     |
|-----------------------------------|-------------------------------------------------------------------------------------|
| <code>_branchingPolynomial</code> | The polynomial to branch at (in most branching strategies this is just a variable). |
| <code>_branchingValue</code>      | The value to branch at.                                                             |

Returns

true, if this branching is probably part of an infinite loop of branchings; false, otherwise.

**0.15.64.4.85 `receivedFormulaChecked()`** `void smtrat::Module::receivedFormulaChecked ( ) [inline], [inherited]`

Notifies that the received formulas has been checked.

**0.15.64.4.86 `receivedFormulasAsInfeasibleSubset()`** `void smtrat::Module::receivedFormulasAs<-InfeasibleSubset ( ModuleInput::const_iterator _subformula ) [inline], [protected], [inherited]`

Stores an infeasible subset consisting only of the given received formula.

```
0.15.64.4.87 receivedVariable() bool smrat::Module::receivedVariable (
 carl::Variable::Arg _var) const [inline], [inherited]
```

```
0.15.64.4.88 remove() void smrat::Module::remove (
 ModuleInput::const_iterator _subformula) [virtual], [inherited]
```

Removes everything related to the given sub-formula of the received formula.

However, it is desired not to lose track of search spaces where no satisfying assignment can be found for the remaining sub-formulas.

#### Parameters

|             |                                                    |
|-------------|----------------------------------------------------|
| _subformula | The sub formula of the received formula to remove. |
|-------------|----------------------------------------------------|

Reimplemented in [smrat::PModule](#).

```
0.15.64.4.89 removeCore() template<typename Settings >
void smrat::BVModule< Settings >::removeCore (
 ModuleInput::const_iterator _subformula) [virtual]
```

Removes the subformula of the received formula at the given position to the considered ones of this module.

Note that this includes every stored calculation which depended on this subformula, but should keep the other stored calculation, if possible, untouched.

#### Parameters

|             |                                           |
|-------------|-------------------------------------------|
| _subformula | The position of the subformula to remove. |
|-------------|-------------------------------------------|

Reimplemented from [smrat::Module](#).

```
0.15.64.4.90 removeOrigin() std::pair<ModuleInput::iterator,bool> smrat::Module::removeOrigin (
 ModuleInput::iterator _formula,
 const FormulaT & _origin) [inline], [protected], [inherited]
```

```
0.15.64.4.91 removeOrigins() std::pair<ModuleInput::iterator,bool> smrat::Module::removeOrigins (
 ModuleInput::iterator _formula,
 const std::shared_ptr< std::vector< FormulaT >> & _origins) [inline], [protected],
[inherited]
```

```
0.15.64.4.92 rPassedFormula() const ModuleInput& smrat::Module::rPassedFormula () const
[inline], [inherited]
```

#### Returns

A reference to the formula passed to the backends of this module.

```
0.15.64.4.93 rReceivedFormula() const ModuleInput& smrat::Module::rReceivedFormula () const
[inline], [inherited]
```

**Returns**

A reference to the formula passed to this module.

**0.15.64.4.94 runBackends() [1/2]** `virtual Answer smtrat::Module::runBackends () [inline], [protected], [virtual], [inherited]`

Reimplemented in [smtrat::PModule](#).

**0.15.64.4.95 runBackends() [2/2]** `Answer smtrat::Module::runBackends ( bool _final, bool _full, carl::Variable _objective ) [protected], [virtual], [inherited]`

Runs the backend solvers on the passed formula.

**Parameters**

|                         |                                                                                                                                       |
|-------------------------|---------------------------------------------------------------------------------------------------------------------------------------|
| <code>_final</code>     | true, if this satisfiability check will be the last one (for a global sat-check), if its result is SAT                                |
| <code>_full</code>      | false, if this module should avoid too expensive procedures and rather return unknown instead.                                        |
| <code>_objective</code> | if not set to NO_VARIABLE, the module should find an assignment minimizing this objective variable; otherwise any assignment is good. |

**Returns**

True, if the passed formula is consistent; False, if the passed formula is inconsistent; Unknown, otherwise.

Reimplemented in [smtrat::PModule](#).

**0.15.64.4.96 setId()** `void smtrat::Module::setId ( std::size_t _id ) [inline], [inherited]`

Sets this modules unique ID to identify itself.

**Parameters**

|                   |                                    |
|-------------------|------------------------------------|
| <code>↔ id</code> | The id to set this module's id to. |
|-------------------|------------------------------------|

**0.15.64.4.97 setThreadPriority()** `void smtrat::Module::setThreadPriority ( thread_priority _threadPriority ) [inline], [inherited]`

Sets the priority of this module to get a thread for running its check procedure.

**Parameters**

|                              |                                                       |
|------------------------------|-------------------------------------------------------|
| <code>_threadPriority</code> | The priority to set this module's thread priority to. |
|------------------------------|-------------------------------------------------------|

**0.15.64.4.98 solverState()** `Answer smtrat::Module::solverState () const [inline], [inherited]`

**Returns**

True, if this module is in a state, such that it has found a solution for its received formula; False, if this module is in a state, such that it has determined that there is no solution for its received formula; Unknown, otherwise.

**0.15.64.4.99 splitUnequalConstraint()** `void smrat::Module::splitUnequalConstraint (`

`const FormulaT & _unequalConstraint ) [protected], [inherited]`

Adds the following lemmas for the given constraint  $p \neq 0$ .

$(p \neq 0 \leftrightarrow (p < 0 \text{ or } p > 0))$

and  $\neg(p < 0 \text{ and } p > 0)$

**Parameters**

|                                 |                                                  |
|---------------------------------|--------------------------------------------------|
| <code>_unequalConstraint</code> | A constraint having the relation symbol $\neq$ . |
|---------------------------------|--------------------------------------------------|

**0.15.64.4.100 threadPriority()** `thread_priority smrat::Module::threadPriority ( ) const [inline], [inherited]`**Returns**

The priority of this module to get a thread for running its check procedure.

**0.15.64.4.101 transferBackendModel()** `template<typename Settings >`

`void smrat::BVModule< Settings >::transferBackendModel ( ) const [protected]`

**0.15.64.4.102 updateAllModels()** `void smrat::Module::updateAllModels ( ) [virtual], [inherited]`

Updates all satisfying models, if the solver has detected the consistency of the received formula, beforehand.

Reimplemented in `smrat::SATModule< Settings >`.

**0.15.64.4.103 updateLemmas()** `void smrat::Module::updateLemmas ( ) [inherited]`

Stores all lemmas of any backend of this module in its own lemma vector.

**0.15.64.4.104 updateModel()** `template<typename Settings >`

`void smrat::BVModule< Settings >::updateModel ( ) const [virtual]`

Updates the current assignment into the model.

Note, that this is a unique but possibly symbolic assignment maybe containing newly introduced variables.

Reimplemented from `smrat::Module`.

**0.15.64.4.105 usedBackends()** `const std::vector<Module*>& smrat::Module::usedBackends ( )`

`const [inline], [inherited]`

**Returns**

The backends of this module which are currently used (conditions to use this module are fulfilled for the passed formula).

**0.15.64.5 Field Documentation**

**0.15.64.5.1 mAllBackends** `std::vector<Module*> smtrat::Module::mAllBackends` [protected], [inherited]

The backends of this module which have been used.

**0.15.64.5.2 mAllModels** `std::vector<Model> smtrat::Module::mAllModels` [mutable], [protected], [inherited]

Stores all satisfying assignments.

**0.15.64.5.3 mBackendsFoundAnswer** `std::atomic_bool* smtrat::Module::mBackendsFoundAnswer` [protected], [inherited]

This flag is passed to any backend and if it determines an answer to a prior check call, this flag is fired.

**0.15.64.5.4 mConstraintsToInform** `carl::FastSet<FormulaT> smtrat::Module::mConstraintsToInform` [protected], [inherited]

Stores the constraints which the backends must be informed about.

**0.15.64.5.5 mFinalCheck** `bool smtrat::Module::mFinalCheck` [protected], [inherited]  
true, if the check procedure should perform a final check which especially means not to postpone splitting decisions

**0.15.64.5.6 mFirstPosInLastBranches** `std::size_t smtrat::Module::mFirstPosInLastBranches = 0` [static], [inherited]

The beginning of the cyclic buffer storing the last branches.

**0.15.64.5.7 mFirstSubformulaToPass** `ModuleInput::iterator smtrat::Module::mFirstSubformulaToPass` [protected], [inherited]

Stores the position of the first sub-formula in the passed formula, which has not yet been considered for a consistency check of the backends.

**0.15.64.5.8 mFirstUncheckedReceivedSubformula** `ModuleInput::const_iterator smtrat::Module::mFirstUncheckedReceivedSubformula` [protected], [inherited]

Stores the position of the first (by this module) unchecked sub-formula of the received formula.

**0.15.64.5.9 mFoundAnswer** `Conditionals smtrat::Module::mFoundAnswer` [protected], [inherited]  
Vector of Booleans: If any of them is true, we have to terminate a running check procedure.

**0.15.64.5.10 mFullCheck** `bool smtrat::Module::mFullCheck` [protected], [inherited]  
false, if this module should avoid too expensive procedures and rather return unknown instead.

**0.15.64.5.11 mInfeasibleSubsets** `std::vector<FormulaSetT> smtrat::Module::mInfeasibleSubsets` [protected], [inherited]

Stores the infeasible subsets.

**0.15.64.5.12 mInformedConstraints** `carl::FastSet<FormulaT> smtrat::Module::mInformedConstraints` [protected], [inherited]  
Stores the position of the first constraint of which no backend has been informed about.

**0.15.64.5.13 mLastBranches** `std::vector< Branching > smtrat::Module::mLastBranches = std::vector< Branching > (mNumOfBranchVarsToStore, Branching(typename Poly::PolyType(), 0))` [static], [inherited]  
Stores the last branches in a cycle buffer.

**0.15.64.5.14 mLemmas** `std::vector<Lemma> smtrat::Module::mLemmas` [protected], [inherited]  
Stores the lemmas being valid formulas this module or its backends made.

**0.15.64.5.15 mModel Model** `smtrat::Module::mModel` [mutable], [protected], [inherited]  
Stores the assignment of the current satisfiable result, if existent.

**0.15.64.5.16 mNumOfBranchVarsToStore** `std::size_t smtrat::Module::mNumOfBranchVarsToStore = 5` [static], [inherited]  
The number of different variables to consider for a probable infinite loop of branchings.

**0.15.64.5.17 mObjectiveVariable** `carl::Variable smtrat::Module::mObjectiveVariable` [protected], [inherited]  
Objective variable to be minimized. If set to NO\_VARIABLE, a normal sat check should be performed.

**0.15.64.5.18 mOldSplittingVariables** `std::vector< FormulaT > smtrat::Module::mOldSplittingVariables` [static], [inherited]  
Reusable splitting variables.

**0.15.64.5.19 mpManager Manager\*** `const smtrat::Module::mpManager` [protected], [inherited]  
A reference to the manager.

**0.15.64.5.20 mSmallerMusesCheckCounter** `unsigned smtrat::Module::mSmallerMusesCheckCounter` [mutable], [protected], [inherited]  
Counter used for the generation of the smt2 files to check for smaller muses.

**0.15.64.5.21 mSolverState** `std::atomic<Answer> smtrat::Module::mSolverState` [protected], [inherited]  
States whether the received formula is known to be satisfiable or unsatisfiable otherwise it is set to unknown.

**0.15.64.5.22 mTheoryPropagations** `std::vector< TheoryPropagation > smtrat::Module::mTheoryPropagations` [protected], [inherited]

**0.15.64.5.23 mUsedBackends** `std::vector< Module* > smtrat::Module::mUsedBackends` [protected], [inherited]  
The backends of this module which are currently used (conditions to use this module are fulfilled for the passed formula).

**0.15.64.5.24 mVariableCounters** `std::vector<std::size_t> smtrat::Module::mVariableCounters`  
[protected], [inherited]  
Maps variables to the number of their occurrences.

## 0.15.65 `smtrat::by_address_hasher<IterType>` Struct Template Reference

Hash an iterator by the pointed-to address.

```
#include <IterHash.h>
```

### Public Types

- `typedef std::iterator_traits<IterType>::pointer pointer_type`

### Public Member Functions

- `std::size_t operator()(const IterType &iter) const noexcept`

#### 0.15.65.1 Detailed Description

```
template<typename IterType>
struct smtrat::by_address_hasher<IterType>
```

Hash an iterator by the pointed-to address.

#### 0.15.65.2 Member Typedef Documentation

**0.15.65.2.1 pointer\_type** `template<typename IterType>`  
`typedef std::iterator_traits<IterType>::pointer smtrat::by_address_hasher<IterType>::pointer_type`

#### 0.15.65.3 Member Function Documentation

**0.15.65.3.1 operator()** `template<typename IterType>`  
`std::size_t smtrat::by_address_hasher<IterType>::operator()(const IterType & iter) const [inline], [noexcept]`

`SampledDerivationRef<P> smtrat::cadcells::datastructures::CellRepresentation< P >::derivation`  
 Derivation.

**0.15.90.3.2 description** template<typename P >  
`SymbolicInterval smtrat::cadcells::datastructures::CellRepresentation< P >::description`  
 Description of a cell.

**0.15.90.3.3 equational** template<typename P >  
`boost::container::flat_set<PolyRef> smtrat::cadcells::datastructures::CellRepresentation< P >::equational`  
 Polynomials that should be projected using the equational constraints projection.

**0.15.90.3.4 ordering** template<typename P >  
`IndexedRootOrdering smtrat::cadcells::datastructures::CellRepresentation< P >::ordering`  
 An ordering on the roots that protects the cell.

## 0.15.91 delta::Checker Class Reference

This class takes care of calling the actual solver.

```
#include <Checker.h>
```

### Public Member Functions

- **Checker** (const std::string &exec, std::size\_t memout, std::size\_t timeout, const std::string &original)  
*Creates a new checker.*
- bool **operator()** (const **Node** &n, const std::string &temp) const  
*Call the solver with the given node.*
- int **expectedCode** () const  
*Return expected exit code.*
- std::size\_t **getKilled** () const
- void **resetKilled** () const
- void **resetTimeout** (std::size\_t t)

### 0.15.91.1 Detailed Description

This class takes care of calling the actual solver.

### 0.15.91.2 Constructor & Destructor Documentation

```
0.15.91.2.1 Checker() delta::Checker::Checker (
 const std::string & exec,
 std::size_t memout,
 std::size_t timeout,
 const std::string & original) [inline]
```

Creates a new checker.

#### Parameters

|                 |                                                                 |
|-----------------|-----------------------------------------------------------------|
| <i>exec</i>     | Filename of the solver executable.                              |
| <i>timeout</i>  | Timeout for a single call to the solver.                        |
| <i>original</i> | Filename of the original file to obtain the expected exit code. |

### 0.15.91.3 Member Function Documentation

```
0.15.91.3.1 expectedCode() int delta::Checker::expectedCode () const [inline]
```

Return expected exit code.

#### Returns

Expected exit code.

```
0.15.91.3.2 getKilled() std::size_t delta::Checker::getKilled () const [inline]
```

```
0.15.91.3.3 operator() bool delta::Checker::operator() (
 const Node & n,
 const std::string & temp) const [inline]
```

Call the solver with the given node.

Checks if the exit code is the same as for the original file.

#### Parameters

|             |                                 |
|-------------|---------------------------------|
| <i>n</i>    | Input data.                     |
| <i>temp</i> | Filename of the temporary file. |

#### Returns

If the exit code is still the same.

```
0.15.91.3.4 resetKilled() void delta::Checker::resetKilled () const [inline]
```

```
0.15.91.3.5 resetTimeout() void delta::Checker::resetTimeout (
 std::size_t t) [inline]
```

## 0.15.92 **benchmax::slurm::ChunkedSubmitfileProperties Struct Reference**

All properties needed to create a submit file.

```
#include <SlurmUtilities.h>
```

## Data Fields

- std::string **file\_suffix**  
*Suffix for job and submit file.*
- std::string **filename\_jobs**  
*Filename of the job list file.*
- std::string **tmp\_dir**  
*Temporary directory for log files.*
- carl::settings::duration **limit\_time**  
*Time limit in seconds.*
- carl::settings::duration **grace\_time**  
*Grace time in seconds.*
- carl::settings::binary\_quantity **limit\_memory**  
*Memory limit in megabytes.*
- std::size\_t **array\_size**  
*Array size.*
- std::size\_t **slice\_size**  
*Slice size.*
- std::pair< std::size\_t, std::size\_t > **job\_range**  
*This slice size.*

### 0.15.92.1 Detailed Description

All properties needed to create a submit file.

### 0.15.92.2 Field Documentation

**0.15.92.2.1 array\_size** std::size\_t benchmax::slurm::ChunkedSubmitfileProperties::array\_size  
Array size.

**0.15.92.2.2 file\_suffix** std::string benchmax::slurm::ChunkedSubmitfileProperties::file\_suffix  
Suffix for job and submit file.

**0.15.92.2.3 filename\_jobs** std::string benchmax::slurm::ChunkedSubmitfileProperties::filename\_jobs  
Filename of the job list file.

**0.15.92.2.4 grace\_time** carl::settings::duration benchmax::slurm::ChunkedSubmitfileProperties::grace\_time  
Grace time in seconds.

**0.15.92.2.5 job\_range** std::pair<std::size\_t, std::size\_t> benchmax::slurm::ChunkedSubmitfileProperties::job\_range  
This slice size.

**0.15.92.2.6 limit\_memory** carl::settings::binary\_quantity benchmax::slurm::ChunkedSubmitfileProperties::limit\_memory  
Memory limit in megabytes.

**0.15.92.2.7 limit\_time** carl::settings::duration benchmax::slurm::ChunkedSubmitfileProperties::limit\_time  
Time limit in seconds.

**0.15.92.2.8 slice\_size** std::size\_t benchmax::slurm::ChunkedSubmitfileProperties::slice\_size  
Slice size.

**0.15.92.2.9 tmp\_dir** std::string benchmax::slurm::ChunkedSubmitfileProperties::tmp\_dir  
Temporary directory for log files.

## 0.15.95 smrat::mcsat::ClauseChain Class Reference

An explanation is either a single clause or a chain of clauses, satisfying the following properties:

```
#include <ClauseChain.h>
```

### Data Structures

- struct [Link](#)

### Public Types

- using `const_iterator` = typename std::vector<[Link](#)>::const\_iterator

### Public Member Functions

- `ClauseChain ()`
- `FormulaT createTseitinVar (const FormulaT &formula)`

*Create a Tseitin variable for the given formula.*
- `void appendPropagating (const FormulaT &&clause, const FormulaT &&impliedTseitinLiteral)`

*Append a clause that implies impliedTseitinLiteral under the current assignment.*
- `void appendConflicting (const FormulaT &&clause)`

*Append a conflicting clause (regarding the current assignment).*
- `void appendOptional (const FormulaT &&clause)`

*Append an additional clause which is neither propagating nor conflicting.*
- `const std::vector<Link> & chain () const`
- `const_iterator begin () const`
- `const_iterator end () const`
- `FormulaT resolve () const`

*Performs resolution on the chain.*
- `FormulaT to_formula () const`

*Transforms the clause chain into a formula (containing Tseitin variables).*

### Static Public Member Functions

- static `ClauseChain from_formula (const FormulaT &f, const Model &model, bool with_equivalence)`

*Transforms a given Boolean conjunction over AND and OR to CNF via Tseitin-Transformation so that, if the input formula is conflicting under the current assignment, after all clauses in "implications" have been propagated in the given order, the returned formula evaluates to false.*

## Friends

- std::ostream & `operator<<` (std::ostream &stream, const ClauseChain &chain)

### 0.15.95.1 Detailed Description

An explanation is either a single clause or a chain of clauses, satisfying the following properties:

- If the clauses are inserted and propagated in the chain's order, at least the last clause should be conflicting.
- Each conflicting clause is already conflicting after preceding clauses have been inserted and propagated.
- Tseitin vars should be used so that a Tseitin variable C is equivalent to its corresponding subformula F (or at least  $C \rightarrow F$ ).

### 0.15.95.2 Member Typedef Documentation

**0.15.95.2.1 const\_iterator** using `smtrat::mcsat::ClauseChain::const_iterator` = typename std::vector<[Link](#)>::const\_iterator

### 0.15.95.3 Constructor & Destructor Documentation

**0.15.95.3.1 ClauseChain()** `smtrat::mcsat::ClauseChain::ClauseChain()` [inline]

### 0.15.95.4 Member Function Documentation

**0.15.95.4.1 appendConflicting()** `void smtrat::mcsat::ClauseChain::appendConflicting(const FormulaT && clause)` [inline]  
Append a conflicting clause (regarding the current assignment).

**0.15.95.4.2 appendOptional()** `void smtrat::mcsat::ClauseChain::appendOptional(const FormulaT && clause)` [inline]  
Append an additional clause which is neither propagating nor conflicting.  
Can be used to pass additional knowledge.

**0.15.95.4.3 appendPropagating()** `void smtrat::mcsat::ClauseChain::appendPropagating(const FormulaT && clause, const FormulaT && impliedTseitinLiteral)` [inline]  
Append a clause that implies impliedTseitinLiteral under the current assignment.  
Note that impliedTseitinLiteral =  $\sim v$  for a Tseitin variable v obtained via createTseitinVar.

**0.15.95.4.4 begin()** `const_iterator smtrat::mcsat::ClauseChain::begin()` const [inline]  
Returns

A constant iterator to the beginning of this chain.

**0.15.95.4.5 chain()** `const std::vector<Link>& smtrat::mcsat::ClauseChain::chain()` const [inline]  
Returns

A vector representing this chain.

**0.15.95.4.6 `createTseitinVar()`** `FormulaT smtrat::mcsat::ClauseChain::createTseitinVar ( const FormulaT & formula ) [inline]`

Create a Tseitin variable for the given formula.

The returned variable C should be used so that  $C \leftrightarrow formula$  or at least  $\sim formula \rightarrow \sim C$

**0.15.95.4.7 `end()`** `const_iterator smtrat::mcsat::ClauseChain::end () const [inline]`

Returns

A constant iterator to the end of this chain.

**0.15.95.4.8 `from_formula()`** `ClauseChain smtrat::mcsat::ClauseChain::from_formula ( const FormulaT & f, const Model & model, bool with_equivalence ) [static]`

Transforms a given Boolean conjunction over AND and OR to CNF via Tseitin-Transformation so that, if the input formula is conflicting under the current assignment, after all clauses in "implications" have been propagated in the given order, the returned formula evaluates to false.

**0.15.95.4.9 `resolve()`** `FormulaT smtrat::mcsat::ClauseChain::resolve () const`

Performs resolution on the chain.

Uses the last clause for resolution.

Returns

A single clause conflicting under the current assignment.

**0.15.95.4.10 `to_formula()`** `FormulaT smtrat::mcsat::ClauseChain::to_formula () const`

Transforms the clause chain into a formula (containing Tseitin variables).

*Adds a lemmas which provoke a branching for the given variable at the given value, if this module returns Unknown and there exists a preceding SATModule.*
- bool [branchAt](#) (const [Poly](#) &\_polynomial, bool \_integral, const [Rational](#) &\_value, std::vector< [FormulaT](#) > &&\_premise, bool \_leftCaseWeak=true, bool \_preferLeftCase=true, bool \_useReceivedFormulaAsPremise=false)
 

*bool [branchAt](#) (const [Poly](#) &\_polynomial, bool \_integral, const [Rational](#) &\_value, bool \_leftCaseWeak=true, bool \_preferLeftCase=true, bool \_useReceivedFormulaAsPremise=false, const std::vector< [FormulaT](#) > &\_premise=std::vector< [FormulaT](#) >())
   
bool [branchAt](#) (carl::Variable::Arg \_var, const [Rational](#) &\_value, std::vector< [FormulaT](#) > &&\_premise, bool \_leftCaseWeak=true, bool \_preferLeftCase=true, bool \_useReceivedFormulaAsPremise=false)
   
bool [branchAt](#) (carl::Variable::Arg \_var, const [Rational](#) &\_value, bool \_leftCaseWeak=true, bool \_preferLeftCase=true, bool \_useReceivedFormulaAsPremise=false, const std::vector< [FormulaT](#) > &\_premise=std::vector< [FormulaT](#) >())*
- void [splitUnequalConstraint](#) (const [FormulaT](#) &)
 

*Adds the following lemmas for the given constraint p!=0.*
- unsigned [checkModel](#) () const
 

*Adds a formula to the InformationRelevantFormula.*
- void [addInformationRelevantFormula](#) (const [FormulaT](#) &formula)
 

*Gets all InformationRelevantFormulas.*
- const std::set< [FormulaT](#) > & [getInformationRelevantFormulas](#) ()
 

*Checks if current lemma level is greater or equal to given level.*

## Static Protected Member Functions

- static bool `modelsDisjoint` (const `Model` &\_modelA, const `Model` &\_modelB)

*Checks whether there is no variable assigned by both models.*

## Protected Attributes

- `std::vector<FormulaSetT> mInfeasibleSubsets`

*Stores the infeasible subsets.*

- `Manager *const mpManager`

*A reference to the manager.*

- `Model mModel`

*Stores the assignment of the current satisfiable result, if existent.*

- `std::vector<Model> mAllModels`

*Stores all satisfying assignments.*

- `bool mModelComputed`

*True, if the model has already been computed.*

- `bool mFinalCheck`

*true, if the check procedure should perform a final check which especially means not to postpone splitting decisions*

- `bool mFullCheck`

*false, if this module should avoid too expensive procedures and rather return unknown instead.*

- `carl::Variable mObjectiveVariable`

*Objective variable to be minimized. If set to NO\_VARIABLE, a normal sat check should be performed.*

- `std::vector<TheoryPropagation> mTheoryPropagations`

- `std::atomic<Answer> mSolverState`

*States whether the received formula is known to be satisfiable or unsatisfiable otherwise it is set to unknown.*

- `std::atomic_bool * mBackendsFoundAnswer`

*This flag is passed to any backend and if it determines an answer to a prior check call, this flag is fired.*

- `Conditionals mFoundAnswer`

*Vector of Booleans: If any of them is true, we have to terminate a running check procedure.*

- `std::vector<Module*> mUsedBackends`

*The backends of this module which are currently used (conditions to use this module are fulfilled for the passed formula).*

- `std::vector<Module*> mAllBackends`

*The backends of this module which have been used.*

- `std::vector<Lemma> mLemmas`

*Stores the lemmas being valid formulas this module or its backends made.*

- `ModuleInput::iterator mFirstSubformulaToPass`

*Stores the position of the first sub-formula in the passed formula, which has not yet been considered for a consistency check of the backends.*

- `carl::FastSet<FormulaT> mConstraintsToInform`

*Stores the constraints which the backends must be informed about.*

- `carl::FastSet<FormulaT> mInformedConstraints`

*Stores the position of the first constraint of which no backend has been informed about.*

- `ModuleInput::const_iterator mFirstUncheckedReceivedSubformula`

*Stores the position of the first (by this module) unchecked sub-formula of the received formula.*

- `unsigned mSmallerMusesCheckCounter`

*Counter used for the generation of the smt2 files to check for smaller muses.*

- `std::vector<std::size_t> mVariableCounters`

*Maps variables to the number of their occurrences.*

**0.15.99.1 Member Enumeration Documentation****0.15.99.1.1 LemmaType** enum `smtrat::Module::LemmaType` : unsigned [strong], [inherited]

## Enumerator

|           |  |
|-----------|--|
| NORMAL    |  |
| PERMANENT |  |

## 0.15.99.2 Constructor &amp; Destructor Documentation

**0.15.99.2.1 CNFerModule()** smtrat::CNFerModule::CNFerModule (

```
const ModuleInput * ,
Conditionals & ,
Manager * const = NULL)
```

Constructs a [CNFerModule](#).

**0.15.99.2.2 ~CNFerModule()** smtrat::CNFerModule::~CNFerModule ( )

Destructs a [CNFerModule](#).

## 0.15.99.3 Member Function Documentation

**0.15.99.3.1 add()** bool smtrat::PModule::add (

```
ModuleInput::const_iterator _subformula) [inherited]
```

The module has to take the given sub-formula of the received formula into account.

## Parameters

|             |                                                    |
|-------------|----------------------------------------------------|
| _subformula | The sub-formula to take additionally into account. |
|-------------|----------------------------------------------------|

## Returns

false, if it can be easily decided that this sub-formula causes a conflict with the already considered sub-formulas; true, otherwise.

**0.15.99.3.2 addConstraintToInform()** void smtrat::Module::addConstraintToInform (

```
const FormulaT & _constraint) [protected], [virtual], [inherited]
```

Adds a constraint to the collection of constraints of this module, which are informed to a freshly generated backend.

## Parameters

|             |                        |
|-------------|------------------------|
| _constraint | The constraint to add. |
|-------------|------------------------|

Reimplemented in [smtrat::SATModule< Settings >](#).

**0.15.99.3.3 addCore()** virtual bool smtrat::Module::addCore (

```
ModuleInput::const_iterator formula) [inline], [protected], [virtual], [inherited]
```

The module has to take the given sub-formula of the received formula into account.

## Parameters

|         |                                                    |
|---------|----------------------------------------------------|
| formula | The sub-formula to take additionally into account. |
|---------|----------------------------------------------------|

**Returns**

false, if it can be easily decided that this sub-formula causes a conflict with the already considered sub-formulas; true, otherwise.

Reimplemented in [smrat::VSModule< Settings >](#), [smrat::SATModule< Settings >](#), [smrat::PFEModule< Settings >](#), [smrat::ICPModule< Settings >](#), [smrat::ICPModule< ICPSettings4 >](#), [smrat::ICPModule< ICPSettings1 >](#), [smrat::UnionFindModule< Settings >](#), [smrat::UFCegarModule< Settings >](#), [smrat::STropModule< Settings >](#), [smrat::PBPPModule< Settings >](#), [smrat::PBGaussModule< Settings >](#), [smrat::NRAILModule< Settings >](#), [smrat::NewCoveringModule< Settings >](#), [smrat::NewCADModule< Settings >](#), [smrat::LRAModule< Settings >](#), [smrat::LRAModule< LRASettingsICP >](#), [smrat::LRAModule< LRASettings1 >](#), [smrat::IntEqModule< Settings >](#), [smrat::IntBlastModule< Settings >](#), [smrat::IncWidthModule< Settings >](#), [smrat::ICEModule< Settings >](#), [smrat::FPPModule< Settings >](#), [smrat::FouMoModule< Settings >](#), [smrat::EQModule< Settings >](#), [smrat::CurryModule< Settings >](#), [smrat::CubeLIAModule< Settings >](#), [smrat::CSplitModule< Settings >](#), [smrat::BVMModule< Settings >](#), and [smrat::GBModule< Settings >](#).

**0.15.99.3.4 addInformationRelevantFormula()** void smrat::Module::addInformationRelevantFormula (

const [FormulaT](#) & formula ) [protected], [inherited]

Adds a formula to the InformationRelevantFormula.

**Parameters**

|                |                |
|----------------|----------------|
| <i>formula</i> | Formula to add |
|----------------|----------------|

**0.15.99.3.5 addLemma()** void smrat::Module::addLemma (

const [FormulaT](#) & \_lemma,

const [LemmaType](#) & \_lt = [LemmaType::NORMAL](#),

const [FormulaT](#) & \_preferredFormula = [FormulaT\( carl::FormulaType::TRUE \)](#) ) [inline],

[inherited]

Stores a lemma being a valid formula.

**Parameters**

|                          |                                                                       |
|--------------------------|-----------------------------------------------------------------------|
| <i>_lemma</i>            | The eduction/lemma to store.                                          |
| <i>_lt</i>               | The type of the lemma.                                                |
| <i>_preferredFormula</i> | Hint for the next decision, which formula should be assigned to true. |

**0.15.99.3.6 addOrigin()** void smrat::Module::addOrigin (

[ModuleInput::iterator](#) \_formula,

const [FormulaT](#) & \_origin ) [inline], [protected], [inherited]

Adds the given set of formulas in the received formula to the origins of the given passed formula.

**Parameters**

|                 |                                                           |
|-----------------|-----------------------------------------------------------|
| <i>_formula</i> | The passed formula to set the origins for.                |
| <i>_origin</i>  | A set of formulas in the received formula of this module. |

**0.15.99.3.7 addReceivedSubformulaToPassedFormula()** std::pair<[ModuleInput::iterator](#),bool> smrat::Module::addReceivedSubformulaToPassedFormula (

---

```
ModuleInput::const_iterator _subformula) [inline], [protected], [inherited]
```

Copies the given sub-formula of the received formula to the passed formula.

Note, that there is always a link between sub-formulas of the passed formulas to sub-formulas of the received formulas, which are responsible for its occurrence.

#### Parameters

|                          |                                                  |
|--------------------------|--------------------------------------------------|
| <code>_subformula</code> | The sub-formula of the received formula to copy. |
|--------------------------|--------------------------------------------------|

**0.15.99.3.8 addSubformulaToPassedFormula()** [1/3] `std::pair<ModuleInput::iterator,bool> smtrat→`  
`::Module::addSubformulaToPassedFormula (`

```
 const FormulaT & _formula) [inline], [protected], [inherited]
```

Adds the given formula to the passed formula with no origin.

Note that in the next call of this module's removeSubformula, all formulas in the passed formula without origins will be removed.

#### Parameters

|                       |                                           |
|-----------------------|-------------------------------------------|
| <code>_formula</code> | The formula to add to the passed formula. |
|-----------------------|-------------------------------------------|

#### Returns

A pair to the position where the formula to add has been inserted (or its first sub-formula which has not yet been in the passed formula, in case the formula to add is a conjunction), and a Boolean stating whether anything has been added to the passed formula.

**0.15.99.3.9 addSubformulaToPassedFormula()** [2/3] `std::pair<ModuleInput::iterator,bool> smtrat→`  
`::Module::addSubformulaToPassedFormula (`

```
 const FormulaT & _formula,
```

```
 const FormulaT & _origin) [inline], [protected], [inherited]
```

Adds the given formula to the passed formula.

#### Parameters

|                       |                                                                                                                           |
|-----------------------|---------------------------------------------------------------------------------------------------------------------------|
| <code>_formula</code> | The formula to add to the passed formula.                                                                                 |
| <code>_origin</code>  | The sub-formula of the received formula being responsible for the occurrence of the formula to add to the passed formula. |

#### Returns

A pair to the position where the formula to add has been inserted (or its first sub-formula which has not yet been in the passed formula, in case the formula to add is a conjunction), and a Boolean stating whether anything has been added to the passed formula.

**0.15.99.3.10 addSubformulaToPassedFormula()** [3/3] `std::pair<ModuleInput::iterator,bool> smtrat→`  
`::Module::addSubformulaToPassedFormula (`

```
 const FormulaT & _formula,
```

```
 const std::shared_ptr< std::vector< FormulaT >> & _origins) [inline], [protected],
```

[inherited]

Adds the given formula to the passed formula.

**Parameters**

|                       |                                                                                                                                         |
|-----------------------|-----------------------------------------------------------------------------------------------------------------------------------------|
| <code>_formula</code> | The formula to add to the passed formula.                                                                                               |
| <code>_origins</code> | The link of the formula to add to the passed formula to sub-formulas of the received formulas, which are responsible for its occurrence |

**Returns**

A pair to the position where the formula to add has been inserted (or its first sub-formula which has not yet been in the passed formula, in case the formula to add is a conjunction), and a Boolean stating whether anything has been added to the passed formula.

**0.15.99.3.11 `allModels()`** `const std::vector<Model>& smtrat::Module::allModels () const [inline], [inherited]`

**Returns**

All satisfying assignments, if existent.

**0.15.99.3.12 `anAnswerFound()`** `bool smtrat::Module::anAnswerFound () const [inline], [protected], [inherited]`

Checks for all antecedent modules and those which run in parallel with the same antecedent modules, whether one of them has determined a result.

**Returns**

True, if one of them has determined a result.

**0.15.99.3.13 `answerFound()`** `const smtrat::Conditionals& smtrat::Module::answerFound () const [inline], [inherited]`

**Returns**

A vector of Booleans: If any of them is true, we have to terminate a running check procedure.

**0.15.99.3.14 `appliedPreprocessing()`** `bool smtrat::PModule::appliedPreprocessing () const [inline], [inherited]`

**Returns**

true, if the current received formula has been simplified and the result of this simplification is stored in the passed formula.

**0.15.99.3.15 `backendsModel()`** `const Model & smtrat::Module::backendsModel () const [protected], [inherited]`

Stores the model of a backend which determined satisfiability of the passed formula in the model of this module.

---

**0.15.99.3.16 branchAt() [1/4]** bool smrat::Module::branchAt (

```
carl::Variable::Arg _var,
const Rational & _value,
bool _leftCaseWeak = true,
bool _preferLeftCase = true,
bool _useReceivedFormulaAsPremise = false,
const std::vector< FormulaT > & _premise = std::vector<FormulaT>()) [inline],
[protected], [inherited]
```

**0.15.99.3.17 branchAt() [2/4]** bool smrat::Module::branchAt (

```
carl::Variable::Arg _var,
const Rational & _value,
std::vector< FormulaT > && _premise,
bool _leftCaseWeak = true,
bool _preferLeftCase = true,
bool _useReceivedFormulaAsPremise = false) [inline], [protected], [inherited]
```

**0.15.99.3.18 branchAt() [3/4]** bool smrat::Module::branchAt (

```
const Poly & _polynomial,
bool _integral,
const Rational & _value,
bool _leftCaseWeak = true,
bool _preferLeftCase = true,
bool _useReceivedFormulaAsPremise = false,
const std::vector< FormulaT > & _premise = std::vector<FormulaT>()) [inline],
[protected], [inherited]
```

**0.15.99.3.19 branchAt() [4/4]** bool smrat::Module::branchAt (

```
const Poly & _polynomial,
bool _integral,
const Rational & _value,
std::vector< FormulaT > && _premise,
bool _leftCaseWeak = true,
bool _preferLeftCase = true,
bool _useReceivedFormulaAsPremise = false) [protected], [inherited]
```

Adds a lemmas which provoke a branching for the given variable at the given value, if this module returns Unknown and there exists a preceding [SATModule](#).

Note that the given value is rounded down and up, if the given variable is integer-valued.

#### Parameters

|                                           |                                                                                                                                                                                                                |
|-------------------------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>_polynomial</code>                  | The variable to branch for.                                                                                                                                                                                    |
| <code>_integral</code>                    | A flag being true, if all variables in the polynomial to branch for are integral.                                                                                                                              |
| <code>_value</code>                       | The value to branch at.                                                                                                                                                                                        |
| <code>_premise</code>                     | The sub-formulas of the received formula from which the branch is followed. Note, that a premise is not necessary, as every branch is a valid formula. But a premise can prevent from branching unnecessarily. |
| <code>_leftCaseWeak</code>                | true, if a branching in the form of (or ( $\leq p b$ ) ( $> p b$ )) is desired. false, if a branching in the form of (or ( $< p b$ ) ( $\geq p b$ )) is desired.                                               |
| <code>_preferLeftCase</code>              | true, if the left case (polynomial less(or equal) 0 shall be chosen first. false, otherwise.                                                                                                                   |
| <code>_useReceivedFormulaAsPremise</code> | true, if the whole received formula should be used as premise                                                                                                                                                  |

```
0.15.99.3.20 check() Answer smrat::PModule::check (
 bool _final = false,
 bool _full = true,
 carl::Variable _objective = carl::Variable::NO_VARIABLE) [virtual], [inherited]
```

Checks the received formula for consistency.

Note, that this is an implementation of the satisfiability check of the conjunction of the so far received formulas, which does actually nothing but passing the problem to its backends. This implementation is only used internally and must be overwritten by any derived module.

#### Parameters

|                   |                                                                                                                                       |
|-------------------|---------------------------------------------------------------------------------------------------------------------------------------|
| <i>_final</i>     | true, if this satisfiability check will be the last one (for a global sat-check), if its result is SAT                                |
| <i>_full</i>      | false, if this module should avoid too expensive procedures and rather return unknown instead.                                        |
| <i>_objective</i> | if not set to NO_VARIABLE, the module should find an assignment minimizing this objective variable; otherwise any assignment is good. |

#### Returns

True, if the received formula is satisfiable; False, if the received formula is not satisfiable; Unknown, otherwise.

Reimplemented from [smrat::Module](#).

```
0.15.99.3.21 checkCore() Answer smrat::CNFerModule::checkCore () [virtual]
```

Checks the received formula for consistency.

#### Returns

SAT, if the received formula is satisfiable; UNSAT, if the received formula is not satisfiable; Unknown, otherwise.

Reimplemented from [smrat::Module](#).

```
0.15.99.3.22 checkInfSubsetForMinimality() void smrat::Module::checkInfSubsetForMinimality (
 std::vector< FormulaSetT >::const_iterator _infssubset,
 const std::string & _filename = "smaller_muses",
 unsigned _maxSizeDifference = 1) const [inherited]
```

Checks the given infeasible subset for minimality by storing all subsets of it, which have a smaller size which differs from the size of the infeasible subset not more than the given threshold.

#### Parameters

|                           |                                                                                                        |
|---------------------------|--------------------------------------------------------------------------------------------------------|
| <i>_infssubset</i>        | The infeasible subset to check for minimality.                                                         |
| <i>_filename</i>          | The name of the file to store the infeasible subsets in order to be able to check their infeasibility. |
| <i>_maxSizeDifference</i> | The maximal difference between the sizes of the subsets compared to the size of the infeasible subset. |

```
0.15.99.3.23 checkModel() unsigned smrat::Module::checkModel () const [protected], [inherited]
```

#### Returns

false, if the current model of this module does not satisfy the current given formula; true, if it cannot be said whether the model satisfies the given formula.

**0.15.99.3.24 cleanModel()** void smtrat::Module::cleanModel ( ) const [inline], [protected], [inherited]

Substitutes variable occurrences by its model value in the model values of other variables.

**0.15.99.3.25 clearLemmas()** void smtrat::Module::clearLemmas ( ) [inline], [inherited]

Deletes all yet found lemmas.

**0.15.99.3.26 clearModel()** void smtrat::Module::clearModel ( ) const [inline], [protected], [inherited]

Clears the assignment, if any was found.

**0.15.99.3.27 clearModels()** void smtrat::Module::clearModels ( ) const [inline], [protected], [inherited]

Clears all assignments, if any was found.

**0.15.99.3.28 clearPassedFormula()** void smtrat::Module::clearPassedFormula ( ) [protected], [inherited]

**0.15.99.3.29 collectOrigins() [1/2]** void smtrat::Module::collectOrigins (

```
const FormulaT & _formula,
FormulaSetT & _origins) const [inherited]
```

**0.15.99.3.30 collectOrigins() [2/2]** void smtrat::Module::collectOrigins (

```
const FormulaT & _formula,
FormulasT & _origins) const [inherited]
```

Collects the formulas in the given formula, which are part of the received formula.

If the given formula directly occurs in the received formula, it is inserted into the given set. Otherwise, the given formula must be of type AND and all its sub-formulas part of the received formula. Hence, they will be added to the given set.

#### Parameters

|                       |                                                                                                      |
|-----------------------|------------------------------------------------------------------------------------------------------|
| <code>_formula</code> | The formula from which to collect the formulas being sub-formulas of the received formula (origins). |
| <code>_origins</code> | The set in which to store the origins.                                                               |

**0.15.99.3.31 collectTheoryPropagations()** void smtrat::Module::collectTheoryPropagations ( )

[inherited]

**0.15.99.3.32 constraintsToInform()** const carl::FastSet<`FormulaT`>& smtrat::Module::constraintsToInform ( ) const [inline], [inherited]

#### Returns

The constraints which the backends must be informed about.

```
0.15.99.3.33 currentlySatisfied() virtual unsigned smtrat::Module::currentlySatisfied (
 const FormulaT &) const [inline], [virtual], [inherited]
```

**Returns**

0, if the given formula is conflicted by the current model; 1, if the given formula is satisfied by the current model; 2, otherwise; 3, if we do not know anything (default)

Reimplemented in [smtrat::LRAModule< Settings >](#), [smtrat::LRAModule< LRASettingsICP >](#), and [smtrat::LRAModule< LRASettings >](#)

```
0.15.99.3.34 currentlySatisfiedByBackend() unsigned smtrat::Module::currentlySatisfiedByBackend (
 const FormulaT & _formula) const [inherited]
```

**Returns**

0, if the given formula is conflicted by the current model; 1, if the given formula is satisfied by the current model; 2, otherwise 3, if we do not know anything (default)

```
0.15.99.3.35 deinform() void smtrat::Module::deinform (
 const FormulaT & _constraint) [inherited]
```

The inverse of informing about a constraint.

All data structures which were kept regarding this constraint are going to be removed. Note, that this makes only sense if it is not likely enough that a formula with this constraint must be solved again.

**Parameters**

|                          |                                                         |
|--------------------------|---------------------------------------------------------|
| <code>_constraint</code> | The constraint to remove from internal data structures. |
|--------------------------|---------------------------------------------------------|

```
0.15.99.3.36 deinformCore() virtual void smtrat::Module::deinformCore (
 const FormulaT & _constraint) [inline], [protected], [virtual], [inherited]
```

The inverse of informing about a constraint.

All data structures which were kept regarding this constraint are going to be removed. Note, that this makes only sense if it is not likely enough that a formula with this constraint must be solved again.

**Parameters**

|                          |                                                         |
|--------------------------|---------------------------------------------------------|
| <code>_constraint</code> | The constraint to remove from internal data structures. |
|--------------------------|---------------------------------------------------------|

Reimplemented in [smtrat::LRAModule< Settings >](#), [smtrat::LRAModule< LRASettingsICP >](#), and [smtrat::LRAModule< LRASettings >](#)

```
0.15.99.3.37 determine_smallest_origin() size_t smtrat::Module::determine_smallest_origin (
 const std::vector< FormulaT > & origins) const [protected], [inherited]
```

**Parameters**

|                      |                              |
|----------------------|------------------------------|
| <code>origins</code> | A vector of sets of origins. |
|----------------------|------------------------------|

**Returns**

The index of the smallest (regarding the size of the sets) element of origins

---

**0.15.99.3.38 eraseSubformulaFromPassedFormula()** `ModuleInput::iterator smtrat::Module::eraseSubformulaFromPassedFormula (`

`ModuleInput::iterator _subformula,`

`bool _ignoreOrigins = false ) [protected], [virtual], [inherited]`

Removes everything related to the sub-formula to remove from the passed formula in the backends of this module. Afterwards the sub-formula is removed from the passed formula.

#### Parameters

|                             |                                                                                                              |
|-----------------------------|--------------------------------------------------------------------------------------------------------------|
| <code>_subformula</code>    | The sub-formula to remove from the passed formula.                                                           |
| <code>_ignoreOrigins</code> | True, if the sub-formula shall be removed regardless of its origins (should only be applied with expertise). |

#### Returns

Reimplemented in `smtrat::ICPModule< Settings >`, `smtrat::ICPModule< ICPSettings4 >`, and `smtrat::ICPModule< ICPSettings1 >`.

**0.15.99.3.39 excludeNotReceivedVariablesFromModel()** `void smtrat::Module::excludeNotReceivedVariablesFromModel ( ) const [inherited]`

Excludes all variables from the current model, which do not occur in the received formula.

**0.15.99.3.40 findBestOrigin()** `std::vector< FormulaT >::const_iterator smtrat::Module::findBestOrigin (`

`const std::vector< FormulaT > & _origins ) const [protected], [inherited]`

#### Parameters

|                       |  |
|-----------------------|--|
| <code>_origins</code> |  |
|-----------------------|--|

#### Returns

**0.15.99.3.41 firstSubformulaToPass()** `ModuleInput::const_iterator smtrat::Module::firstSubformulaToPass ( ) const [inline], [inherited]`

#### Returns

The position of the first sub-formula in the passed formula, which has not yet been considered for a consistency check of the backends.

**0.15.99.3.42 firstUncheckedReceivedSubformula()** `ModuleInput::const_iterator smtrat::Module::firstUncheckedReceivedSubformula ( ) const [inline], [inherited]`

#### Returns

The position of the first (by this module) unchecked sub-formula of the received formula.

**0.15.99.3.43 freeSplittingVariable()** `static void smtrat::Module::freeSplittingVariable (`

`const FormulaT & _splittingVariable ) [inline], [static], [inherited]`

**0.15.99.3.44 generateTrivialInfeasibleSubset()** void smtrat::Module::generateTrivialInfeasibleSubset ( ) [inline], [protected], [inherited]  
 Stores the trivial infeasible subset being the set of received formulas.

**0.15.99.3.45 getBackendsAllModels()** void smtrat::Module::getBackendsAllModels ( ) const [protected], [inherited]  
 Stores all models of a backend in the list of all models of this module.

**0.15.99.3.46 getBackendsModel()** void smtrat::Module::getBackendsModel ( ) const [protected], [inherited]

**0.15.99.3.47 getInfeasibleSubsets() [1/2]** void smtrat::Module::getInfeasibleSubsets ( ) [protected], [inherited]  
 Copies the infeasible subsets of the passed formula.

**0.15.99.3.48 getInfeasibleSubsets() [2/2]** std::vector< [FormulaSetT](#) > smtrat::Module::getInfeasibleSubsets ( ) const [protected], [inherited]

Get the infeasible subsets the given backend provides.

Note, that an infeasible subset in a backend contains sub formulas of the passed formula and an infeasible subset of this module contains sub formulas of the received formula. In this method the LATTER is returned.

#### Parameters

|                       |                                                          |
|-----------------------|----------------------------------------------------------|
| <code>_backend</code> | The backend from which to obtain the infeasible subsets. |
|-----------------------|----------------------------------------------------------|

#### Returns

The infeasible subsets the given backend provides.

**0.15.99.3.49 getInformationRelevantFormulas()** const std::set< [FormulaT](#) > & smtrat::Module::getInformationRelevantFormulas ( ) [protected], [inherited]  
 Gets all InformationRelevantFormulas.

#### Returns

Set of all formulas

**0.15.99.3.50 getModelEqualities()** std::list< std::vector< [carl::Variable](#) > > smtrat::Module::getModelEqualities ( ) const [virtual], [inherited]  
 Partition the variables from the current model into equivalence classes according to their assigned value.  
 The result is a set of equivalence classes of variables where all variables within one class are assigned the same value. Note that the number of classes may not be minimal, i.e. two classes may actually be equivalent.

#### Returns

Equivalence classes.

**0.15.99.3.51 getOrigins() [1/3]** void smtrat::Module::getOrigins ( ) const [inline], [protected], [inherited]

**Parameters**

|                       |  |
|-----------------------|--|
| <code>_formula</code> |  |
| <code>_origins</code> |  |

**0.15.99.3.52 `getOrigins()` [2/3]** `void smtrat::Module::getOrigins (`  
    `const FormulaT & _formula,`  
    `FormulasT & _origins ) const [inline], [protected], [inherited]`

**Parameters**

|                       |  |
|-----------------------|--|
| <code>_formula</code> |  |
| <code>_origins</code> |  |

**0.15.99.3.53 `getOrigins()` [3/3]** `const FormulaT& smtrat::Module::getOrigins (`  
    `ModuleInput::const_iterator _formula ) const [inline], [protected], [inherited]`  
Gets the origins of the passed formula at the given position.

**Parameters**

|                       |                                                   |
|-----------------------|---------------------------------------------------|
| <code>_formula</code> | The position of a formula in the passed formulas. |
|-----------------------|---------------------------------------------------|

**Returns**

The origins of the passed formula at the given position.

**0.15.99.3.54 `getReceivedFormulaSimplified()`** `std::pair< bool, FormulaT > smtrat::PModule::getReceivedFormulaSimplified ( ) [virtual], [inherited]`

**Returns**

A pair of a Boolean and a formula, where the Boolean is true, if the received formula could be simplified to an equisatisfiable formula. The formula is equisatisfiable to this module's received formula, if the Boolean is true.

Reimplemented from [smtrat::Module](#).

**0.15.99.3.55 `hasLemmas()`** `bool smtrat::Module::hasLemmas ( ) [inline], [inherited]`  
Checks whether this module or any of its backends provides any lemmas.

**0.15.99.3.56 `hasValidInfeasibleSubset()`** `bool smtrat::Module::hasValidInfeasibleSubset ( ) const [inherited]`

**Returns**

true, if the module has at least one valid infeasible subset, that is all its elements are sub-formulas of the received formula (pointer must be equal).

**0.15.99.3.57 id()** std::size\_t smrat::Module::id ( ) const [inline], [inherited]

#### Returns

A unique ID to identify this module instance.

**0.15.99.3.58 infeasibleSubsets()** const std::vector<FormulaSetT>& smrat::Module::infeasibleSubsets ( ) const [inline], [inherited]

#### Returns

The infeasible subsets of the set of received formulas (empty, if this module has not detected unsatisfiability of the conjunction of received formulas).

**0.15.99.3.59 inform()** bool smrat::Module::inform ( const FormulaT & \_constraint ) [inherited]

Informs the module about the given constraint.

It should be tried to inform this module about any constraint it could receive eventually before assertSubformula is called (preferably for the first time, but at least before adding a formula containing that constraint).

#### Parameters

|             |                                 |
|-------------|---------------------------------|
| _constraint | The constraint to inform about. |
|-------------|---------------------------------|

#### Returns

false, if it can be easily decided whether the given constraint is inconsistent; true, otherwise.

**0.15.99.3.60 informBackends()** void smrat::Module::informBackends ( const FormulaT & \_constraint ) [inline], [protected], [inherited]

Informs all backends of this module about the given constraint.

#### Parameters

|             |                                 |
|-------------|---------------------------------|
| _constraint | The constraint to inform about. |
|-------------|---------------------------------|

**0.15.99.3.61 informCore()** virtual bool smrat::Module::informCore ( const FormulaT & \_constraint ) [inline], [protected], [virtual], [inherited]

Informs the module about the given constraint.

It should be tried to inform this module about any constraint it could receive eventually before assertSubformula is called (preferably for the first time, but at least before adding a formula containing that constraint).

#### Parameters

|             |                                 |
|-------------|---------------------------------|
| _constraint | The constraint to inform about. |
|-------------|---------------------------------|

#### Returns

false, if it can be easily decided whether the given constraint is inconsistent; true, otherwise.

Reimplemented in [smrat::UnionFindModule< Settings >](#), [smrat::PBPPModule< Settings >](#), [smrat::PBGaussModule< Settings >](#), [smrat::NRAILModule< Settings >](#), [smrat::NewCoveringModule< Settings >](#), [smrat::NewCADModule< Settings >](#),

`smrat::LRAModule< Settings >, smrat::LRAModule< LRASettingsICP >, smrat::LRAModule< LRASettings1 >, smrat::IntBlastModule< Settings >, smrat::FPPModule< Settings >, smrat::EQModule< Settings >, smrat::CurryModule< Settings >, smrat::BVMModule< Settings >, smrat::ICPModule< Settings >, smrat::ICPModule< ICPSettings4 >, and smrat::ICPModule< ICPSettings1 >.`

**0.15.99.3.62 informedConstraints()** `const carl::FastSet<FormulaT>& smrat::Module::informedConstraints ( ) const [inline], [inherited]`

**Returns**

The position of the first constraint of which no backend has been informed about.

**0.15.99.3.63 init()** `void smrat::Module::init ( ) [virtual], [inherited]`

Informs all backends about the so far encountered constraints, which have not yet been communicated.

This method must not be called twice and only before the first runBackends call.

Reimplemented in `smrat::PBPPModule< Settings >, smrat::PBGaussModule< Settings >, smrat::NRAILModule< Settings >, smrat::NewCoveringModule< Settings >, smrat::NewCADModule< Settings >, smrat::LRAModule< Settings >, smrat::LRAModule< LRASettingsICP >, smrat::LRAModule< LRASettings1 >, smrat::IntBlastModule< Settings >, smrat::FPPModule< Settings >, smrat::EQModule< Settings >, smrat::CurryModule< Settings >, and smrat::BVMModule< Settings >.`

**0.15.99.3.64 is\_minimizing()** `bool smrat::Module::is_minimizing ( ) const [inline], [inherited]`

**0.15.99.3.65 isLemmaLevel()** `bool smrat::Module::isLemmaLevel ( LemmaLevel level ) [protected], [inherited]`

Checks if current lemma level is greater or equal to given level.

**Parameters**

|                    |                 |
|--------------------|-----------------|
| <code>level</code> | Level to check. |
|--------------------|-----------------|

**0.15.99.3.66 isPreprocessor()** `bool smrat::PModule::isPreprocessor ( ) const [inline], [inherited]`

**Returns**

true, if this module is a preprocessor that is a module, which simplifies its received formula to an equisatisfiable formula being passed to its backends. The simplified formula can be obtained with `getReceivedFormulaSimplified()`.

**0.15.99.3.67 lemmas()** `const std::vector<Lemma>& smrat::Module::lemmas ( ) const [inline], [inherited]`

**Returns**

A constant reference to the lemmas being valid formulas this module or its backends made.

**0.15.99.3.68 merge()** `std::vector< FormulaT > smrat::Module::merge ( const std::vector< FormulaT > & _vecSetA, const std::vector< FormulaT > & _vecSetB ) const [protected], [inherited]`

Merges the two vectors of sets into the first one.

({a,b},{a,c}) and ({b,d},{b}) -> ({a,b,d},{a,b},{a,b,c,d},{a,b,c})

**Parameters**

|                       |                                  |
|-----------------------|----------------------------------|
| <code>_vecSetA</code> | A vector of sets of constraints. |
| <code>_vecSetB</code> | A vector of sets of constraints. |

**Returns**

The vector being the two given vectors merged.

**0.15.99.3.69 `model()`** `const Model& smtrat::Module::model() const [inline], [inherited]`**Returns**

The assignment of the current satisfiable result, if existent.

**0.15.99.3.70 `modelsDisjoint()`** `bool smtrat::Module::modelsDisjoint()`

```
const Model & _modelA,
const Model & _modelB) [static], [protected], [inherited]
```

Checks whether there is no variable assigned by both models.

**Parameters**

|                      |                                |
|----------------------|--------------------------------|
| <code>_modelA</code> | The first model to check for.  |
| <code>_modelB</code> | The second model to check for. |

**Returns**

true, if there is no variable assigned by both models; false, otherwise.

**0.15.99.3.71 `moduleName()`** `virtual std::string smtrat::Module::moduleName() const [inline], [virtual], [inherited]`**Returns**

The name of the given module type as name.

Reimplemented in [smtrat::VSModule< Settings >](#), [smtrat::UnionFindModule< Settings >](#), [smtrat::UFCegarModule< Settings >](#), [smtrat::STropModule< Settings >](#), [smtrat::SplitSOSModule< Settings >](#), [smtrat::PBPPModule< Settings >](#), [smtrat::PBGaussModule< Settings >](#), [smtrat::NRAILModule< Settings >](#), [smtrat::NewCADModule< Settings >](#), [smtrat::LVEModule< Settings >](#), [smtrat::LRAModule< Settings >](#), [smtrat::LRAModule< LRASettingsICP >](#), [smtrat::LRAModule< LRASettings1 >](#), [smtrat::IntEqModule< Settings >](#), [smtrat::IntBlastModule< Settings >](#), [smtrat::IncWidthModule< Settings >](#), [smtrat::ICPModule< Settings >](#), [smtrat::ICPModule< ICPSettings4 >](#), [smtrat::ICPModule< ICPSettings1 >](#), [smtrat::GBModule< Settings >](#), [smtrat::FouMoModule< Settings >](#), [smtrat::EQPreprocessingModule< Settings >](#), [smtrat::EQModule< Settings >](#), [smtrat::CurryModule< Settings >](#), [smtrat::CubeLIAModule< Settings >](#), [smtrat::CSplitModule< Settings >](#), [smtrat::BVMModule< Settings >](#), and [smtrat::BEModule< Settings >](#).

**0.15.99.3.72 `objective()`** `carl::Variable smtrat::Module::objective() const [inline], [inherited]`**0.15.99.3.73 `originInReceivedFormula()`** `bool smtrat::Module::originInReceivedFormula( const FormulaT & _origin ) const [protected], [inherited]`

**0.15.99.3.74 passedFormulaBegin()** `ModuleInput::iterator smtrat::Module::passedFormulaBegin ( )`  
[inline], [protected], [inherited]

**Returns**

An iterator to the end of the passed formula. TODO: disable this method

**0.15.99.3.75 passedFormulaEnd()** `ModuleInput::iterator smtrat::Module::passedFormulaEnd ( )`  
[inline], [protected], [inherited]

**Returns**

An iterator to the end of the passed formula.

**0.15.99.3.76 pPassedFormula()** `const ModuleInput* smtrat::Module::pPassedFormula ( ) const`  
[inline], [inherited]

**Returns**

A pointer to the formula passed to the backends of this module.

**0.15.99.3.77 pReceivedFormula()** `const ModuleInput* smtrat::Module::pReceivedFormula ( ) const`  
[inline], [inherited]

**Returns**

A pointer to the formula passed to this module.

**0.15.99.3.78 print()** `void smtrat::Module::print (`  
`const std::string & _initiation = "***" ) const` [inherited]

Prints everything relevant of the solver.

**Parameters**

|                          |                      |
|--------------------------|----------------------|
| <code>_initiation</code> | The line initiation. |
|--------------------------|----------------------|

**0.15.99.3.79 printAllModels()** `void smtrat::Module::printAllModels (`  
`std::ostream & _out = std::cout )` [inherited]

Prints all assignments of this module satisfying its received formula if it satisfiable and this module could find an assignment.

**Parameters**

|                   |                                        |
|-------------------|----------------------------------------|
| <code>_out</code> | The stream to print the assignment on. |
|-------------------|----------------------------------------|

**0.15.99.3.80 printInfeasibleSubsets()** `void smtrat::Module::printInfeasibleSubsets (`  
`const std::string & _initiation = "***" ) const` [inherited]

Prints the infeasible subsets.

**Parameters**

|                    |                      |
|--------------------|----------------------|
| <i>_initiation</i> | The line initiation. |
|--------------------|----------------------|

**0.15.99.3.81 `printModel()`** void smtrat::Module::printModel ( std::ostream & *\_out* = std::cout ) const [inherited]

Prints the assignment of this module satisfying its received formula if it satisfiable and this module could find an assignment.

**Parameters**

|             |                                        |
|-------------|----------------------------------------|
| <i>_out</i> | The stream to print the assignment on. |
|-------------|----------------------------------------|

**0.15.99.3.82 `printPassedFormula()`** void smtrat::Module::printPassedFormula ( const std::string & *\_initiation* = "\*\*\*" ) const [inherited]

Prints the vector of passed formula.

**Parameters**

|                    |                      |
|--------------------|----------------------|
| <i>_initiation</i> | The line initiation. |
|--------------------|----------------------|

**0.15.99.3.83 `printReceivedFormula()`** void smtrat::Module::printReceivedFormula ( const std::string & *\_initiation* = "\*\*\*" ) const [inherited]

Prints the vector of the received formula.

**Parameters**

|                    |                      |
|--------------------|----------------------|
| <i>_initiation</i> | The line initiation. |
|--------------------|----------------------|

**0.15.99.3.84 `probablyLooping()`** bool smtrat::Module::probablyLooping ( const typename Poly::PolyType & *\_branchingPolynomial*, const Rational & *\_branchingValue* ) const [protected], [inherited]

Checks whether given the current branching value and branching variable/polynomial it is (highly) probable that this branching is part of an infinite loop of branchings.

**Parameters**

|                             |                                                                                     |
|-----------------------------|-------------------------------------------------------------------------------------|
| <i>_branchingPolynomial</i> | The polynomial to branch at (in most branching strategies this is just a variable). |
| <i>_branchingValue</i>      | The value to branch at.                                                             |

**Returns**

true, if this branching is probably part of an infinite loop of branchings; false, otherwise.

**0.15.99.3.85 `receivedFormulaChecked()`** void smtrat::Module::receivedFormulaChecked ( ) [inline], [inherited]

Notifies that the received formulas has been checked.

**0.15.99.3.86 `receivedFormulasAsInfeasibleSubset()`** void smrat::Module::receivedFormulasAsInfeasibleSubset (

```
 ModuleInput::const_iterator _subformula) [inline], [protected], [inherited]
```

Stores an infeasible subset consisting only of the given received formula.

**0.15.99.3.87 `receivedVariable()`** bool smrat::Module::receivedVariable (

```
 carl::Variable::Arg _var) const [inline], [inherited]
```

**0.15.99.3.88 `remove()`** void smrat::PModule::remove (

```
 ModuleInput::const_iterator _subformula) [virtual], [inherited]
```

Removes everything related to the given sub-formula of the received formula.

However, it is desired not to lose track of search spaces where no satisfying assignment can be found for the remaining sub-formulas.

#### Parameters

|                          |                                                    |
|--------------------------|----------------------------------------------------|
| <code>_subformula</code> | The sub formula of the received formula to remove. |
|--------------------------|----------------------------------------------------|

Reimplemented from [smrat::Module](#).

**0.15.99.3.89 `removeCore()`** virtual void smrat::Module::removeCore (

```
 ModuleInput::const_iterator formula) [inline], [protected], [virtual], [inherited]
```

Removes everything related to the given sub-formula of the received formula.

However, it is desired not to lose track of search spaces where no satisfying assignment can be found for the remaining sub-formulas.

#### Parameters

|                      |                                                    |
|----------------------|----------------------------------------------------|
| <code>formula</code> | The sub formula of the received formula to remove. |
|----------------------|----------------------------------------------------|

Reimplemented in [smrat::VSModule< Settings >](#), [smrat::SATModule< Settings >](#), [smrat::PFEModule< Settings >](#), [smrat::ICPModule< Settings >](#), [smrat::ICPModule< ICPSettings4 >](#), [smrat::ICPModule< ICPSettings1 >](#), [smrat::UnionFindModule< Settings >](#), [smrat::UFCegarModule< Settings >](#), [smrat::STropModule< Settings >](#), [smrat::PBPPModule< Settings >](#), [smrat::PBGaussModule< Settings >](#), [smrat::NRAILModule< Settings >](#), [smrat::NewCoveringModule< Settings >](#), [smrat::NewCADModule< Settings >](#), [smrat::LRAModule< Settings >](#), [smrat::LRAModule< LRASettingsICP >](#), [smrat::LRAModule< LRASettings1 >](#), [smrat::IntEqModule< Settings >](#), [smrat::IntBlastModule< Settings >](#), [smrat::IncWidthModule< Settings >](#), [smrat::ICEModule< Settings >](#), [smrat::FPPModule< Settings >](#), [smrat::FouMoModule< Settings >](#), [smrat::EQModule< Settings >](#), [smrat::CurryModule< Settings >](#), [smrat::CubeLIAModule< Settings >](#), [smrat::CSplitModule< Settings >](#), [smrat::BVMModule< Settings >](#), and [smrat::GBModule< Settings >](#).

**0.15.99.3.90 `removeOrigin()`** std::pair<ModuleInput::iterator,bool> smrat::Module::removeOrigin (

```
 ModuleInput::iterator _formula,
 const FormulaT & _origin) [inline], [protected], [inherited]
```

**0.15.99.3.91 `removeOrigins()`** std::pair<ModuleInput::iterator,bool> smrat::Module::removeOrigins (

```
ModuleInput::iterator _formula,
const std::shared_ptr< std::vector< FormulaT >> & _origins) [inline], [protected],
[inherited]
```

**0.15.99.3.92 rPassedFormula()** const ModuleInput& smtrat::Module::rPassedFormula () const  
[inline], [inherited]

**Returns**

A reference to the formula passed to the backends of this module.

**0.15.99.3.93 rReceivedFormula()** const ModuleInput& smtrat::Module::rReceivedFormula () const  
[inline], [inherited]

**Returns**

A reference to the formula passed to this module.

**0.15.99.3.94 runBackends() [1/2]** virtual Answer smtrat::PModule::runBackends () [inline],  
[virtual], [inherited]

Reimplemented from [smtrat::Module](#).

**0.15.99.3.95 runBackends() [2/2]** Answer smtrat::PModule::runBackends (
 bool \_final,
 bool \_full,
 carl::Variable \_objective ) [virtual], [inherited]

Runs the backend solvers on the passed formula.

**Parameters**

|            |                                                                                                                                       |
|------------|---------------------------------------------------------------------------------------------------------------------------------------|
| _final     | true, if this satisfiability check will be the last one (for a global sat-check), if its result is SAT.                               |
| _full      | false, if this module should avoid too expensive procedures and rather return unknown instead.                                        |
| _objective | if not set to NO_VARIABLE, the module should find an assignment minimizing this objective variable; otherwise any assignment is good. |

**Returns**

True, if the passed formula is consistent; False, if the passed formula is inconsistent; Unknown, otherwise.

Reimplemented from [smtrat::Module](#).

**0.15.99.3.96 setId()** void smtrat::Module::setId (
 std::size\_t \_id ) [inline], [inherited]

Sets this modules unique ID to identify itself.

**Parameters**

|                     |                                    |
|---------------------|------------------------------------|
| ↔<br>↔<br><i>id</i> | The id to set this module's id to. |
|---------------------|------------------------------------|

**0.15.99.3.97 `setThreadPriority()`** `void smtrat::Module::setThreadPriority ( thread_priority _threadPriority ) [inline], [inherited]`  
Sets the priority of this module to get a thread for running its check procedure.

Parameters

|                              |                                                       |
|------------------------------|-------------------------------------------------------|
| <code>_threadPriority</code> | The priority to set this module's thread priority to. |
|------------------------------|-------------------------------------------------------|

**0.15.99.3.98 `solverState()`** `Answer smtrat::Module::solverState () const [inline], [inherited]`

Returns

True, if this module is in a state, such that it has found a solution for its received formula; False, if this module is in a state, such that it has determined that there is no solution for its received formula; Unknown, otherwise.

**0.15.99.3.99 `splitUnequalConstraint()`** `void smtrat::Module::splitUnequalConstraint ( const FormulaT & _unequalConstraint ) [protected], [inherited]`

Adds the following lemmas for the given constraint  $p \neq 0$ .

$(p \neq 0 \leftrightarrow (p < 0 \text{ or } p > 0))$

and  $\neg(p < 0 \text{ and } p > 0)$

Parameters

|                                 |                                                  |
|---------------------------------|--------------------------------------------------|
| <code>_unequalConstraint</code> | A constraint having the relation symbol $\neq$ . |
|---------------------------------|--------------------------------------------------|

**0.15.99.3.100 `threadPriority()`** `thread_priority smtrat::Module::threadPriority () const [inline], [inherited]`

Returns

The priority of this module to get a thread for running its check procedure.

**0.15.99.3.101 `updateAllModels()`** `void smtrat::Module::updateAllModels () [virtual], [inherited]`

Updates all satisfying models, if the solver has detected the consistency of the received formula, beforehand.

Reimplemented in [smtrat::SATModule< Settings >](#).

**0.15.99.3.102 `updateLemmas()`** `void smtrat::Module::updateLemmas () [inherited]`

Stores all lemmas of any backend of this module in its own lemma vector.

**0.15.99.3.103 `updateModel()`** `void smtrat::PModule::updateModel () const [virtual], [inherited]`  
Updates the current assignment into the model.

Note, that this is a unique but possibly symbolic assignment maybe containing newly introduced variables.  
Reimplemented from [smtrat::Module](#).

**0.15.99.3.104 `usedBackends()`** `const std::vector<Module*>& smtrat::Module::usedBackends () const [inline], [inherited]`

**Returns**

The backends of this module which are currently used (conditions to use this module are fulfilled for the passed formula).

**0.15.99.4 Field Documentation**

**0.15.99.4.1 mAllBackends** `std::vector<Module*> smrat::Module::mAllBackends [protected], [inherited]`

The backends of this module which have been used.

**0.15.99.4.2 mAllModels** `std::vector<Model> smrat::Module::mAllModels [mutable], [protected], [inherited]`

Stores all satisfying assignments.

**0.15.99.4.3 mBackendsFoundAnswer** `std::atomic_bool* smrat::Module::mBackendsFoundAnswer [protected], [inherited]`

This flag is passed to any backend and if it determines an answer to a prior check call, this flag is fired.

**0.15.99.4.4 mConstraintsToInform** `carl::FastSet<FormulaT> smrat::Module::mConstraintsToInform [protected], [inherited]`

Stores the constraints which the backends must be informed about.

**0.15.99.4.5 mFinalCheck** `bool smrat::Module::mFinalCheck [protected], [inherited]`  
true, if the check procedure should perform a final check which especially means not to postpone splitting decisions

**0.15.99.4.6 mFirstPosInLastBranches** `std::size_t smrat::Module::mFirstPosInLastBranches = 0 [static], [inherited]`

The beginning of the cyclic buffer storing the last branches.

**0.15.99.4.7 mFirstSubformulaToPass** `ModuleInput::iterator smrat::Module::mFirstSubformulaToPass [protected], [inherited]`

Stores the position of the first sub-formula in the passed formula, which has not yet been considered for a consistency check of the backends.

**0.15.99.4.8 mFirstUncheckedReceivedSubformula** `ModuleInput::const_iterator smrat::Module::mFirstUncheckedReceivedSubformula [protected], [inherited]`

Stores the position of the first (by this module) unchecked sub-formula of the received formula.

**0.15.99.4.9 mFoundAnswer** `Conditionals smrat::Module::mFoundAnswer [protected], [inherited]`  
Vector of Booleans: If any of them is true, we have to terminate a running check procedure.

**0.15.99.4.10 mFullCheck** `bool smrat::Module::mFullCheck [protected], [inherited]`  
false, if this module should avoid too expensive procedures and rather return unknown instead.

**0.15.99.4.11 mInfeasibleSubsets** std::vector<[FormulaSetT](#)> smtrat::Module::mInfeasibleSubsets  
[protected], [inherited]  
Stores the infeasible subsets.

**0.15.99.4.12 mInformedConstraints** carl::FastSet<[FormulaT](#)> smtrat::Module::mInformedConstraints  
[protected], [inherited]  
Stores the position of the first constraint of which no backend has been informed about.

**0.15.99.4.13 mLastBranches** std::vector< [Branching](#) > smtrat::Module::mLastBranches = std::vector<[Branching](#)> (mNumOfBranchVarsToStore, Branching(typename Poly::PolyType(), 0)) [static],  
[inherited]  
Stores the last branches in a cycle buffer.

**0.15.99.4.14 mLemmas** std::vector<[Lemma](#)> smtrat::Module::mLemmas [protected], [inherited]  
Stores the lemmas being valid formulas this module or its backends made.

**0.15.99.4.15 mModel** [Model](#) smtrat::Module::mModel [mutable], [protected], [inherited]  
Stores the assignment of the current satisfiable result, if existent.

**0.15.99.4.16 mModelComputed** bool smtrat::Module::mModelComputed [mutable], [protected],  
[inherited]  
True, if the model has already been computed.

**0.15.99.4.17 mNumOfBranchVarsToStore** std::size\_t smtrat::Module::mNumOfBranchVarsToStore = 5  
[static], [inherited]  
The number of different variables to consider for a probable infinite loop of branchings.

**0.15.99.4.18 mObjectiveVariable** carl::Variable smtrat::Module::mObjectiveVariable [protected],  
[inherited]  
Objective variable to be minimized. If set to NO\_VARIABLE, a normal sat check should be performed.

**0.15.99.4.19 mOldSplittingVariables** std::vector< [FormulaT](#) > smtrat::Module::mOldSplittingVariables [static], [inherited]  
Reusable splitting variables.

**0.15.99.4.20 mpManager** [Manager](#)\* const smtrat::Module::mpManager [protected], [inherited]  
A reference to the manager.

**0.15.99.4.21 mSmallerMusesCheckCounter** unsigned smtrat::Module::mSmallerMusesCheckCounter [mutable], [protected], [inherited]  
Counter used for the generation of the smt2 files to check for smaller muses.

**0.15.99.4.22 mSolverState** std::atomic<[Answer](#)> smtrat::Module::mSolverState [protected], [inherited]  
States whether the received formula is known to be satisfiable or unsatisfiable otherwise it is set to unknown.

---

**0.15.99.4.23 mTheoryPropagations** std::vector<TheoryPropagation> smtrat::Module::mTheory←  
Propagations [protected], [inherited]

**0.15.99.4.24 mUsedBackends** std::vector<Module\*> smtrat::Module::mUsedBackends [protected], [inherited]

The backends of this module which are currently used (conditions to use this module are fulfilled for the passed formula).

**0.15.99.4.25 mVariableCounters** std::vector<std::size\_t> smtrat::Module::mVariableCounters [protected], [inherited]

Maps variables to the number of their occurrences.

## 0.15.100 smtrat::CoCoAGBModule< Settings > Class Template Reference

*Stores the assignment of the current satisfiable result, if existent.*
- std::vector< `Model` > `mAllModels`  
*Stores all satisfying assignments.*
- bool `mModelComputed`  
*True, if the model has already been computed.*
- bool `mFinalCheck`  
*true, if the check procedure should perform a final check which especially means not to postpone splitting decisions*
- bool `mFullCheck`  
*false, if this module should avoid too expensive procedures and rather return unknown instead.*
- carl::Variable `mObjectiveVariable`  
*Objective variable to be minimized. If set to NO\_VARIABLE, a normal sat check should be performed.*
- std::vector< `TheoryPropagation` > `mTheoryPropagations`
- std::atomic< `Answer` > `mSolverState`  
*States whether the received formula is known to be satisfiable or unsatisfiable otherwise it is set to unknown.*
- std::atomic\_bool \* `mBackendsFoundAnswer`  
*This flag is passed to any backend and if it determines an answer to a prior check call, this flag is fired.*
- Conditionals `mFoundAnswer`  
*Vector of Booleans: If any of them is true, we have to terminate a running check procedure.*
- std::vector< `Module` \* > `mUsedBackends`  
*The backends of this module which are currently used (conditions to use this module are fulfilled for the passed formula).*
- std::vector< `Module` \* > `mAllBackends`  
*The backends of this module which have been used.*
- std::vector< `Lemma` > `mLemmas`  
*Stores the lemmas being valid formulas this module or its backends made.*
- `ModuleInput`::iterator `mFirstSubformulaToPass`  
*Stores the position of the first sub-formula in the passed formula, which has not yet been considered for a consistency check of the backends.*
- carl::FastSet< `FormulaT` > `mConstraintsToInform`  
*Stores the constraints which the backends must be informed about.*

- `carl::FastSet< FormulaT > mInformedConstraints`  
*Stores the position of the first constraint of which no backend has been informed about.*
- `ModuleInput::const_iterator mFirstUncheckedReceivedSubformula`  
*Stores the position of the first (by this module) unchecked sub-formula of the received formula.*
- `unsigned mSmallerMusesCheckCounter`  
*Counter used for the generation of the smt2 files to check for smaller muses.*
- `std::vector< std::size_t > mVariableCounters`  
*Maps variables to the number of their occurrences.*

### 0.15.100.1 Member Enumeration Documentation

#### 0.15.100.1.1 LemmaType `enum smtrat::Module::LemmaType : unsigned [strong], [inherited]`

Enumerator

|           |  |
|-----------|--|
| NORMAL    |  |
| PERMANENT |  |

### 0.15.100.2 Member Function Documentation

#### 0.15.100.2.1 add() `bool smtrat::Module::add ( ModuleInput::const_iterator _subformula ) [inherited]`

The module has to take the given sub-formula of the received formula into account.

Parameters

|                          |                                                    |
|--------------------------|----------------------------------------------------|
| <code>_subformula</code> | The sub-formula to take additionally into account. |
|--------------------------|----------------------------------------------------|

Returns

false, if it can be easily decided that this sub-formula causes a conflict with the already considered sub-formulas; true, otherwise.

#### 0.15.100.2.2 addConstraintToInform() `void smtrat::Module::addConstraintToInform ( const FormulaT & _constraint ) [protected], [virtual], [inherited]`

Adds a constraint to the collection of constraints of this module, which are informed to a freshly generated backend.

Parameters

|                          |                        |
|--------------------------|------------------------|
| <code>_constraint</code> | The constraint to add. |
|--------------------------|------------------------|

Reimplemented in `smtrat::SATModule< Settings >`.

#### 0.15.100.2.3 addCore() `virtual bool smtrat::Module::addCore ( ModuleInput::const_iterator formula ) [inline], [protected], [virtual], [inherited]`

The module has to take the given sub-formula of the received formula into account.

**Parameters**

|                |                                                    |
|----------------|----------------------------------------------------|
| <i>formula</i> | The sub-formula to take additionally into account. |
|----------------|----------------------------------------------------|

**Returns**

false, if it can be easily decided that this sub-formula causes a conflict with the already considered sub-formulas; true, otherwise.

Reimplemented in [smrat::VSModule< Settings >](#), [smrat::SATModule< Settings >](#), [smrat::PFEModule< Settings >](#), [smrat::ICPModule< Settings >](#), [smrat::ICPModule< ICPSettings4 >](#), [smrat::ICPModule< ICPSettings1 >](#), [smrat::UnionFindModule< Settings >](#), [smrat::UFCegarModule< Settings >](#), [smrat::STropModule< Settings >](#), [smrat::PBPPModule< Settings >](#), [smrat::PBGaussModule< Settings >](#), [smrat::NRAILModule< Settings >](#), [smrat::NewCoveringModule< Settings >](#), [smrat::NewCADModule< Settings >](#), [smrat::LRAModule< Settings >](#), [smrat::LRAModule< LRASettingsICP >](#), [smrat::LRAModule< LRASettings1 >](#), [smrat::IntEqModule< Settings >](#), [smrat::IntBlastModule< Settings >](#), [smrat::IncWidthModule< Settings >](#), [smrat::ICEModule< Settings >](#), [smrat::FPPModule< Settings >](#), [smrat::FouMoModule< Settings >](#), [smrat::EQModule< Settings >](#), [smrat::CurryModule< Settings >](#), [smrat::CubeLIAModule< Settings >](#), [smrat::CSplitModule< Settings >](#), [smrat::BVMModule< Settings >](#), and [smrat::GBModule< Settings >](#).

**0.15.100.2.4 addInformationRelevantFormula()** void smrat::Module::addInformationRelevantFormula (  
 const *FormulaT* & *formula*) [protected], [inherited]

Adds a formula to the InformationRelevantFormula.

**Parameters**

|                |                |
|----------------|----------------|
| <i>formula</i> | Formula to add |
|----------------|----------------|

**0.15.100.2.5 addLemma()** void smrat::Module::addLemma (  
 const *FormulaT* & *\_lemma*,  
 const *LemmaType* & *\_lt* = *LemmaType::NORMAL*,  
 const *FormulaT* & *\_preferredFormula* = *FormulaT( carl::FormulaType::TRUE )*) [inline],  
[inherited]

Stores a lemma being a valid formula.

**Parameters**

|                          |                                                                       |
|--------------------------|-----------------------------------------------------------------------|
| <i>_lemma</i>            | The eduction/lemma to store.                                          |
| <i>_lt</i>               | The type of the lemma.                                                |
| <i>_preferredFormula</i> | Hint for the next decision, which formula should be assigned to true. |

**0.15.100.2.6 addOrigin()** void smrat::Module::addOrigin (  
*ModuleInput::iterator* *\_formula*,  
 const *FormulaT* & *\_origin*) [inline], [protected], [inherited]

Adds the given set of formulas in the received formula to the origins of the given passed formula.

**Parameters**

|                 |                                                           |
|-----------------|-----------------------------------------------------------|
| <i>_formula</i> | The passed formula to set the origins for.                |
| <i>_origin</i>  | A set of formulas in the received formula of this module. |

```
0.15.100.2.7 addReceivedSubformulaToPassedFormula() std::pair<ModuleInput::iterator,bool>
smrat::Module::addReceivedSubformulaToPassedFormula (
 ModuleInput::const_iterator _subformula) [inline], [protected], [inherited]
```

Copies the given sub-formula of the received formula to the passed formula.

Note, that there is always a link between sub-formulas of the passed formulas to sub-formulas of the received formulas, which are responsible for its occurrence.

#### Parameters

|                          |                                                  |
|--------------------------|--------------------------------------------------|
| <code>_subformula</code> | The sub-formula of the received formula to copy. |
|--------------------------|--------------------------------------------------|

```
0.15.100.2.8 addSubformulaToPassedFormula() [1/3] std::pair<ModuleInput::iterator,bool> smrat<-
::Module::addSubformulaToPassedFormula (
 const FormulaT & _formula) [inline], [protected], [inherited]
```

Adds the given formula to the passed formula with no origin.

Note that in the next call of this module's removeSubformula, all formulas in the passed formula without origins will be removed.

#### Parameters

|                       |                                           |
|-----------------------|-------------------------------------------|
| <code>_formula</code> | The formula to add to the passed formula. |
|-----------------------|-------------------------------------------|

#### Returns

A pair to the position where the formula to add has been inserted (or its first sub-formula which has not yet been in the passed formula, in case the formula to add is a conjunction), and a Boolean stating whether anything has been added to the passed formula.

```
0.15.100.2.9 addSubformulaToPassedFormula() [2/3] std::pair<ModuleInput::iterator,bool> smrat<-
::Module::addSubformulaToPassedFormula (
 const FormulaT & _formula,
 const FormulaT & _origin) [inline], [protected], [inherited]
```

Adds the given formula to the passed formula.

#### Parameters

|                       |                                                                                                                           |
|-----------------------|---------------------------------------------------------------------------------------------------------------------------|
| <code>_formula</code> | The formula to add to the passed formula.                                                                                 |
| <code>_origin</code>  | The sub-formula of the received formula being responsible for the occurrence of the formula to add to the passed formula. |

#### Returns

A pair to the position where the formula to add has been inserted (or its first sub-formula which has not yet been in the passed formula, in case the formula to add is a conjunction), and a Boolean stating whether anything has been added to the passed formula.

```
0.15.100.2.10 addSubformulaToPassedFormula() [3/3] std::pair<ModuleInput::iterator,bool>
smrat::Module::addSubformulaToPassedFormula (
 const FormulaT & _formula,
```

```
const std::shared_ptr< std::vector< FormulaT >> & _origins) [inline], [protected],
[inherited]
Adds the given formula to the passed formula.
```

**Parameters**

|                       |                                                                                                                                         |
|-----------------------|-----------------------------------------------------------------------------------------------------------------------------------------|
| <code>_formula</code> | The formula to add to the passed formula.                                                                                               |
| <code>_origins</code> | The link of the formula to add to the passed formula to sub-formulas of the received formulas, which are responsible for its occurrence |

**Returns**

A pair to the position where the formula to add has been inserted (or its first sub-formula which has not yet been in the passed formula, in case the formula to add is a conjunction), and a Boolean stating whether anything has been added to the passed formula.

**0.15.100.2.11 `allModels()`** const std::vector<[Model](#)>& smtrat::Module::allModels () const [inline], [inherited]

**Returns**

All satisfying assignments, if existent.

**0.15.100.2.12 `anAnswerFound()`** bool smtrat::Module::anAnswerFound () const [inline], [protected], [inherited]

Checks for all antecedent modules and those which run in parallel with the same antecedent modules, whether one of them has determined a result.

**Returns**

True, if one of them has determined a result.

**0.15.100.2.13 `answerFound()`** const [smtrat::Conditionals](#)& smtrat::Module::answerFound () const [inline], [inherited]

**Returns**

A vector of Booleans: If any of them is true, we have to terminate a running check procedure.

**0.15.100.2.14 `backendsModel()`** const [Model](#) & smtrat::Module::backendsModel () const [protected], [inherited]

Stores the model of a backend which determined satisfiability of the passed formula in the model of this module.

**0.15.100.2.15 `branchAt()` [1/4]** bool smtrat::Module::branchAt (

```
carl::Variable::Arg _var,
const Rational & _value,
bool _leftCaseWeak = true,
bool _preferLeftCase = true,
bool _useReceivedFormulaAsPremise = false,
const std::vector< FormulaT > & _premise = std::vector< FormulaT >()) [inline],
[protected], [inherited]
```

```
0.15.100.2.16 branchAt() [2/4] bool smtrat::Module::branchAt (
 carl::Variable::Arg _var,
 const Rational & _value,
 std::vector< FormulaT > && _premise,
 bool _leftCaseWeak = true,
 bool _preferLeftCase = true,
 bool _useReceivedFormulaAsPremise = false) [inline], [protected], [inherited]
```

```
0.15.100.2.17 branchAt() [3/4] bool smtrat::Module::branchAt (
 const Poly & _polynomial,
 bool _integral,
 const Rational & _value,
 bool _leftCaseWeak = true,
 bool _preferLeftCase = true,
 bool _useReceivedFormulaAsPremise = false,
 const std::vector< FormulaT > & _premise = std::vector<FormulaT>()) [inline],
[protected], [inherited]
```

```
0.15.100.2.18 branchAt() [4/4] bool smtrat::Module::branchAt (
 const Poly & _polynomial,
 bool _integral,
 const Rational & _value,
 std::vector< FormulaT > && _premise,
 bool _leftCaseWeak = true,
 bool _preferLeftCase = true,
 bool _useReceivedFormulaAsPremise = false) [protected], [inherited]
```

Adds a lemmas which provoke a branching for the given variable at the given value, if this module returns Unknown and there exists a preceding [SATModule](#).

Note that the given value is rounded down and up, if the given variable is integer-valued.

#### Parameters

|                                           |                                                                                                                                                                                                                |
|-------------------------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>_polynomial</code>                  | The variable to branch for.                                                                                                                                                                                    |
| <code>_integral</code>                    | A flag being true, if all variables in the polynomial to branch for are integral.                                                                                                                              |
| <code>_value</code>                       | The value to branch at.                                                                                                                                                                                        |
| <code>_premise</code>                     | The sub-formulas of the received formula from which the branch is followed. Note, that a premise is not necessary, as every branch is a valid formula. But a premise can prevent from branching unnecessarily. |
| <code>_leftCaseWeak</code>                | true, if a branching in the form of (or ( $\leq p b$ ) ( $> p b$ )) is desired. false, if a branching in the form of (or ( $< p b$ ) ( $\geq p b$ )) is desired.                                               |
| <code>_preferLeftCase</code>              | true, if the left case (polynomial less(or equal) 0 shall be chosen first. false, otherwise.                                                                                                                   |
| <code>_useReceivedFormulaAsPremise</code> | true, if the whole received formula should be used as premise                                                                                                                                                  |

```
0.15.100.2.19 check() Answer smtrat::Module::check (
 bool _final = false,
 bool _full = true,
 carl::Variable _objective = carl::Variable::NO_VARIABLE) [virtual], [inherited]
```

Checks the received formula for consistency.

Note, that this is an implementation of the satisfiability check of the conjunction of the so far received formulas, which does actually nothing but passing the problem to its backends. This implementation is only used internally and must be overwritten by any derived module.

**Parameters**

|                         |                                                                                                                                       |
|-------------------------|---------------------------------------------------------------------------------------------------------------------------------------|
| <code>_final</code>     | true, if this satisfiability check will be the last one (for a global sat-check), if its result is SAT                                |
| <code>_full</code>      | false, if this module should avoid too expensive procedures and rather return unknown instead.                                        |
| <code>_objective</code> | if not set to NO_VARIABLE, the module should find an assignment minimizing this objective variable; otherwise any assignment is good. |

**Returns**

True, if the received formula is satisfiable; False, if the received formula is not satisfiable; Unknown, otherwise.

Reimplemented in [smrat::PModule](#).

### 0.15.100.2.20 `checkCore()` Answer [smrat::Module::checkCore](#) ( ) [protected], [virtual], [inherited]

Checks the received formula for consistency.

Note, that this is an implementation of the satisfiability check of the conjunction of the so far received formulas, which does actually nothing but passing the problem to its backends. This implementation is only used internally and must be overwritten by any derived module.

**Returns**

True, if the received formula is satisfiable; False, if the received formula is not satisfiable; Unknown, otherwise.

Reimplemented in [smrat::VSModule< Settings >](#), [smrat::UnionFindModule< Settings >](#), [smrat::UFCegarModule< Settings >](#), [smrat::SymmetryModule< Settings >](#), [smrat::STropModule< Settings >](#), [smrat::SplitSOSModule< Settings >](#), [smrat::SATModule< Settings >](#), [smrat::PFEModule< Settings >](#), [smrat::PBPPModule< Settings >](#), [smrat::PBGaussModule< Settings >](#), [smrat::NRAILModule< Settings >](#), [smrat::NewCoveringModule< Settings >](#), [smrat::NewCADModule< Settings >](#), [smrat::MCBModule< Settings >](#), [smrat::LVEModule< Settings >](#), [smrat::LRAModule< Settings >](#), [smrat::LRAModule< LRASettings1 >](#), [smrat::IntEqModule< Settings >](#), [smrat::IntBlastModule< Settings >](#), [smrat::IncWidthModule< Settings >](#), [smrat::ICPModule< Settings >](#), [smrat::ICPModule< ICPSettings4 >](#), [smrat::ICPModule< ICPSettings1 >](#), [smrat::ICEModule< Settings >](#), [smrat::GBPPModule< Settings >](#), [smrat::GBModule< Settings >](#), [smrat::FPPModule< Settings >](#), [smrat::FouMoModule< Settings >](#), [smrat::ESModule< Settings >](#), [smrat::EQPreprocessingModule< Settings >](#), [smrat::EQModule< Settings >](#), [smrat::EMModule< Settings >](#), [smrat::CurryModule< Settings >](#), [smrat::CubeLIAModule< Settings >](#), [smrat::CSplitModule< Settings >](#), [smrat::CNFerModule](#), [smrat::BVMModule< Settings >](#), and [smrat::BEModule< Settings >](#).

### 0.15.100.2.21 `checkInfeasibleSubsetForMinimality()` void [smrat::Module::checkInfeasibleSubsetForMinimality](#) ( `std::vector< FormulaSetT >::const_iterator _infssubset,` `const std::string & _filename = "smaller_muses",` `unsigned _maxSizeDifference = 1` ) const [inherited]

Checks the given infeasible subset for minimality by storing all subsets of it, which have a smaller size which differs from the size of the infeasible subset not more than the given threshold.

**Parameters**

|                                 |                                                                                                        |
|---------------------------------|--------------------------------------------------------------------------------------------------------|
| <code>_infssubset</code>        | The infeasible subset to check for minimality.                                                         |
| <code>_filename</code>          | The name of the file to store the infeasible subsets in order to be able to check their infeasibility. |
| <code>_maxSizeDifference</code> | The maximal difference between the sizes of the subsets compared to the size of the infeasible subset. |

### 0.15.100.2.22 `checkModel()` unsigned [smrat::Module::checkModel](#) ( ) const [protected], [inherited]

**Returns**

false, if the current model of this module does not satisfy the current given formula; true, if it cannot be said whether the model satisfies the given formula.

**0.15.100.2.23 cleanModel()** void smtrat::Module::cleanModel ( ) const [inline], [protected], [inherited]

Substitutes variable occurrences by its model value in the model values of other variables.

**0.15.100.2.24 clearLemmas()** void smtrat::Module::clearLemmas ( ) [inline], [inherited]

Deletes all yet found lemmas.

**0.15.100.2.25 clearModel()** void smtrat::Module::clearModel ( ) const [inline], [protected], [inherited]

Clears the assignment, if any was found.

**0.15.100.2.26 clearModels()** void smtrat::Module::clearModels ( ) const [inline], [protected], [inherited]

Clears all assignments, if any was found.

**0.15.100.2.27 clearPassedFormula()** void smtrat::Module::clearPassedFormula ( ) [protected], [inherited]

**0.15.100.2.28 collectOrigins() [1/2]** void smtrat::Module::collectOrigins ( const `FormulaT` & `_formula`, `FormulaSetT` & `_origins` ) const [inherited]

**0.15.100.2.29 collectOrigins() [2/2]** void smtrat::Module::collectOrigins ( const `FormulaT` & `_formula`, `FormulasT` & `_origins` ) const [inherited]

Collects the formulas in the given formula, which are part of the received formula.

If the given formula directly occurs in the received formula, it is inserted into the given set. Otherwise, the given formula must be of type AND and all its sub-formulas part of the received formula. Hence, they will be added to the given set.

**Parameters**

|                       |                                                                                                      |
|-----------------------|------------------------------------------------------------------------------------------------------|
| <code>_formula</code> | The formula from which to collect the formulas being sub-formulas of the received formula (origins). |
| <code>_origins</code> | The set in which to store the origins.                                                               |

**0.15.100.2.30 collectTheoryPropagations()** void smtrat::Module::collectTheoryPropagations ( ) [inherited]

**0.15.100.2.31 constraintsToInform()** const carl::FastSet<`FormulaT`>& smtrat::Module::constraintsToInform ( ) const [inline], [inherited]

**Returns**

The constraints which the backends must be informed about.

**0.15.100.2.32 currentlySatisfied()** `virtual unsigned smtrat::Module::currentlySatisfied ( const FormulaT & ) const [inline], [virtual], [inherited]`

**Returns**

0, if the given formula is conflicted by the current model; 1, if the given formula is satisfied by the current model; 2, otherwise; 3, if we do not know anything (default)

Reimplemented in [smtrat::LRAModule< Settings >](#), [smtrat::LRAModule< LRASettingsICP >](#), and [smtrat::LRAModule< LRASettings >](#)

**0.15.100.2.33 currentlySatisfiedByBackend()** `unsigned smtrat::Module::currentlySatisfiedByBackend ( const FormulaT & _formula ) const [inherited]`

**Returns**

0, if the given formula is conflicted by the current model; 1, if the given formula is satisfied by the current model; 2, otherwise 3, if we do not know anything (default)

**0.15.100.2.34 deinform()** `void smtrat::Module::deinform ( const FormulaT & _constraint ) [inherited]`

The inverse of informing about a constraint.

All data structures which were kept regarding this constraint are going to be removed. Note, that this makes only sense if it is not likely enough that a formula with this constraint must be solved again.

**Parameters**

|                          |                                                         |
|--------------------------|---------------------------------------------------------|
| <code>_constraint</code> | The constraint to remove from internal data structures. |
|--------------------------|---------------------------------------------------------|

**0.15.100.2.35 deinformCore()** `virtual void smtrat::Module::deinformCore ( const FormulaT & _constraint ) [inline], [protected], [virtual], [inherited]`

The inverse of informing about a constraint.

All data structures which were kept regarding this constraint are going to be removed. Note, that this makes only sense if it is not likely enough that a formula with this constraint must be solved again.

**Parameters**

|                          |                                                         |
|--------------------------|---------------------------------------------------------|
| <code>_constraint</code> | The constraint to remove from internal data structures. |
|--------------------------|---------------------------------------------------------|

Reimplemented in [smtrat::LRAModule< Settings >](#), [smtrat::LRAModule< LRASettingsICP >](#), and [smtrat::LRAModule< LRASettings >](#)

**0.15.100.2.36 determine\_smallest\_origin()** `size_t smtrat::Module::determine_smallest_origin ( const std::vector< FormulaT > & origins ) const [protected], [inherited]`

**Parameters**

|                      |                              |
|----------------------|------------------------------|
| <code>origins</code> | A vector of sets of origins. |
|----------------------|------------------------------|

**Returns**

The index of the smallest (regarding the size of the sets) element of origins

**0.15.100.2.37 `eraseSubformulaFromPassedFormula()`** `ModuleInput::iterator smtrat::Module::eraseSubformulaFromPassedFormula ( ModuleInput::iterator _subformula, bool _ignoreOrigins = false )` [protected], [virtual], [inherited]

Removes everything related to the sub-formula to remove from the passed formula in the backends of this module. Afterwards the sub-formula is removed from the passed formula.

**Parameters**

|                             |                                                                                                              |
|-----------------------------|--------------------------------------------------------------------------------------------------------------|
| <code>_subformula</code>    | The sub-formula to remove from the passed formula.                                                           |
| <code>_ignoreOrigins</code> | True, if the sub-formula shall be removed regardless of its origins (should only be applied with expertise). |

**Returns**

Reimplemented in `smtrat::ICPModule< Settings >`, `smtrat::ICPModule< ICPSettings4 >`, and `smtrat::ICPModule< ICPSettings1 >`.

**0.15.100.2.38 `excludeNotReceivedVariablesFromModel()`** `void smtrat::Module::excludeNotReceivedVariablesFromModel ( ) const` [inherited]

Excludes all variables from the current model, which do not occur in the received formula.

**0.15.100.2.39 `findBestOrigin()`** `std::vector< FormulaT >::const_iterator smtrat::Module::findBestOrigin ( const std::vector< FormulaT > & _origins ) const` [protected], [inherited]

**Parameters**

|                       |  |
|-----------------------|--|
| <code>_origins</code> |  |
|-----------------------|--|

**Returns**

**0.15.100.2.40 `firstSubformulaToPass()`** `ModuleInput::const_iterator smtrat::Module::firstSubformulaToPass ( ) const` [inline], [inherited]

**Returns**

The position of the first sub-formula in the passed formula, which has not yet been considered for a consistency check of the backends.

**0.15.100.2.41 `firstUncheckedReceivedSubformula()`** `ModuleInput::const_iterator smtrat::Module::firstUncheckedReceivedSubformula ( ) const` [inline], [inherited]

**Returns**

The position of the first (by this module) unchecked sub-formula of the received formula.

**0.15.100.2.42 freeSplittingVariable()** static void smtrat::Module::freeSplittingVariable ( const `FormulaT` & `_splittingVariable` ) [inline], [static], [inherited]

**0.15.100.2.43 generateTrivialInfeasibleSubset()** void smtrat::Module::generateTrivialInfeasibleSubset ( ) [inline], [protected], [inherited]  
Stores the trivial infeasible subset being the set of received formulas.

**0.15.100.2.44 getBackendsAllModels()** void smtrat::Module::getBackendsAllModels ( ) const [protected], [inherited]  
Stores all models of a backend in the list of all models of this module.

**0.15.100.2.45 getBackendsModel()** void smtrat::Module::getBackendsModel ( ) const [protected], [inherited]

**0.15.100.2.46 getInfeasibleSubsets() [1/2]** void smtrat::Module::getInfeasibleSubsets ( ) [protected], [inherited]  
Copies the infeasible subsets of the passed formula.

**0.15.100.2.47 getInfeasibleSubsets() [2/2]** std::vector< `FormulaSetT` > smtrat::Module::getInfeasibleSubsets ( const `Module` & `_backend` ) const [protected], [inherited]

Get the infeasible subsets the given backend provides.  
Note, that an infeasible subset in a backend contains sub formulas of the passed formula and an infeasible subset of this module contains sub formulas of the received formula. In this method the LATTER is returned.

#### Parameters

|                       |                                                          |
|-----------------------|----------------------------------------------------------|
| <code>_backend</code> | The backend from which to obtain the infeasible subsets. |
|-----------------------|----------------------------------------------------------|

#### Returns

The infeasible subsets the given backend provides.

**0.15.100.2.48 getInformationRelevantFormulas()** const std::set< `FormulaT` > & smtrat::Module::getInformationRelevantFormulas ( ) [protected], [inherited]  
Gets all InformationRelevantFormulas.

#### Returns

Set of all formulas

**0.15.100.2.49 getModelEqualities()** std::list< std::vector< carl::Variable > > smtrat::Module::getModelEqualities ( ) const [virtual], [inherited]

Partition the variables from the current model into equivalence classes according to their assigned value.  
The result is a set of equivalence classes of variables where all variables within one class are assigned the same value. Note that the number of classes may not be minimal, i.e. two classes may actually be equivalent.

#### Returns

Equivalence classes.

**0.15.100.2.50 getOrigins() [1/3]** void smtrat::Module::getOrigins ( const FormulaT & \_formula, FormulaSetT & \_origins ) const [inline], [protected], [inherited]

#### Parameters

|          |  |
|----------|--|
| _formula |  |
| _origins |  |

**0.15.100.2.51 getOrigins() [2/3]** void smtrat::Module::getOrigins ( const FormulaT & \_formula, FormulasT & \_origins ) const [inline], [protected], [inherited]

#### Parameters

|          |  |
|----------|--|
| _formula |  |
| _origins |  |

**0.15.100.2.52 getOrigins() [3/3]** const FormulaT& smtrat::Module::getOrigins ( ModuleInput::const\_iterator \_formula ) const [inline], [protected], [inherited]

Gets the origins of the passed formula at the given position.

#### Parameters

|          |                                                   |
|----------|---------------------------------------------------|
| _formula | The position of a formula in the passed formulas. |
|----------|---------------------------------------------------|

#### Returns

The origins of the passed formula at the given position.

**0.15.100.2.53 getReceivedFormulaSimplified()** std::pair< bool, FormulaT > smtrat::Module::getReceivedFormulaSimplified ( ) [virtual], [inherited]

#### Returns

A pair of a Boolean and a formula, where the Boolean is true, if the received formula could be simplified to an equisatisfiable formula. The formula is equisatisfiable to this module's received formula, if the Boolean is true.

Reimplemented in [smtrat::PModule](#).

**0.15.100.2.54 hasLemmas()** bool smtrat::Module::hasLemmas ( ) [inline], [inherited]

Checks whether this module or any of its backends provides any lemmas.

**0.15.100.2.55 hasValidInfeasibleSubset()** bool smtrat::Module::hasValidInfeasibleSubset ( ) const [inherited]

#### Returns

true, if the module has at least one valid infeasible subset, that is all its elements are sub-formulas of the received formula (pointer must be equal).

**0.15.100.2.56 `id()`** `std::size_t smtrat::Module::id ( ) const [inline], [inherited]`

**Returns**

A unique ID to identify this module instance.

**0.15.100.2.57 `infeasibleSubsets()`** `const std::vector<FormulaSetT>& smtrat::Module::infeasibleSubsets ( ) const [inline], [inherited]`

**Returns**

The infeasible subsets of the set of received formulas (empty, if this module has not detected unsatisfiability of the conjunction of received formulas).

**0.15.100.2.58 `inform()`** `bool smtrat::Module::inform ( const FormulaT & _constraint ) [inherited]`

Informs the module about the given constraint.

It should be tried to inform this module about any constraint it could receive eventually before assertSubformula is called (preferably for the first time, but at least before adding a formula containing that constraint).

**Parameters**

|                          |                                 |
|--------------------------|---------------------------------|
| <code>_constraint</code> | The constraint to inform about. |
|--------------------------|---------------------------------|

**Returns**

false, if it can be easily decided whether the given constraint is inconsistent; true, otherwise.

**0.15.100.2.59 `informBackends()`** `void smtrat::Module::informBackends ( const FormulaT & _constraint ) [inline], [protected], [inherited]`

Informs all backends of this module about the given constraint.

**Parameters**

|                          |                                 |
|--------------------------|---------------------------------|
| <code>_constraint</code> | The constraint to inform about. |
|--------------------------|---------------------------------|

**0.15.100.2.60 `informCore()`** `virtual bool smtrat::Module::informCore ( const FormulaT & _constraint ) [inline], [protected], [virtual], [inherited]`

Informs the module about the given constraint.

It should be tried to inform this module about any constraint it could receive eventually before assertSubformula is called (preferably for the first time, but at least before adding a formula containing that constraint).

**Parameters**

|                          |                                 |
|--------------------------|---------------------------------|
| <code>_constraint</code> | The constraint to inform about. |
|--------------------------|---------------------------------|

**Returns**

false, if it can be easily decided whether the given constraint is inconsistent; true, otherwise.

Reimplemented in [smtrat::UnionFindModule< Settings >](#), [smtrat::PBPPModule< Settings >](#), [smtrat::PBGaussModule< Settings >](#), [smtrat::NRAILModule< Settings >](#), [smtrat::NewCoveringModule< Settings >](#), [smtrat::NewCADModule< Settings >](#),

`smrat::LRAModule< Settings >, smrat::LRAModule< LRASettingsICP >, smrat::LRAModule< LRASettings1 >, smrat::IntBlastModule< Settings >, smrat::FPPModule< Settings >, smrat::EQModule< Settings >, smrat::CurryModule< Settings >, smrat::BVMModule< Settings >, smrat::ICPModule< Settings >, smrat::ICPModule< ICPSettings4 >, and smrat::ICPModule< ICPSettings1 >.`

**0.15.100.2.61 informedConstraints()** `const carl::FastSet<FormulaT>& smrat::Module::informedConstraints( ) const [inline], [inherited]`

#### Returns

The position of the first constraint of which no backend has been informed about.

**0.15.100.2.62 init()** `void smrat::Module::init( ) [virtual], [inherited]`

Informs all backends about the so far encountered constraints, which have not yet been communicated.

This method must not be called twice and only before the first runBackends call.

Reimplemented in `smrat::PBPPModule< Settings >, smrat::PBGaussModule< Settings >, smrat::NRAILModule< Settings >, smrat::NewCoveringModule< Settings >, smrat::NewCADModule< Settings >, smrat::LRAModule< Settings >, smrat::LRAModule< LRASettingsICP >, smrat::LRAModule< LRASettings1 >, smrat::IntBlastModule< Settings >, smrat::FPPModule< Settings >, smrat::EQModule< Settings >, smrat::CurryModule< Settings >, and smrat::BVMModule< Settings >.`

**0.15.100.2.63 is\_minimizing()** `bool smrat::Module::is_minimizing( ) const [inline], [inherited]`

**0.15.100.2.64 isLemmaLevel()** `bool smrat::Module::isLemmaLevel( LemmaLevel level ) [protected], [inherited]`

Checks if current lemma level is greater or equal to given level.

#### Parameters

|                    |                 |
|--------------------|-----------------|
| <code>level</code> | Level to check. |
|--------------------|-----------------|

**0.15.100.2.65 isPreprocessor()** `bool smrat::Module::isPreprocessor( ) const [inline], [inherited]`

#### Returns

true, if this module is a preprocessor that is a module, which simplifies its received formula to an equisatisfiable formula being passed to its backends. The simplified formula can be obtained with `getReceivedFormulaSimplified()`.

**0.15.100.2.66 lemmas()** `const std::vector<Lemma>& smrat::Module::lemmas( ) const [inline], [inherited]`

#### Returns

A constant reference to the lemmas being valid formulas this module or its backends made.

**0.15.100.2.67 merge()** `std::vector< FormulaT > smrat::Module::merge( const std::vector< FormulaT > & _vecSetA, const std::vector< FormulaT > & _vecSetB ) const [protected], [inherited]`

Merges the two vectors of sets into the first one.

({a,b},{a,c}) and ({b,d},{b}) -> ({a,b,d},{a,b},{a,b,c,d},{a,b,c})

**Parameters**

|                       |                                  |
|-----------------------|----------------------------------|
| <code>_vecSetA</code> | A vector of sets of constraints. |
| <code>_vecSetB</code> | A vector of sets of constraints. |

**Returns**

The vector being the two given vectors merged.

**0.15.100.2.68 `model()`** `const Model& smtrat::Module::model () const [inline], [inherited]`**Returns**

The assignment of the current satisfiable result, if existent.

**0.15.100.2.69 `modelsDisjoint()`** `bool smtrat::Module::modelsDisjoint (const Model & _modelA, const Model & _modelB ) [static], [protected], [inherited]`

Checks whether there is no variable assigned by both models.

**Parameters**

|                      |                                |
|----------------------|--------------------------------|
| <code>_modelA</code> | The first model to check for.  |
| <code>_modelB</code> | The second model to check for. |

**Returns**

true, if there is no variable assigned by both models; false, otherwise.

**0.15.100.2.70 `moduleName()`** `virtual std::string smtrat::Module::moduleName () const [inline], [virtual], [inherited]`**Returns**

The name of the given module type as name.

Reimplemented in [smtrat::VSModule< Settings >](#), [smtrat::UnionFindModule< Settings >](#), [smtrat::UFCegarModule< Settings >](#), [smtrat::STropModule< Settings >](#), [smtrat::SplitSOSModule< Settings >](#), [smtrat::PBPPModule< Settings >](#), [smtrat::PBGaussModule< Settings >](#), [smtrat::NRAILModule< Settings >](#), [smtrat::NewCADModule< Settings >](#), [smtrat::LVEModule< Settings >](#), [smtrat::LRAModule< Settings >](#), [smtrat::LRAModule< LRASettingsICP >](#), [smtrat::LRAModule< LRASettings1 >](#), [smtrat::IntEqModule< Settings >](#), [smtrat::IntBlastModule< Settings >](#), [smtrat::IncWidthModule< Settings >](#), [smtrat::ICPModule< Settings >](#), [smtrat::ICPModule< ICPSettings4 >](#), [smtrat::ICPModule< ICPSettings1 >](#), [smtrat::GBModule< Settings >](#), [smtrat::FouMoModule< Settings >](#), [smtrat::EQPreprocessingModule< Settings >](#), [smtrat::EQModule< Settings >](#), [smtrat::CurryModule< Settings >](#), [smtrat::CubeLIAModule< Settings >](#), [smtrat::CSplitModule< Settings >](#), [smtrat::BVMModule< Settings >](#), and [smtrat::BEModule< Settings >](#).

**0.15.100.2.71 `objective()`** `carl::Variable smtrat::Module::objective () const [inline], [inherited]`**0.15.100.2.72 `originInReceivedFormula()`** `bool smtrat::Module::originInReceivedFormula (const FormulaT & _origin ) const [protected], [inherited]`

**0.15.100.2.73 passedFormulaBegin()** `ModuleInput::iterator smrat::Module::passedFormulaBegin ( )` [inline], [protected], [inherited]

**Returns**

An iterator to the end of the passed formula. TODO: disable this method

**0.15.100.2.74 passedFormulaEnd()** `ModuleInput::iterator smrat::Module::passedFormulaEnd ( )` [inline], [protected], [inherited]

**Returns**

An iterator to the end of the passed formula.

**0.15.100.2.75 pPassedFormula()** `const ModuleInput* smrat::Module::pPassedFormula ( ) const` [inline], [inherited]

**Returns**

A pointer to the formula passed to the backends of this module.

**0.15.100.2.76 pReceivedFormula()** `const ModuleInput* smrat::Module::pReceivedFormula ( ) const` [inline], [inherited]

**Returns**

A pointer to the formula passed to this module.

**0.15.100.2.77 print()** `void smrat::Module::print ( const std::string & _initiation = "***" ) const` [inherited]

Prints everything relevant of the solver.

**Parameters**

|                          |                      |
|--------------------------|----------------------|
| <code>_initiation</code> | The line initiation. |
|--------------------------|----------------------|

**0.15.100.2.78 printAllModels()** `void smrat::Module::printAllModels ( std::ostream & _out = std::cout )` [inherited]

Prints all assignments of this module satisfying its received formula if it satisfiable and this module could find an assignment.

**Parameters**

|                   |                                        |
|-------------------|----------------------------------------|
| <code>_out</code> | The stream to print the assignment on. |
|-------------------|----------------------------------------|

**0.15.100.2.79 printInfeasibleSubsets()** `void smrat::Module::printInfeasibleSubsets ( const std::string & _initiation = "***" ) const` [inherited]

Prints the infeasible subsets.

## Parameters

|                          |                      |
|--------------------------|----------------------|
| <code>_initiation</code> | The line initiation. |
|--------------------------|----------------------|

**0.15.100.2.80 `printModel()`** `void smtrat::Module::printModel ( std::ostream & _out = std::cout ) const [inherited]`

Prints the assignment of this module satisfying its received formula if it satisfiable and this module could find an assignment.

## Parameters

|                   |                                        |
|-------------------|----------------------------------------|
| <code>_out</code> | The stream to print the assignment on. |
|-------------------|----------------------------------------|

**0.15.100.2.81 `printPassedFormula()`** `void smtrat::Module::printPassedFormula ( const std::string & _initiation = "***" ) const [inherited]`

Prints the vector of passed formula.

## Parameters

|                          |                      |
|--------------------------|----------------------|
| <code>_initiation</code> | The line initiation. |
|--------------------------|----------------------|

**0.15.100.2.82 `printReceivedFormula()`** `void smtrat::Module::printReceivedFormula ( const std::string & _initiation = "***" ) const [inherited]`

Prints the vector of the received formula.

## Parameters

|                          |                      |
|--------------------------|----------------------|
| <code>_initiation</code> | The line initiation. |
|--------------------------|----------------------|

**0.15.100.2.83 `probablyLooping()`** `bool smtrat::Module::probablyLooping ( const typename Poly::PolyType & _branchingPolynomial, const Rational & _branchingValue ) const [protected], [inherited]`

Checks whether given the current branching value and branching variable/polynomial it is (highly) probable that this branching is part of an infinite loop of branchings.

## Parameters

|                                   |                                                                                     |
|-----------------------------------|-------------------------------------------------------------------------------------|
| <code>_branchingPolynomial</code> | The polynomial to branch at (in most branching strategies this is just a variable). |
| <code>_branchingValue</code>      | The value to branch at.                                                             |

## Returns

true, if this branching is probably part of an infinite loop of branchings; false, otherwise.

**0.15.100.2.84 `receivedFormulaChecked()`** `void smtrat::Module::receivedFormulaChecked ( ) [inline], [inherited]`

Notifies that the received formulas has been checked.

**0.15.100.2.85 `receivedFormulasAsInfeasibleSubset()`** void smtrat::Module::receivedFormulasAsInfeasibleSubset (

```
 ModuleInput::const_iterator _subformula) [inline], [protected], [inherited]
```

Stores an infeasible subset consisting only of the given received formula.

**0.15.100.2.86 `receivedVariable()`** bool smtrat::Module::receivedVariable (

```
 carl::Variable::Arg _var) const [inline], [inherited]
```

**0.15.100.2.87 `remove()`** void smtrat::Module::remove (

```
 ModuleInput::const_iterator _subformula) [virtual], [inherited]
```

Removes everything related to the given sub-formula of the received formula.

However, it is desired not to lose track of search spaces where no satisfying assignment can be found for the remaining sub-formulas.

#### Parameters

|                          |                                                    |
|--------------------------|----------------------------------------------------|
| <code>_subformula</code> | The sub formula of the received formula to remove. |
|--------------------------|----------------------------------------------------|

Reimplemented in [smtrat::PModule](#).

**0.15.100.2.88 `removeCore()`** virtual void smtrat::Module::removeCore (

```
 ModuleInput::const_iterator formula) [inline], [protected], [virtual], [inherited]
```

Removes everything related to the given sub-formula of the received formula.

However, it is desired not to lose track of search spaces where no satisfying assignment can be found for the remaining sub-formulas.

#### Parameters

|                      |                                                    |
|----------------------|----------------------------------------------------|
| <code>formula</code> | The sub formula of the received formula to remove. |
|----------------------|----------------------------------------------------|

Reimplemented in [smtrat::VSModule< Settings >](#), [smtrat::SATModule< Settings >](#), [smtrat::PFEModule< Settings >](#), [smtrat::ICPModule< Settings >](#), [smtrat::ICPModule< ICPSettings4 >](#), [smtrat::ICPModule< ICPSettings1 >](#), [smtrat::UnionFindModule< Settings >](#), [smtrat::UFCegarModule< Settings >](#), [smtrat::STropModule< Settings >](#), [smtrat::PBPPModule< Settings >](#), [smtrat::PBGaussModule< Settings >](#), [smtrat::NRAILModule< Settings >](#), [smtrat::NewCoveringModule< Settings >](#), [smtrat::NewCADModule< Settings >](#), [smtrat::LRAModule< Settings >](#), [smtrat::LRAModule< LRASettingsICP >](#), [smtrat::LRAModule< LRASettings1 >](#), [smtrat::IntEqModule< Settings >](#), [smtrat::IntBlastModule< Settings >](#), [smtrat::IncWidthModule< Settings >](#), [smtrat::ICEModule< Settings >](#), [smtrat::FPPModule< Settings >](#), [smtrat::FouMoModule< Settings >](#), [smtrat::EQModule< Settings >](#), [smtrat::CurryModule< Settings >](#), [smtrat::CubeLIAModule< Settings >](#), [smtrat::CSplitModule< Settings >](#), [smtrat::BVMModule< Settings >](#), and [smtrat::GBModule< Settings >](#).

**0.15.100.2.89 `removeOrigin()`** std::pair<ModuleInput::iterator, bool> smtrat::Module::removeOrigin (

```
 ModuleInput::iterator _formula,
 const FormulaT & _origin) [inline], [protected], [inherited]
```

**0.15.100.2.90 `removeOrigins()`** std::pair<ModuleInput::iterator, bool> smtrat::Module::removeOrigins (

```
ModuleInput::iterator _formula,
const std::shared_ptr< std::vector< FormulaT >> & _origins) [inline], [protected],
[inherited]
```

#### 0.15.100.2.91 **rPassedFormula()** const ModuleInput& smtrat::Module::rPassedFormula () const [inline], [inherited]

**Returns**

A reference to the formula passed to the backends of this module.

#### 0.15.100.2.92 **rReceivedFormula()** const ModuleInput& smtrat::Module::rReceivedFormula () const [inline], [inherited]

**Returns**

A reference to the formula passed to this module.

#### 0.15.100.2.93 **runBackends()** [1/2] virtual Answer smtrat::Module::runBackends () [inline], [protected], [virtual], [inherited]

Reimplemented in [smtrat::PModule](#).

#### 0.15.100.2.94 **runBackends()** [2/2] Answer smtrat::Module::runBackends (

```
bool _final,
bool _full,
carl::Variable _objective) [protected], [virtual], [inherited]
```

Runs the backend solvers on the passed formula.

**Parameters**

|                         |                                                                                                                                       |
|-------------------------|---------------------------------------------------------------------------------------------------------------------------------------|
| <code>_final</code>     | true, if this satisfiability check will be the last one (for a global sat-check), if its result is SAT                                |
| <code>_full</code>      | false, if this module should avoid too expensive procedures and rather return unknown instead.                                        |
| <code>_objective</code> | if not set to NO_VARIABLE, the module should find an assignment minimizing this objective variable; otherwise any assignment is good. |

**Returns**

True, if the passed formula is consistent; False, if the passed formula is inconsistent; Unknown, otherwise.

Reimplemented in [smtrat::PModule](#).

#### 0.15.100.2.95 **setId()** void smtrat::Module::setId ( std::size\_t \_id ) [inline], [inherited]

Sets this modules unique ID to identify itself.

**Parameters**

|                             |                                    |
|-----------------------------|------------------------------------|
| $\leftrightarrow$<br>$\_id$ | The id to set this module's id to. |
|-----------------------------|------------------------------------|

**0.15.100.2.96 `setThreadPriority()`** `void smtrat::Module::setThreadPriority (`  
    `thread_priority _threadPriority )` [inline], [inherited]  
Sets the priority of this module to get a thread for running its check procedure.

Parameters

|                              |                                                       |
|------------------------------|-------------------------------------------------------|
| <code>_threadPriority</code> | The priority to set this module's thread priority to. |
|------------------------------|-------------------------------------------------------|

**0.15.100.2.97 `solverState()`** `Answer smtrat::Module::solverState ( ) const` [inline], [inherited]

Returns

True, if this module is in a state, such that it has found a solution for its received formula; False, if this module is in a state, such that it has determined that there is no solution for its received formula; Unknown, otherwise.

**0.15.100.2.98 `splitUnequalConstraint()`** `void smtrat::Module::splitUnequalConstraint (`  
    `const FormulaT & _unequalConstraint )` [protected], [inherited]

Adds the following lemmas for the given constraint  $p \neq 0$ .

$(p \neq 0 \Leftrightarrow (p < 0 \text{ or } p > 0))$

and  $\neg(p < 0 \text{ and } p > 0)$

Parameters

|                                 |                                                  |
|---------------------------------|--------------------------------------------------|
| <code>_unequalConstraint</code> | A constraint having the relation symbol $\neq$ . |
|---------------------------------|--------------------------------------------------|

**0.15.100.2.99 `threadPriority()`** `thread_priority smtrat::Module::threadPriority ( ) const` [inline], [inherited]

Returns

The priority of this module to get a thread for running its check procedure.

**0.15.100.2.100 `updateAllModels()`** `void smtrat::Module::updateAllModels ( )` [virtual], [inherited]

Updates all satisfying models, if the solver has detected the consistency of the received formula, beforehand.

Reimplemented in [smtrat::SATModule< Settings >](#).

**0.15.100.2.101 `updateLemmas()`** `void smtrat::Module::updateLemmas ( )` [inherited]

Stores all lemmas of any backend of this module in its own lemma vector.

**0.15.100.2.102 `updateModel()`** `void smtrat::Module::updateModel ( ) const` [virtual], [inherited]

Updates the model, if the solver has detected the consistency of the received formula, beforehand.

Reimplemented in [smtrat::PModule](#), [smtrat::VSModule< Settings >](#), [smtrat::UnionFindModule< Settings >](#), [smtrat::UFCegarModule< Settings >](#), [smtrat::STropModule< Settings >](#), [smtrat::SATModule< Settings >](#), [smtrat::PBPPModule< Settings >](#), [smtrat::PBGaussModule< Settings >](#), [smtrat::NRAILModule< Settings >](#), [smtrat::NewCoveringModule< Settings >](#), [smtrat::NewCADModule< Settings >](#), [smtrat::MCBModule< Settings >](#), [smtrat::LVEModule< Settings >](#), [smtrat::LRAModule< Settings >](#), [smtrat::LRAModule< LRASettingsICP >](#), [smtrat::LRAModule< LRASettings1 >](#), [smtrat::IntEqModule< Settings >](#), [smtrat::IntBlastModule< Settings >](#),

`smrat::IncWidthModule< Settings >, smrat::ICPModule< Settings >, smrat::ICPModule< ICPSettings4 >, smrat::ICPModule< ICPSettings1 >, smrat::GBPPModule< Settings >, smrat::FPPModule< Settings >, smrat::FouMoModule< Settings >, smrat::ESModule< Settings >, smrat::EQPreprocessingModule< Settings >, smrat::EQModule< Settings >, smrat::CurryModule< Settings >, smrat::CubeLIAModule< Settings >, smrat::CSplitModule< Settings >, and smrat::BVMModule< Settings >.`

**0.15.100.2.103 `usedBackends()`** `const std::vector<Module*>& smrat::Module::usedBackends( )`  
`const [inline], [inherited]`

#### Returns

The backends of this module which are currently used (conditions to use this module are fulfilled for the passed formula).

### 0.15.100.3 Field Documentation

**0.15.100.3.1 `mAllBackends`** `std::vector<Module*> smrat::Module::mAllBackends [protected], [inherited]`

The backends of this module which have been used.

**0.15.100.3.2 `mAllModels`** `std::vector<Model> smrat::Module::mAllModels [mutable], [protected], [inherited]`

Stores all satisfying assignments.

**0.15.100.3.3 `mBackendsFoundAnswer`** `std::atomic_bool* smrat::Module::mBackendsFoundAnswer [protected], [inherited]`

This flag is passed to any backend and if it determines an answer to a prior check call, this flag is fired.

**0.15.100.3.4 `mConstraintsToInform`** `carl::FastSet<FormulaT> smrat::Module::mConstraintsToInform [protected], [inherited]`

Stores the constraints which the backends must be informed about.

**0.15.100.3.5 `mFinalCheck`** `bool smrat::Module::mFinalCheck [protected], [inherited]`  
 true, if the check procedure should perform a final check which especially means not to postpone splitting decisions

**0.15.100.3.6 `mFirstPosInLastBranches`** `std::size_t smrat::Module::mFirstPosInLastBranches = 0 [static], [inherited]`

The beginning of the cyclic buffer storing the last branches.

**0.15.100.3.7 `mFirstSubformulaToPass`** `ModuleInput::iterator smrat::Module::mFirstSubformulaToPass [protected], [inherited]`

Stores the position of the first sub-formula in the passed formula, which has not yet been considered for a consistency check of the backends.

**0.15.100.3.8 `mFirstUncheckedReceivedSubformula`** `ModuleInput::const_iterator smrat::Module::mFirstUncheckedReceivedSubformula [protected], [inherited]`

Stores the position of the first (by this module) unchecked sub-formula of the received formula.

**0.15.100.3.9 mFoundAnswer** `Conditionals` `smtrat::Module::mFoundAnswer` [protected], [inherited]  
Vector of Booleans: If any of them is true, we have to terminate a running check procedure.

**0.15.100.3.10 mFullCheck** `bool` `smtrat::Module::mFullCheck` [protected], [inherited]  
false, if this module should avoid too expensive procedures and rather return unknown instead.

**0.15.100.3.11 mInfeasibleSubsets** `std::vector<FormulaSetT>` `smtrat::Module::mInfeasibleSubsets` [protected], [inherited]  
Stores the infeasible subsets.

**0.15.100.3.12 mInformedConstraints** `carl::FastSet<FormulaT>` `smtrat::Module::mInformedConstraints` [protected], [inherited]  
Stores the position of the first constraint of which no backend has been informed about.

**0.15.100.3.13 mLastBranches** `std::vector<Branching>` `smtrat::Module::mLastBranches` = `std::vector<Branching>(mNumOfBranchVarsToStore, Branching(typename Poly::PolyType(), 0))` [static], [inherited]  
Stores the last branches in a cycle buffer.

**0.15.100.3.14 mLemmas** `std::vector<Lemma>` `smtrat::Module::mLemmas` [protected], [inherited]  
Stores the lemmas being valid formulas this module or its backends made.

**0.15.100.3.15 mModel** `Model` `smtrat::Module::mModel` [mutable], [protected], [inherited]  
Stores the assignment of the current satisfiable result, if existent.

**0.15.100.3.16 mModelComputed** `bool` `smtrat::Module::mModelComputed` [mutable], [protected], [inherited]  
True, if the model has already been computed.

**0.15.100.3.17 mNumOfBranchVarsToStore** `std::size_t` `smtrat::Module::mNumOfBranchVarsToStore` = 5 [static], [inherited]  
The number of different variables to consider for a probable infinite loop of branchings.

**0.15.100.3.18 mObjectiveVariable** `carl::Variable` `smtrat::Module::mObjectiveVariable` [protected], [inherited]  
Objective variable to be minimized. If set to NO\_VARIABLE, a normal sat check should be performed.

**0.15.100.3.19 mOldSplittingVariables** `std::vector<FormulaT>` `smtrat::Module::mOldSplittingVariables` [static], [inherited]  
Reusable splitting variables.

**0.15.100.3.20 mpManager** `Manager*` `const smtrat::Module::mpManager` [protected], [inherited]  
A reference to the manager.

**0.15.100.3.21 mSmallerMusesCheckCounter** `unsigned smtrat::Module::mSmallerMusesCheckCounter`  
 [mutable], [protected], [inherited]  
 Counter used for the generation of the smt2 files to check for smaller muses.

**0.15.100.3.22 mSolverState** `std::atomic<Answer> smtrat::Module::mSolverState` [protected],  
 [inherited]  
 States whether the received formula is known to be satisfiable or unsatisfiable otherwise it is set to unknown.

**0.15.100.3.23 mTheoryPropagations** `std::vector<TheoryPropagation> smtrat::Module::mTheory←Propagations` [protected], [inherited]

**0.15.100.3.24 mUsedBackends** `std::vector<Module*> smtrat::Module::mUsedBackends` [protected],  
 [inherited]  
 The backends of this module which are currently used (conditions to use this module are fulfilled for the passed formula).

**0.15.100.3.25 mVariableCounters** `std::vector<std::size_t> smtrat::Module::mVariableCounters`  
 [protected], [inherited]  
 Maps variables to the number of their occurrences.

## 0.15.101 smtrat::CollectBoolsInUEQs Struct Reference

```

```
 const Condition & _condition) const
```

Checks if the given condition (right hand side) is greater than this condition (left hand side).

**Parameters**

|                         |                                      |
|-------------------------|--------------------------------------|
| <code>_condition</code> | The condition to compare with (rhs). |
|-------------------------|--------------------------------------|

**Returns**

true ,if the given substitution is greater than this substitution; false ,otherwise.

**0.15.106.2.5 operator==()** bool smtrat::vs::Condition::operator== (

```
 const Condition & _condition) const
```

Checks the equality of a given condition (right hand side) with this condition (left hand side).

#### Parameters

|                         |                                      |
|-------------------------|--------------------------------------|
| <code>_condition</code> | The condition to compare with (rhs). |
|-------------------------|--------------------------------------|

#### Returns

`true`, if the given condition is equal to this condition; `false`, otherwise.

**0.15.106.2.6 `originalConditions()`** `const carl::PointerSet<Condition>& smtrat::vs::Condition::originalConditions ( ) const [inline]`

**0.15.106.2.7 `pOriginalConditions()`** `carl::PointerSet<Condition>* smtrat::vs::Condition::pOriginalConditions ( ) const [inline]`

**0.15.106.2.8 `print()`** `void smtrat::vs::Condition::print ( std::ostream & _out = std::cout ) const`

Prints the condition to an output stream.

#### Parameters

|                   |                                           |
|-------------------|-------------------------------------------|
| <code>_out</code> | The output stream, where it should print. |
|-------------------|-------------------------------------------|

**0.15.106.2.9 `recentlyAdded()`** `bool smtrat::vs::Condition::recentlyAdded ( ) const [inline]`

**0.15.106.2.10 `rFlag()`** `bool& smtrat::vs::Condition::rFlag ( ) const [inline]`

**0.15.106.2.11 `rRecentlyAdded()`** `bool& smtrat::vs::Condition::rRecentlyAdded ( ) const [inline]`

**0.15.106.2.12 `rValuation()`** `size_t& smtrat::vs::Condition::rValuation ( ) const [inline]`

**0.15.106.2.13 `valuate()`** `double smtrat::vs::Condition::valuate ( const carl::Variable & _consideredVariable, size_t _maxNumberOfVars, bool _preferEquation ) const`

Valuates the constraint according to a variable (it possibly not contains).

#### Parameters

|                                  |                                                     |
|----------------------------------|-----------------------------------------------------|
| <code>_consideredVariable</code> | The variable which is considered in this valuation. |
| <code>_maxNumberOfVars</code>    |                                                     |

**Returns**

A valuation of the constraint according to an heuristic.

**0.15.106.2.14 `valuation()`** `size_t smtrat::vs::Condition::valuation () const [inline]`**0.15.106.3 Friends And Related Function Documentation****0.15.106.3.1 `operator<<`** `std::ostream& operator<< ( std::ostream & _out, const Condition & _condition ) [friend]`**0.15.107 `benchmax::CondorBackend` Class Reference**

**0.15.107.1 Detailed Description**

[Backend](#) for the HTCondor batch system.

Currently submits all jobs individually and asynchronously waits for them to finish.

### 0.15.107.2 Member Function Documentation

**0.15.107.2.1 `addResult()`** void benchmax::Backend::addResult ( const `Tool` \* `tool`, const `fs::path` & `file`, `BenchmarkResult` && `result` ) [inline], [inherited]

Add a result.

**0.15.107.2.2 `collect_results()`** virtual bool benchmax::Backend::collect\_results ( const `Jobs` & , bool ) [inline], [protected], [virtual], [inherited]

**0.15.107.2.3 `execute()`** virtual void benchmax::CondorBackend::execute ( const `Tool` \* , const `fs::path` & ) [inline], [protected], [virtual]

No-op version of `execute`.

Reimplemented from `benchmax::Backend`.

**0.15.107.2.4 `finalize()`** virtual void benchmax::Backend::finalize ( ) [inline], [protected], [virtual], [inherited]

Hook to allow for asynchronous backends to wait for jobs to terminate.

**0.15.107.2.5 `madeProgress()`** void benchmax::Backend::madeProgress ( std::size\_t `files` = 1 ) [inline], [protected], [inherited]

Can be called to give information about the current progress, if available.

**0.15.107.2.6 `process_results()`** void benchmax::Backend::process\_results ( const `Jobs` & `jobs`, bool `check_finished` ) [inline], [inherited]

**0.15.107.2.7 `run()`** void benchmax::CondorBackend::run ( const `Jobs` & , bool ) [inline]

Run all tools on all benchmarks.

**0.15.107.2.8 `sanitize_results()`** void benchmax::Backend::sanitize\_results ( const `Jobs` & `jobs` ) const [inline], [protected], [inherited]

**0.15.107.2.9 `startTool()`** virtual void benchmax::Backend::startTool ( const `Tool` \* ) [inline], [protected], [virtual], [inherited]

Hook for every tool at the beginning.

Can be used to upload the tool to some remote system.

**0.15.107.2.10 `suspendable()`** bool benchmax::Backend::suspendable ( ) const [inline], [inherited]

```
0.15.107.2.11 write_results() void benchmax::Backend::write_results (
 const Jobs & jobs) const [inline], [protected], [inherited]
```

### 0.15.107.3 Field Documentation

**0.15.107.3.1 mExpectedJobs** std::size\_t benchmax::Backend::mExpectedJobs [protected], [inherited]  
Number of jobs that should be run.

**0.15.107.3.2 mFinishedJobs** std::atomic<std::size\_t> benchmax::Backend::mFinishedJobs [protected], [inherited]  
Number of jobs that are finished.

**0.15.107.3.3 mLastPercent** std::atomic<std::size\_t> benchmax::Backend::mLastPercent [protected], [inherited]  
Percentage of finished jobs when [madeProgress\(\)](#) was last called.

### 0.15.109.1 Detailed Description

Representation of a bipartite graph ( $C + S, E$ ) of vertices  $C$  and  $S$ , representing the constraints and samples, respectively.

A vertex from  $C$  and a vertex from  $S$  are connected by an edge in  $E$  iff the corresponding constraint conflicts with the corresponding sample point.

### 0.15.109.2 Constructor & Destructor Documentation

### 0.15.114 delta::Consumer Class Reference

This class takes care of asynchronous execution of calls to the solver.

```
#include <Consumer.h>
```

#### Public Member Functions

- `Consumer` (const std::string &tempPrefix, std::size\_t threads, const `Checker` &checker)  
*Constructor.*
- `~Consumer` ()  
*Destructor.*
- void `consume` (const `Node` &n, const std::string &message, std::size\_t num)  
*Initiate asynchronous check for the given node.*
- bool `wait` ()  
*Wait for at least one job to finish.*
- void `reset` ()  
*Reset this executor.*
- bool `hasResult` () const  
*Checks if at least one job was successful.*
- std::tuple< `Node`, std::string, std::size\_t > `getResult` ()  
*Returns the result, assuming that one exists.*
- std::pair< unsigned, unsigned > `getProgress` () const  
*Returns the current progress.*

#### 0.15.114.1 Detailed Description

This class takes care of asynchronous execution of calls to the solver.

#### 0.15.114.2 Constructor & Destructor Documentation

**0.15.114.2.1 Consumer()** `delta::Consumer::Consumer (`  
`const std::string & tempPrefix,`  
`std::size_t threads,`  
`const Checker & checker ) [inline]`

Constructor.

##### Parameters

|                         |                             |
|-------------------------|-----------------------------|
| <code>tempPrefix</code> | Prefix for temporary files. |
|-------------------------|-----------------------------|

**0.15.114.2.2 ~Consumer()** `delta::Consumer::~Consumer ( ) [inline]`  
Destructor.

#### 0.15.114.3 Member Function Documentation

**0.15.114.3.1 consume()** `void delta::Consumer::consume (`  
`const Node & n,`  
`const std::string & message,`  
`std::size_t num ) [inline]`

Initiate asynchronous check for the given node.

**Parameters**

|                |                                       |
|----------------|---------------------------------------|
| <i>n</i>       | <a href="#">Node</a> to check.        |
| <i>message</i> | Message.                              |
| <i>num</i>     | Number of this node in the iteration. |

**0.15.114.3.2 `getProgress()`** `std::pair<unsigned, unsigned> delta::Consumer::getProgress ( ) const [inline]`  
Returns the current progress.

**Returns**

Pair of finished and total checks.

**0.15.114.3.3 `getResult()`** `std::tuple<Node, std::string, std::size_t> delta::Consumer::getResult ( ) const [inline]`  
Returns the result, assuming that one exists.

**Returns**

Result.

**0.15.114.3.4 `hasResult()`** `bool delta::Consumer::hasResult ( ) const [inline]`  
Checks if at least one job was successful.

**Returns**

If a result is there.

**0.15.114.3.5 `reset()`** `void delta::Consumer::reset ( ) [inline]`  
Reset this executor.  
Waits for all jobs to finish and resets the internal status.

**0.15.114.3.6 `wait()`** `bool delta::Consumer::wait ( ) [inline]`  
Wait for at least one job to finish.

**Returns**

If all jobs have finished.

## 0.15.115 `smrat::LRAModule< Settings >::Context Struct Reference`

Stores a formula, being part of the received formula of this module, and the position of this formula in the passed formula.

```
#include <LRAModule.h>
```

### Public Member Functions

- `Context (const FormulaT &_origin, ModuleInput::iterator _pos)`

## Data Fields

- `FormulaT origin`  
*The formula in the received formula.*
- `ModuleInput::iterator position`  
*The position of this formula in the passed formula.*

### 0.15.115.1 Detailed Description

```
template<class Settings>
struct smrat::LRAbstractModule< Settings >::Context
```

Stores a formula, being part of the received formula of this module, and the position of this formula in the passed formula.

TODO: Maybe it is enough to store a mapping of the formula to the position.

### 0.15.115.2 Constructor & Destructor Documentation

```
0.15.115.2.1 Context() template<class Settings >
smrat::LRAbstractModule< Settings >::Context::Context (
 const FormulaT & _origin,

Constructors.

**0.15.118.1.2 ~ContractionCandidateManager()** smrat::icp::ContractionCandidateManager::~ContractionCandidateManager ( ) [inline]

### 0.15.118.2 Member Function Documentation

**0.15.118.2.1 candidates()** const std::vector<[ContractionCandidate\\*](#)>& smtrat::icp::ContractionCandidateManager::candidates ( ) [inline]

**0.15.118.2.2 closure()** void smtrat::icp::ContractionCandidateManager::closure ( const [ContractionCandidate](#) \*const \_candidate, std::set< const [ContractionCandidate](#) \* > & \_candidates ) const

Calculates the closure of a certain candidate according to the variables contained.

#### Parameters

|                         |  |
|-------------------------|--|
| <code>_candidate</code> |  |
|-------------------------|--|

#### Returns

the set of candidates in the closure of `_candidate`

**0.15.118.2.3 createCandidate()** [ContractionCandidate](#) \* smtrat::icp::ContractionCandidateManager::createCandidate ( carl::Variable `_lhs`, const [Poly](#) `_rhs`, const [ConstraintT](#) & `_constraint`, carl::Variable `_derivationVar`, [Contractor](#)< carl::SimpleNewton > & `_contractor`, bool `_usePropagation` )

Constructor & Functions.

Creates a new candidate with an unique id.

#### Parameters

|                             |                                                                                        |
|-----------------------------|----------------------------------------------------------------------------------------|
| <code>_lhs</code>           | The slack/nonlinear variable which represents the constraint                           |
| <code>_constraint</code>    | The constraint which is to be replaced                                                 |
| <code>_derivationVar</code> | The variable from which the derivative is created when performing contraction          |
| <code>_origin</code>        | The pointer to the original formula, needed for assertions and removals of subformulas |

#### Returns

a pointer to the created contraction candidate

**0.15.118.2.4 getCandidate()** [ContractionCandidate](#) \* smtrat::icp::ContractionCandidateManager::getCandidate ( unsigned `_id` ) const

Returns the contraction candidate for the given id.

#### Parameters

|                  |  |
|------------------|--|
| <code>_id</code> |  |
|------------------|--|

**Returns**

the pointer to the contraction candidate

**0.15.118.2.5 `getId()`** `unsigned smtrat::icp::ContractionCandidateManager::getId (`  
`const ContractionCandidate *const _candidate ) const`

Returns the id of the given contraction candidate.

**Parameters**

|                         |  |
|-------------------------|--|
| <code>_candidate</code> |  |
|-------------------------|--|

**Returns**

id of the candidate

### Static Public Member Functions

- `static void addSimpleSorts (qi::symbols< char, carl::Sort > &sorts)`
- `static void addConstants (qi::symbols< char, types::ConstType > &constants)`

**Data Fields**

- `ParserState * state`

**0.15.125.1 Detailed Description**

Implements the core theory of the booleans.

**0.15.125.2 Member Typedef Documentation**

**0.15.125.2.1 OperatorType** `using smtrat::parser::CoreTheory::OperatorType = boost::variant<carl::FormulaType>`

**0.15.125.3 Constructor & Destructor Documentation**

**0.15.125.3.1 CoreTheory()** `smtrat::parser::CoreTheory::CoreTheory ( ParserState * state )`

**0.15.125.4 Member Function Documentation**

**0.15.125.4.1 addConstants()** `void smtrat::parser::CoreTheory::addConstants ( qi::symbols< char, types::ConstType > & constants ) [static]`

**0.15.125.4.2 addSimpleSorts()** `void smtrat::parser::CoreTheory::addSimpleSorts ( qi::symbols< char, carl::Sort > & sorts ) [static]`

**0.15.125.4.3 declareVariable()** `bool smtrat::parser::CoreTheory::declareVariable ( const std::string &, const carl::Sort &, types::VariableType &, TheoryError & errors ) [virtual]`

Declare a new variable with the given name and the given sort.

Reimplemented from `smtrat::parser::AbstractTheory`.

**0.15.125.4.4 expandDistinct()** `template<typename T, typename Builder > FormulaT smtrat::parser::AbstractTheory::expandDistinct ( const std::vector< T > & values, const Builder & negBuilder ) [inline], [inherited]`

**0.15.125.4.5 functionCall()** `bool smtrat::parser::CoreTheory::functionCall ( const Identifier &, const std::vector< types::TermType > &, types::TermType &, TheoryError & errors ) [virtual]`

Resolve another unknown function call.

Reimplemented from `smtrat::parser::AbstractTheory`.

```
0.15.125.4.6 handleDistinct() bool smtrat::parser::CoreTheory::handleDistinct (
 const std::vector< types::TermType > & ,
 types::TermType & ,
 TheoryError & errors) [virtual]
```

Resolve a distinct operator.

Reimplemented from [smtrat::parser::AbstractTheory](#).

```
0.15.125.4.7 handleITE() bool smtrat::parser::CoreTheory::handleITE (
 const FormulaT & ,
 const types::TermType & ,
 const types::TermType & ,
 types::TermType & ,
 types::TermType & ,
 TheoryError & errors) [virtual]
```

Resolve an if-then-else operator.

Reimplemented from [smtrat::parser::AbstractTheory](#).

```
0.15.125.4.8 instantiate() virtual bool smtrat::parser::AbstractTheory::instantiate (
 const types::VariableType & ,
 const types::TermType & ,
 types::TermType & ,
 TheoryError & errors) [inline], [virtual], [inherited]
```

Instantiate a variable within a term.

Reimplemented in [smtrat::parser::BitvectorTheory](#), and [smtrat::parser::ArithmeticTheory](#).

```
0.15.125.4.9 refreshVariable() virtual bool smtrat::parser::AbstractTheory::refreshVariable (
 const types::VariableType & ,
 types::VariableType & ,
 TheoryError & errors) [inline], [virtual], [inherited]
```

Reimplemented in [smtrat::parser::BitvectorTheory](#).

```
0.15.125.4.10 resolveSymbol() virtual bool smtrat::parser::AbstractTheory::resolveSymbol (
 const Identifier & ,
 types::TermType & ,
 TheoryError & errors) [inline], [virtual], [inherited]
```

Resolve a symbol that was not declared within the [ParserState](#).

This might be a symbol that actually uses indices, for example bitvector constants.

Reimplemented in [smtrat::parser::BitvectorTheory](#).

## 0.15.125.5 Field Documentation

```
0.15.125.5.1 state ParserState* smtrat::parser::AbstractTheory::state [inherited]
```

## 0.15.126 smtrat::parser::types::CoreTheory Struct Reference

Types of the core theory.

```
#include <TheoryTypes.h>
```

### Public Types

#### 0.15.131.1 Member Function Documentation

```
0.15.131.1.1 compute() template<typename T >
static std::optional<datastructures::CoveringRepresentation<T> > smtrat::cadcells::representation::covering<
CoveringHeuristic::CHAIN_COVERING >::compute (
 const std::vector< datastructures::SampledDerivationRef< T >> & ders) [inline],
[static]
```

## 0.15.132 smtrat::cadcells::datastructures::CoveringDescription Class Reference

Describes a covering of the real line by SymbolicIntervals (given an appropriate sample).

```
#include <roots.h>
```

### Public Member Functions

- void **add** (const [SymbolicInterval](#) &c)  
*Add a [SymbolicInterval](#) to the covering.*
- const auto & **cells** () const

### 0.15.132.1 Detailed Description

Describes a covering of the real line by SymbolicIntervals (given an appropriate sample).

### 0.15.132.2 Member Function Documentation

```
0.15.132.2.1 add() void smtrat::cadcells::datastructures::CoveringDescription::add (
 const SymbolicInterval & c) [inline]
```

Add a [SymbolicInterval](#) to the covering.

The added cell needs to be the rightmost cell of the already added cells and not be contained in any of these cells (or vice versa).

- The first cell needs to have -oo as left bound.
- The last cell needs to have oo as right bound.
- All cells need to cover the real line under an appropriate sample.
- Evaluated under an appropriate sample, the left bound of the added cell c is strictly greater than the left bounds of already added cells (considering also "strictness" of the bounds).
- The right bound of the added cell c needs to be greater than all right bounds of already added cells (considering also "strictness" of the bounds).

```
0.15.132.2.2 cells() const auto& smtrat::cadcells::datastructures::CoveringDescription::cells (
) const [inline]
```

## 0.15.133 smtrat::cadcells::datastructures::CoveringRepresentation< P > Struct Template Reference

Represents a covering over a cell.

```
#include <representation.h>
```

## Public Member Functions

- `CoveringDescription get_covering () const`  
*Returns a descriptions of the covering.*
- `std::vector< SampledDerivationRef< P > > sampled_derivations ()`  
*Returns the derivations.*
- `bool is_valid () const`  
*Checks whether this represents a proper non-redundant covering.*

## Data Fields

- `std::vector< CellRepresentation< P > > cells`  
*Cells of the covering in increasing order and no cell is contained in another cell.*
- `IndexedRootOrdering ordering`  
*An ordering on the roots for the cell boundaries mainting the covering.*

### 0.15.133.1 Detailed Description

```
template<typename P>
struct smtrat::cadcells::datastructures::CoveringRepresentation< P >
```

Represents a covering over a cell.

The cells forming the covering are in increasing order (ordered by lower bound) and no cell is contained in another cell.

### 0.15.133.2 Member Function Documentation

**0.15.133.2.1 `get_covering()`** template<typename P >  
`CoveringDescription smtrat::cadcells::datastructures::CoveringRepresentation< P >::get_←`  
`covering ( ) const [inline]`  
 Returns a descriptions of the covering.

**0.15.133.2.2 `is_valid()`** template<typename P >  
`bool smtrat::cadcells::datastructures::CoveringRepresentation< P >::is_valid ( ) const [inline]`  
 Checks whether this represents a proper non-redundant covering.

**0.15.133.2.3 `sampled_derivations()`** template<typename P >  
`std::vector<SampledDerivationRef<P> > smtrat::cadcells::datastructures::CoveringRepresentation< P >::sampled_derivations ( ) [inline]`  
 Returns the derivations.

### 0.15.133.3 Field Documentation

**0.15.133.3.1 `cells`** template<typename P >  
`std::vector<CellRepresentation<P> > smtrat::cadcells::datastructures::CoveringRepresentation< P >::cells`  
 Cells of the covering in increasing order and no cell is contained in another cell.

**0.15.133.3.2 `ordering`** template<typename P >  
`IndexedRootOrdering smtrat::cadcells::datastructures::CoveringRepresentation< P >::ordering`  
 An ordering on the roots for the cell boundaries mainting the covering.

## 0.15.134 smtrat::mcsat::onecellcad::recursive::CoverNullification Struct Reference

```
#include <Explanation.h>
```

### Static Public Attributes

- const carl::FastSet< `FormulaT` > & `informedConstraints ()` const
- void `addLemma (const FormulaT &_lemma, const LemmaType &_lt=LemmaType::NORMAL, const FormulaT &_preferredFormula=FormulaT(carl::FormulaType::TRUE))`

*Stores a lemma being a valid formula.*
- bool `hasLemmas ()`

*Checks whether this module or any of its backends provides any lemmas.*
- void `clearLemmas ()`

*Deletes all yet found lemmas.*
- const std::vector< `Lemma` > & `lemmas ()` const
- `ModuleInput::const_iterator firstUncheckedReceivedSubformula ()` const
- `ModuleInput::const_iterator firstSubformulaToPass ()` const
- void `receivedFormulaChecked ()`

*Notifies that the received formulas has been checked.*
- const `smtsat::Conditionals & answerFound ()` const
- bool `isPreprocessor ()` const
- carl::Variable `objective ()` const
- bool `is_minimizing ()` const
- void `excludeNotReceivedVariablesFromModel ()` const

*Excludes all variables from the current model, which do not occur in the received formula.*
- void `updateLemmas ()`

*Stores all lemmas of any backend of this module in its own lemma vector.*
- void `collectTheoryPropagations ()`
- void `collectOrigins (const FormulaT &_formula, FormulasT &_origins)` const

*Collects the formulas in the given formula, which are part of the received formula.*
- void `collectOrigins (const FormulaT &_formula, FormulaSetT &_origins)` const
- bool `isValidInfeasibleSubset ()` const
- void `checkInfSubsetForMinimality (std::vector< FormulaSetT >::const_iterator _infsubset, const std::string &filename="smaller_muses", unsigned _maxSizeDifference=1)` const

*Checks the given infeasible subset for minimality by storing all subsets of it, which have a smaller size which differs from the size of the infeasible subset not more than the given threshold.*
- virtual std::pair< bool, `FormulaT` > `getReceivedFormulaSimplified ()`
- void `print (const std::string &_initiation="***")` const

*Prints everything relevant of the solver.*
- void `printReceivedFormula (const std::string &_initiation="***")` const

*Prints the vector of the received formula.*
- void `printPassedFormula (const std::string &_initiation="***")` const

- Prints the vector of passed formula.
  - void `printInfeasibleSubsets` (const std::string &\_initiation="\*\*\*") const
    - Prints the infeasible subsets.
  - void `printModel` (std::ostream &\_out=std::cout) const
    - Prints the assignment of this module satisfying its received formula if it satisfiable and this module could find an assignment.
  - void `printAllModels` (std::ostream &\_out=std::cout)
    - Prints all assignments of this module satisfying its received formula if it satisfiable and this module could find an assignment.

## Static Public Member Functions

- static void `freeSplittingVariable` (const `FormulaT` &\_splittingVariable)

## Static Public Attributes

- static size\_t `mNumOfBranchVarsToStore` = 5
  - The number of different variables to consider for a probable infinite loop of branchings.
- static std::vector<`Branching`> `mLastBranches` = std::vector<`Branching`>(mNumOfBranchVarsToStore, `Branching`(typename Poly::PolyType(), 0))
  - Stores the last branches in a cycle buffer.
- static size\_t `mFirstPosInLastBranches` = 0
  - The beginning of the cyclic buffer storing the last branches.
- static std::vector<`FormulaT`> `mOldSplittingVariables`
  - Reusable splitting variables.

## Protected Member Functions

- virtual bool `informCore` (const `FormulaT` &\_constraint)
  - Informs the module about the given constraint.
- virtual void `deinformCore` (const `FormulaT` &\_constraint)
  - The inverse of informing about a constraint.
- bool `anAnswerFound` () const
  - Checks for all antecedent modules and those which run in parallel with the same antecedent modules, whether one of them has determined a result.
- void `clearModel` () const
  - Clears the assignment, if any was found.
- void `clearModels` () const
  - Clears all assignments, if any was found.
- void `cleanModel` () const
  - Substitutes variable occurrences by its model value in the model values of other variables.
- `ModuleInput::iterator` `passedFormulaBegin` ()
- `ModuleInput::iterator` `passedFormulaEnd` ()
- void `addOrigin` (`ModuleInput::iterator` \_formula, const `FormulaT` &\_origin)
  - Adds the given set of formulas in the received formula to the origins of the given passed formula.
- const `FormulaT` & `getOrigins` (`ModuleInput::const_iterator` \_formula) const
  - Gets the origins of the passed formula at the given position.
- void `getOrigins` (const `FormulaT` &\_formula, `FormulasT` &\_origins) const
- void `getOrigins` (const `FormulaT` &\_formula, `FormulaSetT` &\_origins) const
- std::pair<`ModuleInput::iterator`, bool> `removeOrigin` (`ModuleInput::iterator` \_formula, const `FormulaT` &\_origin)
- std::pair<`ModuleInput::iterator`, bool> `removeOrigins` (`ModuleInput::iterator` \_formula, const std::shared\_ptr<std::vector<`FormulaT`>> &\_origins)
- void `informBackends` (const `FormulaT` &\_constraint)

- **virtual void addConstraintToInform** (const `FormulaT` &\_constraint)
 

*Informs all backends of this module about the given constraint.*
- **std::pair< ModuleInput::iterator, bool > addReceivedSubformulaToPassedFormula** (`ModuleInput::const_iterator` \_subformula)
 

*Adds a constraint to the collection of constraints of this module, which are informed to a freshly generated backend.*
- **std::pair< ModuleInput::iterator, bool > addSubformulaToPassedFormula** (const `FormulaT` &\_formula)
 

*Copies the given sub-formula of the received formula to the passed formula.*
- **bool originInReceivedFormula** (const `FormulaT` &\_origin) const
 

*Adds the given formula to the passed formula with no origin.*
- **std::pair< ModuleInput::iterator, bool > addSubformulaToPassedFormula** (const `FormulaT` &\_formula, const `std::shared_ptr< std::vector< FormulaT >>` &\_origins)
 

*Adds the given formula to the passed formula.*
- **std::pair< ModuleInput::iterator, bool > addSubformulaToPassedFormula** (const `FormulaT` &\_formula, const `FormulaT` &\_origin)
 

*Adds the given formula to the passed formula.*
- **void generateTrivialInfeasibleSubset** ()
 

*Stores the trivial infeasible subset being the set of received formulas.*
- **void receivedFormulasAsInfeasibleSubset** (`ModuleInput::const_iterator` \_subformula)
 

*Stores an infeasible subset consisting only of the given received formula.*
- **std::vector< FormulaT >::const\_iterator findBestOrigin** (const `std::vector< FormulaT >` &\_origins) const
 

*Get the infeasible subsets the given backend provides.*
- **void getInfeasibleSubsets** ()
 

*Copies the infeasible subsets of the passed formula.*
- **std::vector< FormulaSetT > getInfeasibleSubsets** (const `Module` &\_backend) const
 

*Stores the model of a backend which determined satisfiability of the passed formula in the model of this module.*
- **const Model & backendsModel** () const
 

*Stores all models of a backend in the list of all models of this module.*
- **virtual Answer runBackends** (bool \_final, bool \_full, carl::Variable \_objective)
 

*Runs the backend solvers on the passed formula.*
- **virtual Answer runBackends** ()
 

*Runs the backend solvers on the passed formula.*
- **virtual ModuleInput::iterator eraseSubformulaFromPassedFormula** (`ModuleInput::iterator` \_subformula, bool \_ignoreOrigins=false)
 

*Removes everything related to the sub-formula to remove from the passed formula in the backends of this module.*
- **void clearPassedFormula** ()
 

*Merges the two vectors of sets into the first one.*
- **size\_t determine\_smallest\_origin** (const `std::vector< FormulaT >` &origins) const
 

*Checks whether given the current branching value and branching variable/polynomial it is (highly) probable that this branching is part of an infinite loop of branchings.*
- **bool probablyLooping** (const typename Poly::PolyType &\_branchingPolynomial, const `Rational` &\_branchingValue) const
 

*Adds a lemmas which provoke a branching for the given variable at the given value, if this module returns Unknown and there exists a preceding SATModule.*
- **bool branchAt** (const `Poly` &\_polynomial, bool \_integral, const `Rational` &\_value, `std::vector< FormulaT >` &&\_premise, bool \_leftCaseWeak=true, bool \_preferLeftCase=true, bool \_useReceivedFormulaAsPremise=false)
 

*Adds a lemmas which provoke a branching for the given variable at the given value, if this module returns Unknown and there exists a preceding SATModule.*
- **bool branchAt** (const `Poly` &\_polynomial, bool \_integral, const `Rational` &\_value, bool \_leftCaseWeak=true, bool \_preferLeftCase=true, bool \_useReceivedFormulaAsPremise=false, const `std::vector< FormulaT >` &&\_premise=std::vector< `FormulaT` >())
 

*Adds a lemmas which provoke a branching for the given variable at the given value, if this module returns Unknown and there exists a preceding SATModule.*
- **bool branchAt** (carl::Variable::Arg \_var, const `Rational` &\_value, `std::vector< FormulaT >` &&\_premise, bool \_leftCaseWeak=true, bool \_preferLeftCase=true, bool \_useReceivedFormulaAsPremise=false)
 

*Adds a lemmas which provoke a branching for the given variable at the given value, if this module returns Unknown and there exists a preceding SATModule.*

- bool `branchAt` (carl::Variable::Arg \_var, const `Rational` &\_value, bool \_leftCaseWeak=true, bool \_preferLeftCase=true, bool \_useReceivedFormulaAsPremise=false, const std::vector< `FormulaT` > &\_premise=std::vector< `FormulaT` >())  
• void `splitUnequalConstraint` (const `FormulaT` &)  
*Adds the following lemmas for the given constraint p!=0.*  
• unsigned `checkModel` () const  
• void `addInformationRelevantFormula` (const `FormulaT` &formula)  
*Adds a formula to the InformationRelevantFormula.*  
• const std::set< `FormulaT` > & `getInformationRelevantFormulas` ()  
*Gets all InformationRelevantFormulas.*  
• bool `isLemmaLevel` (`LemmaLevel` level)  
*Checks if current lemma level is greater or equal to given level.*

### Static Protected Member Functions

- static bool `modelsDisjoint` (const `Model` &\_modelA, const `Model` &\_modelB)  
*Checks whether there is no variable assigned by both models.*

### Protected Attributes

- std::vector< `FormulaSetT` > `mInfeasibleSubsets`  
*Stores the infeasible subsets.*
- `Manager` \*const `mpManager`  
*A reference to the manager.*
- `Model` `mModel`  
*Stores the assignment of the current satisfiable result, if existent.*
- std::vector< `Model` > `mAllModels`  
*Stores all satisfying assignments.*
- bool `mModelComputed`  
*True, if the model has already been computed.*
- bool `mFinalCheck`  
*true, if the check procedure should perform a final check which especially means not to postpone splitting decisions*
- bool `mFullCheck`  
*false, if this module should avoid too expensive procedures and rather return unknown instead.*
- carl::Variable `mObjectiveVariable`  
*Objective variable to be minimized. If set to NO\_VARIABLE, a normal sat check should be performed.*
- std::vector< `TheoryPropagation` > `mTheoryPropagations`
- std::atomic< `Answer` > `mSolverState`  
*States whether the received formula is known to be satisfiable or unsatisfiable otherwise it is set to unknown.*
- std::atomic\_bool \* `mBackendsFoundAnswer`  
*This flag is passed to any backend and if it determines an answer to a prior check call, this flag is fired.*
- `Conditionals` `mFoundAnswer`  
*Vector of Booleans: If any of them is true, we have to terminate a running check procedure.*
- std::vector< `Module` \* > `mUsedBackends`  
*The backends of this module which are currently used (conditions to use this module are fulfilled for the passed formula).*
- std::vector< `Module` \* > `mAllBackends`  
*The backends of this module which have been used.*
- std::vector< `Lemma` > `mLemmas`  
*Stores the lemmas being valid formulas this module or its backends made.*
- `ModuleInput::iterator` `mFirstSubformulaToPass`  
*Stores the position of the first sub-formula in the passed formula, which has not yet been considered for a consistency check of the backends.*

- carl::FastSet< `FormulaT` > `mConstraintsToInform`  
*Stores the constraints which the backends must be informed about.*
- carl::FastSet< `FormulaT` > `mInformedConstraints`  
*Stores the position of the first constraint of which no backend has been informed about.*
- `ModuleInput::const_iterator mFirstUncheckedReceivedSubformula`  
*Stores the position of the first (by this module) unchecked sub-formula of the received formula.*
- `unsigned mSmallerMusesCheckCounter`  
*Counter used for the generation of the smt2 files to check for smaller muses.*
- `std::vector< std::size_t > mVariableCounters`  
*Maps variables to the number of their occurrences.*

### 0.15.135.4 Member Function Documentation

**0.15.135.4.1 add()** `bool smtrat::Module::add (`  
 `ModuleInput::const_iterator _subformula ) [inherited]`

The module has to take the given sub-formula of the received formula into account.

Parameters

|                          |                                                    |
|--------------------------|----------------------------------------------------|
| <code>_subformula</code> | The sub-formula to take additionally into account. |
|--------------------------|----------------------------------------------------|

Returns

false, if it can be easily decided that this sub-formula causes a conflict with the already considered sub-formulas; true, otherwise.

**0.15.135.4.2 addConstraintToInform()** void smtrat::Module::addConstraintToInform ( const `FormulaT` & `_constraint` ) [protected], [virtual], [inherited]

Adds a constraint to the collection of constraints of this module, which are informed to a freshly generated backend.

**Parameters**

|                          |                        |
|--------------------------|------------------------|
| <code>_constraint</code> | The constraint to add. |
|--------------------------|------------------------|

Reimplemented in [smtrat::SATModule< Settings >](#).

**0.15.135.4.3 addCore()** template<typename Settings >

bool smtrat::CSplitModule< Settings >::addCore ( ModuleInput::const\_iterator `_subformula` ) [virtual]

The module has to take the given sub-formula of the received formula into account.

**Parameters**

|                          |                                                    |
|--------------------------|----------------------------------------------------|
| <code>_subformula</code> | The sub-formula to take additionally into account. |
|--------------------------|----------------------------------------------------|

**Returns**

False, if it can be easily decided that this sub-formula causes a conflict with the already considered sub-formulas; True, otherwise.

Reimplemented from [smtrat::Module](#).

**0.15.135.4.4 addInformationRelevantFormula()** void smtrat::Module::addInformationRelevantFormula (

const `FormulaT` & `formula` ) [protected], [inherited]

Adds a formula to the InformationRelevantFormula.

**Parameters**

|                      |                |
|----------------------|----------------|
| <code>formula</code> | Formula to add |
|----------------------|----------------|

**0.15.135.4.5 addLemma()** void smtrat::Module::addLemma (

const `FormulaT` & `_lemma`,

const `LemmaType` & `_lt` = `LemmaType::NORMAL`,

const `FormulaT` & `_preferredFormula` = `FormulaT( carl::FormulaType::TRUE )` ) [inline],

[inherited]

Stores a lemma being a valid formula.

**Parameters**

|                                |                                                                       |
|--------------------------------|-----------------------------------------------------------------------|
| <code>_lemma</code>            | The eduction/lemma to store.                                          |
| <code>_lt</code>               | The type of the lemma.                                                |
| <code>_preferredFormula</code> | Hint for the next decision, which formula should be assigned to true. |

**0.15.135.4.6 addOrigin()** `void smtrat::Module::addOrigin (`  
`ModuleInput::iterator _formula,`  
`const FormulaT & _origin ) [inline], [protected], [inherited]`

Adds the given set of formulas in the received formula to the origins of the given passed formula.

**Parameters**

|                       |                                                           |
|-----------------------|-----------------------------------------------------------|
| <code>_formula</code> | The passed formula to set the origins for.                |
| <code>_origin</code>  | A set of formulas in the received formula of this module. |

**0.15.135.4.7 addReceivedSubformulaToPassedFormula()** `std::pair<ModuleInput::iterator,bool>`  
`smtrat::Module::addReceivedSubformulaToPassedFormula (`  
`ModuleInput::const_iterator _subformula ) [inline], [protected], [inherited]`

Copies the given sub-formula of the received formula to the passed formula.

Note, that there is always a link between sub-formulas of the passed formulas to sub-formulas of the received formulas, which are responsible for its occurrence.

**Parameters**

|                          |                                                  |
|--------------------------|--------------------------------------------------|
| <code>_subformula</code> | The sub-formula of the received formula to copy. |
|--------------------------|--------------------------------------------------|

**0.15.135.4.8 addSubformulaToPassedFormula() [1/3]** `std::pair<ModuleInput::iterator,bool> smtrat::Module::addSubformulaToPassedFormula (`  
`const FormulaT & _formula ) [inline], [protected], [inherited]`

Adds the given formula to the passed formula with no origin.

Note that in the next call of this module's removeSubformula, all formulas in the passed formula without origins will be removed.

**Parameters**

|                       |                                           |
|-----------------------|-------------------------------------------|
| <code>_formula</code> | The formula to add to the passed formula. |
|-----------------------|-------------------------------------------|

**Returns**

A pair to the position where the formula to add has been inserted (or its first sub-formula which has not yet been in the passed formula, in case the formula to add is a conjunction), and a Boolean stating whether anything has been added to the passed formula.

**0.15.135.4.9 addSubformulaToPassedFormula() [2/3]** `std::pair<ModuleInput::iterator,bool> smtrat::Module::addSubformulaToPassedFormula (`  
`const FormulaT & _formula,`  
`const FormulaT & _origin ) [inline], [protected], [inherited]`

Adds the given formula to the passed formula.

**Parameters**

|                       |                                                                                                                           |
|-----------------------|---------------------------------------------------------------------------------------------------------------------------|
| <code>_formula</code> | The formula to add to the passed formula.                                                                                 |
| <code>_origin</code>  | The sub-formula of the received formula being responsible for the occurrence of the formula to add to the passed formula. |

**Returns**

A pair to the position where the formula to add has been inserted (or its first sub-formula which has not yet been in the passed formula, in case the formula to add is a conjunction), and a Boolean stating whether anything has been added to the passed formula.

**0.15.135.4.10 addSubformulaToPassedFormula() [3/3]** `std::pair<ModuleInput::iterator, bool>`

```
smrat::Module::addSubformulaToPassedFormula (
 const FormulaT & _formula,
 const std::shared_ptr< std::vector< FormulaT >> & _origins) [inline], [protected],
[inherited]
```

Adds the given formula to the passed formula.

**Parameters**

|                       |                                                                                                                                         |
|-----------------------|-----------------------------------------------------------------------------------------------------------------------------------------|
| <code>_formula</code> | The formula to add to the passed formula.                                                                                               |
| <code>_origins</code> | The link of the formula to add to the passed formula to sub-formulas of the received formulas, which are responsible for its occurrence |

**Returns**

A pair to the position where the formula to add has been inserted (or its first sub-formula which has not yet been in the passed formula, in case the formula to add is a conjunction), and a Boolean stating whether anything has been added to the passed formula.

**0.15.135.4.11 allModels()** `const std::vector<Model>& smrat::Module::allModels () const [inline], [inherited]`**Returns**

All satisfying assignments, if existent.

**0.15.135.4.12 anAnswerFound()** `bool smrat::Module::anAnswerFound () const [inline], [protected], [inherited]`

Checks for all antecedent modules and those which run in parallel with the same antecedent modules, whether one of them has determined a result.

**Returns**

True, if one of them has determined a result.

**0.15.135.4.13 answerFound()** `const smrat::Conditionals& smrat::Module::answerFound () const [inline], [inherited]`**Returns**

A vector of Booleans: If any of them is true, we have to terminate a running check procedure.

**0.15.135.4.14 backendsModel()** `const Model & smrat::Module::backendsModel () const [protected], [inherited]`

Stores the model of a backend which determined satisfiability of the passed formula in the model of this module.

**0.15.135.4.15** **branchAt()** [1/4] `bool smrat::Module::branchAt (`

```
carl::Variable::Arg _var,
const Rational & _value,
bool _leftCaseWeak = true,
bool _preferLeftCase = true,
bool _useReceivedFormulaAsPremise = false,
const std::vector< FormulaT > & _premise = std::vector<FormulaT>()) [inline],
[protected], [inherited]
```

**0.15.135.4.16** **branchAt()** [2/4] `bool smrat::Module::branchAt (`

```
carl::Variable::Arg _var,
const Rational & _value,
std::vector< FormulaT > && _premise,
bool _leftCaseWeak = true,
bool _preferLeftCase = true,
bool _useReceivedFormulaAsPremise = false) [inline], [protected], [inherited]
```

**0.15.135.4.17** **branchAt()** [3/4] `bool smrat::Module::branchAt (`

```
const Poly & _polynomial,
bool _integral,
const Rational & _value,
bool _leftCaseWeak = true,
bool _preferLeftCase = true,
bool _useReceivedFormulaAsPremise = false,
const std::vector< FormulaT > & _premise = std::vector<FormulaT>()) [inline],
[protected], [inherited]
```

**0.15.135.4.18** **branchAt()** [4/4] `bool smrat::Module::branchAt (`

```
const Poly & _polynomial,
bool _integral,
const Rational & _value,
std::vector< FormulaT > && _premise,
bool _leftCaseWeak = true,
bool _preferLeftCase = true,
bool _useReceivedFormulaAsPremise = false) [protected], [inherited]
```

Adds a lemmas which provoke a branching for the given variable at the given value, if this module returns Unknown and there exists a preceding [SATModule](#).

Note that the given value is rounded down and up, if the given variable is integer-valued.

#### Parameters

|                                           |                                                                                                                                                                                                                |
|-------------------------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>_polynomial</code>                  | The variable to branch for.                                                                                                                                                                                    |
| <code>_integral</code>                    | A flag being true, if all variables in the polynomial to branch for are integral.                                                                                                                              |
| <code>_value</code>                       | The value to branch at.                                                                                                                                                                                        |
| <code>_premise</code>                     | The sub-formulas of the received formula from which the branch is followed. Note, that a premise is not necessary, as every branch is a valid formula. But a premise can prevent from branching unnecessarily. |
| <code>_leftCaseWeak</code>                | true, if a branching in the form of (or ( $\leq p b$ ) ( $> p b$ )) is desired. false, if a branching in the form of (or ( $< p b$ ) ( $\geq p b$ )) is desired.                                               |
| <code>_preferLeftCase</code>              | true, if the left case (polynomial less(or equal) 0 shall be chosen first. false, otherwise.                                                                                                                   |
| <code>_useReceivedFormulaAsPremise</code> | true, if the whole received formula should be used as premise                                                                                                                                                  |

```
0.15.135.4.19 check() Answer smtrat::Module::check (
 bool _final = false,
 bool _full = true,
 carl::Variable _objective = carl::Variable::NO_VARIABLE) [virtual], [inherited]
```

Checks the received formula for consistency.

Note, that this is an implementation of the satisfiability check of the conjunction of the so far received formulas, which does actually nothing but passing the problem to its backends. This implementation is only used internally and must be overwritten by any derived module.

#### Parameters

|                   |                                                                                                                                       |
|-------------------|---------------------------------------------------------------------------------------------------------------------------------------|
| <i>_final</i>     | true, if this satisfiability check will be the last one (for a global sat-check), if its result is SAT                                |
| <i>_full</i>      | false, if this module should avoid too expensive procedures and rather return unknown instead.                                        |
| <i>_objective</i> | if not set to NO_VARIABLE, the module should find an assignment minimizing this objective variable; otherwise any assignment is good. |

#### Returns

True, if the received formula is satisfiable; False, if the received formula is not satisfiable; Unknown, otherwise.

Reimplemented in [smtrat::PModule](#).

```
0.15.135.4.20 checkCore() template<typename Settings >
Answer smtrat::CSplitModule< Settings >::checkCore () [virtual]
```

Checks the received formula for consistency.

#### Returns

SAT, if the received formula is satisfiable; UNSAT, if the received formula is not satisfiable; UNKNOWN, otherwise.

Reimplemented from [smtrat::Module](#).

```
0.15.135.4.21 checkInfeasibleSubsetForMinimality() void smtrat::Module::checkInfeasibleSubsetForMinimality (
 std::vector< FormulaSetT >::const_iterator _infssubset,
 const std::string & _filename = "smaller_muses",
 unsigned _maxSizeDifference = 1) const [inherited]
```

Checks the given infeasible subset for minimality by storing all subsets of it, which have a smaller size which differs from the size of the infeasible subset not more than the given threshold.

#### Parameters

|                           |                                                                                                        |
|---------------------------|--------------------------------------------------------------------------------------------------------|
| <i>_infssubset</i>        | The infeasible subset to check for minimality.                                                         |
| <i>_filename</i>          | The name of the file to store the infeasible subsets in order to be able to check their infeasibility. |
| <i>_maxSizeDifference</i> | The maximal difference between the sizes of the subsets compared to the size of the infeasible subset. |

```
0.15.135.4.22 checkModel() unsigned smtrat::Module::checkModel () const [protected], [inherited]
```

**Returns**

false, if the current model of this module does not satisfy the current given formula; true, if it cannot be said whether the model satisfies the given formula.

**0.15.135.4.23 cleanModel()** void smtrat::Module::cleanModel ( ) const [inline], [protected], [inherited]

Substitutes variable occurrences by its model value in the model values of other variables.

**0.15.135.4.24 clearLemmas()** void smtrat::Module::clearLemmas ( ) [inline], [inherited]

Deletes all yet found lemmas.

**0.15.135.4.25 clearModel()** void smtrat::Module::clearModel ( ) const [inline], [protected], [inherited]

Clears the assignment, if any was found.

**0.15.135.4.26 clearModels()** void smtrat::Module::clearModels ( ) const [inline], [protected], [inherited]

Clears all assignments, if any was found.

**0.15.135.4.27 clearPassedFormula()** void smtrat::Module::clearPassedFormula ( ) [protected], [inherited]

**0.15.135.4.28 collectOrigins() [1/2]** void smtrat::Module::collectOrigins ( const `FormulaT` & `_formula`, `FormulaSetT` & `_origins` ) const [inherited]

**0.15.135.4.29 collectOrigins() [2/2]** void smtrat::Module::collectOrigins ( const `FormulaT` & `_formula`, `FormulasT` & `_origins` ) const [inherited]

Collects the formulas in the given formula, which are part of the received formula.

If the given formula directly occurs in the received formula, it is inserted into the given set. Otherwise, the given formula must be of type AND and all its sub-formulas part of the received formula. Hence, they will be added to the given set.

**Parameters**

|                       |                                                                                                      |
|-----------------------|------------------------------------------------------------------------------------------------------|
| <code>_formula</code> | The formula from which to collect the formulas being sub-formulas of the received formula (origins). |
| <code>_origins</code> | The set in which to store the origins.                                                               |

**0.15.135.4.30 collectTheoryPropagations()** void smtrat::Module::collectTheoryPropagations ( ) [inherited]

**0.15.135.4.31 constraintsToInform()** const carl::FastSet<`FormulaT`>& smtrat::Module::constraintsToInform ( ) const [inline], [inherited]

**Returns**

The constraints which the backends must be informed about.

**0.15.135.4.32 currentlySatisfied()** `virtual unsigned smtrat::Module::currentlySatisfied ( const FormulaT & ) const [inline], [virtual], [inherited]`

**Returns**

0, if the given formula is conflicted by the current model; 1, if the given formula is satisfied by the current model; 2, otherwise; 3, if we do not know anything (default)

Reimplemented in [smtrat::LRAModule< Settings >](#), [smtrat::LRAModule< LRASettingsICP >](#), and [smtrat::LRAModule< LRASettings >](#)

**0.15.135.4.33 currentlySatisfiedByBackend()** `unsigned smtrat::Module::currentlySatisfiedByBackend ( const FormulaT & _formula ) const [inherited]`

**Returns**

0, if the given formula is conflicted by the current model; 1, if the given formula is satisfied by the current model; 2, otherwise 3, if we do not know anything (default)

**0.15.135.4.34 deinform()** `void smtrat::Module::deinform ( const FormulaT & _constraint ) [inherited]`

The inverse of informing about a constraint.

All data structures which were kept regarding this constraint are going to be removed. Note, that this makes only sense if it is not likely enough that a formula with this constraint must be solved again.

**Parameters**

|                          |                                                         |
|--------------------------|---------------------------------------------------------|
| <code>_constraint</code> | The constraint to remove from internal data structures. |
|--------------------------|---------------------------------------------------------|

**0.15.135.4.35 deinformCore()** `virtual void smtrat::Module::deinformCore ( const FormulaT & _constraint ) [inline], [protected], [virtual], [inherited]`

The inverse of informing about a constraint.

All data structures which were kept regarding this constraint are going to be removed. Note, that this makes only sense if it is not likely enough that a formula with this constraint must be solved again.

**Parameters**

|                          |                                                         |
|--------------------------|---------------------------------------------------------|
| <code>_constraint</code> | The constraint to remove from internal data structures. |
|--------------------------|---------------------------------------------------------|

Reimplemented in [smtrat::LRAModule< Settings >](#), [smtrat::LRAModule< LRASettingsICP >](#), and [smtrat::LRAModule< LRASettings >](#)

**0.15.135.4.36 determine\_smallest\_origin()** `size_t smtrat::Module::determine_smallest_origin ( const std::vector< FormulaT > & origins ) const [protected], [inherited]`

**Parameters**

|                      |                              |
|----------------------|------------------------------|
| <code>origins</code> | A vector of sets of origins. |
|----------------------|------------------------------|

**Returns**

The index of the smallest (regarding the size of the sets) element of origins

**0.15.135.4.37 `eraseSubformulaFromPassedFormula()`** `ModuleInput::iterator smtrat::Module::eraseSubformulaFromPassedFormula ( ModuleInput::iterator _subformula, bool _ignoreOrigins = false )` [protected], [virtual], [inherited]

Removes everything related to the sub-formula to remove from the passed formula in the backends of this module. Afterwards the sub-formula is removed from the passed formula.

**Parameters**

|                             |                                                                                                              |
|-----------------------------|--------------------------------------------------------------------------------------------------------------|
| <code>_subformula</code>    | The sub-formula to remove from the passed formula.                                                           |
| <code>_ignoreOrigins</code> | True, if the sub-formula shall be removed regardless of its origins (should only be applied with expertise). |

**Returns**

Reimplemented in `smtrat::ICPModule< Settings >`, `smtrat::ICPModule< ICPSettings4 >`, and `smtrat::ICPModule< ICPSettings1 >`.

**0.15.135.4.38 `excludeNotReceivedVariablesFromModel()`** `void smtrat::Module::excludeNotReceivedVariablesFromModel ( ) const` [inherited]

Excludes all variables from the current model, which do not occur in the received formula.

**0.15.135.4.39 `findBestOrigin()`** `std::vector< FormulaT >::const_iterator smtrat::Module::findBestOrigin ( const std::vector< FormulaT > & _origins ) const` [protected], [inherited]

**Parameters**

|                       |  |
|-----------------------|--|
| <code>_origins</code> |  |
|-----------------------|--|

**Returns**

**0.15.135.4.40 `firstSubformulaToPass()`** `ModuleInput::const_iterator smtrat::Module::firstSubformulaToPass ( ) const` [inline], [inherited]

**Returns**

The position of the first sub-formula in the passed formula, which has not yet been considered for a consistency check of the backends.

**0.15.135.4.41 `firstUncheckedReceivedSubformula()`** `ModuleInput::const_iterator smtrat::Module::firstUncheckedReceivedSubformula ( ) const` [inline], [inherited]

**Returns**

The position of the first (by this module) unchecked sub-formula of the received formula.

**0.15.135.4.42 freeSplittingVariable()** static void smtrat::Module::freeSplittingVariable ( const `FormulaT` & `_splittingVariable` ) [inline], [static], [inherited]

**0.15.135.4.43 generateTrivialInfeasibleSubset()** void smtrat::Module::generateTrivialInfeasibleSubset ( ) [inline], [protected], [inherited]  
Stores the trivial infeasible subset being the set of received formulas.

**0.15.135.4.44 getBackendsAllModels()** void smtrat::Module::getBackendsAllModels ( ) const [protected], [inherited]  
Stores all models of a backend in the list of all models of this module.

**0.15.135.4.45 getBackendsModel()** void smtrat::Module::getBackendsModel ( ) const [protected], [inherited]

**0.15.135.4.46 getInfeasibleSubsets() [1/2]** void smtrat::Module::getInfeasibleSubsets ( ) [protected], [inherited]  
Copies the infeasible subsets of the passed formula.

**0.15.135.4.47 getInfeasibleSubsets() [2/2]** std::vector< `FormulaSetT` > smtrat::Module::getInfeasibleSubsets ( const `Module` & `_backend` ) const [protected], [inherited]

Get the infeasible subsets the given backend provides.  
Note, that an infeasible subset in a backend contains sub formulas of the passed formula and an infeasible subset of this module contains sub formulas of the received formula. In this method the LATTER is returned.

#### Parameters

|                       |                                                          |
|-----------------------|----------------------------------------------------------|
| <code>_backend</code> | The backend from which to obtain the infeasible subsets. |
|-----------------------|----------------------------------------------------------|

#### Returns

The infeasible subsets the given backend provides.

**0.15.135.4.48 getInformationRelevantFormulas()** const std::set< `FormulaT` > & smtrat::Module::getInformationRelevantFormulas ( ) [protected], [inherited]  
Gets all InformationRelevantFormulas.

#### Returns

Set of all formulas

**0.15.135.4.49 getModelEqualities()** std::list< std::vector< carl::Variable > > smtrat::Module::getModelEqualities ( ) const [virtual], [inherited]

Partition the variables from the current model into equivalence classes according to their assigned value.  
The result is a set of equivalence classes of variables where all variables within one class are assigned the same value. Note that the number of classes may not be minimal, i.e. two classes may actually be equivalent.

#### Returns

Equivalence classes.

**0.15.135.4.50 getOrigins() [1/3]** void smtrat::Module::getOrigins ( const FormulaT & \_formula, FormulaSetT & \_origins ) const [inline], [protected], [inherited]

#### Parameters

|          |  |
|----------|--|
| _formula |  |
| _origins |  |

**0.15.135.4.51 getOrigins() [2/3]** void smtrat::Module::getOrigins ( const FormulaT & \_formula, FormulasT & \_origins ) const [inline], [protected], [inherited]

#### Parameters

|          |  |
|----------|--|
| _formula |  |
| _origins |  |

**0.15.135.4.52 getOrigins() [3/3]** const FormulaT& smtrat::Module::getOrigins ( ModuleInput::const\_iterator \_formula ) const [inline], [protected], [inherited]

Gets the origins of the passed formula at the given position.

#### Parameters

|          |                                                   |
|----------|---------------------------------------------------|
| _formula | The position of a formula in the passed formulas. |
|----------|---------------------------------------------------|

#### Returns

The origins of the passed formula at the given position.

**0.15.135.4.53 getReceivedFormulaSimplified()** std::pair< bool, FormulaT > smtrat::Module::getReceivedFormulaSimplified ( ) [virtual], [inherited]

#### Returns

A pair of a Boolean and a formula, where the Boolean is true, if the received formula could be simplified to an equisatisfiable formula. The formula is equisatisfiable to this module's received formula, if the Boolean is true.

Reimplemented in [smtrat::PModule](#).

**0.15.135.4.54 hasLemmas()** bool smtrat::Module::hasLemmas ( ) [inline], [inherited]

Checks whether this module or any of its backends provides any lemmas.

**0.15.135.4.55 hasValidInfeasibleSubset()** bool smtrat::Module::hasValidInfeasibleSubset ( ) const [inherited]

#### Returns

true, if the module has at least one valid infeasible subset, that is all its elements are sub-formulas of the received formula (pointer must be equal).

**0.15.135.4.56 `id()`** `std::size_t smtrat::Module::id () const [inline], [inherited]`

**Returns**

A unique ID to identify this module instance.

**0.15.135.4.57 `infeasibleSubsets()`** `const std::vector<FormulaSetT>& smtrat::Module::infeasibleSubsets () const [inline], [inherited]`

**Returns**

The infeasible subsets of the set of received formulas (empty, if this module has not detected unsatisfiability of the conjunction of received formulas).

**0.15.135.4.58 `inform()`** `bool smtrat::Module::inform (const FormulaT & _constraint) [inherited]`

Informs the module about the given constraint.

It should be tried to inform this module about any constraint it could receive eventually before `assertSubformula` is called (preferably for the first time, but at least before adding a formula containing that constraint).

**Parameters**

|                          |                                 |
|--------------------------|---------------------------------|
| <code>_constraint</code> | The constraint to inform about. |
|--------------------------|---------------------------------|

**Returns**

false, if it can be easily decided whether the given constraint is inconsistent; true, otherwise.

**0.15.135.4.59 `informBackends()`** `void smtrat::Module::informBackends (const FormulaT & _constraint) [inline], [protected], [inherited]`

Informs all backends of this module about the given constraint.

**Parameters**

|                          |                                 |
|--------------------------|---------------------------------|
| <code>_constraint</code> | The constraint to inform about. |
|--------------------------|---------------------------------|

**0.15.135.4.60 `informCore()`** `virtual bool smtrat::Module::informCore (const FormulaT & _constraint) [inline], [protected], [virtual], [inherited]`

Informs the module about the given constraint.

It should be tried to inform this module about any constraint it could receive eventually before `assertSubformula` is called (preferably for the first time, but at least before adding a formula containing that constraint).

**Parameters**

|                          |                                 |
|--------------------------|---------------------------------|
| <code>_constraint</code> | The constraint to inform about. |
|--------------------------|---------------------------------|

**Returns**

false, if it can be easily decided whether the given constraint is inconsistent; true, otherwise.

Reimplemented in [smtrat::UnionFindModule< Settings >](#), [smtrat::PBPPModule< Settings >](#), [smtrat::PBGaussModule< Settings >](#), [smtrat::NRAILModule< Settings >](#), [smtrat::NewCoveringModule< Settings >](#), [smtrat::NewCADModule< Settings >](#),

`smrat::LRAModule< Settings >, smrat::LRAModule< LRASettingsICP >, smrat::LRAModule< LRASettings1 >, smrat::IntBlastModule< Settings >, smrat::FPPModule< Settings >, smrat::EQModule< Settings >, smrat::CurryModule< Settings >, smrat::BVMModule< Settings >, smrat::ICPModule< Settings >, smrat::ICPModule< ICPSettings4 >, and smrat::ICPModule< ICPSettings1 >.`

**0.15.135.4.61 informedConstraints()** `const carl::FastSet<FormulaT>& smrat::Module::informedConstraints( ) const [inline], [inherited]`

**Returns**

The position of the first constraint of which no backend has been informed about.

**0.15.135.4.62 init()** `void smrat::Module::init( ) [virtual], [inherited]`

Informs all backends about the so far encountered constraints, which have not yet been communicated.

This method must not be called twice and only before the first runBackends call.

Reimplemented in `smrat::PBPPModule< Settings >, smrat::PBGaussModule< Settings >, smrat::NRAILModule< Settings >, smrat::NewCoveringModule< Settings >, smrat::NewCADModule< Settings >, smrat::LRAModule< Settings >, smrat::LRAModule< LRASettingsICP >, smrat::LRAModule< LRASettings1 >, smrat::IntBlastModule< Settings >, smrat::FPPModule< Settings >, smrat::EQModule< Settings >, smrat::CurryModule< Settings >, and smrat::BVMModule< Settings >.`

**0.15.135.4.63 is\_minimizing()** `bool smrat::Module::is_minimizing( ) const [inline], [inherited]`

**0.15.135.4.64 isLemmaLevel()** `bool smrat::Module::isLemmaLevel( LemmaLevel level ) [protected], [inherited]`

Checks if current lemma level is greater or equal to given level.

**Parameters**

|                    |                 |
|--------------------|-----------------|
| <code>level</code> | Level to check. |
|--------------------|-----------------|

**0.15.135.4.65 isPreprocessor()** `bool smrat::Module::isPreprocessor( ) const [inline], [inherited]`

**Returns**

true, if this module is a preprocessor that is a module, which simplifies its received formula to an equisatisfiable formula being passed to its backends. The simplified formula can be obtained with `getReceivedFormulaSimplified()`.

**0.15.135.4.66 lemmas()** `const std::vector<Lemma>& smrat::Module::lemmas( ) const [inline], [inherited]`

**Returns**

A constant reference to the lemmas being valid formulas this module or its backends made.

**0.15.135.4.67 merge()** `std::vector< FormulaT > smrat::Module::merge( const std::vector< FormulaT > & _vecSetA, const std::vector< FormulaT > & _vecSetB ) const [protected], [inherited]`

Merges the two vectors of sets into the first one.

({a,b},{a,c}) and ({b,d},{b}) -> ({a,b,d},{a,b},{a,b,c,d},{a,b,c})

**Parameters**

|                       |                                  |
|-----------------------|----------------------------------|
| <code>_vecSetA</code> | A vector of sets of constraints. |
| <code>_vecSetB</code> | A vector of sets of constraints. |

**Returns**

The vector being the two given vectors merged.

**0.15.135.4.68 `model()`** `const Model& smtrat::Module::model ( ) const [inline], [inherited]`**Returns**

The assignment of the current satisfiable result, if existent.

**0.15.135.4.69 `modelsDisjoint()`** `bool smtrat::Module::modelsDisjoint (`

```
const Model & _modelA,
const Model & _modelB) [static], [protected], [inherited]
```

Checks whether there is no variable assigned by both models.

**Parameters**

|                      |                                |
|----------------------|--------------------------------|
| <code>_modelA</code> | The first model to check for.  |
| <code>_modelB</code> | The second model to check for. |

**Returns**

true, if there is no variable assigned by both models; false, otherwise.

**0.15.135.4.70 `moduleName()`** `template<typename Settings >`  
`std::string smtrat::CSplitModule< Settings >::moduleName ( ) const [inline], [virtual]`**Returns**

The name of the given module type as name.

Reimplemented from [smtrat::Module](#).

**0.15.135.4.71 `objective()`** `carl::Variable smtrat::Module::objective ( ) const [inline], [inherited]`**0.15.135.4.72 `originInReceivedFormula()`** `bool smtrat::Module::originInReceivedFormula (`  
`const FormulaT & _origin ) const [protected], [inherited]`**0.15.135.4.73 `passedFormulaBegin()`** `ModuleInput::iterator smtrat::Module::passedFormulaBegin (`  
`) [inline], [protected], [inherited]`**Returns**

An iterator to the end of the passed formula. TODO: disable this method

**0.15.135.4.74 passedFormulaEnd()** `ModuleInput::iterator smtrat::Module::passedFormulaEnd ( )`  
[inline], [protected], [inherited]

**Returns**

An iterator to the end of the passed formula.

**0.15.135.4.75 pPassedFormula()** `const ModuleInput* smtrat::Module::pPassedFormula ( ) const`  
[inline], [inherited]

**Returns**

A pointer to the formula passed to the backends of this module.

**0.15.135.4.76 pReceivedFormula()** `const ModuleInput* smtrat::Module::pReceivedFormula ( ) const`  
[inline], [inherited]

**Returns**

A pointer to the formula passed to this module.

**0.15.135.4.77 print()** `void smtrat::Module::print (`  
`const std::string & _initiation = "***" ) const [inherited]`  
Prints everything relevant of the solver.

**Parameters**

|                          |                      |
|--------------------------|----------------------|
| <code>_initiation</code> | The line initiation. |
|--------------------------|----------------------|

**0.15.135.4.78 printAllModels()** `void smtrat::Module::printAllModels (`  
`std::ostream & _out = std::cout ) [inherited]`

Prints all assignments of this module satisfying its received formula if it satisfiable and this module could find an assignment.

**Parameters**

|                   |                                        |
|-------------------|----------------------------------------|
| <code>_out</code> | The stream to print the assignment on. |
|-------------------|----------------------------------------|

**0.15.135.4.79 printInfeasibleSubsets()** `void smtrat::Module::printInfeasibleSubsets (`  
`const std::string & _initiation = "***" ) const [inherited]`

Prints the infeasible subsets.

**Parameters**

|                          |                      |
|--------------------------|----------------------|
| <code>_initiation</code> | The line initiation. |
|--------------------------|----------------------|

**0.15.135.4.80 printModel()** `void smtrat::Module::printModel (`  
`std::ostream & _out = std::cout ) const [inherited]`

Prints the assignment of this module satisfying its received formula if it satisfiable and this module could find an assignment.

#### Parameters

|                   |                                        |
|-------------------|----------------------------------------|
| <code>_out</code> | The stream to print the assignment on. |
|-------------------|----------------------------------------|

**0.15.135.4.81 `printPassedFormula()`** `void smtrat::Module::printPassedFormula ( const std::string & _initiation = "***" ) const [inherited]`

Prints the vector of passed formula.

#### Parameters

|                          |                      |
|--------------------------|----------------------|
| <code>_initiation</code> | The line initiation. |
|--------------------------|----------------------|

**0.15.135.4.82 `printReceivedFormula()`** `void smtrat::Module::printReceivedFormula ( const std::string & _initiation = "***" ) const [inherited]`

Prints the vector of the received formula.

#### Parameters

|                          |                      |
|--------------------------|----------------------|
| <code>_initiation</code> | The line initiation. |
|--------------------------|----------------------|

**0.15.135.4.83 `probablyLooping()`** `bool smtrat::Module::probablyLooping ( const typename Poly::PolyType & _branchingPolynomial, const Rational & _branchingValue ) const [protected], [inherited]`

Checks whether given the current branching value and branching variable/polynomial it is (highly) probable that this branching is part of an infinite loop of branchings.

#### Parameters

|                                   |                                                                                     |
|-----------------------------------|-------------------------------------------------------------------------------------|
| <code>_branchingPolynomial</code> | The polynomial to branch at (in most branching strategies this is just a variable). |
| <code>_branchingValue</code>      | The value to branch at.                                                             |

#### Returns

true, if this branching is probably part of an infinite loop of branchings; false, otherwise.

**0.15.135.4.84 `receivedFormulaChecked()`** `void smtrat::Module::receivedFormulaChecked ( ) [inline], [inherited]`

Notifies that the received formulas has been checked.

**0.15.135.4.85 `receivedFormulasAsInfeasibleSubset()`** `void smtrat::Module::receivedFormulasAsInfeasibleSubset ( ModuleInput::const_iterator _subformula ) [inline], [protected], [inherited]`

Stores an infeasible subset consisting only of the given received formula.

**0.15.135.4.86 receivedVariable()** `bool smrat::Module::receivedVariable ( carl::Variable::Arg _var ) const [inline], [inherited]`

**0.15.135.4.87 remove()** `void smrat::Module::remove ( ModuleInput::const_iterator _subformula ) [virtual], [inherited]`

Removes everything related to the given sub-formula of the received formula.

However, it is desired not to lose track of search spaces where no satisfying assignment can be found for the remaining sub-formulas.

**Parameters**

|                          |                                                    |
|--------------------------|----------------------------------------------------|
| <code>_subformula</code> | The sub formula of the received formula to remove. |
|--------------------------|----------------------------------------------------|

Reimplemented in [smrat::PModule](#).

**0.15.135.4.88 removeCore()** `template<typename Settings > void smrat::CSplitModule< Settings >::removeCore ( ModuleInput::const_iterator _subformula ) [virtual]`

Removes the subformula of the received formula at the given position to the considered ones of this module. Note that this includes every stored calculation which depended on this subformula, but should keep the other stored calculation, if possible, untouched.

**Parameters**

|                          |                                           |
|--------------------------|-------------------------------------------|
| <code>_subformula</code> | The position of the subformula to remove. |
|--------------------------|-------------------------------------------|

Reimplemented from [smrat::Module](#).

**0.15.135.4.89 removeOrigin()** `std::pair<ModuleInput::iterator,bool> smrat::Module::removeOrigin ( ModuleInput::iterator _formula, const FormulaT & _origin ) [inline], [protected], [inherited]`

**0.15.135.4.90 removeOrigins()** `std::pair<ModuleInput::iterator,bool> smrat::Module::removeOrigins ( ModuleInput::iterator _formula, const std::shared_ptr< std::vector< FormulaT >> & _origins ) [inline], [protected], [inherited]`

**0.15.135.4.91 rPassedFormula()** `const ModuleInput& smrat::Module::rPassedFormula ( ) const [inline], [inherited]`

**Returns**

A reference to the formula passed to the backends of this module.

**0.15.135.4.92 rReceivedFormula()** `const ModuleInput& smrat::Module::rReceivedFormula ( ) const [inline], [inherited]`

**Returns**

A reference to the formula passed to this module.

**0.15.135.4.93 runBackends() [1/2]** `virtual Answer smtrat::Module::runBackends () [inline], [protected], [virtual], [inherited]`

Reimplemented in [smtrat::PModule](#).

**0.15.135.4.94 runBackends() [2/2]** `Answer smtrat::Module::runBackends (`

```
 bool _final,
 bool _full,
 carl::Variable _objective) [protected], [virtual], [inherited]
```

Runs the backend solvers on the passed formula.

**Parameters**

|                         |                                                                                                                                       |
|-------------------------|---------------------------------------------------------------------------------------------------------------------------------------|
| <code>_final</code>     | true, if this satisfiability check will be the last one (for a global sat-check), if its result is SAT                                |
| <code>_full</code>      | false, if this module should avoid too expensive procedures and rather return unknown instead.                                        |
| <code>_objective</code> | if not set to NO_VARIABLE, the module should find an assignment minimizing this objective variable; otherwise any assignment is good. |

**Returns**

True, if the passed formula is consistent; False, if the passed formula is inconsistent; Unknown, otherwise.

Reimplemented in [smtrat::PModule](#).

**0.15.135.4.95 setId()** `void smtrat::Module::setId (`

```
 std::size_t _id) [inline], [inherited]
```

Sets this modules unique ID to identify itself.

**Parameters**

|                 |                                    |
|-----------------|------------------------------------|
| <code>id</code> | The id to set this module's id to. |
|-----------------|------------------------------------|

**0.15.135.4.96 setThreadPriority()** `void smtrat::Module::setThreadPriority (`

```
 thread_priority _threadPriority) [inline], [inherited]
```

Sets the priority of this module to get a thread for running its check procedure.

**Parameters**

|                              |                                                       |
|------------------------------|-------------------------------------------------------|
| <code>_threadPriority</code> | The priority to set this module's thread priority to. |
|------------------------------|-------------------------------------------------------|

**0.15.135.4.97 solverState()** `Answer smtrat::Module::solverState () const [inline], [inherited]`

**Returns**

True, if this module is in a state, such that it has found a solution for its received formula; False, if this module is in a state, such that it has determined that there is no solution for its received formula; Unknown, otherwise.

**0.15.135.4.98 splitUnequalConstraint()** `void smtrat::Module::splitUnequalConstraint (`

`const FormulaT & _unequalConstraint ) [protected], [inherited]`

Adds the following lemmas for the given constraint  $p \neq 0$ .

$(p \neq 0 \leftrightarrow (p < 0 \text{ or } p > 0))$

and  $\neg(p < 0 \text{ and } p > 0)$

**Parameters**

|                                 |                                                  |
|---------------------------------|--------------------------------------------------|
| <code>_unequalConstraint</code> | A constraint having the relation symbol $\neq$ . |
|---------------------------------|--------------------------------------------------|

**0.15.135.4.99 threadPriority()** `thread_priority smtrat::Module::threadPriority ( ) const [inline], [inherited]`**Returns**

The priority of this module to get a thread for running its check procedure.

**0.15.135.4.100 updateAllModels()** `void smtrat::Module::updateAllModels ( ) [virtual], [inherited]`

Updates all satisfying models, if the solver has detected the consistency of the received formula, beforehand.

Reimplemented in [smtrat::SATModule< Settings >](#).

**0.15.135.4.101 updateLemmas()** `void smtrat::Module::updateLemmas ( ) [inherited]`

Stores all lemmas of any backend of this module in its own lemma vector.

**0.15.135.4.102 updateModel()** `template<typename Settings >`

`void smtrat::CSplitModule< Settings >::updateModel ( ) const [virtual]`

Updates the current assignment into the model.

Note, that this is a unique but possibly symbolic assignment maybe containing newly introduced variables.

Reimplemented from [smtrat::Module](#).

**0.15.135.4.103 usedBackends()** `const std::vector<Module*>& smtrat::Module::usedBackends ( )`

`const [inline], [inherited]`

**Returns**

The backends of this module which are currently used (conditions to use this module are fulfilled for the passed formula).

**0.15.135.5 Field Documentation****0.15.135.5.1 mAllBackends** `std::vector<Module*> smtrat::Module::mAllBackends [protected], [inherited]`

The backends of this module which have been used.

**0.15.135.5.2 mAllModels** `std::vector<Model>` `smtrat::Module::mAllModels` [mutable], [protected], [inherited]  
Stores all satisfying assignments.

**0.15.135.5.3 mBackendsFoundAnswer** `std::atomic_bool*` `smtrat::Module::mBackendsFoundAnswer` [protected], [inherited]  
This flag is passed to any backend and if it determines an answer to a prior check call, this flag is fired.

**0.15.135.5.4 mConstraintsToInform** `carl::FastSet<FormulaT>` `smtrat::Module::mConstraintsToInform` [protected], [inherited]  
Stores the constraints which the backends must be informed about.

**0.15.135.5.5 mFinalCheck** `bool` `smtrat::Module::mFinalCheck` [protected], [inherited]  
true, if the check procedure should perform a final check which especially means not to postpone splitting decisions

**0.15.135.5.6 mFirstPosInLastBranches** `std::size_t` `smtrat::Module::mFirstPosInLastBranches` = 0 [static], [inherited]  
The beginning of the cyclic buffer storing the last branches.

**0.15.135.5.7 mFirstSubformulaToPass** `ModuleInput::iterator` `smtrat::Module::mFirstSubformulaToPass` [protected], [inherited]  
Stores the position of the first sub-formula in the passed formula, which has not yet been considered for a consistency check of the backends.

**0.15.135.5.8 mFirstUncheckedReceivedSubformula** `ModuleInput::const_iterator` `smtrat::Module::mFirstUncheckedReceivedSubformula` [protected], [inherited]  
Stores the position of the first (by this module) unchecked sub-formula of the received formula.

**0.15.135.5.9 mFoundAnswer** `Conditionals` `smtrat::Module::mFoundAnswer` [protected], [inherited]  
Vector of Booleans: If any of them is true, we have to terminate a running check procedure.

**0.15.135.5.10 mFullCheck** `bool` `smtrat::Module::mFullCheck` [protected], [inherited]  
false, if this module should avoid too expensive procedures and rather return unknown instead.

**0.15.135.5.11 mInfeasibleSubsets** `std::vector<FormulaSetT>` `smtrat::Module::mInfeasibleSubsets` [protected], [inherited]  
Stores the infeasible subsets.

**0.15.135.5.12 mInformedConstraints** `carl::FastSet<FormulaT>` `smtrat::Module::mInformedConstraints` [protected], [inherited]  
Stores the position of the first constraint of which no backend has been informed about.

**0.15.135.5.13 mLastBranches** std::vector< Branching > smtrat::Module::mLastBranches = std::vector<Branching> (mNumOfBranchVarsToStore, Branching(typename Poly::PolyType(), 0)) [static], [inherited]

Stores the last branches in a cycle buffer.

**0.15.135.5.14 mLemmas** std::vector<Lemma> smtrat::Module::mLemmas [protected], [inherited]  
Stores the lemmas being valid formulas this module or its backends made.

**0.15.135.5.15 mModel** Model smtrat::Module::mModel [mutable], [protected], [inherited]  
Stores the assignment of the current satisfiable result, if existent.

**0.15.135.5.16 mModelComputed** bool smtrat::Module::mModelComputed [mutable], [protected], [inherited]  
True, if the model has already been computed.

**0.15.135.5.17 mNumOfBranchVarsToStore** std::size\_t smtrat::Module::mNumOfBranchVarsToStore = 5 [static], [inherited]  
The number of different variables to consider for a probable infinite loop of branchings.

**0.15.135.5.18 mObjectiveVariable** carl::Variable smtrat::Module::mObjectiveVariable [protected], [inherited]  
Objective variable to be minimized. If set to NO\_VARIABLE, a normal sat check should be performed.

**0.15.135.5.19 mOldSplittingVariables** std::vector< FormulaT > smtrat::Module::mOldSplittingVariables [static], [inherited]  
Reusable splitting variables.

**0.15.135.5.20 mpManager** Manager\* const smtrat::Module::mpManager [protected], [inherited]  
A reference to the manager.

**0.15.135.5.21 mSmallerMusesCheckCounter** unsigned smtrat::Module::mSmallerMusesCheckCounter [mutable], [protected], [inherited]  
Counter used for the generation of the smt2 files to check for smaller muses.

**0.15.135.5.22 mSolverState** std::atomic<Answer> smtrat::Module::mSolverState [protected], [inherited]  
States whether the received formula is known to be satisfiable or unsatisfiable otherwise it is set to unknown.

**0.15.135.5.23 mTheoryPropagations** std::vector<TheoryPropagation> smtrat::Module::mTheoryPropagations [protected], [inherited]

**0.15.135.5.24 mUsedBackends** std::vector<Module\*> smtrat::Module::mUsedBackends [protected], [inherited]

The backends of this module which are currently used (conditions to use this module are fulfilled for the passed formula).

**0.15.135.5.25 mVariableCounters** std::vector<std::size\_t> smtrat::Module::mVariableCounters [protected], [inherited]

Maps variables to the number of their occurrences.

**0.15.136 smtrat::CubeLIAModule< Settings > Class Template Reference**

```
#include <CubeLIAModule.h>
```

**Public Types**

- **typedef Settings SettingsType**
- **enum class LemmaType : unsigned { NORMAL = 0 , PERMANENT = 1 }**

**Public Member Functions**

- **std::string moduleName () const**
- **CubeLIAModule (const ModuleInput \*\_formula, Conditionals &\_conditionals, Manager \*\_manager=nullptr)**
- **~CubeLIAModule ()**
- **bool addCore (ModuleInput::const\_iterator \_subformula)**

*The module has to take the given sub-formula of the received formula into account.*
- **void removeCore (ModuleInput::const\_iterator \_subformula)**

*Removes the subformula of the received formula at the given position to the considered ones of this module.*
- **void updateModel () const**

*Updates the current assignment into the model.*
- **Answer checkCore ()**

*Checks the received formula for consistency.*
- **bool inform (const FormulaT &\_constraint)**

*Informs the module about the given constraint.*
- **void deinform (const FormulaT &\_constraint)**

*The inverse of informing about a constraint.*
- **virtual void init ()**

*Informs all backends about the so far encountered constraints, which have not yet been communicated.*
- **bool add (ModuleInput::const\_iterator \_subformula)**

*The module has to take the given sub-formula of the received formula into account.*
- **virtual Answer check (bool \_final=false, bool \_full=true, carl::Variable \_objective=carl::Variable::NO\_VARIABLE)**

*Checks the received formula for consistency.*
- **virtual void remove (ModuleInput::const\_iterator \_subformula)**

*Removes everything related to the given sub-formula of the received formula.*
- **virtual void updateAllModels ()**

*Updates all satisfying models, if the solver has detected the consistency of the received formula, beforehand.*
- **virtual std::list< std::vector< carl::Variable > > getModelEqualities () const**

*Partition the variables from the current model into equivalence classes according to their assigned value.*
- **unsigned currentlySatisfiedByBackend (const FormulaT &\_formula) const**
- **virtual unsigned currentlySatisfied (const FormulaT &) const**
- **bool receivedVariable (carl::Variable::Arg \_var) const**
- **Answer solverState () const**
- **std::size\_t id () const**

- void `setId` (std::size\_t \_id)  
*Sets this module's unique ID to identify itself.*
- `thread_priority threadPriority () const`
- void `setThreadPriority (thread_priority _threadPriority)`  
*Sets the priority of this module to get a thread for running its check procedure.*
- const `ModuleInput * pReceivedFormula () const`
- const `ModuleInput & rReceivedFormula () const`
- const `ModuleInput * pPassedFormula () const`
- const `ModuleInput & rPassedFormula () const`
- const `Model & model () const`
- const std::vector< `Model` > & `allModels () const`
- const std::vector< `FormulaSetT` > & `infeasibleSubsets () const`
- const std::vector< `Module` \* > & `usedBackends () const`
- const carl::FastSet< `FormulaT` > & `constraintsToInform () const`
- const carl::FastSet< `FormulaT` > & `informedConstraints () const`
- void `addLemma (const FormulaT &_lemma, const LemmaType &_lt=LemmaType::NORMAL, const FormulaT &_preferredFormula=FormulaT(carl::FormulaType::TRUE))`  
*Stores a lemma being a valid formula.*
- bool `hasLemmas ()`  
*Checks whether this module or any of its backends provides any lemmas.*
- void `clearLemmas ()`  
*Deletes all yet found lemmas.*
- const std::vector< `Lemma` > & `lemmas () const`
- `ModuleInput::const_iterator firstUncheckedReceivedSubformula () const`
- `ModuleInput::const_iterator firstSubformulaToPass () const`
- void `receivedFormulaChecked ()`  
*Notifies that the received formulas has been checked.*
- const `smtat::Conditionals & answerFound () const`
- bool `isPreprocessor () const`
- carl::Variable `objective () const`
- bool `is_minimizing () const`
- void `excludeNotReceivedVariablesFromModel () const`  
*Excludes all variables from the current model, which do not occur in the received formula.*
- void `updateLemmas ()`  
*Stores all lemmas of any backend of this module in its own lemma vector.*
- void `collectTheoryPropagations ()`
- void `collectOrigins (const FormulaT &_formula, FormulasT &_origins) const`  
*Collects the formulas in the given formula, which are part of the received formula.*
- void `collectOrigins (const FormulaT &_formula, FormulaSetT &_origins) const`
- bool `isValidInfeasibleSubset () const`
- void `checkInfSubsetForMinimality (std::vector< FormulaSetT >::const_iterator _infsubset, const std::string &_filename="smaller_muses", unsigned _maxSizeDifference=1) const`  
*Checks the given infeasible subset for minimality by storing all subsets of it, which have a smaller size which differs from the size of the infeasible subset not more than the given threshold.*
- virtual std::pair< bool, `FormulaT` > `getReceivedFormulaSimplified ()`
- void `print (const std::string &_initiation="***") const`  
*Prints everything relevant of the solver.*
- void `printReceivedFormula (const std::string &_initiation="***") const`  
*Prints the vector of the received formula.*
- void `printPassedFormula (const std::string &_initiation="***") const`  
*Prints the vector of passed formula.*
- void `printInfeasibleSubsets (const std::string &_initiation="***") const`  
*Prints the infeasible subsets.*

- void `printModel` (std::ostream &\_out=std::cout) const  
*Prints the assignment of this module satisfying its received formula if it satisfiable and this module could find an assignment.*
- void `printAllModels` (std::ostream &\_out=std::cout)  
*Prints all assignments of this module satisfying its received formula if it satisfiable and this module could find an assignment.*

### Static Public Member Functions

- static void `freeSplittingVariable` (const `FormulaT` &\_splittingVariable)

### Static Public Attributes

- static size\_t `mNumOfBranchVarsToStore` = 5  
*The number of different variables to consider for a probable infinite loop of branchings.*
- static std::vector< `Branching` > `mLastBranches` = std::vector<`Branching`>(mNumOfBranchVarsToStore, `Branching`(typename Poly::PolyType(), 0))  
*Stores the last branches in a cycle buffer.*
- static size\_t `mFirstPosInLastBranches` = 0  
*The beginning of the cyclic buffer storing the last branches.*
- static std::vector< `FormulaT` > `mOldSplittingVariables`  
*Reusable splitting variables.*

### Protected Member Functions

- virtual bool `informCore` (const `FormulaT` &\_constraint)  
*Informs the module about the given constraint.*
- virtual void `deinformCore` (const `FormulaT` &\_constraint)  
*The inverse of informing about a constraint.*
- bool `anAnswerFound` () const  
*Checks for all antecedent modules and those which run in parallel with the same antecedent modules, whether one of them has determined a result.*
- void `clearModel` () const  
*Clears the assignment, if any was found.*
- void `clearModels` () const  
*Clears all assignments, if any was found.*
- void `cleanModel` () const  
*Substitutes variable occurrences by its model value in the model values of other variables.*
- `ModuleInput::iterator` `passedFormulaBegin` ()
- `ModuleInput::iterator` `passedFormulaEnd` ()
- void `addOrigin` (`ModuleInput::iterator` \_formula, const `FormulaT` &\_origin)  
*Adds the given set of formulas in the received formula to the origins of the given passed formula.*
- const `FormulaT` & `getOrigins` (`ModuleInput::const_iterator` \_formula) const  
*Gets the origins of the passed formula at the given position.*
- void `getOrigins` (const `FormulaT` &\_formula, `FormulasT` &\_origins) const
- void `getOrigins` (const `FormulaT` &\_formula, `FormulaSetT` &\_origins) const
- std::pair< `ModuleInput::iterator`, bool > `removeOrigin` (`ModuleInput::iterator` \_formula, const `FormulaT` &\_origin)  
*Removes the origin of the given formula from the passed formula.*
- std::pair< `ModuleInput::iterator`, bool > `removeOrigins` (`ModuleInput::iterator` \_formula, const std::shared\_ptr< std::vector< `FormulaT` >> &\_origins)  
*Removes all origins of the given formula from the passed formula.*
- void `informBackends` (const `FormulaT` &\_constraint)  
*Informs all backends of this module about the given constraint.*
- virtual void `addConstraintToInform` (const `FormulaT` &\_constraint)  
*Adds a constraint to the collection of constraints of this module, which are informed to a freshly generated backend.*

- std::pair< `ModuleInput::iterator`, bool > `addReceivedSubformulaToPassedFormula` (`ModuleInput::const_iterator` \_subformula)
 

*Copies the given sub-formula of the received formula to the passed formula.*
- bool `originInReceivedFormula` (const `FormulaT` &\_origin) const
- std::pair< `ModuleInput::iterator`, bool > `addSubformulaToPassedFormula` (const `FormulaT` &\_formula)
 

*Adds the given formula to the passed formula with no origin.*
- std::pair< `ModuleInput::iterator`, bool > `addSubformulaToPassedFormula` (const `FormulaT` &\_formula, const std::shared\_ptr< std::vector< `FormulaT` >> &\_origins)
 

*Adds the given formula to the passed formula.*
- std::pair< `ModuleInput::iterator`, bool > `addSubformulaToPassedFormula` (const `FormulaT` &\_formula, const `FormulaT` &\_origin)
 

*Adds the given formula to the passed formula.*
- void `generateTrivialInfeasibleSubset` ()
 

*Stores the trivial infeasible subset being the set of received formulas.*
- void `receivedFormulasAsInfeasibleSubset` (`ModuleInput::const_iterator` \_subformula)
 

*Stores an infeasible subset consisting only of the given received formula.*
- std::vector< `FormulaT` >::const\_iterator `findBestOrigin` (const std::vector< `FormulaT` > &\_origins) const
- void `getInfeasibleSubsets` ()
 

*Copies the infeasible subsets of the passed formula.*
- std::vector< `FormulaSetT` > `getInfeasibleSubsets` (const `Module` &\_backend) const
 

*Get the infeasible subsets the given backend provides.*
- const `Model` & `backendsModel` () const
 

*Stores the model of a backend which determined satisfiability of the passed formula in the model of this module.*
- void `getBackendsModel` () const
- void `getBackendsAllModels` () const
 

*Stores all models of a backend in the list of all models of this module.*
- virtual `Answer runBackends` (bool \_final, bool \_full, carl::Variable \_objective)
 

*Runs the backend solvers on the passed formula.*
- virtual `Answer runBackends` ()
- virtual `ModuleInput::iterator eraseSubformulaFromPassedFormula` (`ModuleInput::iterator` \_subformula, bool \_ignoreOrigins=false)
 

*Removes everything related to the sub-formula to remove from the passed formula in the backends of this module.*
- void `clearPassedFormula` ()
- std::vector< `FormulaT` > `merge` (const std::vector< `FormulaT` > &, const std::vector< `FormulaT` > &) const
 

*Merges the two vectors of sets into the first one.*
- size\_t `determine_smallest_origin` (const std::vector< `FormulaT` > &origins) const
- bool `probablyLooping` (const typename Poly::PolyType &\_branchingPolynomial, const Rational &\_branchingValue) const
 

*Checks whether given the current branching value and branching variable/polynomial it is (highly) probable that this branching is part of an infinite loop of branchings.*
- bool `branchAt` (const Poly &\_polynomial, bool \_integral, const Rational &\_value, std::vector< `FormulaT` > &&\_premise, bool \_leftCaseWeak=true, bool \_preferLeftCase=true, bool \_useReceivedFormulaAsPremise=false)
 

*Adds a lemmas which provoke a branching for the given variable at the given value, if this module returns Unknown and there exists a preceding SATModule.*
- bool `branchAt` (const Poly &\_polynomial, bool \_integral, const Rational &\_value, bool \_leftCaseWeak=true, bool \_preferLeftCase=true, bool \_useReceivedFormulaAsPremise=false, const std::vector< `FormulaT` > &←\_premise=std::vector< `FormulaT` >())
 

*Adds a lemmas which provoke a branching for the given variable at the given value, if this module returns Unknown and there exists a preceding SATModule.*
- bool `branchAt` (carl::Variable::Arg \_var, const Rational &\_value, std::vector< `FormulaT` > &&\_premise, bool \_leftCaseWeak=true, bool \_preferLeftCase=true, bool \_useReceivedFormulaAsPremise=false)
 

*Adds a lemmas which provoke a branching for the given variable at the given value, if this module returns Unknown and there exists a preceding SATModule.*
- bool `branchAt` (carl::Variable::Arg \_var, const Rational &\_value, bool \_leftCaseWeak=true, bool \_preferLeftCase=true, bool \_useReceivedFormulaAsPremise=false, const std::vector< `FormulaT` > &\_premise=std::vector< `FormulaT` >())
 

*Adds a lemmas which provoke a branching for the given variable at the given value, if this module returns Unknown and there exists a preceding SATModule.*

- void `splitUnequalConstraint` (const `FormulaT` &)
 

*Adds the following lemmas for the given constraint  $p \neq 0$ .*
- unsigned `checkModel` () const
- void `addInformationRelevantFormula` (const `FormulaT` &`formula`)
 

*Adds a formula to the InformationRelevantFormula.*
- const std::set< `FormulaT` > & `getInformationRelevantFormulas` ()
 

*Gets all InformationRelevantFormulas.*
- bool `isLemmaLevel` (`LemmaLevel` level)
 

*Checks if current lemma level is greater or equal to given level.*

### Static Protected Member Functions

- static bool `modelsDisjoint` (const `Model` &`_modelA`, const `Model` &`_modelB`)
 

*Checks whether there is no variable assigned by both models.*

### Protected Attributes

- std::vector< `FormulaSetT` > `mInfeasibleSubsets`

*Stores the infeasible subsets.*
- `Manager` \*const `mpManager`

*A reference to the manager.*
- `Model` `mModel`

*Stores the assignment of the current satisfiable result, if existent.*
- std::vector< `Model` > `mAllModels`

*Stores all satisfying assignments.*
- bool `mModelComputed`

*True, if the model has already been computed.*
- bool `mFinalCheck`

*true, if the check procedure should perform a final check which especially means not to postpone splitting decisions*
- bool `mFullCheck`

*false, if this module should avoid too expensive procedures and rather return unknown instead.*
- carl::Variable `mObjectiveVariable`

*Objective variable to be minimized. If set to NO\_VARIABLE, a normal sat check should be performed.*
- std::vector< `TheoryPropagation` > `mTheoryPropagations`
- std::atomic< `Answer` > `mSolverState`

*States whether the received formula is known to be satisfiable or unsatisfiable otherwise it is set to unknown.*
- std::atomic\_bool \* `mBackendsFoundAnswer`

*This flag is passed to any backend and if it determines an answer to a prior check call, this flag is fired.*
- Conditionals `mFoundAnswer`

*Vector of Booleans: If any of them is true, we have to terminate a running check procedure.*
- std::vector< `Module` \* > `mUsedBackends`

*The backends of this module which are currently used (conditions to use this module are fulfilled for the passed formula).*
- std::vector< `Module` \* > `mAllBackends`

*The backends of this module which have been used.*
- std::vector< `Lemma` > `mLemmas`

*Stores the lemmas being valid formulas this module or its backends made.*
- `ModuleInput`::iterator `mFirstSubformulaToPass`

*Stores the position of the first sub-formula in the passed formula, which has not yet been considered for a consistency check of the backends.*
- carl::FastSet< `FormulaT` > `mConstraintsToInform`

*Stores the constraints which the backends must be informed about.*

- `carl::FastSet< FormulaT > mInformedConstraints`  
*Stores the position of the first constraint of which no backend has been informed about.*
- `ModuleInput::const_iterator mFirstUncheckedReceivedSubformula`  
*Stores the position of the first (by this module) unchecked sub-formula of the received formula.*
- `unsigned mSmallerMusesCheckCounter`  
*Counter used for the generation of the smt2 files to check for smaller muses.*
- `std::vector< std::size_t > mVariableCounters`  
*Maps variables to the number of their occurrences.*

### 0.15.136.4 Member Function Documentation

**0.15.136.4.1 add()** `bool smtrat::Module::add (`  
`ModuleInput::const_iterator _subformula ) [inherited]`

The module has to take the given sub-formula of the received formula into account.

Parameters

|                          |                                                    |
|--------------------------|----------------------------------------------------|
| <code>_subformula</code> | The sub-formula to take additionally into account. |
|--------------------------|----------------------------------------------------|

**Returns**

false, if it can be easily decided that this sub-formula causes a conflict with the already considered sub-formulas; true, otherwise.

**0.15.136.4.2 addConstraintToInform()** `void smtrat::Module::addConstraintToInform (`

```
const FormulaT & _constraint) [protected], [virtual], [inherited]
```

Adds a constraint to the collection of constraints of this module, which are informed to a freshly generated backend.

**Parameters**

|                          |                        |
|--------------------------|------------------------|
| <code>_constraint</code> | The constraint to add. |
|--------------------------|------------------------|

Reimplemented in [smtrat::SATModule< Settings >](#).

**0.15.136.4.3 addCore()** `template<typename Settings >`

```
bool smtrat::CubeLIAModule< Settings >::addCore (
 ModuleInput::const_iterator _subformula) [virtual]
```

The module has to take the given sub-formula of the received formula into account.

**Parameters**

|                          |                                                    |
|--------------------------|----------------------------------------------------|
| <code>_subformula</code> | The sub-formula to take additionally into account. |
|--------------------------|----------------------------------------------------|

**Returns**

false, if it can be easily decided that this sub-formula causes a conflict with the already considered sub-formulas; true, otherwise.

Reimplemented from [smtrat::Module](#).

**0.15.136.4.4 addInformationRelevantFormula()** `void smtrat::Module::addInformationRelevantFormula`

```
(
```

```
const FormulaT & formula) [protected], [inherited]
```

Adds a formula to the InformationRelevantFormula.

**Parameters**

|                      |                |
|----------------------|----------------|
| <code>formula</code> | Formula to add |
|----------------------|----------------|

**0.15.136.4.5 addLemma()** `void smtrat::Module::addLemma (`

```
const FormulaT & _lemma,
```

```
const LemmaType & _lt = LemmaType::NORMAL,
```

```
const FormulaT & _preferredFormula = FormulaT(carl::FormulaType::TRUE)) [inline],
```

```
[inherited]
```

Stores a lemma being a valid formula.

**Parameters**

|                                |                                                                       |
|--------------------------------|-----------------------------------------------------------------------|
| <code>_lemma</code>            | The eduction/lemma to store.                                          |
| <code>_lt</code>               | The type of the lemma.                                                |
| <code>_preferredFormula</code> | Hint for the next decision, which formula should be assigned to true. |

**0.15.136.4.6 addOrigin()** `void smtrat::Module::addOrigin (`

```
 ModuleInput::iterator _formula,
 const FormulaT & _origin) [inline], [protected], [inherited]
```

Adds the given set of formulas in the received formula to the origins of the given passed formula.

**Parameters**

|                       |                                                           |
|-----------------------|-----------------------------------------------------------|
| <code>_formula</code> | The passed formula to set the origins for.                |
| <code>_origin</code>  | A set of formulas in the received formula of this module. |

**0.15.136.4.7 addReceivedSubformulaToPassedFormula()** `std::pair<ModuleInput::iterator, bool>`

```
smtrat::Module::addReceivedSubformulaToPassedFormula (
```

```
 ModuleInput::const_iterator _subformula) [inline], [protected], [inherited]
```

Copies the given sub-formula of the received formula to the passed formula.

Note, that there is always a link between sub-formulas of the passed formulas to sub-formulas of the received formulas, which are responsible for its occurrence.

**Parameters**

|                          |                                                  |
|--------------------------|--------------------------------------------------|
| <code>_subformula</code> | The sub-formula of the received formula to copy. |
|--------------------------|--------------------------------------------------|

**0.15.136.4.8 addSubformulaToPassedFormula() [1/3]** `std::pair<ModuleInput::iterator, bool>` `smtrat::Module::addSubformulaToPassedFormula (`

```
 const FormulaT & _formula) [inline], [protected], [inherited]
```

Adds the given formula to the passed formula with no origin.

Note that in the next call of this module's removeSubformula, all formulas in the passed formula without origins will be removed.

**Parameters**

|                       |                                           |
|-----------------------|-------------------------------------------|
| <code>_formula</code> | The formula to add to the passed formula. |
|-----------------------|-------------------------------------------|

**Returns**

A pair to the position where the formula to add has been inserted (or its first sub-formula which has not yet been in the passed formula, in case the formula to add is a conjunction), and a Boolean stating whether anything has been added to the passed formula.

**0.15.136.4.9 addSubformulaToPassedFormula() [2/3]** `std::pair<ModuleInput::iterator, bool>` `smtrat::Module::addSubformulaToPassedFormula (`

```
 const FormulaT & _formula,
 const FormulaT & _origin) [inline], [protected], [inherited]
```

Adds the given formula to the passed formula.

**Parameters**

|                       |                                                                                                                           |
|-----------------------|---------------------------------------------------------------------------------------------------------------------------|
| <code>_formula</code> | The formula to add to the passed formula.                                                                                 |
| <code>_origin</code>  | The sub-formula of the received formula being responsible for the occurrence of the formula to add to the passed formula. |

**Returns**

A pair to the position where the formula to add has been inserted (or its first sub-formula which has not yet been in the passed formula, in case the formula to add is a conjunction), and a Boolean stating whether anything has been added to the passed formula.

**0.15.136.4.10 addSubformulaToPassedFormula() [3/3] std::pair<ModuleInput::iterator,bool>**

```
smtrat::Module::addSubformulaToPassedFormula (
 const FormulaT & _formula,
 const std::shared_ptr< std::vector< FormulaT >> & _origins) [inline], [protected],
[inherited]
```

Adds the given formula to the passed formula.

**Parameters**

|                       |                                                                                                                                         |
|-----------------------|-----------------------------------------------------------------------------------------------------------------------------------------|
| <code>_formula</code> | The formula to add to the passed formula.                                                                                               |
| <code>_origins</code> | The link of the formula to add to the passed formula to sub-formulas of the received formulas, which are responsible for its occurrence |

**Returns**

A pair to the position where the formula to add has been inserted (or its first sub-formula which has not yet been in the passed formula, in case the formula to add is a conjunction), and a Boolean stating whether anything has been added to the passed formula.

**0.15.136.4.11 allModels() const std::vector<Model>& smtrat::Module::allModels () const [inline], [inherited]****Returns**

All satisfying assignments, if existent.

**0.15.136.4.12 anAnswerFound() bool smtrat::Module::anAnswerFound () const [inline], [protected], [inherited]**

Checks for all antecedent modules and those which run in parallel with the same antecedent modules, whether one of them has determined a result.

**Returns**

True, if one of them has determined a result.

**0.15.136.4.13 answerFound() const smtrat::Conditionals& smtrat::Module::answerFound () const [inline], [inherited]****Returns**

A vector of Booleans: If any of them is true, we have to terminate a running check procedure.

**0.15.136.4.14 backendsModel() const Model & smtrat::Module::backendsModel () const [protected], [inherited]**

Stores the model of a backend which determined satisfiability of the passed formula in the model of this module.

---

**0.15.136.4.15** **branchAt()** [1/4] `bool smrat::Module::branchAt (`

```
carl::Variable::Arg _var,
const Rational & _value,
bool _leftCaseWeak = true,
bool _preferLeftCase = true,
bool _useReceivedFormulaAsPremise = false,
const std::vector< FormulaT > & _premise = std::vector<FormulaT>()) [inline],
[protected], [inherited]
```

**0.15.136.4.16** **branchAt()** [2/4] `bool smrat::Module::branchAt (`

```
carl::Variable::Arg _var,
const Rational & _value,
std::vector< FormulaT > && _premise,
bool _leftCaseWeak = true,
bool _preferLeftCase = true,
bool _useReceivedFormulaAsPremise = false) [inline], [protected], [inherited]
```

**0.15.136.4.17** **branchAt()** [3/4] `bool smrat::Module::branchAt (`

```
const Poly & _polynomial,
bool _integral,
const Rational & _value,
bool _leftCaseWeak = true,
bool _preferLeftCase = true,
bool _useReceivedFormulaAsPremise = false,
const std::vector< FormulaT > & _premise = std::vector<FormulaT>()) [inline],
[protected], [inherited]
```

**0.15.136.4.18** **branchAt()** [4/4] `bool smrat::Module::branchAt (`

```
const Poly & _polynomial,
bool _integral,
const Rational & _value,
std::vector< FormulaT > && _premise,
bool _leftCaseWeak = true,
bool _preferLeftCase = true,
bool _useReceivedFormulaAsPremise = false) [protected], [inherited]
```

Adds a lemmas which provoke a branching for the given variable at the given value, if this module returns Unknown and there exists a preceding [SATModule](#).

Note that the given value is rounded down and up, if the given variable is integer-valued.

#### Parameters

|                                           |                                                                                                                                                                                                                |
|-------------------------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>_polynomial</code>                  | The variable to branch for.                                                                                                                                                                                    |
| <code>_integral</code>                    | A flag being true, if all variables in the polynomial to branch for are integral.                                                                                                                              |
| <code>_value</code>                       | The value to branch at.                                                                                                                                                                                        |
| <code>_premise</code>                     | The sub-formulas of the received formula from which the branch is followed. Note, that a premise is not necessary, as every branch is a valid formula. But a premise can prevent from branching unnecessarily. |
| <code>_leftCaseWeak</code>                | true, if a branching in the form of (or ( $\leq p b$ ) ( $> p b$ )) is desired. false, if a branching in the form of (or ( $< p b$ ) ( $\geq p b$ )) is desired.                                               |
| <code>_preferLeftCase</code>              | true, if the left case (polynomial less(or equal) 0 shall be chosen first. false, otherwise.                                                                                                                   |
| <code>_useReceivedFormulaAsPremise</code> | true, if the whole received formula should be used as premise                                                                                                                                                  |

```
0.15.136.4.19 check() Answer smrat::Module::check (
 bool _final = false,
 bool _full = true,
 carl::Variable _objective = carl::Variable::NO_VARIABLE) [virtual], [inherited]
```

Checks the received formula for consistency.

Note, that this is an implementation of the satisfiability check of the conjunction of the so far received formulas, which does actually nothing but passing the problem to its backends. This implementation is only used internally and must be overwritten by any derived module.

#### Parameters

|                   |                                                                                                                                       |
|-------------------|---------------------------------------------------------------------------------------------------------------------------------------|
| <i>_final</i>     | true, if this satisfiability check will be the last one (for a global sat-check), if its result is SAT                                |
| <i>_full</i>      | false, if this module should avoid too expensive procedures and rather return unknown instead.                                        |
| <i>_objective</i> | if not set to NO_VARIABLE, the module should find an assignment minimizing this objective variable; otherwise any assignment is good. |

#### Returns

True, if the received formula is satisfiable; False, if the received formula is not satisfiable; Unknown, otherwise.

Reimplemented in [smrat::PModule](#).

```
0.15.136.4.20 checkCore() template<typename Settings >
Answer smrat::CubeLIAModule< Settings >::checkCore () [virtual]
```

Checks the received formula for consistency.

#### Returns

SAT, if the received formula is satisfiable; UNSAT, if the received formula is not satisfiable; Unknown, otherwise.

Reimplemented from [smrat::Module](#).

```
0.15.136.4.21 checkInfeasibleSubsetForMinimality() void smrat::Module::checkInfeasibleSubsetForMinimality (
 std::vector< FormulaSetT >::const_iterator _infssubset,
 const std::string & _filename = "smaller_muses",
 unsigned _maxSizeDifference = 1) const [inherited]
```

Checks the given infeasible subset for minimality by storing all subsets of it, which have a smaller size which differs from the size of the infeasible subset not more than the given threshold.

#### Parameters

|                           |                                                                                                        |
|---------------------------|--------------------------------------------------------------------------------------------------------|
| <i>_infssubset</i>        | The infeasible subset to check for minimality.                                                         |
| <i>_filename</i>          | The name of the file to store the infeasible subsets in order to be able to check their infeasibility. |
| <i>_maxSizeDifference</i> | The maximal difference between the sizes of the subsets compared to the size of the infeasible subset. |

```
0.15.136.4.22 checkModel() unsigned smrat::Module::checkModel () const [protected], [inherited]
```

**Returns**

false, if the current model of this module does not satisfy the current given formula; true, if it cannot be said whether the model satisfies the given formula.

**0.15.136.4.23 cleanModel()** void smtrat::Module::cleanModel ( ) const [inline], [protected], [inherited]

Substitutes variable occurrences by its model value in the model values of other variables.

**0.15.136.4.24 clearLemmas()** void smtrat::Module::clearLemmas ( ) [inline], [inherited]

Deletes all yet found lemmas.

**0.15.136.4.25 clearModel()** void smtrat::Module::clearModel ( ) const [inline], [protected], [inherited]

Clears the assignment, if any was found.

**0.15.136.4.26 clearModels()** void smtrat::Module::clearModels ( ) const [inline], [protected], [inherited]

Clears all assignments, if any was found.

**0.15.136.4.27 clearPassedFormula()** void smtrat::Module::clearPassedFormula ( ) [protected], [inherited]

**0.15.136.4.28 collectOrigins() [1/2]** void smtrat::Module::collectOrigins ( const `FormulaT` & `_formula`, `FormulaSetT` & `_origins` ) const [inherited]

**0.15.136.4.29 collectOrigins() [2/2]** void smtrat::Module::collectOrigins ( const `FormulaT` & `_formula`, `FormulasT` & `_origins` ) const [inherited]

Collects the formulas in the given formula, which are part of the received formula.

If the given formula directly occurs in the received formula, it is inserted into the given set. Otherwise, the given formula must be of type AND and all its sub-formulas part of the received formula. Hence, they will be added to the given set.

**Parameters**

|                       |                                                                                                      |
|-----------------------|------------------------------------------------------------------------------------------------------|
| <code>_formula</code> | The formula from which to collect the formulas being sub-formulas of the received formula (origins). |
| <code>_origins</code> | The set in which to store the origins.                                                               |

**0.15.136.4.30 collectTheoryPropagations()** void smtrat::Module::collectTheoryPropagations ( ) [inherited]

**0.15.136.4.31 constraintsToInform()** const carl::FastSet<`FormulaT`>& smtrat::Module::constraintsToInform ( ) const [inline], [inherited]

**Returns**

The constraints which the backends must be informed about.

**0.15.136.4.32 currentlySatisfied()** `virtual unsigned smtrat::Module::currentlySatisfied ( const FormulaT & ) const [inline], [virtual], [inherited]`

**Returns**

0, if the given formula is conflicted by the current model; 1, if the given formula is satisfied by the current model; 2, otherwise; 3, if we do not know anything (default)

Reimplemented in [smtrat::LRAModule< Settings >](#), [smtrat::LRAModule< LRASettingsICP >](#), and [smtrat::LRAModule< LRASettings >](#)

**0.15.136.4.33 currentlySatisfiedByBackend()** `unsigned smtrat::Module::currentlySatisfiedByBackend ( const FormulaT & _formula ) const [inherited]`

**Returns**

0, if the given formula is conflicted by the current model; 1, if the given formula is satisfied by the current model; 2, otherwise 3, if we do not know anything (default)

**0.15.136.4.34 deinform()** `void smtrat::Module::deinform ( const FormulaT & _constraint ) [inherited]`

The inverse of informing about a constraint.

All data structures which were kept regarding this constraint are going to be removed. Note, that this makes only sense if it is not likely enough that a formula with this constraint must be solved again.

**Parameters**

|                          |                                                         |
|--------------------------|---------------------------------------------------------|
| <code>_constraint</code> | The constraint to remove from internal data structures. |
|--------------------------|---------------------------------------------------------|

**0.15.136.4.35 deinformCore()** `virtual void smtrat::Module::deinformCore ( const FormulaT & _constraint ) [inline], [protected], [virtual], [inherited]`

The inverse of informing about a constraint.

All data structures which were kept regarding this constraint are going to be removed. Note, that this makes only sense if it is not likely enough that a formula with this constraint must be solved again.

**Parameters**

|                          |                                                         |
|--------------------------|---------------------------------------------------------|
| <code>_constraint</code> | The constraint to remove from internal data structures. |
|--------------------------|---------------------------------------------------------|

Reimplemented in [smtrat::LRAModule< Settings >](#), [smtrat::LRAModule< LRASettingsICP >](#), and [smtrat::LRAModule< LRASettings >](#)

**0.15.136.4.36 determine\_smallest\_origin()** `size_t smtrat::Module::determine_smallest_origin ( const std::vector< FormulaT > & origins ) const [protected], [inherited]`

**Parameters**

|                      |                              |
|----------------------|------------------------------|
| <code>origins</code> | A vector of sets of origins. |
|----------------------|------------------------------|

**Returns**

The index of the smallest (regarding the size of the sets) element of origins

**0.15.136.4.37 eraseSubformulaFromPassedFormula()** `ModuleInput::iterator smtrat::Module::eraseSubformulaFromPassedFormula (`

```
 ModuleInput::iterator _subformula,
 bool _ignoreOrigins = false) [protected], [virtual], [inherited]
```

Removes everything related to the sub-formula to remove from the passed formula in the backends of this module. Afterwards the sub-formula is removed from the passed formula.

**Parameters**

|                             |                                                                                                              |
|-----------------------------|--------------------------------------------------------------------------------------------------------------|
| <code>_subformula</code>    | The sub-formula to remove from the passed formula.                                                           |
| <code>_ignoreOrigins</code> | True, if the sub-formula shall be removed regardless of its origins (should only be applied with expertise). |

**Returns**

Reimplemented in `smtrat::ICPModule< Settings >`, `smtrat::ICPModule< ICPSettings4 >`, and `smtrat::ICPModule< ICPSettings1 >`.

**0.15.136.4.38 excludeNotReceivedVariablesFromModel()** `void smtrat::Module::excludeNotReceivedVariablesFromModel ( ) const [inherited]`

Excludes all variables from the current model, which do not occur in the received formula.

**0.15.136.4.39 findBestOrigin()** `std::vector< FormulaT >::const_iterator smtrat::Module::findBestOrigin (`

```
 const std::vector< FormulaT > & _origins) const [protected], [inherited]
```

**Parameters**

|                       |
|-----------------------|
| <code>_origins</code> |
|-----------------------|

**Returns****0.15.136.4.40 firstSubformulaToPass()** `ModuleInput::const_iterator smtrat::Module::firstSubformulaToPass ( ) const [inline], [inherited]`**Returns**

The position of the first sub-formula in the passed formula, which has not yet been considered for a consistency check of the backends.

**0.15.136.4.41 firstUncheckedReceivedSubformula()** `ModuleInput::const_iterator smtrat::Module::firstUncheckedReceivedSubformula ( ) const [inline], [inherited]`**Returns**

The position of the first (by this module) unchecked sub-formula of the received formula.

**0.15.136.4.42 freeSplittingVariable()** static void smtrat::Module::freeSplittingVariable ( const `FormulaT` & `_splittingVariable` ) [inline], [static], [inherited]

**0.15.136.4.43 generateTrivialInfeasibleSubset()** void smtrat::Module::generateTrivialInfeasibleSubset ( ) [inline], [protected], [inherited]  
Stores the trivial infeasible subset being the set of received formulas.

**0.15.136.4.44 getBackendsAllModels()** void smtrat::Module::getBackendsAllModels ( ) const [protected], [inherited]  
Stores all models of a backend in the list of all models of this module.

**0.15.136.4.45 getBackendsModel()** void smtrat::Module::getBackendsModel ( ) const [protected], [inherited]

**0.15.136.4.46 getInfeasibleSubsets() [1/2]** void smtrat::Module::getInfeasibleSubsets ( ) [protected], [inherited]  
Copies the infeasible subsets of the passed formula.

**0.15.136.4.47 getInfeasibleSubsets() [2/2]** std::vector< `FormulaSetT` > smtrat::Module::getInfeasibleSubsets ( const `Module` & `_backend` ) const [protected], [inherited]

Get the infeasible subsets the given backend provides.  
Note, that an infeasible subset in a backend contains sub formulas of the passed formula and an infeasible subset of this module contains sub formulas of the received formula. In this method the LATTER is returned.

#### Parameters

|                       |                                                          |
|-----------------------|----------------------------------------------------------|
| <code>_backend</code> | The backend from which to obtain the infeasible subsets. |
|-----------------------|----------------------------------------------------------|

#### Returns

The infeasible subsets the given backend provides.

**0.15.136.4.48 getInformationRelevantFormulas()** const std::set< `FormulaT` > & smtrat::Module::getInformationRelevantFormulas ( ) [protected], [inherited]  
Gets all InformationRelevantFormulas.

#### Returns

Set of all formulas

**0.15.136.4.49 getModelEqualities()** std::list< std::vector< `carl::Variable` > > smtrat::Module::getModelEqualities ( ) const [virtual], [inherited]

Partition the variables from the current model into equivalence classes according to their assigned value.  
The result is a set of equivalence classes of variables where all variables within one class are assigned the same value. Note that the number of classes may not be minimal, i.e. two classes may actually be equivalent.

#### Returns

Equivalence classes.

**0.15.136.4.50 getOrigins() [1/3]** void smtrat::Module::getOrigins ( const FormulaT & \_formula, FormulaSetT & \_origins ) const [inline], [protected], [inherited]

**Parameters**

|          |  |
|----------|--|
| _formula |  |
| _origins |  |

**0.15.136.4.51 getOrigins() [2/3]** void smtrat::Module::getOrigins ( const FormulaT & \_formula, FormulasT & \_origins ) const [inline], [protected], [inherited]

**Parameters**

|          |  |
|----------|--|
| _formula |  |
| _origins |  |

**0.15.136.4.52 getOrigins() [3/3]** const FormulaT& smtrat::Module::getOrigins ( ModuleInput::const\_iterator \_formula ) const [inline], [protected], [inherited]

Gets the origins of the passed formula at the given position.

**Parameters**

|          |                                                   |
|----------|---------------------------------------------------|
| _formula | The position of a formula in the passed formulas. |
|----------|---------------------------------------------------|

**Returns**

The origins of the passed formula at the given position.

**0.15.136.4.53 getReceivedFormulaSimplified()** std::pair< bool, FormulaT > smtrat::Module::getReceivedFormulaSimplified ( ) [virtual], [inherited]

**Returns**

A pair of a Boolean and a formula, where the Boolean is true, if the received formula could be simplified to an equisatisfiable formula. The formula is equisatisfiable to this module's received formula, if the Boolean is true.

Reimplemented in [smtrat::PModule](#).

**0.15.136.4.54 hasLemmas()** bool smtrat::Module::hasLemmas ( ) [inline], [inherited]

Checks whether this module or any of its backends provides any lemmas.

**0.15.136.4.55 hasValidInfeasibleSubset()** bool smtrat::Module::hasValidInfeasibleSubset ( ) const [inherited]

**Returns**

true, if the module has at least one valid infeasible subset, that is all its elements are sub-formulas of the received formula (pointer must be equal).

**0.15.136.4.56 `id()`** `std::size_t smtrat::Module::id ( ) const [inline], [inherited]`

**Returns**

A unique ID to identify this module instance.

**0.15.136.4.57 `infeasibleSubsets()`** `const std::vector<FormulaSetT>& smtrat::Module::infeasibleSubsets ( ) const [inline], [inherited]`

**Returns**

The infeasible subsets of the set of received formulas (empty, if this module has not detected unsatisfiability of the conjunction of received formulas).

**0.15.136.4.58 `inform()`** `bool smtrat::Module::inform ( const FormulaT & _constraint ) [inherited]`

Informs the module about the given constraint.

It should be tried to inform this module about any constraint it could receive eventually before assertSubformula is called (preferably for the first time, but at least before adding a formula containing that constraint).

**Parameters**

|                          |                                 |
|--------------------------|---------------------------------|
| <code>_constraint</code> | The constraint to inform about. |
|--------------------------|---------------------------------|

**Returns**

false, if it can be easily decided whether the given constraint is inconsistent; true, otherwise.

**0.15.136.4.59 `informBackends()`** `void smtrat::Module::informBackends ( const FormulaT & _constraint ) [inline], [protected], [inherited]`

Informs all backends of this module about the given constraint.

**Parameters**

|                          |                                 |
|--------------------------|---------------------------------|
| <code>_constraint</code> | The constraint to inform about. |
|--------------------------|---------------------------------|

**0.15.136.4.60 `informCore()`** `virtual bool smtrat::Module::informCore ( const FormulaT & _constraint ) [inline], [protected], [virtual], [inherited]`

Informs the module about the given constraint.

It should be tried to inform this module about any constraint it could receive eventually before assertSubformula is called (preferably for the first time, but at least before adding a formula containing that constraint).

**Parameters**

|                          |                                 |
|--------------------------|---------------------------------|
| <code>_constraint</code> | The constraint to inform about. |
|--------------------------|---------------------------------|

**Returns**

false, if it can be easily decided whether the given constraint is inconsistent; true, otherwise.

Reimplemented in [smtrat::UnionFindModule< Settings >](#), [smtrat::PBPPModule< Settings >](#), [smtrat::PBGaussModule< Settings >](#), [smtrat::NRAILModule< Settings >](#), [smtrat::NewCoveringModule< Settings >](#), [smtrat::NewCADModule< Settings >](#),

`smrat::LRAModule< Settings >, smrat::LRAModule< LRASettingsICP >, smrat::LRAModule< LRASettings1 >, smrat::IntBlastModule< Settings >, smrat::FPPModule< Settings >, smrat::EQModule< Settings >, smrat::CurryModule< Settings >, smrat::BVMModule< Settings >, smrat::ICPModule< Settings >, smrat::ICPModule< ICPSettings4 >, and smrat::ICPModule< ICPSettings1 >.`

**0.15.136.4.61 informedConstraints()** `const carl::FastSet<FormulaT>& smrat::Module::informedConstraints( ) const [inline], [inherited]`

**Returns**

The position of the first constraint of which no backend has been informed about.

**0.15.136.4.62 init()** `void smrat::Module::init( ) [virtual], [inherited]`

Informs all backends about the so far encountered constraints, which have not yet been communicated.

This method must not be called twice and only before the first runBackends call.

Reimplemented in `smrat::PBPPModule< Settings >, smrat::PBGaussModule< Settings >, smrat::NRAILModule< Settings >, smrat::NewCoveringModule< Settings >, smrat::NewCADModule< Settings >, smrat::LRAModule< Settings >, smrat::LRAModule< LRASettingsICP >, smrat::LRAModule< LRASettings1 >, smrat::IntBlastModule< Settings >, smrat::FPPModule< Settings >, smrat::EQModule< Settings >, smrat::CurryModule< Settings >, and smrat::BVMModule< Settings >.`

**0.15.136.4.63 is\_minimizing()** `bool smrat::Module::is_minimizing( ) const [inline], [inherited]`

**0.15.136.4.64 isLemmaLevel()** `bool smrat::Module::isLemmaLevel( LemmaLevel level ) [protected], [inherited]`

Checks if current lemma level is greater or equal to given level.

**Parameters**

|                    |                 |
|--------------------|-----------------|
| <code>level</code> | Level to check. |
|--------------------|-----------------|

**0.15.136.4.65 isPreprocessor()** `bool smrat::Module::isPreprocessor( ) const [inline], [inherited]`

**Returns**

true, if this module is a preprocessor that is a module, which simplifies its received formula to an equisatisfiable formula being passed to its backends. The simplified formula can be obtained with `getReceivedFormulaSimplified()`.

**0.15.136.4.66 lemmas()** `const std::vector<Lemma>& smrat::Module::lemmas( ) const [inline], [inherited]`

**Returns**

A constant reference to the lemmas being valid formulas this module or its backends made.

**0.15.136.4.67 merge()** `std::vector< FormulaT > smrat::Module::merge( const std::vector< FormulaT > & _vecSetA, const std::vector< FormulaT > & _vecSetB ) const [protected], [inherited]`

Merges the two vectors of sets into the first one.

({a,b},{a,c}) and ({b,d},{b}) -> ({a,b,d},{a,b},{a,b,c,d},{a,b,c})

**Parameters**

|                       |                                  |
|-----------------------|----------------------------------|
| <code>_vecSetA</code> | A vector of sets of constraints. |
| <code>_vecSetB</code> | A vector of sets of constraints. |

**Returns**

The vector being the two given vectors merged.

**0.15.136.4.68 `model()`** `const Model& smtrat::Module::model( ) const [inline], [inherited]`**Returns**

The assignment of the current satisfiable result, if existent.

**0.15.136.4.69 `modelsDisjoint()`** `bool smtrat::Module::modelsDisjoint( const Model & _modelA, const Model & _modelB ) [static], [protected], [inherited]`

Checks whether there is no variable assigned by both models.

**Parameters**

|                      |                                |
|----------------------|--------------------------------|
| <code>_modelA</code> | The first model to check for.  |
| <code>_modelB</code> | The second model to check for. |

**Returns**

true, if there is no variable assigned by both models; false, otherwise.

**0.15.136.4.70 `moduleName()`** `template<typename Settings> std::string smtrat::CubeLIAModule< Settings >::moduleName( ) const [inline], [virtual]`**Returns**

The name of the given module type as name.

Reimplemented from [smtrat::Module](#).

**0.15.136.4.71 `objective()`** `carl::Variable smtrat::Module::objective( ) const [inline], [inherited]`**0.15.136.4.72 `originInReceivedFormula()`** `bool smtrat::Module::originInReceivedFormula( const FormulaT & _origin ) const [protected], [inherited]`**0.15.136.4.73 `passedFormulaBegin()`** `ModuleInput::iterator smtrat::Module::passedFormulaBegin( ) [inline], [protected], [inherited]`**Returns**

An iterator to the end of the passed formula. TODO: disable this method

**0.15.136.4.74 passedFormulaEnd()** `ModuleInput::iterator smtrat::Module::passedFormulaEnd ()`  
[inline], [protected], [inherited]

**Returns**

An iterator to the end of the passed formula.

**0.15.136.4.75 pPassedFormula()** `const ModuleInput* smtrat::Module::pPassedFormula () const`  
[inline], [inherited]

**Returns**

A pointer to the formula passed to the backends of this module.

**0.15.136.4.76 pReceivedFormula()** `const ModuleInput* smtrat::Module::pReceivedFormula () const`  
[inline], [inherited]

**Returns**

A pointer to the formula passed to this module.

**0.15.136.4.77 print()** `void smtrat::Module::print (`  
`const std::string & _initiation = "***" ) const` [inherited]  
Prints everything relevant of the solver.

**Parameters**

|                          |                      |
|--------------------------|----------------------|
| <code>_initiation</code> | The line initiation. |
|--------------------------|----------------------|

**0.15.136.4.78 printAllModels()** `void smtrat::Module::printAllModels (`  
`std::ostream & _out = std::cout )` [inherited]

Prints all assignments of this module satisfying its received formula if it satisfiable and this module could find an assignment.

**Parameters**

|                   |                                        |
|-------------------|----------------------------------------|
| <code>_out</code> | The stream to print the assignment on. |
|-------------------|----------------------------------------|

**0.15.136.4.79 printInfeasibleSubsets()** `void smtrat::Module::printInfeasibleSubsets (`  
`const std::string & _initiation = "***" ) const` [inherited]

Prints the infeasible subsets.

**Parameters**

|                          |                      |
|--------------------------|----------------------|
| <code>_initiation</code> | The line initiation. |
|--------------------------|----------------------|

**0.15.136.4.80 printModel()** `void smtrat::Module::printModel (`  
`std::ostream & _out = std::cout ) const` [inherited]

Prints the assignment of this module satisfying its received formula if it satisfiable and this module could find an assignment.

Parameters

|                   |                                        |
|-------------------|----------------------------------------|
| <code>_out</code> | The stream to print the assignment on. |
|-------------------|----------------------------------------|

**0.15.136.4.81 `printPassedFormula()`** `void smtrat::Module::printPassedFormula ( const std::string & _initiation = "***" ) const [inherited]`

Prints the vector of passed formula.

Parameters

|                          |                      |
|--------------------------|----------------------|
| <code>_initiation</code> | The line initiation. |
|--------------------------|----------------------|

**0.15.136.4.82 `printReceivedFormula()`** `void smtrat::Module::printReceivedFormula ( const std::string & _initiation = "***" ) const [inherited]`

Prints the vector of the received formula.

Parameters

|                          |                      |
|--------------------------|----------------------|
| <code>_initiation</code> | The line initiation. |
|--------------------------|----------------------|

**0.15.136.4.83 `probablyLooping()`** `bool smtrat::Module::probablyLooping ( const typename Poly::PolyType & _branchingPolynomial, const Rational & _branchingValue ) const [protected], [inherited]`

Checks whether given the current branching value and branching variable/polynomial it is (highly) probable that this branching is part of an infinite loop of branchings.

Parameters

|                                   |                                                                                     |
|-----------------------------------|-------------------------------------------------------------------------------------|
| <code>_branchingPolynomial</code> | The polynomial to branch at (in most branching strategies this is just a variable). |
| <code>_branchingValue</code>      | The value to branch at.                                                             |

Returns

true, if this branching is probably part of an infinite loop of branchings; false, otherwise.

**0.15.136.4.84 `receivedFormulaChecked()`** `void smtrat::Module::receivedFormulaChecked ( ) [inline], [inherited]`

Notifies that the received formulas has been checked.

**0.15.136.4.85 `receivedFormulasAsInfeasibleSubset()`** `void smtrat::Module::receivedFormulasAsInfeasibleSubset ( ModuleInput::const_iterator _subformula ) [inline], [protected], [inherited]`

Stores an infeasible subset consisting only of the given received formula.

**0.15.136.4.86 receivedVariable()** `bool smrat::Module::receivedVariable ( carl::Variable::Arg _var ) const [inline], [inherited]`

**0.15.136.4.87 remove()** `void smrat::Module::remove ( ModuleInput::const_iterator _subformula ) [virtual], [inherited]`

Removes everything related to the given sub-formula of the received formula.

However, it is desired not to lose track of search spaces where no satisfying assignment can be found for the remaining sub-formulas.

#### Parameters

|                          |                                                    |
|--------------------------|----------------------------------------------------|
| <code>_subformula</code> | The sub formula of the received formula to remove. |
|--------------------------|----------------------------------------------------|

Reimplemented in [smrat::PModule](#).

**0.15.136.4.88 removeCore()** `template<typename Settings > void smrat::CubeLIAModule< Settings >::removeCore ( ModuleInput::const_iterator _subformula ) [virtual]`

Removes the subformula of the received formula at the given position to the considered ones of this module.

Note that this includes every stored calculation which depended on this subformula, but should keep the other stored calculation, if possible, untouched.

#### Parameters

|                          |                                           |
|--------------------------|-------------------------------------------|
| <code>_subformula</code> | The position of the subformula to remove. |
|--------------------------|-------------------------------------------|

Reimplemented from [smrat::Module](#).

**0.15.136.4.89 removeOrigin()** `std::pair<ModuleInput::iterator,bool> smrat::Module::removeOrigin ( ModuleInput::iterator _formula, const FormulaT & _origin ) [inline], [protected], [inherited]`

**0.15.136.4.90 removeOrigins()** `std::pair<ModuleInput::iterator,bool> smrat::Module::removeOrigins ( ModuleInput::iterator _formula, const std::shared_ptr< std::vector< FormulaT >> & _origins ) [inline], [protected], [inherited]`

**0.15.136.4.91 rPassedFormula()** `const ModuleInput& smrat::Module::rPassedFormula ( ) const [inline], [inherited]`

#### Returns

A reference to the formula passed to the backends of this module.

**0.15.136.4.92 rReceivedFormula()** `const ModuleInput& smrat::Module::rReceivedFormula ( ) const [inline], [inherited]`

**Returns**

A reference to the formula passed to this module.

**0.15.136.4.93 runBackends() [1/2]** `virtual Answer smtrat::Module::runBackends () [inline], [protected], [virtual], [inherited]`

Reimplemented in [smtrat::PModule](#).

**0.15.136.4.94 runBackends() [2/2]** `Answer smtrat::Module::runBackends (`

```
 bool _final,
 bool _full,
 carl::Variable _objective) [protected], [virtual], [inherited]
```

Runs the backend solvers on the passed formula.

**Parameters**

|                         |                                                                                                                                       |
|-------------------------|---------------------------------------------------------------------------------------------------------------------------------------|
| <code>_final</code>     | true, if this satisfiability check will be the last one (for a global sat-check), if its result is SAT                                |
| <code>_full</code>      | false, if this module should avoid too expensive procedures and rather return unknown instead.                                        |
| <code>_objective</code> | if not set to NO_VARIABLE, the module should find an assignment minimizing this objective variable; otherwise any assignment is good. |

**Returns**

True, if the passed formula is consistent; False, if the passed formula is inconsistent; Unknown, otherwise.

Reimplemented in [smtrat::PModule](#).

**0.15.136.4.95 setId()** `void smtrat::Module::setId (`  
 `std::size_t _id ) [inline], [inherited]`

Sets this modules unique ID to identify itself.

**Parameters**

|                   |                                    |
|-------------------|------------------------------------|
| <code>↔ id</code> | The id to set this module's id to. |
|-------------------|------------------------------------|

**0.15.136.4.96 setThreadPriority()** `void smtrat::Module::setThreadPriority (`  
 `thread_priority _threadPriority ) [inline], [inherited]`

Sets the priority of this module to get a thread for running its check procedure.

**Parameters**

|                              |                                                       |
|------------------------------|-------------------------------------------------------|
| <code>_threadPriority</code> | The priority to set this module's thread priority to. |
|------------------------------|-------------------------------------------------------|

**0.15.136.4.97 solverState()** `Answer smtrat::Module::solverState () const [inline], [inherited]`

**Returns**

True, if this module is in a state, such that it has found a solution for its received formula; False, if this module is in a state, such that it has determined that there is no solution for its received formula; Unknown, otherwise.

**0.15.136.4.98 splitUnequalConstraint()** `void smtrat::Module::splitUnequalConstraint (`

`const FormulaT & _unequalConstraint ) [protected], [inherited]`

Adds the following lemmas for the given constraint  $p \neq 0$ .

$(p \neq 0 \leftrightarrow (p < 0 \text{ or } p > 0))$

and  $\neg(p < 0 \text{ and } p > 0)$

**Parameters**

|                                 |                                                  |
|---------------------------------|--------------------------------------------------|
| <code>_unequalConstraint</code> | A constraint having the relation symbol $\neq$ . |
|---------------------------------|--------------------------------------------------|

**0.15.136.4.99 threadPriority()** `thread_priority smtrat::Module::threadPriority ( ) const [inline], [inherited]`**Returns**

The priority of this module to get a thread for running its check procedure.

**0.15.136.4.100 updateAllModels()** `void smtrat::Module::updateAllModels ( ) [virtual], [inherited]`

Updates all satisfying models, if the solver has detected the consistency of the received formula, beforehand.

Reimplemented in [smtrat::SATModule< Settings >](#).

**0.15.136.4.101 updateLemmas()** `void smtrat::Module::updateLemmas ( ) [inherited]`

Stores all lemmas of any backend of this module in its own lemma vector.

**0.15.136.4.102 updateModel()** `template<typename Settings >`

`void smtrat::CubeLIAModule< Settings >::updateModel ( ) const [virtual]`

Updates the current assignment into the model.

Note, that this is a unique but possibly symbolic assignment maybe containing newly introduced variables.

Reimplemented from [smtrat::Module](#).

**0.15.136.4.103 usedBackends()** `const std::vector<Module*>& smtrat::Module::usedBackends ( )`

`const [inline], [inherited]`

**Returns**

The backends of this module which are currently used (conditions to use this module are fulfilled for the passed formula).

**0.15.136.5 Field Documentation****0.15.136.5.1 mAllBackends** `std::vector<Module*> smtrat::Module::mAllBackends [protected], [inherited]`

The backends of this module which have been used.

**0.15.136.5.2 mAllModels** `std::vector<Model>` `smtrat::Module::mAllModels` [mutable], [protected], [inherited]  
Stores all satisfying assignments.

**0.15.136.5.3 mBackendsFoundAnswer** `std::atomic_bool*` `smtrat::Module::mBackendsFoundAnswer` [protected], [inherited]  
This flag is passed to any backend and if it determines an answer to a prior check call, this flag is fired.

**0.15.136.5.4 mConstraintsToInform** `carl::FastSet<FormulaT>` `smtrat::Module::mConstraintsToInform` [protected], [inherited]  
Stores the constraints which the backends must be informed about.

**0.15.136.5.5 mFinalCheck** `bool` `smtrat::Module::mFinalCheck` [protected], [inherited]  
true, if the check procedure should perform a final check which especially means not to postpone splitting decisions

**0.15.136.5.6 mFirstPosInLastBranches** `std::size_t` `smtrat::Module::mFirstPosInLastBranches` = 0 [static], [inherited]  
The beginning of the cyclic buffer storing the last branches.

**0.15.136.5.7 mFirstSubformulaToPass** `ModuleInput::iterator` `smtrat::Module::mFirstSubformulaToPass` [protected], [inherited]  
Stores the position of the first sub-formula in the passed formula, which has not yet been considered for a consistency check of the backends.

**0.15.136.5.8 mFirstUncheckedReceivedSubformula** `ModuleInput::const_iterator` `smtrat::Module::mFirstUncheckedReceivedSubformula` [protected], [inherited]  
Stores the position of the first (by this module) unchecked sub-formula of the received formula.

**0.15.136.5.9 mFoundAnswer** `Conditionals` `smtrat::Module::mFoundAnswer` [protected], [inherited]  
Vector of Booleans: If any of them is true, we have to terminate a running check procedure.

**0.15.136.5.10 mFullCheck** `bool` `smtrat::Module::mFullCheck` [protected], [inherited]  
false, if this module should avoid too expensive procedures and rather return unknown instead.

**0.15.136.5.11 mInfeasibleSubsets** `std::vector<FormulaSetT>` `smtrat::Module::mInfeasibleSubsets` [protected], [inherited]  
Stores the infeasible subsets.

**0.15.136.5.12 mInformedConstraints** `carl::FastSet<FormulaT>` `smtrat::Module::mInformedConstraints` [protected], [inherited]  
Stores the position of the first constraint of which no backend has been informed about.

**0.15.136.5.13 mLastBranches** std::vector< Branching > smtrat::Module::mLastBranches = std::vector<Branching> (mNumOfBranchVarsToStore, Branching(typename Poly::PolyType(), 0)) [static], [inherited]

Stores the last branches in a cycle buffer.

**0.15.136.5.14 mLemmas** std::vector<Lemma> smtrat::Module::mLemmas [protected], [inherited]

Stores the lemmas being valid formulas this module or its backends made.

**0.15.136.5.15 mModel** Model smtrat::Module::mModel [mutable], [protected], [inherited]

Stores the assignment of the current satisfiable result, if existent.

**0.15.136.5.16 mModelComputed** bool smtrat::Module::mModelComputed [mutable], [protected], [inherited]

True, if the model has already been computed.

**0.15.136.5.17 mNumOfBranchVarsToStore** std::size\_t smtrat::Module::mNumOfBranchVarsToStore =

5 [static], [inherited]

The number of different variables to consider for a probable infinite loop of branchings.

**0.15.136.5.18 mObjectiveVariable** carl::Variable smtrat::Module::mObjectiveVariable [protected], [inherited]

Objective variable to be minimized. If set to NO\_VARIABLE, a normal sat check should be performed.

**0.15.136.5.19 mOldSplittingVariables** std::vector< FormulaT > smtrat::Module::mOldSplittingVariables [static], [inherited]

Reusable splitting variables.

**0.15.136.5.20 mpManager** Manager\* const smtrat::Module::mpManager [protected], [inherited]

A reference to the manager.

**0.15.136.5.21 mSmallerMusesCheckCounter** unsigned smtrat::Module::mSmallerMusesCheckCounter [mutable], [protected], [inherited]

Counter used for the generation of the smt2 files to check for smaller muses.

**0.15.136.5.22 mSolverState** std::atomic<Answer> smtrat::Module::mSolverState [protected], [inherited]

States whether the received formula is known to be satisfiable or unsatisfiable otherwise it is set to unknown.

**0.15.136.5.23 mTheoryPropagations** std::vector<TheoryPropagation> smtrat::Module::mTheoryPropagations [protected], [inherited]

**0.15.136.5.24 mUsedBackends** std::vector<Module\*> smtrat::Module::mUsedBackends [protected], [inherited]

The backends of this module which are currently used (conditions to use this module are fulfilled for the passed formula).

**0.15.136.5.25 mVariableCounters** std::vector<std::size\_t> smtrat::Module::mVariableCounters [protected], [inherited]

Maps variables to the number of their occurrences.

**0.15.137 smtrat::CurryModule< Settings > Class Template Reference**

```
#include <CurryModule.h>
```

- `virtual std::pair< bool, FormulaT > getReceivedFormulaSimplified ()`
- `void print (const std::string &_initiation="***") const`

*Prints everything relevant of the solver.*
- `void printReceivedFormula (const std::string &_initiation="***") const`

*Prints the vector of the received formula.*
- `void printPassedFormula (const std::string &_initiation="***") const`

*Prints the vector of passed formula.*

- void `printInfeasibleSubsets` (const std::string &\_initiation="\*\*\*") const  
*Prints the infeasible subsets.*
- void `printModel` (std::ostream &\_out=std::cout) const  
*Prints the assignment of this module satisfying its received formula if it satisfiable and this module could find an assignment.*
- void `printAllModels` (std::ostream &\_out=std::cout)  
*Prints all assignments of this module satisfying its received formula if it satisfiable and this module could find an assignment.*

### Static Public Member Functions

- static void `freeSplittingVariable` (const `FormulaT` &\_splittingVariable)

### Static Public Attributes

- static size\_t `mNumOfBranchVarsToStore` = 5  
*The number of different variables to consider for a probable infinite loop of branchings.*
- static std::vector<`Branching`> `mLastBranches` = std::vector<`Branching`>(mNumOfBranchVarsToStore, `Branching`(typename Poly::PolyType(), 0))  
*Stores the last branches in a cycle buffer.*
- static size\_t `mFirstPosInLastBranches` = 0  
*The beginning of the cyclic buffer storing the last branches.*
- static std::vector<`FormulaT`> `mOldSplittingVariables`  
*Reusable splitting variables.*

### Protected Member Functions

- virtual void `deinformCore` (const `FormulaT` &\_constraint)  
*The inverse of informing about a constraint.*
- bool `anAnswerFound` () const  
*Checks for all antecedent modules and those which run in parallel with the same antecedent modules, whether one of them has determined a result.*
- void `clearModel` () const  
*Clears the assignment, if any was found.*
- void `clearModels` () const  
*Clears all assignments, if any was found.*
- void `cleanModel` () const  
*Substitutes variable occurrences by its model value in the model values of other variables.*
- `ModuleInput::iterator` `passedFormulaBegin` ()
- `ModuleInput::iterator` `passedFormulaEnd` ()
- void `addOrigin` (`ModuleInput::iterator` \_formula, const `FormulaT` &\_origin)  
*Adds the given set of formulas in the received formula to the origins of the given passed formula.*
- const `FormulaT` & `getOrigins` (`ModuleInput::const_iterator` \_formula) const  
*Gets the origins of the passed formula at the given position.*
- void `getOrigins` (const `FormulaT` &\_formula, `FormulasT` &\_origins) const
- void `getOrigins` (const `FormulaT` &\_formula, `FormulaSetT` &\_origins) const

  - std::pair< [ModuleInput::iterator](#), bool > [addSubformulaToPassedFormula](#) (const [FormulaT](#) &\_formula, const [FormulaT](#) &\_origin)
 

*Adds the given formula to the passed formula.*
- void [generateTrivialInfeasibleSubset](#) ()
 

*Stores the trivial infeasible subset being the set of received formulas.*
- void [receivedFormulasAsInfeasibleSubset](#) ([ModuleInput::const\\_iterator](#) \_subformula)
 

*Stores an infeasible subset consisting only of the given received formula.*
- std::vector< [FormulaT](#) >::const\_iterator [findBestOrigin](#) (const std::vector< [FormulaT](#) > &\_origins) const
  - void [getInfeasibleSubsets](#) ()
 

*Copies the infeasible subsets of the passed formula.*
  - std::vector< [FormulaSetT](#) > [getInfeasibleSubsets](#) (const [Module](#) &\_backend) const
 

*Get the infeasible subsets the given backend provides.*
  - const [Model](#) & [backendsModel](#) () const
 

*Stores the model of a backend which determined satisfiability of the passed formula in the model of this module.*
  - void [getBackendsModel](#) () const
 

*Stores all models of a backend in the list of all models of this module.*
  - void [getBackendsAllModels](#) () const
 

*Runs the backend solvers on the passed formula.*
  - virtual [Answer](#) [runBackends](#) (bool \_final, bool \_full, carl::Variable \_objective)
 

*Removes everything related to the sub-formula to remove from the passed formula in the backends of this module.*
  - virtual [Answer](#) [runBackends](#) ()
 

*Merges the two vectors of sets into the first one.*
  - size\_t [determine\\_smallest\\_origin](#) (const std::vector< [FormulaT](#) > &origins) const
 

*Checks whether given the current branching value and branching variable/polynomial it is (highly) probable that this branching is part of an infinite loop of branchings.*
  - bool [probablyLooping](#) (const typename Poly::PolyType &\_branchingPolynomial, const Rational &\_branchingValue) const
 

*Adds a lemmas which provoke a branching for the given variable at the given value, if this module returns Unknown and there exists a preceding SATModule.*
  - bool [branchAt](#) (const Poly &\_polynomial, bool \_integral, const Rational &\_value, std::vector< [FormulaT](#) > &&\_premise, bool \_leftCaseWeak=true, bool \_preferLeftCase=true, bool \_useReceivedFormulaAsPremise=false)
 

*branchAt (const Poly &\_polynomial, bool \_integral, const Rational &\_value, bool \_leftCaseWeak=true, bool \_preferLeftCase=true, bool \_useReceivedFormulaAsPremise=false, const std::vector< [FormulaT](#) > &\_premise=std::vector< [FormulaT](#) >())*
  - bool [branchAt](#) (carl::Variable::Arg \_var, const Rational &\_value, std::vector< [FormulaT](#) > &&\_premise, bool \_leftCaseWeak=true, bool \_preferLeftCase=true, bool \_useReceivedFormulaAsPremise=false)
 

*branchAt (carl::Variable::Arg \_var, const Rational &\_value, bool \_leftCaseWeak=true, bool \_preferLeftCase=true, bool \_useReceivedFormulaAsPremise=false, const std::vector< [FormulaT](#) > &\_premise=std::vector< [FormulaT](#) >())*
  - bool [branchAt](#) (carl::Variable::Arg \_var, const Rational &\_value, bool \_leftCaseWeak=true, bool \_preferLeftCase=true, bool \_useReceivedFormulaAsPremise=false, const std::vector< [FormulaT](#) > &\_premise=std::vector< [FormulaT](#) >())
 

*branchAt (carl::Variable::Arg \_var, const Rational &\_value, bool \_leftCaseWeak=true, bool \_preferLeftCase=true, bool \_useReceivedFormulaAsPremise=false, const std::vector< [FormulaT](#) > &\_premise=std::vector< [FormulaT](#) >())*

- void `splitUnequalConstraint` (const `FormulaT` &)  
*Adds the following lemmas for the given constraint  $p \neq 0$ .*
- unsigned `checkModel` () const
- void `addInformationRelevantFormula` (const `FormulaT` &`formula`)  
*Adds a formula to the InformationRelevantFormula.*
- const std::set< `FormulaT` > & `getInformationRelevantFormulas` ()  
*Gets all InformationRelevantFormulas.*
- bool `isLemmaLevel` (`LemmaLevel` level)  
*Checks if current lemma level is greater or equal to given level.*

## Static Protected Member Functions

- static bool `modelsDisjoint` (const `Model` &`_modelA`, const `Model` &`_modelB`)  
*Checks whether there is no variable assigned by both models.*

## Protected Attributes

- std::vector< `FormulaSetT` > `mInfeasibleSubsets`  
*Stores the infeasible subsets.*
- `Manager` \*const `mpManager`  
*A reference to the manager.*
- `Model` `mModel`  
*Stores the assignment of the current satisfiable result, if existent.*
- std::vector< `Model` > `mAllModels`  
*Stores all satisfying assignments.*
- bool `mModelComputed`  
*True, if the model has already been computed.*
- bool `mFinalCheck`  
*true, if the check procedure should perform a final check which especially means not to postpone splitting decisions*
- bool `mFullCheck`  
*false, if this module should avoid too expensive procedures and rather return unknown instead.*
- carl::Variable `mObjectiveVariable`  
*Objective variable to be minimized. If set to NO\_VARIABLE, a normal sat check should be performed.*
- std::vector< `TheoryPropagation` > `mTheoryPropagations`
- std::atomic< `Answer` > `mSolverState`  
*States whether the received formula is known to be satisfiable or unsatisfiable otherwise it is set to unknown.*
- std::atomic\_bool \* `mBackendsFoundAnswer`  
*This flag is passed to any backend and if it determines an answer to a prior check call, this flag is fired.*
- Conditionals `mFoundAnswer`  
*Vector of Booleans: If any of them is true, we have to terminate a running check procedure.*
- std::vector< `Module` \* > `mUsedBackends`  
*The backends of this module which are currently used (conditions to use this module are fulfilled for the passed formula).*
- std::vector< `Module` \* > `mAllBackends`  
*The backends of this module which have been used.*
- std::vector< `Lemma` > `mLemmas`  
*Stores the lemmas being valid formulas this module or its backends made.*
- `ModuleInput`::iterator `mFirstSubformulaToPass`  
*Stores the position of the first sub-formula in the passed formula, which has not yet been considered for a consistency check of the backends.*
- carl::FastSet< `FormulaT` > `mConstraintsToInform`  
*Stores the constraints which the backends must be informed about.*

- `carl::FastSet< FormulaT > mInformedConstraints`  
*Stores the position of the first constraint of which no backend has been informed about.*
- `ModuleInput::const_iterator mFirstUncheckedReceivedSubformula`  
*Stores the position of the first (by this module) unchecked sub-formula of the received formula.*
- `unsigned mSmallerMusesCheckCounter`  
*Counter used for the generation of the smt2 files to check for smaller muses.*
- `std::vector< std::size_t > mVariableCounters`  
*Maps variables to the number of their occurrences.*

`smtrat::CurryModule< Settings >::~CurryModule ( )`

### 0.15.137.4 Member Function Documentation

**0.15.137.4.1 add()** `bool smtrat::Module::add (`  
 `ModuleInput::const_iterator _subformula ) [inherited]`

The module has to take the given sub-formula of the received formula into account.

Parameters

|                          |                                                    |
|--------------------------|----------------------------------------------------|
| <code>_subformula</code> | The sub-formula to take additionally into account. |
|--------------------------|----------------------------------------------------|

**Returns**

false, if it can be easily decided that this sub-formula causes a conflict with the already considered sub-formulas; true, otherwise.

**0.15.137.4.2 addConstraintToInform()** `void smtrat::Module::addConstraintToInform (`

`const FormulaT & _constraint ) [protected], [virtual], [inherited]`

Adds a constraint to the collection of constraints of this module, which are informed to a freshly generated backend.

**Parameters**

|                          |                        |
|--------------------------|------------------------|
| <code>_constraint</code> | The constraint to add. |
|--------------------------|------------------------|

Reimplemented in [smtrat::SATModule< Settings >](#).

**0.15.137.4.3 addCore()** `template<typename Settings >`

`bool smtrat::CurryModule< Settings >::addCore (`  
`ModuleInput::const_iterator _subformula ) [virtual]`

The module has to take the given sub-formula of the received formula into account.

**Parameters**

|                          |                                                    |
|--------------------------|----------------------------------------------------|
| <code>_subformula</code> | The sub-formula to take additionally into account. |
|--------------------------|----------------------------------------------------|

**Returns**

false, if it can be easily decided that this sub-formula causes a conflict with the already considered sub-formulas; true, otherwise.

Reimplemented from [smtrat::Module](#).

**0.15.137.4.4 addInformationRelevantFormula()** `void smtrat::Module::addInformationRelevantFormula (`

`const FormulaT & formula ) [protected], [inherited]`

Adds a formula to the InformationRelevantFormula.

**Parameters**

|                      |                |
|----------------------|----------------|
| <code>formula</code> | Formula to add |
|----------------------|----------------|

**0.15.137.4.5 addLemma()** `void smtrat::Module::addLemma (`

`const FormulaT & _lemma,`

`const LemmaType & _lt = LemmaType::NORMAL,`

`const FormulaT & _preferredFormula = FormulaT( carl::FormulaType::TRUE ) ) [inline],`

[inherited]

Stores a lemma being a valid formula.

**Parameters**

|                                |                                                                       |
|--------------------------------|-----------------------------------------------------------------------|
| <code>_lemma</code>            | The eduction/lemma to store.                                          |
| <code>_lt</code>               | The type of the lemma.                                                |
| <code>_preferredFormula</code> | Hint for the next decision, which formula should be assigned to true. |

```
0.15.137.4.6 addOrigin() void smtrat::Module::addOrigin (
 ModuleInput::iterator _formula,
 const FormulaT & _origin) [inline], [protected], [inherited]
```

Adds the given set of formulas in the received formula to the origins of the given passed formula.

#### Parameters

|                       |                                                           |
|-----------------------|-----------------------------------------------------------|
| <code>_formula</code> | The passed formula to set the origins for.                |
| <code>_origin</code>  | A set of formulas in the received formula of this module. |

```
0.15.137.4.7 addReceivedSubformulaToPassedFormula() std::pair<ModuleInput::iterator,bool>
smtrat::Module::addReceivedSubformulaToPassedFormula (
 ModuleInput::const_iterator _subformula) [inline], [protected], [inherited]
```

Copies the given sub-formula of the received formula to the passed formula.

Note, that there is always a link between sub-formulas of the passed formulas to sub-formulas of the received formulas, which are responsible for its occurrence.

#### Parameters

|                          |                                                  |
|--------------------------|--------------------------------------------------|
| <code>_subformula</code> | The sub-formula of the received formula to copy. |
|--------------------------|--------------------------------------------------|

```
0.15.137.4.8 addSubformulaToPassedFormula() [1/3] std::pair<ModuleInput::iterator,bool> smtrat<-
::Module::addSubformulaToPassedFormula (
 const FormulaT & _formula) [inline], [protected], [inherited]
```

Adds the given formula to the passed formula with no origin.

Note that in the next call of this module's removeSubformula, all formulas in the passed formula without origins will be removed.

#### Parameters

|                       |                                           |
|-----------------------|-------------------------------------------|
| <code>_formula</code> | The formula to add to the passed formula. |
|-----------------------|-------------------------------------------|

#### Returns

A pair to the position where the formula to add has been inserted (or its first sub-formula which has not yet been in the passed formula, in case the formula to add is a conjunction), and a Boolean stating whether anything has been added to the passed formula.

```
0.15.137.4.9 addSubformulaToPassedFormula() [2/3] std::pair<ModuleInput::iterator,bool> smtrat<-
::Module::addSubformulaToPassedFormula (
 const FormulaT & _formula,
 const FormulaT & _origin) [inline], [protected], [inherited]
```

Adds the given formula to the passed formula.

#### Parameters

|                       |                                                                                                                           |
|-----------------------|---------------------------------------------------------------------------------------------------------------------------|
| <code>_formula</code> | The formula to add to the passed formula.                                                                                 |
| <code>_origin</code>  | The sub-formula of the received formula being responsible for the occurrence of the formula to add to the passed formula. |

**Returns**

A pair to the position where the formula to add has been inserted (or its first sub-formula which has not yet been in the passed formula, in case the formula to add is a conjunction), and a Boolean stating whether anything has been added to the passed formula.

**0.15.137.4.10 addSubformulaToPassedFormula() [3/3]** `std::pair<ModuleInput::iterator, bool>`

```
smrat::Module::addSubformulaToPassedFormula (
 const FormulaT & _formula,
 const std::shared_ptr< std::vector< FormulaT >> & _origins) [inline], [protected],
[inherited]
```

Adds the given formula to the passed formula.

**Parameters**

|                       |                                                                                                                                         |
|-----------------------|-----------------------------------------------------------------------------------------------------------------------------------------|
| <code>_formula</code> | The formula to add to the passed formula.                                                                                               |
| <code>_origins</code> | The link of the formula to add to the passed formula to sub-formulas of the received formulas, which are responsible for its occurrence |

**Returns**

A pair to the position where the formula to add has been inserted (or its first sub-formula which has not yet been in the passed formula, in case the formula to add is a conjunction), and a Boolean stating whether anything has been added to the passed formula.

**0.15.137.4.11 allModels()** `const std::vector<Model>& smrat::Module::allModels () const [inline], [inherited]`**Returns**

All satisfying assignments, if existent.

**0.15.137.4.12 anAnswerFound()** `bool smrat::Module::anAnswerFound () const [inline], [protected], [inherited]`

Checks for all antecedent modules and those which run in parallel with the same antecedent modules, whether one of them has determined a result.

**Returns**

True, if one of them has determined a result.

**0.15.137.4.13 answerFound()** `const smrat::Conditionals& smrat::Module::answerFound () const [inline], [inherited]`**Returns**

A vector of Booleans: If any of them is true, we have to terminate a running check procedure.

**0.15.137.4.14 backendsModel()** `const Model & smrat::Module::backendsModel () const [protected], [inherited]`

Stores the model of a backend which determined satisfiability of the passed formula in the model of this module.

**0.15.137.4.15** **branchAt()** [1/4] `bool smrat::Module::branchAt (`

```
carl::Variable::Arg _var,
const Rational & _value,
bool _leftCaseWeak = true,
bool _preferLeftCase = true,
bool _useReceivedFormulaAsPremise = false,
const std::vector< FormulaT > & _premise = std::vector<FormulaT>()) [inline],
[protected], [inherited]
```

**0.15.137.4.16** **branchAt()** [2/4] `bool smrat::Module::branchAt (`

```
carl::Variable::Arg _var,
const Rational & _value,
std::vector< FormulaT > && _premise,
bool _leftCaseWeak = true,
bool _preferLeftCase = true,
bool _useReceivedFormulaAsPremise = false) [inline], [protected], [inherited]
```

**0.15.137.4.17** **branchAt()** [3/4] `bool smrat::Module::branchAt (`

```
const Poly & _polynomial,
bool _integral,
const Rational & _value,
bool _leftCaseWeak = true,
bool _preferLeftCase = true,
bool _useReceivedFormulaAsPremise = false,
const std::vector< FormulaT > & _premise = std::vector<FormulaT>()) [inline],
[protected], [inherited]
```

**0.15.137.4.18** **branchAt()** [4/4] `bool smrat::Module::branchAt (`

```
const Poly & _polynomial,
bool _integral,
const Rational & _value,
std::vector< FormulaT > && _premise,
bool _leftCaseWeak = true,
bool _preferLeftCase = true,
bool _useReceivedFormulaAsPremise = false) [protected], [inherited]
```

Adds a lemmas which provoke a branching for the given variable at the given value, if this module returns Unknown and there exists a preceding [SATModule](#).

Note that the given value is rounded down and up, if the given variable is integer-valued.

#### Parameters

|                                           |                                                                                                                                                                                                                |
|-------------------------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>_polynomial</code>                  | The variable to branch for.                                                                                                                                                                                    |
| <code>_integral</code>                    | A flag being true, if all variables in the polynomial to branch for are integral.                                                                                                                              |
| <code>_value</code>                       | The value to branch at.                                                                                                                                                                                        |
| <code>_premise</code>                     | The sub-formulas of the received formula from which the branch is followed. Note, that a premise is not necessary, as every branch is a valid formula. But a premise can prevent from branching unnecessarily. |
| <code>_leftCaseWeak</code>                | true, if a branching in the form of (or ( $\leq p b$ ) ( $> p b$ )) is desired. false, if a branching in the form of (or ( $< p b$ ) ( $\geq p b$ )) is desired.                                               |
| <code>_preferLeftCase</code>              | true, if the left case (polynomial less(or equal) 0 shall be chosen first. false, otherwise.                                                                                                                   |
| <code>_useReceivedFormulaAsPremise</code> | true, if the whole received formula should be used as premise                                                                                                                                                  |

---

**0.15.137.4.19 check()** *Answer* smrat::Module::check (

```
 bool _final = false,
 bool _full = true,
 carl::Variable _objective = carl::Variable::NO_VARIABLE) [virtual], [inherited]
```

Checks the received formula for consistency.

Note, that this is an implementation of the satisfiability check of the conjunction of the so far received formulas, which does actually nothing but passing the problem to its backends. This implementation is only used internally and must be overwritten by any derived module.

#### Parameters

|                   |                                                                                                                                       |
|-------------------|---------------------------------------------------------------------------------------------------------------------------------------|
| <i>_final</i>     | true, if this satisfiability check will be the last one (for a global sat-check), if its result is SAT                                |
| <i>_full</i>      | false, if this module should avoid too expensive procedures and rather return unknown instead.                                        |
| <i>_objective</i> | if not set to NO_VARIABLE, the module should find an assignment minimizing this objective variable; otherwise any assignment is good. |

#### Returns

True, if the received formula is satisfiable; False, if the received formula is not satisfiable; Unknown, otherwise.

Reimplemented in [smrat::PModule](#).

**0.15.137.4.20 checkCore()** template<typename Settings >  
*Answer* smrat::CurryModule< Settings >::checkCore ( ) [virtual]

Checks the received formula for consistency.

#### Returns

True, if the received formula is satisfiable; False, if the received formula is not satisfiable; Unknown, otherwise.

Reimplemented from [smrat::Module](#).

**0.15.137.4.21 checkInfSubsetForMinimality()** void smrat::Module::checkInfSubsetForMinimality (

```
 std::vector< FormulaSetT >::const_iterator _infssubset,
 const std::string & _filename = "smaller_muses",
 unsigned _maxSizeDifference = 1) const [inherited]
```

Checks the given infeasible subset for minimality by storing all subsets of it, which have a smaller size which differs from the size of the infeasible subset not more than the given threshold.

#### Parameters

|                           |                                                                                                        |
|---------------------------|--------------------------------------------------------------------------------------------------------|
| <i>_infssubset</i>        | The infeasible subset to check for minimality.                                                         |
| <i>_filename</i>          | The name of the file to store the infeasible subsets in order to be able to check their infeasibility. |
| <i>_maxSizeDifference</i> | The maximal difference between the sizes of the subsets compared to the size of the infeasible subset. |

**0.15.137.4.22 checkModel()** unsigned smrat::Module::checkModel ( ) const [protected], [inherited]

**Returns**

false, if the current model of this module does not satisfy the current given formula; true, if it cannot be said whether the model satisfies the given formula.

**0.15.137.4.23 cleanModel()** void smtrat::Module::cleanModel ( ) const [inline], [protected], [inherited]

Substitutes variable occurrences by its model value in the model values of other variables.

**0.15.137.4.24 clearLemmas()** void smtrat::Module::clearLemmas ( ) [inline], [inherited]

Deletes all yet found lemmas.

**0.15.137.4.25 clearModel()** void smtrat::Module::clearModel ( ) const [inline], [protected], [inherited]

Clears the assignment, if any was found.

**0.15.137.4.26 clearModels()** void smtrat::Module::clearModels ( ) const [inline], [protected], [inherited]

Clears all assignments, if any was found.

**0.15.137.4.27 clearPassedFormula()** void smtrat::Module::clearPassedFormula ( ) [protected], [inherited]

**0.15.137.4.28 collectOrigins() [1/2]** void smtrat::Module::collectOrigins ( const `FormulaT` & `_formula`, `FormulaSetT` & `_origins` ) const [inherited]

**0.15.137.4.29 collectOrigins() [2/2]** void smtrat::Module::collectOrigins ( const `FormulaT` & `_formula`, `FormulasT` & `_origins` ) const [inherited]

Collects the formulas in the given formula, which are part of the received formula.

If the given formula directly occurs in the received formula, it is inserted into the given set. Otherwise, the given formula must be of type AND and all its sub-formulas part of the received formula. Hence, they will be added to the given set.

**Parameters**

|                       |                                                                                                      |
|-----------------------|------------------------------------------------------------------------------------------------------|
| <code>_formula</code> | The formula from which to collect the formulas being sub-formulas of the received formula (origins). |
| <code>_origins</code> | The set in which to store the origins.                                                               |

**0.15.137.4.30 collectTheoryPropagations()** void smtrat::Module::collectTheoryPropagations ( ) [inherited]

**0.15.137.4.31 constraintsToInform()** const carl::FastSet<`FormulaT`>& smtrat::Module::constraintsToInform ( ) const [inline], [inherited]

**Returns**

The constraints which the backends must be informed about.

**0.15.137.4.32 currentlySatisfied()** `virtual unsigned smtrat::Module::currentlySatisfied ( const FormulaT & ) const [inline], [virtual], [inherited]`

**Returns**

0, if the given formula is conflicted by the current model; 1, if the given formula is satisfied by the current model; 2, otherwise; 3, if we do not know anything (default)

Reimplemented in [smtrat::LRAModule< Settings >](#), [smtrat::LRAModule< LRASettingsICP >](#), and [smtrat::LRAModule< LRASettings >](#)

**0.15.137.4.33 currentlySatisfiedByBackend()** `unsigned smtrat::Module::currentlySatisfiedByBackend ( const FormulaT & _formula ) const [inherited]`

**Returns**

0, if the given formula is conflicted by the current model; 1, if the given formula is satisfied by the current model; 2, otherwise 3, if we do not know anything (default)

**0.15.137.4.34 deinform()** `void smtrat::Module::deinform ( const FormulaT & _constraint ) [inherited]`

The inverse of informing about a constraint.

All data structures which were kept regarding this constraint are going to be removed. Note, that this makes only sense if it is not likely enough that a formula with this constraint must be solved again.

**Parameters**

|                          |                                                         |
|--------------------------|---------------------------------------------------------|
| <code>_constraint</code> | The constraint to remove from internal data structures. |
|--------------------------|---------------------------------------------------------|

**0.15.137.4.35 deinformCore()** `virtual void smtrat::Module::deinformCore ( const FormulaT & _constraint ) [inline], [protected], [virtual], [inherited]`

The inverse of informing about a constraint.

All data structures which were kept regarding this constraint are going to be removed. Note, that this makes only sense if it is not likely enough that a formula with this constraint must be solved again.

**Parameters**

|                          |                                                         |
|--------------------------|---------------------------------------------------------|
| <code>_constraint</code> | The constraint to remove from internal data structures. |
|--------------------------|---------------------------------------------------------|

Reimplemented in [smtrat::LRAModule< Settings >](#), [smtrat::LRAModule< LRASettingsICP >](#), and [smtrat::LRAModule< LRASettings >](#)

**0.15.137.4.36 determine\_smallest\_origin()** `size_t smtrat::Module::determine_smallest_origin ( const std::vector< FormulaT > & origins ) const [protected], [inherited]`

**Parameters**

|                      |                              |
|----------------------|------------------------------|
| <code>origins</code> | A vector of sets of origins. |
|----------------------|------------------------------|

**Returns**

The index of the smallest (regarding the size of the sets) element of origins

**0.15.137.4.37 `eraseSubformulaFromPassedFormula()`** `ModuleInput::iterator smtrat::Module::eraseSubformulaFromPassedFormula ( ModuleInput::iterator _subformula, bool _ignoreOrigins = false ) [protected], [virtual], [inherited]`

Removes everything related to the sub-formula to remove from the passed formula in the backends of this module. Afterwards the sub-formula is removed from the passed formula.

**Parameters**

|                             |                                                                                                              |
|-----------------------------|--------------------------------------------------------------------------------------------------------------|
| <code>_subformula</code>    | The sub-formula to remove from the passed formula.                                                           |
| <code>_ignoreOrigins</code> | True, if the sub-formula shall be removed regardless of its origins (should only be applied with expertise). |

**Returns**

Reimplemented in `smtrat::ICPModule< Settings >`, `smtrat::ICPModule< ICPSettings4 >`, and `smtrat::ICPModule< ICPSettings1 >`.

**0.15.137.4.38 `excludeNotReceivedVariablesFromModel()`** `void smtrat::Module::excludeNotReceivedVariablesFromModel ( ) const [inherited]`

Excludes all variables from the current model, which do not occur in the received formula.

**0.15.137.4.39 `findBestOrigin()`** `std::vector< FormulaT >::const_iterator smtrat::Module::findBestOrigin ( const std::vector< FormulaT > & _origins ) const [protected], [inherited]`

**Parameters**

|                       |  |
|-----------------------|--|
| <code>_origins</code> |  |
|-----------------------|--|

**Returns**

**0.15.137.4.40 `firstSubformulaToPass()`** `ModuleInput::const_iterator smtrat::Module::firstSubformulaToPass ( ) const [inline], [inherited]`

**Returns**

The position of the first sub-formula in the passed formula, which has not yet been considered for a consistency check of the backends.

**0.15.137.4.41 `firstUncheckedReceivedSubformula()`** `ModuleInput::const_iterator smtrat::Module::firstUncheckedReceivedSubformula ( ) const [inline], [inherited]`

**Returns**

The position of the first (by this module) unchecked sub-formula of the received formula.

**0.15.137.4.42 freeSplittingVariable()** static void smtrat::Module::freeSplittingVariable ( const `FormulaT` & `_splittingVariable` ) [inline], [static], [inherited]

**0.15.137.4.43 generateTrivialInfeasibleSubset()** void smtrat::Module::generateTrivialInfeasibleSubset ( ) [inline], [protected], [inherited]  
Stores the trivial infeasible subset being the set of received formulas.

**0.15.137.4.44 getBackendsAllModels()** void smtrat::Module::getBackendsAllModels ( ) const [protected], [inherited]  
Stores all models of a backend in the list of all models of this module.

**0.15.137.4.45 getBackendsModel()** void smtrat::Module::getBackendsModel ( ) const [protected], [inherited]

**0.15.137.4.46 getInfeasibleSubsets() [1/2]** void smtrat::Module::getInfeasibleSubsets ( ) [protected], [inherited]  
Copies the infeasible subsets of the passed formula.

**0.15.137.4.47 getInfeasibleSubsets() [2/2]** std::vector< `FormulaSetT` > smtrat::Module::getInfeasibleSubsets ( const `Module` & `_backend` ) const [protected], [inherited]

Get the infeasible subsets the given backend provides.  
Note, that an infeasible subset in a backend contains sub formulas of the passed formula and an infeasible subset of this module contains sub formulas of the received formula. In this method the LATTER is returned.

#### Parameters

|                       |                                                          |
|-----------------------|----------------------------------------------------------|
| <code>_backend</code> | The backend from which to obtain the infeasible subsets. |
|-----------------------|----------------------------------------------------------|

#### Returns

The infeasible subsets the given backend provides.

**0.15.137.4.48 getInformationRelevantFormulas()** const std::set< `FormulaT` > & smtrat::Module::getInformationRelevantFormulas ( ) [protected], [inherited]  
Gets all InformationRelevantFormulas.

#### Returns

Set of all formulas

**0.15.137.4.49 getModelEqualities()** std::list< std::vector< carl::Variable > > smtrat::Module::getModelEqualities ( ) const [virtual], [inherited]

Partition the variables from the current model into equivalence classes according to their assigned value.  
The result is a set of equivalence classes of variables where all variables within one class are assigned the same value. Note that the number of classes may not be minimal, i.e. two classes may actually be equivalent.

#### Returns

Equivalence classes.

**0.15.137.4.50 getOrigins() [1/3]** void smtrat::Module::getOrigins ( const FormulaT & \_formula, FormulaSetT & \_origins ) const [inline], [protected], [inherited]

#### Parameters

|          |  |
|----------|--|
| _formula |  |
| _origins |  |

**0.15.137.4.51 getOrigins() [2/3]** void smtrat::Module::getOrigins ( const FormulaT & \_formula, FormulasT & \_origins ) const [inline], [protected], [inherited]

#### Parameters

|          |  |
|----------|--|
| _formula |  |
| _origins |  |

**0.15.137.4.52 getOrigins() [3/3]** const FormulaT& smtrat::Module::getOrigins ( ModuleInput::const\_iterator \_formula ) const [inline], [protected], [inherited]

Gets the origins of the passed formula at the given position.

#### Parameters

|          |                                                   |
|----------|---------------------------------------------------|
| _formula | The position of a formula in the passed formulas. |
|----------|---------------------------------------------------|

#### Returns

The origins of the passed formula at the given position.

**0.15.137.4.53 getReceivedFormulaSimplified()** std::pair< bool, FormulaT > smtrat::Module::getReceivedFormulaSimplified ( ) [virtual], [inherited]

#### Returns

A pair of a Boolean and a formula, where the Boolean is true, if the received formula could be simplified to an equisatisfiable formula. The formula is equisatisfiable to this module's received formula, if the Boolean is true.

Reimplemented in [smtrat::PModule](#).

**0.15.137.4.54 hasLemmas()** bool smtrat::Module::hasLemmas ( ) [inline], [inherited]

Checks whether this module or any of its backends provides any lemmas.

**0.15.137.4.55 hasValidInfeasibleSubset()** bool smtrat::Module::hasValidInfeasibleSubset ( ) const [inherited]

#### Returns

true, if the module has at least one valid infeasible subset, that is all its elements are sub-formulas of the received formula (pointer must be equal).

**0.15.137.4.56 `id()`** `std::size_t smtrat::Module::id () const [inline], [inherited]`

**Returns**

A unique ID to identify this module instance.

**0.15.137.4.57 `infeasibleSubsets()`** `const std::vector<FormulaSetT>& smtrat::Module::infeasibleSubsets () const [inline], [inherited]`

**Returns**

The infeasible subsets of the set of received formulas (empty, if this module has not detected unsatisfiability of the conjunction of received formulas).

**0.15.137.4.58 `inform()`** `bool smtrat::Module::inform (const FormulaT & _constraint) [inherited]`

Informs the module about the given constraint.

It should be tried to inform this module about any constraint it could receive eventually before assertSubformula is called (preferably for the first time, but at least before adding a formula containing that constraint).

**Parameters**

|                          |                                 |
|--------------------------|---------------------------------|
| <code>_constraint</code> | The constraint to inform about. |
|--------------------------|---------------------------------|

**Returns**

false, if it can be easily decided whether the given constraint is inconsistent; true, otherwise.

**0.15.137.4.59 `informBackends()`** `void smtrat::Module::informBackends (const FormulaT & _constraint) [inline], [protected], [inherited]`

Informs all backends of this module about the given constraint.

**Parameters**

|                          |                                 |
|--------------------------|---------------------------------|
| <code>_constraint</code> | The constraint to inform about. |
|--------------------------|---------------------------------|

**0.15.137.4.60 `informCore()`** `template<typename Settings > bool smtrat::CurryModule< Settings >::informCore (const FormulaT & _constraint) [virtual]`

Informs the module about the given constraint.

It should be tried to inform this module about any constraint it could receive eventually before assertSubformula is called (preferably for the first time, but at least before adding a formula containing that constraint).

**Parameters**

|                          |                                 |
|--------------------------|---------------------------------|
| <code>_constraint</code> | The constraint to inform about. |
|--------------------------|---------------------------------|

**Returns**

false, if it can be easily decided whether the given constraint is inconsistent; true, otherwise.

Reimplemented from [smtrat::Module](#).

**0.15.137.4.61 informedConstraints()** const carl::FastSet<[FormulaT](#)>& smtrat::Module::informedConstraints ( ) const [inline], [inherited]

**Returns**

The position of the first constraint of which no backend has been informed about.

**0.15.137.4.62 init()** template<typename Settings >

void smtrat::CurryModule< Settings >::init ( ) [virtual]

Informs all backends about the so far encountered constraints, which have not yet been communicated.

This method must not and will not be called more than once and only before the first runBackends call.

Reimplemented from [smtrat::Module](#).

**0.15.137.4.63 is\_minimizing()** bool smtrat::Module::is\_minimizing ( ) const [inline], [inherited]

**0.15.137.4.64 isLemmaLevel()** bool smtrat::Module::isLemmaLevel (

[LemmaLevel](#) level ) [protected], [inherited]

Checks if current lemma level is greater or equal to given level.

**Parameters**

|              |                 |
|--------------|-----------------|
| <i>level</i> | Level to check. |
|--------------|-----------------|

**0.15.137.4.65 isPreprocessor()** bool smtrat::Module::isPreprocessor ( ) const [inline], [inherited]

**Returns**

true, if this module is a preprocessor that is a module, which simplifies its received formula to an equisatisfiable formula being passed to its backends. The simplified formula can be obtained with [getReceivedFormulaSimplified\(\)](#).

**0.15.137.4.66 lemmas()** const std::vector<[Lemma](#)>& smtrat::Module::lemmas ( ) const [inline], [inherited]

**Returns**

A constant reference to the lemmas being valid formulas this module or its backends made.

**0.15.137.4.67 merge()** std::vector< [FormulaT](#) > smtrat::Module::merge (

const std::vector< [FormulaT](#) > & \_vecSetA,

const std::vector< [FormulaT](#) > & \_vecSetB ) const [protected], [inherited]

Merges the two vectors of sets into the first one.

({a,b},{a,c}) and ({b,d},{b}) -> ({a,b,d},{a,b},{a,b,c,d},{a,b,c})

**Parameters**

|                       |                                  |
|-----------------------|----------------------------------|
| <code>_vecSetA</code> | A vector of sets of constraints. |
| <code>_vecSetB</code> | A vector of sets of constraints. |

**Returns**

The vector being the two given vectors merged.

**0.15.137.4.68 `model()`** `const Model& smtrat::Module::model () const [inline], [inherited]`**Returns**

The assignment of the current satisfiable result, if existent.

**0.15.137.4.69 `modelsDisjoint()`** `bool smtrat::Module::modelsDisjoint (const Model & _modelA, const Model & _modelB) [static], [protected], [inherited]`

Checks whether there is no variable assigned by both models.

**Parameters**

|                      |                                |
|----------------------|--------------------------------|
| <code>_modelA</code> | The first model to check for.  |
| <code>_modelB</code> | The second model to check for. |

**Returns**

true, if there is no variable assigned by both models; false, otherwise.

**0.15.137.4.70 `moduleName()`** `template<typename Settings> std::string smtrat::CurryModule<Settings>::moduleName () const [inline], [virtual]`**Returns**

The name of the given module type as name.

Reimplemented from [smtrat::Module](#).

**0.15.137.4.71 `objective()`** `carl::Variable smtrat::Module::objective () const [inline], [inherited]`**0.15.137.4.72 `originInReceivedFormula()`** `bool smtrat::Module::originInReceivedFormula (const FormulaT & _origin) const [protected], [inherited]`**0.15.137.4.73 `passedFormulaBegin()`** `ModuleInput::iterator smtrat::Module::passedFormulaBegin () [inline], [protected], [inherited]`**Returns**

An iterator to the end of the passed formula. TODO: disable this method

**0.15.137.4.74 passedFormulaEnd()** `ModuleInput::iterator smtrat::Module::passedFormulaEnd ()`  
[inline], [protected], [inherited]

**Returns**

An iterator to the end of the passed formula.

**0.15.137.4.75 pPassedFormula()** `const ModuleInput* smtrat::Module::pPassedFormula () const`  
[inline], [inherited]

**Returns**

A pointer to the formula passed to the backends of this module.

**0.15.137.4.76 pReceivedFormula()** `const ModuleInput* smtrat::Module::pReceivedFormula () const`  
[inline], [inherited]

**Returns**

A pointer to the formula passed to this module.

**0.15.137.4.77 print()** `void smtrat::Module::print (`  
`const std::string & _initiation = "***" ) const` [inherited]  
Prints everything relevant of the solver.

**Parameters**

|                          |                      |
|--------------------------|----------------------|
| <code>_initiation</code> | The line initiation. |
|--------------------------|----------------------|

**0.15.137.4.78 printAllModels()** `void smtrat::Module::printAllModels (`  
`std::ostream & _out = std::cout )` [inherited]

Prints all assignments of this module satisfying its received formula if it satisfiable and this module could find an assignment.

**Parameters**

|                   |                                        |
|-------------------|----------------------------------------|
| <code>_out</code> | The stream to print the assignment on. |
|-------------------|----------------------------------------|

**0.15.137.4.79 printInfeasibleSubsets()** `void smtrat::Module::printInfeasibleSubsets (`  
`const std::string & _initiation = "***" ) const` [inherited]

Prints the infeasible subsets.

**Parameters**

|                          |                      |
|--------------------------|----------------------|
| <code>_initiation</code> | The line initiation. |
|--------------------------|----------------------|

**0.15.137.4.80 printModel()** `void smtrat::Module::printModel (`  
`std::ostream & _out = std::cout ) const` [inherited]

Prints the assignment of this module satisfying its received formula if it satisfiable and this module could find an assignment.

Parameters

|                   |                                        |
|-------------------|----------------------------------------|
| <code>_out</code> | The stream to print the assignment on. |
|-------------------|----------------------------------------|

**0.15.137.4.81 `printPassedFormula()`** `void smtrat::Module::printPassedFormula ( const std::string & _initiation = "***" ) const [inherited]`

Prints the vector of passed formula.

Parameters

|                          |                      |
|--------------------------|----------------------|
| <code>_initiation</code> | The line initiation. |
|--------------------------|----------------------|

**0.15.137.4.82 `printReceivedFormula()`** `void smtrat::Module::printReceivedFormula ( const std::string & _initiation = "***" ) const [inherited]`

Prints the vector of the received formula.

Parameters

|                          |                      |
|--------------------------|----------------------|
| <code>_initiation</code> | The line initiation. |
|--------------------------|----------------------|

**0.15.137.4.83 `probablyLooping()`** `bool smtrat::Module::probablyLooping ( const typename Poly::PolyType & _branchingPolynomial, const Rational & _branchingValue ) const [protected], [inherited]`

Checks whether given the current branching value and branching variable/polynomial it is (highly) probable that this branching is part of an infinite loop of branchings.

Parameters

|                                   |                                                                                     |
|-----------------------------------|-------------------------------------------------------------------------------------|
| <code>_branchingPolynomial</code> | The polynomial to branch at (in most branching strategies this is just a variable). |
| <code>_branchingValue</code>      | The value to branch at.                                                             |

Returns

true, if this branching is probably part of an infinite loop of branchings; false, otherwise.

**0.15.137.4.84 `receivedFormulaChecked()`** `void smtrat::Module::receivedFormulaChecked ( ) [inline], [inherited]`

Notifies that the received formulas has been checked.

**0.15.137.4.85 `receivedFormulasAsInfeasibleSubset()`** `void smtrat::Module::receivedFormulasAsInfeasibleSubset ( ModuleInput::const_iterator _subformula ) [inline], [protected], [inherited]`

Stores an infeasible subset consisting only of the given received formula.

**0.15.137.4.86 receivedVariable()** `bool smrat::Module::receivedVariable ( carl::Variable::Arg _var ) const [inline], [inherited]`

**0.15.137.4.87 remove()** `void smrat::Module::remove ( ModuleInput::const_iterator _subformula ) [virtual], [inherited]`

Removes everything related to the given sub-formula of the received formula.

However, it is desired not to lose track of search spaces where no satisfying assignment can be found for the remaining sub-formulas.

#### Parameters

|                          |                                                    |
|--------------------------|----------------------------------------------------|
| <code>_subformula</code> | The sub formula of the received formula to remove. |
|--------------------------|----------------------------------------------------|

Reimplemented in [smrat::PModule](#).

**0.15.137.4.88 removeCore()** `template<typename Settings > void smrat::CurryModule< Settings >::removeCore ( ModuleInput::const_iterator _subformula ) [virtual]`

Removes the subformula of the received formula at the given position to the considered ones of this module.

Note that this includes every stored calculation which depended on this subformula, but should keep the other stored calculation, if possible, untouched.

#### Parameters

|                          |                                           |
|--------------------------|-------------------------------------------|
| <code>_subformula</code> | The position of the subformula to remove. |
|--------------------------|-------------------------------------------|

Reimplemented from [smrat::Module](#).

**0.15.137.4.89 removeOrigin()** `std::pair<ModuleInput::iterator,bool> smrat::Module::removeOrigin ( ModuleInput::iterator _formula, const FormulaT & _origin ) [inline], [protected], [inherited]`

**0.15.137.4.90 removeOrigins()** `std::pair<ModuleInput::iterator,bool> smrat::Module::removeOrigins ( ModuleInput::iterator _formula, const std::shared_ptr< std::vector< FormulaT >> & _origins ) [inline], [protected], [inherited]`

**0.15.137.4.91 rPassedFormula()** `const ModuleInput& smrat::Module::rPassedFormula ( ) const [inline], [inherited]`

#### Returns

A reference to the formula passed to the backends of this module.

**0.15.137.4.92 rReceivedFormula()** `const ModuleInput& smrat::Module::rReceivedFormula ( ) const [inline], [inherited]`

**Returns**

A reference to the formula passed to this module.

**0.15.137.4.93 runBackends() [1/2]** `virtual Answer smtrat::Module::runBackends () [inline], [protected], [virtual], [inherited]`

Reimplemented in [smtrat::PModule](#).

**0.15.137.4.94 runBackends() [2/2]** `Answer smtrat::Module::runBackends (`

```
 bool _final,
 bool _full,
 carl::Variable _objective) [protected], [virtual], [inherited]
```

Runs the backend solvers on the passed formula.

**Parameters**

|                         |                                                                                                                                       |
|-------------------------|---------------------------------------------------------------------------------------------------------------------------------------|
| <code>_final</code>     | true, if this satisfiability check will be the last one (for a global sat-check), if its result is SAT                                |
| <code>_full</code>      | false, if this module should avoid too expensive procedures and rather return unknown instead.                                        |
| <code>_objective</code> | if not set to NO_VARIABLE, the module should find an assignment minimizing this objective variable; otherwise any assignment is good. |

**Returns**

True, if the passed formula is consistent; False, if the passed formula is inconsistent; Unknown, otherwise.

Reimplemented in [smtrat::PModule](#).

**0.15.137.4.95 setId()** `void smtrat::Module::setId (`

```
 std::size_t _id) [inline], [inherited]
```

Sets this modules unique ID to identify itself.

**Parameters**

|                   |                                    |
|-------------------|------------------------------------|
| <code>↔ id</code> | The id to set this module's id to. |
|-------------------|------------------------------------|

**0.15.137.4.96 setThreadPriority()** `void smtrat::Module::setThreadPriority (`

```
 thread_priority _threadPriority) [inline], [inherited]
```

Sets the priority of this module to get a thread for running its check procedure.

**Parameters**

|                              |                                                       |
|------------------------------|-------------------------------------------------------|
| <code>_threadPriority</code> | The priority to set this module's thread priority to. |
|------------------------------|-------------------------------------------------------|

**0.15.137.4.97 solverState()** `Answer smtrat::Module::solverState () const [inline], [inherited]`

**Returns**

True, if this module is in a state, such that it has found a solution for its received formula; False, if this module is in a state, such that it has determined that there is no solution for its received formula; Unknown, otherwise.

**0.15.137.4.98 splitUnequalConstraint()** `void smtrat::Module::splitUnequalConstraint (`

`const FormulaT & _unequalConstraint ) [protected], [inherited]`

Adds the following lemmas for the given constraint  $p \neq 0$ .

$(p \neq 0 \leftrightarrow (p < 0 \text{ or } p > 0))$

and  $\neg(p < 0 \text{ and } p > 0)$

**Parameters**

|                                 |                                                  |
|---------------------------------|--------------------------------------------------|
| <code>_unequalConstraint</code> | A constraint having the relation symbol $\neq$ . |
|---------------------------------|--------------------------------------------------|

**0.15.137.4.99 threadPriority()** `thread_priority smtrat::Module::threadPriority ( ) const [inline], [inherited]`**Returns**

The priority of this module to get a thread for running its check procedure.

**0.15.137.4.100 updateAllModels()** `void smtrat::Module::updateAllModels ( ) [virtual], [inherited]`

Updates all satisfying models, if the solver has detected the consistency of the received formula, beforehand.

Reimplemented in [smtrat::SATModule< Settings >](#).

**0.15.137.4.101 updateLemmas()** `void smtrat::Module::updateLemmas ( ) [inherited]`

Stores all lemmas of any backend of this module in its own lemma vector.

**0.15.137.4.102 updateModel()** `template<typename Settings >`

`void smtrat::CurryModule< Settings >::updateModel ( ) const [virtual]`

Updates the current assignment into the model.

Note, that this is a unique but possibly symbolic assignment maybe containing newly introduced variables.

Reimplemented from [smtrat::Module](#).

**0.15.137.4.103 usedBackends()** `const std::vector<Module*>& smtrat::Module::usedBackends ( )`

`const [inline], [inherited]`

**Returns**

The backends of this module which are currently used (conditions to use this module are fulfilled for the passed formula).

**0.15.137.5 Field Documentation****0.15.137.5.1 mAllBackends** `std::vector<Module*> smtrat::Module::mAllBackends [protected], [inherited]`

The backends of this module which have been used.

**0.15.137.5.2 mAllModels** `std::vector<Model>` `smtrat::Module::mAllModels` [mutable], [protected], [inherited]  
Stores all satisfying assignments.

**0.15.137.5.3 mBackendsFoundAnswer** `std::atomic_bool*` `smtrat::Module::mBackendsFoundAnswer` [protected], [inherited]  
This flag is passed to any backend and if it determines an answer to a prior check call, this flag is fired.

**0.15.137.5.4 mConstraintsToInform** `carl::FastSet<FormulaT>` `smtrat::Module::mConstraintsToInform` [protected], [inherited]  
Stores the constraints which the backends must be informed about.

**0.15.137.5.5 mFinalCheck** `bool` `smtrat::Module::mFinalCheck` [protected], [inherited]  
true, if the check procedure should perform a final check which especially means not to postpone splitting decisions

**0.15.137.5.6 mFirstPosInLastBranches** `std::size_t` `smtrat::Module::mFirstPosInLastBranches` = 0 [static], [inherited]  
The beginning of the cyclic buffer storing the last branches.

**0.15.137.5.7 mFirstSubformulaToPass** `ModuleInput::iterator` `smtrat::Module::mFirstSubformulaToPass` [protected], [inherited]  
Stores the position of the first sub-formula in the passed formula, which has not yet been considered for a consistency check of the backends.

**0.15.137.5.8 mFirstUncheckedReceivedSubformula** `ModuleInput::const_iterator` `smtrat::Module::mFirstUncheckedReceivedSubformula` [protected], [inherited]  
Stores the position of the first (by this module) unchecked sub-formula of the received formula.

**0.15.137.5.9 mFoundAnswer** `Conditionals` `smtrat::Module::mFoundAnswer` [protected], [inherited]  
Vector of Booleans: If any of them is true, we have to terminate a running check procedure.

**0.15.137.5.10 mFullCheck** `bool` `smtrat::Module::mFullCheck` [protected], [inherited]  
false, if this module should avoid too expensive procedures and rather return unknown instead.

**0.15.137.5.11 mInfeasibleSubsets** `std::vector<FormulaSetT>` `smtrat::Module::mInfeasibleSubsets` [protected], [inherited]  
Stores the infeasible subsets.

**0.15.137.5.12 mInformedConstraints** `carl::FastSet<FormulaT>` `smtrat::Module::mInformedConstraints` [protected], [inherited]  
Stores the position of the first constraint of which no backend has been informed about.

**0.15.137.5.13 mLastBranches** std::vector< Branching > smtrat::Module::mLastBranches = std::vector<Branching> (mNumOfBranchVarsToStore, Branching(typename Poly::PolyType(), 0)) [static], [inherited]

Stores the last branches in a cycle buffer.

**0.15.137.5.14 mLemmas** std::vector<Lemma> smtrat::Module::mLemmas [protected], [inherited]

Stores the lemmas being valid formulas this module or its backends made.

**0.15.137.5.15 mModel** Model smtrat::Module::mModel [mutable], [protected], [inherited]

Stores the assignment of the current satisfiable result, if existent.

**0.15.137.5.16 mModelComputed** bool smtrat::Module::mModelComputed [mutable], [protected], [inherited]

True, if the model has already been computed.

**0.15.137.5.17 mNumOfBranchVarsToStore** std::size\_t smtrat::Module::mNumOfBranchVarsToStore =

5 [static], [inherited]

The number of different variables to consider for a probable infinite loop of branchings.

**0.15.137.5.18 mObjectiveVariable** carl::Variable smtrat::Module::mObjectiveVariable [protected], [inherited]

Objective variable to be minimized. If set to NO\_VARIABLE, a normal sat check should be performed.

**0.15.137.5.19 mOldSplittingVariables** std::vector< FormulaT > smtrat::Module::mOldSplittingVariables [static], [inherited]

Reusable splitting variables.

**0.15.137.5.20 mpManager** Manager\* const smtrat::Module::mpManager [protected], [inherited]

A reference to the manager.

**0.15.137.5.21 mSmallerMusesCheckCounter** unsigned smtrat::Module::mSmallerMusesCheckCounter [mutable], [protected], [inherited]

Counter used for the generation of the smt2 files to check for smaller muses.

**0.15.137.5.22 mSolverState** std::atomic<Answer> smtrat::Module::mSolverState [protected], [inherited]

States whether the received formula is known to be satisfiable or unsatisfiable otherwise it is set to unknown.

**0.15.137.5.23 mTheoryPropagations** std::vector<TheoryPropagation> smtrat::Module::mTheoryPropagations [protected], [inherited]

**0.15.137.5.24 mUsedBackends** std::vector<[Module](#)\*> smtrat::Module::mUsedBackends [protected], [inherited]

The backends of this module which are currently used (conditions to use this module are fulfilled for the passed formula).

**0.15.137.5.25 mVariableCounters** std::vector<std::size\_t> smtrat::Module::mVariableCounters [protected], [inherited]

Maps variables to the number of their occurrences.

## 0.15.138 smtrat::CycleEnumerator< FHG, Collector > Struct Template Reference

This class encapsulates an algorithm for enumerating all cycles.

```
#include <ForwardHyperGraph.h>
```

### Public Member Functions

- [CycleEnumerator](#) (const FHG &fhg, Collector &c)

*Constructor from a graph and a collector object.*

- bool [findAll](#) ()

*Start the search for all cycles. Returns whether the search was finished (true) or aborted (false).*

### 0.15.138.1 Detailed Description

```
template<typename FHG, typename Collector>
struct smtrat::CycleEnumerator< FHG, Collector >
```

This class encapsulates an algorithm for enumerating all cycles.

This class implements an adaption of the algorithm described in [\[Johnson75\]](#). Unlike the algorithm described there, this version works on forward hypergraphs as implemented by [ForwardHyperGraph](#).

Although the algorithm works recursively, this implementation can be used somewhat iteratively. The cycles are given to the caller using an collector functor. If this functor returns true, the search for more cycles is aborted immediately. Due to this pattern, there is no need to store the cycles within this class and thus the memory usage is minimized.

### 0.15.138.2 Constructor & Destructor Documentation

#### 0.15.138.2.1 CycleEnumerator()

```
template<typename FHG , typename Collector >
smtrat::CycleEnumerator< FHG, Collector >::CycleEnumerator (
 const FHG & fhg,
 Collector & c) [inline]
```

Constructor from a graph and a collector object.

### 0.15.138.3 Member Function Documentation

#### 0.15.138.3.1 findAll()

```
template<typename FHG , typename Collector >
bool smtrat::CycleEnumerator< FHG, Collector >::findAll ()
```

Start the search for all cycles. Returns whether the search was finished (true) or aborted (false).

## 0.15.139 benchmax::Database Class Reference

Dummy database that effectively disables storing to database. Set BENCHMAX\_DATABASE to actually use a database.

```
#include <Database.h>
```

## Public Types

- using `Index` = `std::size_t`

*Dummy index type.*

## Public Member Functions

- `Index addTool (const Tool *)`  
*Dummy.*
- `Index getToolID (const Tool *)`  
*Dummy.*
- `Index addFile (const fs::path &)`  
*Dummy.*
- `Index getFileID (const fs::path &)`  
*Dummy.*
- `Index createBenchmark ()`  
*Dummy.*
- `Index addBenchmarkResult (Index, Index, Index, int, std::size_t)`  
*Dummy.*
- void `addBenchmarkAttribute (Index, const std::string &, const std::string &)`  
*Dummy.*

### 0.15.139.1 Detailed Description

Dummy database that effectively disables storing to database. Set BENCHMAX\_DATABASE to actually use a database.

### 0.15.139.2 Member Typedef Documentation

#### 0.15.139.2.1 `Index` using `benchmax::Database::Index` = `std::size_t`

Dummy index type.

### 0.15.139.3 Member Function Documentation

#### 0.15.139.3.1 `addBenchmarkAttribute()`

```
void benchmax::Database::addBenchmarkAttribute (
 Index ,
 const std::string & ,
 const std::string &) [inline]
```

Dummy.

#### 0.15.139.3.2 `addBenchmarkResult()`

```
Index benchmax::Database::addBenchmarkResult (
 Index ,
 Index ,
 Index ,
 int ,
 std::size_t) [inline]
```

Dummy.

**0.15.139.3.3 addFile()** `Index` `benchmax::Database::addFile (`  
    `const fs::path & )` [inline]  
Dummy.

**0.15.139.3.4 addTool()** `Index` `benchmax::Database::addTool (`  
    `const Tool * )` [inline]  
Dummy.

**0.15.139.3.5 createBenchmark()** `Index` `benchmax::Database::createBenchmark ( )` [inline]  
Dummy.

**0.15.139.3.6 getFileID()** `Index` `benchmax::Database::getFileID (`  
    `const fs::path & )` [inline]  
Dummy.

**0.15.139.3.7 getToolID()** `Index` `benchmax::Database::getToolID (`  
    `const Tool * )` [inline]  
Dummy.

## 0.15.140 benchmax::DBAL Class Reference

```
#include <Database_mysqlconnector.h>
```

### Public Types

- using `Index` = `std::size_t`  
*Indec type.*
- using `Statement` = `std::unique_ptr<sql::PreparedStatement>`  
*Statement type.*
- using `Results` = `std::unique_ptr<sql::ResultSet>`  
*Results type.*
- `typedef mysqlpp::sql_bigint_unsigned Index`
- `typedef mysqlpp::Query Statement`
- `typedef mysqlpp::StoreQueryResult Results`

### Public Member Functions

- `bool connect (const std::string &db, const std::string &host, const std::string &user, const std::string &password)`  
*Connect to the given database.*
- `Statement prepare (const std::string &query)`  
*Prepare a statement.*
- `Results execute (Statement &stmt)`  
*Execute a statement without arguments.*
- `Results execute (Statement &stmt, const std::string &a1)`  
*Execute a statement with a single string.*
- `Results execute (Statement &stmt, const std::string &a1, std::size_t a2)`  
*Execute a statement with a string and a number.*
- `Results execute (Statement &stmt, const std::string &a1, const std::string &a2, const Index &a3)`  
*Execute a statement with two strings and an index.*

- **Results execute** (`Statement &stmt, int a1, std::size_t a2, std::size_t a3, const Index &a4, const Index &a5, const Index &a6)`  
*Execute a statement with an int, two numbers and three indices.*
- template<typename... Args>  
**Index insert** (`const std::string &query, const Args &... args)`  
*Insert some data and return the new index.*
- template<typename... Args>  
**Results select** (`const std::string &query, const Args &... args)`  
*Select some data.*
- `std::size_t size` (`const Results &res)`  
*Return the size of the results.*
- **Index getIndex** (`const Results &res, const std::string &name)`  
*Get the index of some name within the results.*
- `bool connect` (`const std::string &db, const std::string &host, const std::string &user, const std::string &password)`
- **Statement prepare** (`const std::string &query)`
- template<typename... Args>  
`void execute` (`Statement &stmt, const Args &... args)`
- template<typename... Args>  
**Index insert** (`const std::string &query, const Args &... args)`
- template<typename... Args>  
**Results select** (`const std::string &query, const Args &... args)`
- `std::size_t size` (`const Results &res)`
- **Index getIndex** (`const Results &res, const std::string &name)`

#### 0.15.140.1 Member Typedef Documentation

**0.15.140.1.1 Index [1/2]** using `benchmax::DBAL::Index` = `std::size_t`  
Indec type.

**0.15.140.1.2 Index [2/2]** typedef `mysqlpp::sql bigint_unsigned` `benchmax::DBAL::Index`

**0.15.140.1.3 Results [1/2]** using `benchmax::DBAL::Results` = `std::unique_ptr<sql::ResultSet>`  
Results type.

**0.15.140.1.4 Results [2/2]** typedef `mysqlpp::StoreQueryResult` `benchmax::DBAL::Results`

**0.15.140.1.5 Statement [1/2]** using `benchmax::DBAL::Statement` = `std::unique_ptr<sql::PreparedStatement>`  
Statement type.

**0.15.140.1.6 Statement [2/2]** typedef `mysqlpp::Query` `benchmax::DBAL::Statement`

#### 0.15.140.2 Member Function Documentation

```
0.15.140.2.1 connect() [1/2] bool benchmax::DBAL::connect (
 const std::string & db,
 const std::string & host,
 const std::string & user,
 const std::string & password) [inline]
```

Connect to the given database.

```
0.15.140.2.2 connect() [2/2] bool benchmax::DBAL::connect (
 const std::string & db,
 const std::string & host,
 const std::string & user,
 const std::string & password) [inline]
```

```
0.15.140.2.3 execute() [1/6] Results benchmax::DBAL::execute (
 Statement & stmt) [inline]
```

Execute a statement without arguments.

```
0.15.140.2.4 execute() [2/6] template<typename... Args>
void benchmax::DBAL::execute (
 Statement & stmt,
 const Args &... args) [inline]
```

```
0.15.140.2.5 execute() [3/6] Results benchmax::DBAL::execute (
 Statement & stmt,
 const std::string & a1) [inline]
```

Execute a statement with a single string.

```
0.15.140.2.6 execute() [4/6] Results benchmax::DBAL::execute (
 Statement & stmt,
 const std::string & a1,
 const std::string & a2,
 const Index & a3) [inline]
```

Execute a statement with two strings and an index.

```
0.15.140.2.7 execute() [5/6] Results benchmax::DBAL::execute (
 Statement & stmt,
 const std::string & a1,
 std::size_t a2) [inline]
```

Execute a statement with a string and a number.

```
0.15.140.2.8 execute() [6/6] Results benchmax::DBAL::execute (
 Statement & stmt,
 int a1,
 std::size_t a2,
 std::size_t a3,
 const Index & a4,
 const Index & a5,
 const Index & a6) [inline]
```

Execute a statement with an int, two numbers and three indices.

**0.15.140.2.9 getIndex() [1/2]** `Index` `benchmax::DBAL::getIndex (`  
    `const Results & res,`  
    `const std::string & name )` [inline]

Get the index of some name within the results.

**0.15.140.2.10 getIndex() [2/2]** `Index` `benchmax::DBAL::getIndex (`  
    `const Results & res,`  
    `const std::string & name )` [inline]

**0.15.140.2.11 insert() [1/2]** `template<typename... Args>`  
`Index` `benchmax::DBAL::insert (`  
    `const std::string & query,`  
    `const Args &... args )` [inline]

Insert some data and return the new index.

**0.15.140.2.12 insert() [2/2]** `template<typename... Args>`  
`Index` `benchmax::DBAL::insert (`  
    `const std::string & query,`  
    `const Args &... args )` [inline]

**0.15.140.2.13 prepare() [1/2]** `Statement` `benchmax::DBAL::prepare (`  
    `const std::string & query )` [inline]

Prepare a statement.

**0.15.140.2.14 prepare() [2/2]** `Statement` `benchmax::DBAL::prepare (`  
    `const std::string & query )` [inline]

**0.15.140.2.15 select() [1/2]** `template<typename... Args>`  
`Results` `benchmax::DBAL::select (`  
    `const std::string & query,`  
    `const Args &... args )` [inline]

Select some data.

**0.15.140.2.16 select() [2/2]** `template<typename... Args>`  
`Results` `benchmax::DBAL::select (`  
    `const std::string & query,`  
    `const Args &... args )` [inline]

**0.15.140.2.17 size() [1/2]** `std::size_t` `benchmax::DBAL::size (`  
    `const Results & res )` [inline]

Return the size of the results.

**0.15.140.2.18 size() [2/2]** `std::size_t` `benchmax::DBAL::size (`  
    `const Results & res )` [inline]

`bool operator==(const DerivationRef< P > &lhs, const DerivationRef< P > &rhs)`
- `template<typename P >`  
`bool operator<(const DerivationRef< P > &lhs, const DerivationRef< P > &rhs)`

### 0.15.156.1 Detailed Description

```
template<typename Properties>
class smtrat::cadcells::datastructures::DerivationRef< Properties >
```

A reference to a derivation, which is either.

- a `BaseDerivation` (a set of properties for each level)

- a **DelineatedDerivation** (a **BaseDerivation** with an underlying **SampledDerivation** on which the properties can be delineated)
- a **SampledDerivation** (a **DelineatedDerivation** with an underlying **SampledDerivation** plus a sample on the current level such that a delineated interval can be computed)

**0.15.156.1.1 Memory management** Memory management is based on std::shared\_ptr. A **SampledDerivation** holds a shared pointer to a **DelineatedDerivation**, which in turn holds a shared pointer to **BaseDerivation**. The **BaseDerivation** holds a **DerivationRef** to the underlying derivation. Note that not all combinations are legal; i.e. the underlying derivation of a delineated derivation must be a sampled derivation.

#### 0.15.163.1 Detailed Description

```
template<typename T>
class smtrat::dynarray< T >
```

`dynarray` is similar to `std::vector`, but has only a reduced interface.

Moreover, it releases its memory to a `dynarray_allocator` in its destructor and supports an optimized `consume` method to move-add all elements from some `dynarray` to another, and also a `swap-to-end` remove method. It is to be used in contexts where dynamic arrays have to be allocated and freed relatively frequently.

#### 0.15.163.2 Member Typedef Documentation

```

### 0.15.168.1 Detailed Description

```
template<typename Settings>
template<typename EdgeType>
struct smtrat::EQModule< Settings >::graph_info::edge_list_type< EdgeType >
```

Implements a list of edges.

This is similar to a vector of edge-pointers, but allocates pointers from a freelist and supports O(1) removal by storing the index of an edge in this list inside the edge.

### 0.15.168.2 Member Typedef Documentation

```
0.15.168.2.1 const_iterator template<typename Settings >

- void `informBackends` (const `FormulaT` &\_constraint)
 

*Informs all backends of this module about the given constraint.*
- virtual void `addConstraintToInform` (const `FormulaT` &\_constraint)
 

*Adds a constraint to the collection of constraints of this module, which are informed to a freshly generated backend.*
- std::pair< `ModuleInput::iterator`, bool > `addReceivedSubformulaToPassedFormula` (`ModuleInput::const_iterator` \_subformula)
 

*Copies the given sub-formula of the received formula to the passed formula.*
- bool `originInReceivedFormula` (const `FormulaT` &\_origin) const
- std::pair< `ModuleInput::iterator`, bool > `addSubformulaToPassedFormula` (const `FormulaT` &\_formula)
 

*Adds the given formula to the passed formula with no origin.*
- std::pair< `ModuleInput::iterator`, bool > `addSubformulaToPassedFormula` (const `FormulaT` &\_formula, const std::shared\_ptr< std::vector< `FormulaT` >> &\_origins)
 

*Adds the given formula to the passed formula.*
- std::pair< `ModuleInput::iterator`, bool > `addSubformulaToPassedFormula` (const `FormulaT` &\_formula, const `FormulaT` &\_origin)
 

*Adds the given formula to the passed formula.*
- void `generateTrivialInfeasibleSubset` ()
 

*Stores the trivial infeasible subset being the set of received formulas.*
- void `receivedFormulasAsInfeasibleSubset` (`ModuleInput::const_iterator` \_subformula)
 

*Stores an infeasible subset consisting only of the given received formula.*
- std::vector< `FormulaT` >::const\_iterator `findBestOrigin` (const std::vector< `FormulaT` > &\_origins) const
- void `getInfeasibleSubsets` ()

- Copies the infeasible subsets of the passed formula.
- std::vector< `FormulaSetT` > `getInfeasibleSubsets` (const `Module` &\_backend) const
  - Get the infeasible subsets the given backend provides.
- const `Model` & `backendsModel` () const
  - Stores the model of a backend which determined satisfiability of the passed formula in the model of this module.
- void `getBackendsModel` () const
- void `getBackendsAllModels` () const
  - Stores all models of a backend in the list of all models of this module.
- virtual `ModuleInput`::iterator `eraseSubformulaFromPassedFormula` (`ModuleInput`::iterator \_subformula, bool \_ignoreOrigins=false)
  - Removes everything related to the sub-formula to remove from the passed formula in the backends of this module.
- void `clearPassedFormula` ()
- std::vector< `FormulaT` > `merge` (const std::vector< `FormulaT` > &, const std::vector< `FormulaT` > &) const
  - Merges the two vectors of sets into the first one.
- size\_t `determine_smallest_origin` (const std::vector< `FormulaT` > &origins) const
- bool `probablyLooping` (const typename `Poly`::`PolyType` &\_branchingPolynomial, const `Rational` &\_branchingValue) const
  - Checks whether given the current branching value and branching variable/polynomial it is (highly) probable that this branching is part of an infinite loop of branchings.
- bool `branchAt` (const `Poly` &\_polynomial, bool \_integral, const `Rational` &\_value, std::vector< `FormulaT` > &&\_premise, bool \_leftCaseWeak=true, bool \_preferLeftCase=true, bool \_useReceivedFormulaAsPremise=false)
  - Adds a lemmas which provoke a branching for the given variable at the given value, if this module returns Unknown and there exists a preceding SATModule.
- bool `branchAt` (const `Poly` &\_polynomial, bool \_integral, const `Rational` &\_value, bool \_leftCaseWeak=true, bool \_preferLeftCase=true, bool \_useReceivedFormulaAsPremise=false, const std::vector< `FormulaT` > &&\_premise=std::vector< `FormulaT` >())
  - Adds a lemmas which provoke a branching for the given variable at the given value, if this module returns Unknown and there exists a preceding SATModule.
- bool `branchAt` (carl::Variable::Arg \_var, const `Rational` &\_value, std::vector< `FormulaT` > &&\_premise, bool \_leftCaseWeak=true, bool \_preferLeftCase=true, bool \_useReceivedFormulaAsPremise=false)
  - Adds a lemmas which provoke a branching for the given variable at the given value, if this module returns Unknown and there exists a preceding SATModule.
- bool `branchAt` (carl::Variable::Arg \_var, const `Rational` &\_value, bool \_leftCaseWeak=true, bool \_preferLeftCase=true, bool \_useReceivedFormulaAsPremise=false, const std::vector< `FormulaT` > &\_premise=std::vector< `FormulaT` >())
  - Adds a lemmas which provoke a branching for the given variable at the given value, if this module returns Unknown and there exists a preceding SATModule.
- void `splitUnequalConstraint` (const `FormulaT` &)
  - Adds the following lemmas for the given constraint  $p \neq 0$ .
- unsigned `checkModel` () const
- void `addInformationRelevantFormula` (const `FormulaT` &formula)
  - Adds a formula to the InformationRelevantFormula.
- const std::set< `FormulaT` > & `getInformationRelevantFormulas` ()
  - Gets all InformationRelevantFormulas.
- bool `isLemmaLevel` (`LemmaLevel` level)
  - Checks if current lemma level is greater or equal to given level.

## Static Protected Member Functions

- static bool `modelsDisjoint` (const `Model` &\_modelA, const `Model` &\_modelB)
  - Checks whether there is no variable assigned by both models.

## Protected Attributes

- std::vector< `FormulaSetT` > `mInfeasibleSubsets`
  - Stores the infeasible subsets.
- `Manager` \*const `mpManager`
  - A reference to the manager.
- `Model` `mModel`

- Stores the assignment of the current satisfiable result, if existent.*
- std::vector< Model > mAllModels  
*Stores all satisfying assignments.*
  - bool mModelComputed  
*True, if the model has already been computed.*
  - bool mFinalCheck  
*true, if the check procedure should perform a final check which especially means not to postpone splitting decisions*
  - bool mFullCheck  
*false, if this module should avoid too expensive procedures and rather return unknown instead.*
  - carl::Variable mObjectiveVariable  
*Objective variable to be minimized. If set to NO\_VARIABLE, a normal sat check should be performed.*
  - std::vector< TheoryPropagation > mTheoryPropagations
  - std::atomic< Answer > mSolverState  
*States whether the received formula is known to be satisfiable or unsatisfiable otherwise it is set to unknown.*
  - std::atomic\_bool \* mBackendsFoundAnswer  
*This flag is passed to any backend and if it determines an answer to a prior check call, this flag is fired.*
  - Conditionals mFoundAnswer  
*Vector of Booleans: If any of them is true, we have to terminate a running check procedure.*
  - std::vector< Module \* > mUsedBackends  
*The backends of this module which are currently used (conditions to use this module are fulfilled for the passed formula).*
  - std::vector< Module \* > mAllBackends  
*The backends of this module which have been used.*
  - std::vector< Lemma > mLemmas  
*Stores the lemmas being valid formulas this module or its backends made.*
  - ModuleInput::iterator mFirstSubformulaToPass  
*Stores the position of the first sub-formula in the passed formula, which has not yet been considered for a consistency check of the backends.*
  - carl::FastSet< FormulaT > mConstraintsToInform  
*Stores the constraints which the backends must be informed about.*
  - carl::FastSet< FormulaT > mInformedConstraints  
*Stores the position of the first constraint of which no backend has been informed about.*
  - ModuleInput::const\_iterator mFirstUncheckedReceivedSubformula  
*Stores the position of the first (by this module) unchecked sub-formula of the received formula.*
  - unsigned mSmallerMusesCheckCounter  
*Counter used for the generation of the smt2 files to check for smaller muses.*
  - std::vector< std::size\_t > mVariableCounters  
*Maps variables to the number of their occurrences.*

### 0.15.170.4 Member Function Documentation

**0.15.170.4.1 `add()`** bool smtrat::PModule::add(

`ModuleInput::const_iterator _subformula`) [inherited]

The module has to take the given sub-formula of the received formula into account.

Parameters

|                          |                                                    |
|--------------------------|----------------------------------------------------|
| <code>_subformula</code> | The sub-formula to take additionally into account. |
|--------------------------|----------------------------------------------------|

Returns

false, if it can be easily decided that this sub-formula causes a conflict with the already considered sub-formulas; true, otherwise.

**0.15.170.4.2 `addConstraintToInform()`** void smtrat::Module::addConstraintToInform(

`const FormulaT & _constraint`) [protected], [virtual], [inherited]

Adds a constraint to the collection of constraints of this module, which are informed to a freshly generated backend.

Parameters

|                          |                        |
|--------------------------|------------------------|
| <code>_constraint</code> | The constraint to add. |
|--------------------------|------------------------|

Reimplemented in `smtrat::SATModule< Settings >`.

**0.15.170.4.3 `addCore()`** virtual bool smtrat::Module::addCore(

`ModuleInput::const_iterator formula`) [inline], [protected], [virtual], [inherited]

The module has to take the given sub-formula of the received formula into account.

Parameters

|                      |                                                    |
|----------------------|----------------------------------------------------|
| <code>formula</code> | The sub-formula to take additionally into account. |
|----------------------|----------------------------------------------------|

**Returns**

false, if it can be easily decided that this sub-formula causes a conflict with the already considered sub-formulas; true, otherwise.

Reimplemented in [smrat::VSModule< Settings >](#), [smrat::SATModule< Settings >](#), [smrat::PFEModule< Settings >](#), [smrat::ICPModule< Settings >](#), [smrat::ICPModule< ICPSettings4 >](#), [smrat::ICPModule< ICPSettings1 >](#), [smrat::UnionFindModule< Settings >](#), [smrat::UFCegarModule< Settings >](#), [smrat::STropModule< Settings >](#), [smrat::PBPPModule< Settings >](#), [smrat::PBGaussModule< Settings >](#), [smrat::NRAILModule< Settings >](#), [smrat::NewCoveringModule< Settings >](#), [smrat::NewCADModule< Settings >](#), [smrat::LRAModule< Settings >](#), [smrat::LRAModule< LRASettingsICP >](#), [smrat::LRAModule< LRASettings1 >](#), [smrat::IntEqModule< Settings >](#), [smrat::IntBlastModule< Settings >](#), [smrat::IncWidthModule< Settings >](#), [smrat::ICEModule< Settings >](#), [smrat::FPPModule< Settings >](#), [smrat::FouMoModule< Settings >](#), [smrat::EQModule< Settings >](#), [smrat::CurryModule< Settings >](#), [smrat::CubeLIAModule< Settings >](#), [smrat::CSplitModule< Settings >](#), [smrat::BVMModule< Settings >](#), and [smrat::GBModule< Settings >](#).

**0.15.170.4.4 addInformationRelevantFormula()** void smrat::Module::addInformationRelevantFormula (

const [FormulaT](#) & formula ) [protected], [inherited]

Adds a formula to the InformationRelevantFormula.

**Parameters**

|                         |                |
|-------------------------|----------------|
| <a href="#">formula</a> | Formula to add |
|-------------------------|----------------|

**0.15.170.4.5 addLemma()** void smrat::Module::addLemma (

const [FormulaT](#) & \_lemma,

const [LemmaType](#) & \_lt = [LemmaType::NORMAL](#),

const [FormulaT](#) & \_preferredFormula = [FormulaT\( carl::FormulaType::TRUE \)](#) ) [inline],

[inherited]

Stores a lemma being a valid formula.

**Parameters**

|                                   |                                                                       |
|-----------------------------------|-----------------------------------------------------------------------|
| <a href="#">_lemma</a>            | The eduction/lemma to store.                                          |
| <a href="#">_lt</a>               | The type of the lemma.                                                |
| <a href="#">_preferredFormula</a> | Hint for the next decision, which formula should be assigned to true. |

**0.15.170.4.6 addOrigin()** void smrat::Module::addOrigin (

[ModuleInput::iterator](#) \_formula,

const [FormulaT](#) & \_origin ) [inline], [protected], [inherited]

Adds the given set of formulas in the received formula to the origins of the given passed formula.

**Parameters**

|                          |                                                           |
|--------------------------|-----------------------------------------------------------|
| <a href="#">_formula</a> | The passed formula to set the origins for.                |
| <a href="#">_origin</a>  | A set of formulas in the received formula of this module. |

**0.15.170.4.7 addReceivedSubformulaToPassedFormula()** std::pair<[ModuleInput::iterator](#), bool> smrat::Module::addReceivedSubformulaToPassedFormula (

```
ModuleInput::const_iterator _subformula) [inline], [protected], [inherited]
```

Copies the given sub-formula of the received formula to the passed formula.

Note, that there is always a link between sub-formulas of the passed formulas to sub-formulas of the received formulas, which are responsible for its occurrence.

#### Parameters

|                          |                                                  |
|--------------------------|--------------------------------------------------|
| <code>_subformula</code> | The sub-formula of the received formula to copy. |
|--------------------------|--------------------------------------------------|

```
0.15.170.4.8 addSubformulaToPassedFormula() [1/3] std::pair<ModuleInput::iterator,bool> smtrat<-
::Module::addSubformulaToPassedFormula (
 const FormulaT & _formula) [inline], [protected], [inherited]
```

Adds the given formula to the passed formula with no origin.

Note that in the next call of this module's removeSubformula, all formulas in the passed formula without origins will be removed.

#### Parameters

|                       |                                           |
|-----------------------|-------------------------------------------|
| <code>_formula</code> | The formula to add to the passed formula. |
|-----------------------|-------------------------------------------|

#### Returns

A pair to the position where the formula to add has been inserted (or its first sub-formula which has not yet been in the passed formula, in case the formula to add is a conjunction), and a Boolean stating whether anything has been added to the passed formula.

```
0.15.170.4.9 addSubformulaToPassedFormula() [2/3] std::pair<ModuleInput::iterator,bool> smtrat<-
::Module::addSubformulaToPassedFormula (
 const FormulaT & _formula,
 const FormulaT & _origin) [inline], [protected], [inherited]
```

Adds the given formula to the passed formula.

#### Parameters

|                       |                                                                                                                           |
|-----------------------|---------------------------------------------------------------------------------------------------------------------------|
| <code>_formula</code> | The formula to add to the passed formula.                                                                                 |
| <code>_origin</code>  | The sub-formula of the received formula being responsible for the occurrence of the formula to add to the passed formula. |

#### Returns

A pair to the position where the formula to add has been inserted (or its first sub-formula which has not yet been in the passed formula, in case the formula to add is a conjunction), and a Boolean stating whether anything has been added to the passed formula.

```
0.15.170.4.10 addSubformulaToPassedFormula() [3/3] std::pair<ModuleInput::iterator,bool>
smtrat::Module::addSubformulaToPassedFormula (
 const FormulaT & _formula,
 const std::shared_ptr< std::vector< FormulaT >> & _origins) [inline], [protected],
[inherited]
```

Adds the given formula to the passed formula.

**Parameters**

|                       |                                                                                                                                         |
|-----------------------|-----------------------------------------------------------------------------------------------------------------------------------------|
| <code>_formula</code> | The formula to add to the passed formula.                                                                                               |
| <code>_origins</code> | The link of the formula to add to the passed formula to sub-formulas of the received formulas, which are responsible for its occurrence |

**Returns**

A pair to the position where the formula to add has been inserted (or its first sub-formula which has not yet been in the passed formula, in case the formula to add is a conjunction), and a Boolean stating whether anything has been added to the passed formula.

**0.15.170.4.11 `allModels()`** `const std::vector<Model>& smtrat::Module::allModels () const [inline], [inherited]`

**Returns**

All satisfying assignments, if existent.

**0.15.170.4.12 `anAnswerFound()`** `bool smtrat::Module::anAnswerFound () const [inline], [protected], [inherited]`

Checks for all antecedent modules and those which run in parallel with the same antecedent modules, whether one of them has determined a result.

**Returns**

True, if one of them has determined a result.

**0.15.170.4.13 `answerFound()`** `const smtrat::Conditionals& smtrat::Module::answerFound () const [inline], [inherited]`

**Returns**

A vector of Booleans: If any of them is true, we have to terminate a running check procedure.

**0.15.170.4.14 `appliedPreprocessing()`** `bool smtrat::PModule::appliedPreprocessing () const [inline], [inherited]`

**Returns**

true, if the current received formula has been simplified and the result of this simplification is stored in the passed formula.

**0.15.170.4.15 `backendsModel()`** `const Model & smtrat::Module::backendsModel () const [protected], [inherited]`

Stores the model of a backend which determined satisfiability of the passed formula in the model of this module.

**0.15.170.4.16 branchAt() [1/4]** bool smtrat::Module::branchAt (

```
carl::Variable::Arg _var,
const Rational & _value,
bool _leftCaseWeak = true,
bool _preferLeftCase = true,
bool _useReceivedFormulaAsPremise = false,
const std::vector< FormulaT > & _premise = std::vector<FormulaT>()) [inline],
[protected], [inherited]
```

**0.15.170.4.17 branchAt() [2/4]** bool smtrat::Module::branchAt (

```
carl::Variable::Arg _var,
const Rational & _value,
std::vector< FormulaT > && _premise,
bool _leftCaseWeak = true,
bool _preferLeftCase = true,
bool _useReceivedFormulaAsPremise = false) [inline], [protected], [inherited]
```

**0.15.170.4.18 branchAt() [3/4]** bool smtrat::Module::branchAt (

```
const Poly & _polynomial,
bool _integral,
const Rational & _value,
bool _leftCaseWeak = true,
bool _preferLeftCase = true,
bool _useReceivedFormulaAsPremise = false,
const std::vector< FormulaT > & _premise = std::vector<FormulaT>()) [inline],
[protected], [inherited]
```

**0.15.170.4.19 branchAt() [4/4]** bool smtrat::Module::branchAt (

```
const Poly & _polynomial,
bool _integral,
const Rational & _value,
std::vector< FormulaT > && _premise,
bool _leftCaseWeak = true,
bool _preferLeftCase = true,
bool _useReceivedFormulaAsPremise = false) [protected], [inherited]
```

Adds a lemmas which provoke a branching for the given variable at the given value, if this module returns Unknown and there exists a preceding [SATModule](#).

Note that the given value is rounded down and up, if the given variable is integer-valued.

#### Parameters

|                                           |                                                                                                                                                                                                                |
|-------------------------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>_polynomial</code>                  | The variable to branch for.                                                                                                                                                                                    |
| <code>_integral</code>                    | A flag being true, if all variables in the polynomial to branch for are integral.                                                                                                                              |
| <code>_value</code>                       | The value to branch at.                                                                                                                                                                                        |
| <code>_premise</code>                     | The sub-formulas of the received formula from which the branch is followed. Note, that a premise is not necessary, as every branch is a valid formula. But a premise can prevent from branching unnecessarily. |
| <code>_leftCaseWeak</code>                | true, if a branching in the form of (or ( $\leq p b$ ) ( $> p b$ )) is desired. false, if a branching in the form of (or ( $< p b$ ) ( $\geq p b$ )) is desired.                                               |
| <code>_preferLeftCase</code>              | true, if the left case (polynomial less(or equal) 0 shall be chosen first. false, otherwise.                                                                                                                   |
| <code>_useReceivedFormulaAsPremise</code> | true, if the whole received formula should be used as premise                                                                                                                                                  |

**0.15.170.4.20 check()** `Answer smtrat::PModule::check (`  
    `bool _final = false,`  
    `bool _full = true,`  
    `carl::Variable _objective = carl::Variable::NO_VARIABLE ) [virtual], [inherited]`

Checks the received formula for consistency.

Note, that this is an implementation of the satisfiability check of the conjunction of the so far received formulas, which does actually nothing but passing the problem to its backends. This implementation is only used internally and must be overwritten by any derived module.

#### Parameters

|                         |                                                                                                                                       |
|-------------------------|---------------------------------------------------------------------------------------------------------------------------------------|
| <code>_final</code>     | true, if this satisfiability check will be the last one (for a global sat-check), if its result is SAT                                |
| <code>_full</code>      | false, if this module should avoid too expensive procedures and rather return unknown instead.                                        |
| <code>_objective</code> | if not set to NO_VARIABLE, the module should find an assignment minimizing this objective variable; otherwise any assignment is good. |

#### Returns

True, if the received formula is satisfiable; False, if the received formula is not satisfiable; Unknown, otherwise.

Reimplemented from [smtrat::Module](#).

**0.15.170.4.21 checkCore()** `template<typename Settings >`  
`Answer smtrat::EMModule< Settings >::checkCore ( ) [virtual]`

Checks the received formula for consistency.

#### Returns

SAT, if the received formula is satisfiable; UNSAT, if the received formula is not satisfiable; Unknown, otherwise.

Reimplemented from [smtrat::Module](#).

**0.15.170.4.22 checkInfeasibleSubsetForMinimality()** `void smtrat::Module::checkInfeasibleSubsetForMinimality (`  
    `std::vector< FormulaSetT >::const_iterator _infssubset,`  
    `const std::string & _filename = "smaller_muses",`  
    `unsigned _maxSizeDifference = 1 ) const [inherited]`

Checks the given infeasible subset for minimality by storing all subsets of it, which have a smaller size which differs from the size of the infeasible subset not more than the given threshold.

#### Parameters

|                                 |                                                                                                        |
|---------------------------------|--------------------------------------------------------------------------------------------------------|
| <code>_infssubset</code>        | The infeasible subset to check for minimality.                                                         |
| <code>_filename</code>          | The name of the file to store the infeasible subsets in order to be able to check their infeasibility. |
| <code>_maxSizeDifference</code> | The maximal difference between the sizes of the subsets compared to the size of the infeasible subset. |

**0.15.170.4.23 checkModel()** `unsigned smtrat::Module::checkModel ( ) const [protected], [inherited]`

**Returns**

false, if the current model of this module does not satisfy the current given formula; true, if it cannot be said whether the model satisfies the given formula.

**0.15.170.4.24 cleanModel()** void smtrat::Module::cleanModel ( ) const [inline], [protected], [inherited]

Substitutes variable occurrences by its model value in the model values of other variables.

**0.15.170.4.25 clearLemmas()** void smtrat::Module::clearLemmas ( ) [inline], [inherited]

Deletes all yet found lemmas.

**0.15.170.4.26 clearModel()** void smtrat::Module::clearModel ( ) const [inline], [protected], [inherited]

Clears the assignment, if any was found.

**0.15.170.4.27 clearModels()** void smtrat::Module::clearModels ( ) const [inline], [protected], [inherited]

Clears all assignments, if any was found.

**0.15.170.4.28 clearPassedFormula()** void smtrat::Module::clearPassedFormula ( ) [protected], [inherited]

**0.15.170.4.29 collectOrigins() [1/2]** void smtrat::Module::collectOrigins ( const `FormulaT` & `_formula`, `FormulaSetT` & `_origins` ) const [inherited]

**0.15.170.4.30 collectOrigins() [2/2]** void smtrat::Module::collectOrigins ( const `FormulaT` & `_formula`, `FormulasT` & `_origins` ) const [inherited]

Collects the formulas in the given formula, which are part of the received formula.

If the given formula directly occurs in the received formula, it is inserted into the given set. Otherwise, the given formula must be of type AND and all its sub-formulas part of the received formula. Hence, they will be added to the given set.

**Parameters**

|                       |                                                                                                      |
|-----------------------|------------------------------------------------------------------------------------------------------|
| <code>_formula</code> | The formula from which to collect the formulas being sub-formulas of the received formula (origins). |
| <code>_origins</code> | The set in which to store the origins.                                                               |

**0.15.170.4.31 collectTheoryPropagations()** void smtrat::Module::collectTheoryPropagations ( ) [inherited]

**0.15.170.4.32 constraintsToInform()** const carl::FastSet<`FormulaT`>& smtrat::Module::constraintsToInform ( ) const [inline], [inherited]

**Returns**

The constraints which the backends must be informed about.

**0.15.170.4.33 currentlySatisfied()** `virtual unsigned smtrat::Module::currentlySatisfied ( const FormulaT & ) const [inline], [virtual], [inherited]`

**Returns**

0, if the given formula is conflicted by the current model; 1, if the given formula is satisfied by the current model; 2, otherwise; 3, if we do not know anything (default)

Reimplemented in [smtrat::LRAModule< Settings >](#), [smtrat::LRAModule< LRASettingsICP >](#), and [smtrat::LRAModule< LRASettings >](#)

**0.15.170.4.34 currentlySatisfiedByBackend()** `unsigned smtrat::Module::currentlySatisfiedByBackend ( const FormulaT & _formula ) const [inherited]`

**Returns**

0, if the given formula is conflicted by the current model; 1, if the given formula is satisfied by the current model; 2, otherwise 3, if we do not know anything (default)

**0.15.170.4.35 deinform()** `void smtrat::Module::deinform ( const FormulaT & _constraint ) [inherited]`

The inverse of informing about a constraint.

All data structures which were kept regarding this constraint are going to be removed. Note, that this makes only sense if it is not likely enough that a formula with this constraint must be solved again.

**Parameters**

|                          |                                                         |
|--------------------------|---------------------------------------------------------|
| <code>_constraint</code> | The constraint to remove from internal data structures. |
|--------------------------|---------------------------------------------------------|

**0.15.170.4.36 deinformCore()** `virtual void smtrat::Module::deinformCore ( const FormulaT & _constraint ) [inline], [protected], [virtual], [inherited]`

The inverse of informing about a constraint.

All data structures which were kept regarding this constraint are going to be removed. Note, that this makes only sense if it is not likely enough that a formula with this constraint must be solved again.

**Parameters**

|                          |                                                         |
|--------------------------|---------------------------------------------------------|
| <code>_constraint</code> | The constraint to remove from internal data structures. |
|--------------------------|---------------------------------------------------------|

Reimplemented in [smtrat::LRAModule< Settings >](#), [smtrat::LRAModule< LRASettingsICP >](#), and [smtrat::LRAModule< LRASettings >](#)

**0.15.170.4.37 determine\_smallest\_origin()** `size_t smtrat::Module::determine_smallest_origin ( const std::vector< FormulaT > & origins ) const [protected], [inherited]`

**Parameters**

|                      |                              |
|----------------------|------------------------------|
| <code>origins</code> | A vector of sets of origins. |
|----------------------|------------------------------|

**Returns**

The index of the smallest (regarding the size of the sets) element of origins

**0.15.170.4.38 `eraseSubformulaFromPassedFormula()`** `ModuleInput::iterator smtrat::Module::eraseSubformulaFromPassedFormula ( ModuleInput::iterator _subformula, bool _ignoreOrigins = false )` [protected], [virtual], [inherited]

Removes everything related to the sub-formula to remove from the passed formula in the backends of this module. Afterwards the sub-formula is removed from the passed formula.

**Parameters**

|                             |                                                                                                              |
|-----------------------------|--------------------------------------------------------------------------------------------------------------|
| <code>_subformula</code>    | The sub-formula to remove from the passed formula.                                                           |
| <code>_ignoreOrigins</code> | True, if the sub-formula shall be removed regardless of its origins (should only be applied with expertise). |

**Returns**

Reimplemented in `smtrat::ICPModule< Settings >`, `smtrat::ICPModule< ICPSettings4 >`, and `smtrat::ICPModule< ICPSettings1 >`.

**0.15.170.4.39 `excludeNotReceivedVariablesFromModel()`** `void smtrat::Module::excludeNotReceivedVariablesFromModel ( ) const` [inherited]

Excludes all variables from the current model, which do not occur in the received formula.

**0.15.170.4.40 `findBestOrigin()`** `std::vector< FormulaT >::const_iterator smtrat::Module::findBestOrigin ( const std::vector< FormulaT > & _origins ) const` [protected], [inherited]

**Parameters**

|                       |  |
|-----------------------|--|
| <code>_origins</code> |  |
|-----------------------|--|

**Returns**

**0.15.170.4.41 `firstSubformulaToPass()`** `ModuleInput::const_iterator smtrat::Module::firstSubformulaToPass ( ) const` [inline], [inherited]

**Returns**

The position of the first sub-formula in the passed formula, which has not yet been considered for a consistency check of the backends.

**0.15.170.4.42 `firstUncheckedReceivedSubformula()`** `ModuleInput::const_iterator smtrat::Module::firstUncheckedReceivedSubformula ( ) const` [inline], [inherited]

**Returns**

The position of the first (by this module) unchecked sub-formula of the received formula.

**0.15.170.4.43 freeSplittingVariable()** static void smtrat::Module::freeSplittingVariable ( const `FormulaT` & `_splittingVariable` ) [inline], [static], [inherited]

**0.15.170.4.44 generateTrivialInfeasibleSubset()** void smtrat::Module::generateTrivialInfeasibleSubset ( ) [inline], [protected], [inherited]  
Stores the trivial infeasible subset being the set of received formulas.

**0.15.170.4.45 getBackendsAllModels()** void smtrat::Module::getBackendsAllModels ( ) const [protected], [inherited]  
Stores all models of a backend in the list of all models of this module.

**0.15.170.4.46 getBackendsModel()** void smtrat::Module::getBackendsModel ( ) const [protected], [inherited]

**0.15.170.4.47 getInfeasibleSubsets() [1/2]** void smtrat::Module::getInfeasibleSubsets ( ) [protected], [inherited]  
Copies the infeasible subsets of the passed formula.

**0.15.170.4.48 getInfeasibleSubsets() [2/2]** std::vector< `FormulaSetT` > smtrat::Module::getInfeasibleSubsets ( const `Module` & `_backend` ) const [protected], [inherited]

Get the infeasible subsets the given backend provides.

Note, that an infeasible subset in a backend contains sub formulas of the passed formula and an infeasible subset of this module contains sub formulas of the received formula. In this method the LATTER is returned.

#### Parameters

|                       |                                                          |
|-----------------------|----------------------------------------------------------|
| <code>_backend</code> | The backend from which to obtain the infeasible subsets. |
|-----------------------|----------------------------------------------------------|

#### Returns

The infeasible subsets the given backend provides.

**0.15.170.4.49 getInformationRelevantFormulas()** const std::set< `FormulaT` > & smtrat::Module::getInformationRelevantFormulas ( ) [protected], [inherited]  
Gets all InformationRelevantFormulas.

#### Returns

Set of all formulas

**0.15.170.4.50 getModelEqualities()** std::list< std::vector< carl::Variable > > smtrat::Module::getModelEqualities ( ) const [virtual], [inherited]

Partition the variables from the current model into equivalence classes according to their assigned value.

The result is a set of equivalence classes of variables where all variables within one class are assigned the same value. Note that the number of classes may not be minimal, i.e. two classes may actually be equivalent.

#### Returns

Equivalence classes.

**0.15.170.4.51 getOrigins() [1/3]** void smtrat::Module::getOrigins ( const FormulaT & \_formula, FormulaSetT & \_origins ) const [inline], [protected], [inherited]

#### Parameters

|          |  |
|----------|--|
| _formula |  |
| _origins |  |

**0.15.170.4.52 getOrigins() [2/3]** void smtrat::Module::getOrigins ( const FormulaT & \_formula, FormulasT & \_origins ) const [inline], [protected], [inherited]

#### Parameters

|          |  |
|----------|--|
| _formula |  |
| _origins |  |

**0.15.170.4.53 getOrigins() [3/3]** const FormulaT& smtrat::Module::getOrigins ( ModuleInput::const\_iterator \_formula ) const [inline], [protected], [inherited]

Gets the origins of the passed formula at the given position.

#### Parameters

|          |                                                   |
|----------|---------------------------------------------------|
| _formula | The position of a formula in the passed formulas. |
|----------|---------------------------------------------------|

#### Returns

The origins of the passed formula at the given position.

**0.15.170.4.54 getReceivedFormulaSimplified()** std::pair< bool, FormulaT > smtrat::PModule::getReceivedFormulaSimplified ( ) [virtual], [inherited]

#### Returns

A pair of a Boolean and a formula, where the Boolean is true, if the received formula could be simplified to an equisatisfiable formula. The formula is equisatisfiable to this module's received formula, if the Boolean is true.

Reimplemented from [smtrat::Module](#).

**0.15.170.4.55 hasLemmas()** bool smtrat::Module::hasLemmas ( ) [inline], [inherited]

Checks whether this module or any of its backends provides any lemmas.

**0.15.170.4.56 hasValidInfeasibleSubset()** bool smtrat::Module::hasValidInfeasibleSubset ( ) const [inherited]

#### Returns

true, if the module has at least one valid infeasible subset, that is all its elements are sub-formulas of the received formula (pointer must be equal).

**0.15.170.4.57 `id()`** `std::size_t smtrat::Module::id ( ) const [inline], [inherited]`

**Returns**

A unique ID to identify this module instance.

**0.15.170.4.58 `infeasibleSubsets()`** `const std::vector<FormulaSetT>& smtrat::Module::infeasibleSubsets ( ) const [inline], [inherited]`

**Returns**

The infeasible subsets of the set of received formulas (empty, if this module has not detected unsatisfiability of the conjunction of received formulas).

**0.15.170.4.59 `inform()`** `bool smtrat::Module::inform ( const FormulaT & _constraint ) [inherited]`

Informs the module about the given constraint.

It should be tried to inform this module about any constraint it could receive eventually before assertSubformula is called (preferably for the first time, but at least before adding a formula containing that constraint).

**Parameters**

|                          |                                 |
|--------------------------|---------------------------------|
| <code>_constraint</code> | The constraint to inform about. |
|--------------------------|---------------------------------|

**Returns**

false, if it can be easily decided whether the given constraint is inconsistent; true, otherwise.

**0.15.170.4.60 `informBackends()`** `void smtrat::Module::informBackends ( const FormulaT & _constraint ) [inline], [protected], [inherited]`

Informs all backends of this module about the given constraint.

**Parameters**

|                          |                                 |
|--------------------------|---------------------------------|
| <code>_constraint</code> | The constraint to inform about. |
|--------------------------|---------------------------------|

**0.15.170.4.61 `informCore()`** `virtual bool smtrat::Module::informCore ( const FormulaT & _constraint ) [inline], [protected], [virtual], [inherited]`

Informs the module about the given constraint.

It should be tried to inform this module about any constraint it could receive eventually before assertSubformula is called (preferably for the first time, but at least before adding a formula containing that constraint).

**Parameters**

|                          |                                 |
|--------------------------|---------------------------------|
| <code>_constraint</code> | The constraint to inform about. |
|--------------------------|---------------------------------|

**Returns**

false, if it can be easily decided whether the given constraint is inconsistent; true, otherwise.

Reimplemented in [smtrat::UnionFindModule< Settings >](#), [smtrat::PBPPModule< Settings >](#), [smtrat::PBGaussModule< Settings >](#), [smtrat::NRAILModule< Settings >](#), [smtrat::NewCoveringModule< Settings >](#), [smtrat::NewCADModule< Settings >](#),

`smrat::LRAModule< Settings >, smrat::LRAModule< LRASettingsICP >, smrat::LRAModule< LRASettings1 >, smrat::IntBlastModule< Settings >, smrat::FPPModule< Settings >, smrat::EQModule< Settings >, smrat::CurryModule< Settings >, smrat::BVMModule< Settings >, smrat::ICPModule< Settings >, smrat::ICPModule< ICPSettings4 >, and smrat::ICPModule< ICPSettings1 >.`

**0.15.170.4.62 informedConstraints()** `const carl::FastSet<FormulaT>& smrat::Module::informedConstraints( ) const [inline], [inherited]`

#### Returns

The position of the first constraint of which no backend has been informed about.

**0.15.170.4.63 init()** `void smrat::Module::init( ) [virtual], [inherited]`

Informs all backends about the so far encountered constraints, which have not yet been communicated.

This method must not be called twice and only before the first runBackends call.

Reimplemented in `smrat::PBPPModule< Settings >, smrat::PBGaussModule< Settings >, smrat::NRAILModule< Settings >, smrat::NewCoveringModule< Settings >, smrat::NewCADModule< Settings >, smrat::LRAModule< Settings >, smrat::LRAModule< LRASettingsICP >, smrat::LRAModule< LRASettings1 >, smrat::IntBlastModule< Settings >, smrat::FPPModule< Settings >, smrat::EQModule< Settings >, smrat::CurryModule< Settings >, and smrat::BVMModule< Settings >.`

**0.15.170.4.64 is\_minimizing()** `bool smrat::Module::is_minimizing( ) const [inline], [inherited]`

**0.15.170.4.65 isLemmaLevel()** `bool smrat::Module::isLemmaLevel( LemmaLevel level ) [protected], [inherited]`

Checks if current lemma level is greater or equal to given level.

#### Parameters

|                    |                 |
|--------------------|-----------------|
| <code>level</code> | Level to check. |
|--------------------|-----------------|

**0.15.170.4.66 isPreprocessor()** `bool smrat::PModule::isPreprocessor( ) const [inline], [inherited]`

#### Returns

true, if this module is a preprocessor that is a module, which simplifies its received formula to an equisatisfiable formula being passed to its backends. The simplified formula can be obtained with `getReceivedFormulaSimplified()`.

**0.15.170.4.67 lemmas()** `const std::vector<Lemma>& smrat::Module::lemmas( ) const [inline], [inherited]`

#### Returns

A constant reference to the lemmas being valid formulas this module or its backends made.

**0.15.170.4.68 merge()** `std::vector< FormulaT > smrat::Module::merge( const std::vector< FormulaT > & _vecSetA, const std::vector< FormulaT > & _vecSetB ) const [protected], [inherited]`

Merges the two vectors of sets into the first one.

({a,b},{a,c}) and ({b,d},{b}) -> ({a,b,d},{a,b},{a,b,c,d},{a,b,c})

**Parameters**

|                       |                                  |
|-----------------------|----------------------------------|
| <code>_vecSetA</code> | A vector of sets of constraints. |
| <code>_vecSetB</code> | A vector of sets of constraints. |

**Returns**

The vector being the two given vectors merged.

**0.15.170.4.69 `model()`** `const Model& smtrat::Module::model () const [inline], [inherited]`**Returns**

The assignment of the current satisfiable result, if existent.

**0.15.170.4.70 `modelsDisjoint()`** `bool smtrat::Module::modelsDisjoint (`

```
const Model & _modelA,
const Model & _modelB) [static], [protected], [inherited]
```

Checks whether there is no variable assigned by both models.

**Parameters**

|                      |                                |
|----------------------|--------------------------------|
| <code>_modelA</code> | The first model to check for.  |
| <code>_modelB</code> | The second model to check for. |

**Returns**

true, if there is no variable assigned by both models; false, otherwise.

**0.15.170.4.71 `moduleName()`** `virtual std::string smtrat::Module::moduleName () const [inline], [virtual], [inherited]`**Returns**

The name of the given module type as name.

Reimplemented in [smtrat::VSModule< Settings >](#), [smtrat::UnionFindModule< Settings >](#), [smtrat::UFCegarModule< Settings >](#), [smtrat::STropModule< Settings >](#), [smtrat::SplitSOSModule< Settings >](#), [smtrat::PBPPModule< Settings >](#), [smtrat::PBGaussModule< Settings >](#), [smtrat::NRAILModule< Settings >](#), [smtrat::NewCADModule< Settings >](#), [smtrat::LVEModule< Settings >](#), [smtrat::LRAModule< Settings >](#), [smtrat::LRAModule< LRASettingsICP >](#), [smtrat::LRAModule< LRASettings1 >](#), [smtrat::IntEqModule< Settings >](#), [smtrat::IntBlastModule< Settings >](#), [smtrat::IncWidthModule< Settings >](#), [smtrat::ICPModule< Settings >](#), [smtrat::ICPModule< ICPSettings4 >](#), [smtrat::ICPModule< ICPSettings1 >](#), [smtrat::GBModule< Settings >](#), [smtrat::FouMoModule< Settings >](#), [smtrat::EQPreprocessingModule< Settings >](#), [smtrat::EQModule< Settings >](#), [smtrat::CurryModule< Settings >](#), [smtrat::CubeLIAModule< Settings >](#), [smtrat::CSplitModule< Settings >](#), [smtrat::BVMModule< Settings >](#), and [smtrat::BEModule< Settings >](#).

**0.15.170.4.72 `objective()`** `carl::Variable smtrat::Module::objective () const [inline], [inherited]`**0.15.170.4.73 `originInReceivedFormula()`** `bool smtrat::Module::originInReceivedFormula (`

```
const FormulaT & _origin) const [protected], [inherited]
```

**0.15.170.4.74 passedFormulaBegin()** `ModuleInput::iterator smtrat::Module::passedFormulaBegin ( )` [inline], [protected], [inherited]

**Returns**

An iterator to the end of the passed formula. TODO: disable this method

**0.15.170.4.75 passedFormulaEnd()** `ModuleInput::iterator smtrat::Module::passedFormulaEnd ( )` [inline], [protected], [inherited]

**Returns**

An iterator to the end of the passed formula.

**0.15.170.4.76 pPassedFormula()** `const ModuleInput* smtrat::Module::pPassedFormula ( ) const` [inline], [inherited]

**Returns**

A pointer to the formula passed to the backends of this module.

**0.15.170.4.77 pReceivedFormula()** `const ModuleInput* smtrat::Module::pReceivedFormula ( ) const` [inline], [inherited]

**Returns**

A pointer to the formula passed to this module.

**0.15.170.4.78 print()** `void smtrat::Module::print ( const std::string & _initiation = "***" ) const` [inherited]

Prints everything relevant of the solver.

**Parameters**

|                          |                      |
|--------------------------|----------------------|
| <code>_initiation</code> | The line initiation. |
|--------------------------|----------------------|

**0.15.170.4.79 printAllModels()** `void smtrat::Module::printAllModels ( std::ostream & _out = std::cout )` [inherited]

Prints all assignments of this module satisfying its received formula if it satisfiable and this module could find an assignment.

**Parameters**

|                   |                                        |
|-------------------|----------------------------------------|
| <code>_out</code> | The stream to print the assignment on. |
|-------------------|----------------------------------------|

**0.15.170.4.80 printInfeasibleSubsets()** `void smtrat::Module::printInfeasibleSubsets ( const std::string & _initiation = "***" ) const` [inherited]

Prints the infeasible subsets.

## Parameters

|                          |                      |
|--------------------------|----------------------|
| <code>_initiation</code> | The line initiation. |
|--------------------------|----------------------|

**0.15.170.4.81 `printModel()`** `void smtrat::Module::printModel ( std::ostream & _out = std::cout ) const [inherited]`

Prints the assignment of this module satisfying its received formula if it satisfiable and this module could find an assignment.

## Parameters

|                   |                                        |
|-------------------|----------------------------------------|
| <code>_out</code> | The stream to print the assignment on. |
|-------------------|----------------------------------------|

**0.15.170.4.82 `printPassedFormula()`** `void smtrat::Module::printPassedFormula ( const std::string & _initiation = "***" ) const [inherited]`

Prints the vector of passed formula.

## Parameters

|                          |                      |
|--------------------------|----------------------|
| <code>_initiation</code> | The line initiation. |
|--------------------------|----------------------|

**0.15.170.4.83 `printReceivedFormula()`** `void smtrat::Module::printReceivedFormula ( const std::string & _initiation = "***" ) const [inherited]`

Prints the vector of the received formula.

## Parameters

|                          |                      |
|--------------------------|----------------------|
| <code>_initiation</code> | The line initiation. |
|--------------------------|----------------------|

**0.15.170.4.84 `probablyLooping()`** `bool smtrat::Module::probablyLooping ( const typename Poly::PolyType & _branchingPolynomial, const Rational & _branchingValue ) const [protected], [inherited]`

Checks whether given the current branching value and branching variable/polynomial it is (highly) probable that this branching is part of an infinite loop of branchings.

## Parameters

|                                   |                                                                                     |
|-----------------------------------|-------------------------------------------------------------------------------------|
| <code>_branchingPolynomial</code> | The polynomial to branch at (in most branching strategies this is just a variable). |
| <code>_branchingValue</code>      | The value to branch at.                                                             |

## Returns

true, if this branching is probably part of an infinite loop of branchings; false, otherwise.

**0.15.170.4.85 `receivedFormulaChecked()`** `void smtrat::Module::receivedFormulaChecked ( ) [inline], [inherited]`

Notifies that the received formulas has been checked.

**0.15.170.4.86 `receivedFormulasAsInfeasibleSubset()`** void smtrat::Module::receivedFormulasAsInfeasibleSubset (

```
 ModuleInput::const_iterator _subformula) [inline], [protected], [inherited]
```

Stores an infeasible subset consisting only of the given received formula.

**0.15.170.4.87 `receivedVariable()`** bool smtrat::Module::receivedVariable (

```
 carl::Variable::Arg _var) const [inline], [inherited]
```

**0.15.170.4.88 `remove()`** void smtrat::PModule::remove (

```
 ModuleInput::const_iterator _subformula) [virtual], [inherited]
```

Removes everything related to the given sub-formula of the received formula.

However, it is desired not to lose track of search spaces where no satisfying assignment can be found for the remaining sub-formulas.

#### Parameters

|                          |                                                    |
|--------------------------|----------------------------------------------------|
| <code>_subformula</code> | The sub formula of the received formula to remove. |
|--------------------------|----------------------------------------------------|

Reimplemented from [smtrat::Module](#).

**0.15.170.4.89 `removeCore()`** virtual void smtrat::Module::removeCore (

```
 ModuleInput::const_iterator formula) [inline], [protected], [virtual], [inherited]
```

Removes everything related to the given sub-formula of the received formula.

However, it is desired not to lose track of search spaces where no satisfying assignment can be found for the remaining sub-formulas.

#### Parameters

|                      |                                                    |
|----------------------|----------------------------------------------------|
| <code>formula</code> | The sub formula of the received formula to remove. |
|----------------------|----------------------------------------------------|

Reimplemented in [smtrat::VSModule< Settings >](#), [smtrat::SATModule< Settings >](#), [smtrat::PFEModule< Settings >](#), [smtrat::ICPModule< Settings >](#), [smtrat::ICPModule< ICPSettings4 >](#), [smtrat::ICPModule< ICPSettings1 >](#), [smtrat::UnionFindModule< Settings >](#), [smtrat::UFCegarModule< Settings >](#), [smtrat::STropModule< Settings >](#), [smtrat::PBPPModule< Settings >](#), [smtrat::PBGaussModule< Settings >](#), [smtrat::NRAILModule< Settings >](#), [smtrat::NewCoveringModule< Settings >](#), [smtrat::NewCADModule< Settings >](#), [smtrat::LRAModule< Settings >](#), [smtrat::LRAModule< LRASettingsICP >](#), [smtrat::LRAModule< LRASettings1 >](#), [smtrat::IntEqModule< Settings >](#), [smtrat::IntBlastModule< Settings >](#), [smtrat::IncWidthModule< Settings >](#), [smtrat::ICEModule< Settings >](#), [smtrat::FPPModule< Settings >](#), [smtrat::FouMoModule< Settings >](#), [smtrat::EQModule< Settings >](#), [smtrat::CurryModule< Settings >](#), [smtrat::CubeLIAModule< Settings >](#), [smtrat::CSplitModule< Settings >](#), [smtrat::BVMModule< Settings >](#), and [smtrat::GBModule< Settings >](#).

**0.15.170.4.90 `removeOrigin()`** std::pair<ModuleInput::iterator, bool> smtrat::Module::removeOrigin (

```
 ModuleInput::iterator _formula,
 const FormulaT & _origin) [inline], [protected], [inherited]
```

**0.15.170.4.91 `removeOrigins()`** std::pair<ModuleInput::iterator, bool> smtrat::Module::removeOrigins (

```
ModuleInput::iterator _formula,
const std::shared_ptr< std::vector< FormulaT >> & _origins) [inline], [protected],
[inherited]
```

#### 0.15.170.4.92 rPassedFormula() const ModuleInput& smtrat::Module::rPassedFormula () const [inline], [inherited]

**Returns**

A reference to the formula passed to the backends of this module.

#### 0.15.170.4.93 rReceivedFormula() const ModuleInput& smtrat::Module::rReceivedFormula () const [inline], [inherited]

**Returns**

A reference to the formula passed to this module.

#### 0.15.170.4.94 runBackends() [1/2] virtual Answer smtrat::PModule::runBackends () [inline], [virtual], [inherited]

Reimplemented from [smtrat::Module](#).

#### 0.15.170.4.95 runBackends() [2/2] Answer smtrat::PModule::runBackends (

```
bool _final,
bool _full,
carl::Variable _objective) [virtual], [inherited]
```

Runs the backend solvers on the passed formula.

**Parameters**

|                         |                                                                                                                                       |
|-------------------------|---------------------------------------------------------------------------------------------------------------------------------------|
| <code>_final</code>     | true, if this satisfiability check will be the last one (for a global sat-check), if its result is SAT.                               |
| <code>_full</code>      | false, if this module should avoid too expensive procedures and rather return unknown instead.                                        |
| <code>_objective</code> | if not set to NO_VARIABLE, the module should find an assignment minimizing this objective variable; otherwise any assignment is good. |

**Returns**

True, if the passed formula is consistent; False, if the passed formula is inconsistent; Unknown, otherwise.

Reimplemented from [smtrat::Module](#).

#### 0.15.170.4.96 setId() void smtrat::Module::setId ( std::size\_t \_id ) [inline], [inherited]

Sets this modules unique ID to identify itself.

**Parameters**

|                                                                                                     |                                    |
|-----------------------------------------------------------------------------------------------------|------------------------------------|
|  <code>id</code> | The id to set this module's id to. |
|-----------------------------------------------------------------------------------------------------|------------------------------------|

**0.15.170.4.97 `setThreadPriority()`** `void smtrat::Module::setThreadPriority (`  
    `thread_priority _threadPriority )` [inline], [inherited]  
Sets the priority of this module to get a thread for running its check procedure.

Parameters

|                              |                                                       |
|------------------------------|-------------------------------------------------------|
| <code>_threadPriority</code> | The priority to set this module's thread priority to. |
|------------------------------|-------------------------------------------------------|

**0.15.170.4.98 `solverState()`** `Answer smtrat::Module::solverState ( ) const` [inline], [inherited]

Returns

True, if this module is in a state, such that it has found a solution for its received formula; False, if this module is in a state, such that it has determined that there is no solution for its received formula; Unknown, otherwise.

**0.15.170.4.99 `splitUnequalConstraint()`** `void smtrat::Module::splitUnequalConstraint (`  
    `const FormulaT & _unequalConstraint )` [protected], [inherited]

Adds the following lemmas for the given constraint  $p \neq 0$ .

$(p \neq 0 \Leftrightarrow (p < 0 \text{ or } p > 0))$

and  $\neg(p < 0 \text{ and } p > 0)$

Parameters

|                                 |                                                  |
|---------------------------------|--------------------------------------------------|
| <code>_unequalConstraint</code> | A constraint having the relation symbol $\neq$ . |
|---------------------------------|--------------------------------------------------|

**0.15.170.4.100 `threadPriority()`** `thread_priority smtrat::Module::threadPriority ( ) const` [inline], [inherited]

Returns

The priority of this module to get a thread for running its check procedure.

**0.15.170.4.101 `updateAllModels()`** `void smtrat::Module::updateAllModels ( )` [virtual], [inherited]

Updates all satisfying models, if the solver has detected the consistency of the received formula, beforehand.

Reimplemented in [smtrat::SATModule< Settings >](#).

**0.15.170.4.102 `updateLemmas()`** `void smtrat::Module::updateLemmas ( )` [inherited]

Stores all lemmas of any backend of this module in its own lemma vector.

**0.15.170.4.103 `updateModel()`** `void smtrat::PModule::updateModel ( ) const` [virtual], [inherited]

Updates the current assignment into the model.

Note, that this is a unique but possibly symbolic assignment maybe containing newly introduced variables.

Reimplemented from [smtrat::Module](#).

**0.15.170.4.104 `usedBackends()`** `const std::vector<Module*>& smtrat::Module::usedBackends ( )`  
const [inline], [inherited]

**Returns**

The backends of this module which are currently used (conditions to use this module are fulfilled for the passed formula).

### 0.15.170.5 Field Documentation

**0.15.170.5.1 mAllBackends** `std::vector<Module*> smtrat::Module::mAllBackends [protected], [inherited]`

The backends of this module which have been used.

**0.15.170.5.2 mAllModels** `std::vector<Model> smtrat::Module::mAllModels [mutable], [protected], [inherited]`

Stores all satisfying assignments.

**0.15.170.5.3 mBackendsFoundAnswer** `std::atomic_bool* smtrat::Module::mBackendsFoundAnswer [protected], [inherited]`

This flag is passed to any backend and if it determines an answer to a prior check call, this flag is fired.

**0.15.170.5.4 mConstraintsToInform** `carl::FastSet<FormulaT> smtrat::Module::mConstraintsToInform [protected], [inherited]`

Stores the constraints which the backends must be informed about.

**0.15.170.5.5 mFinalCheck** `bool smtrat::Module::mFinalCheck [protected], [inherited]`  
true, if the check procedure should perform a final check which especially means not to postpone splitting decisions

**0.15.170.5.6 mFirstPosInLastBranches** `std::size_t smtrat::Module::mFirstPosInLastBranches = 0 [static], [inherited]`

The beginning of the cyclic buffer storing the last branches.

**0.15.170.5.7 mFirstSubformulaToPass** `ModuleInput::iterator smtrat::Module::mFirstSubformulaToPass [protected], [inherited]`

Stores the position of the first sub-formula in the passed formula, which has not yet been considered for a consistency check of the backends.

**0.15.170.5.8 mFirstUncheckedReceivedSubformula** `ModuleInput::const_iterator smtrat::Module::mFirstUncheckedReceivedSubformula [protected], [inherited]`

Stores the position of the first (by this module) unchecked sub-formula of the received formula.

**0.15.170.5.9 mFoundAnswer** `Conditionals smtrat::Module::mFoundAnswer [protected], [inherited]`  
Vector of Booleans: If any of them is true, we have to terminate a running check procedure.

**0.15.170.5.10 mFullCheck** `bool smtrat::Module::mFullCheck [protected], [inherited]`  
false, if this module should avoid too expensive procedures and rather return unknown instead.

**0.15.170.5.11 mInfeasibleSubsets** std::vector<[FormulaSetT](#)> smtrat::Module::mInfeasibleSubsets  
[protected], [inherited]  
Stores the infeasible subsets.

**0.15.170.5.12 mInformedConstraints** carl::FastSet<[FormulaT](#)> smtrat::Module::mInformedConstraints  
[protected], [inherited]  
Stores the position of the first constraint of which no backend has been informed about.

**0.15.170.5.13 mLastBranches** std::vector< [Branching](#) > smtrat::Module::mLastBranches = std::vector<[Branching](#)>([mNumOfBranchVarsToStore](#), [Branching](#)(typename Poly::PolyType(), 0)) [static],  
[inherited]  
Stores the last branches in a cycle buffer.

**0.15.170.5.14 mLemmas** std::vector<[Lemma](#)> smtrat::Module::mLemmas [protected], [inherited]  
Stores the lemmas being valid formulas this module or its backends made.

**0.15.170.5.15 mModel** [Model](#) smtrat::Module::mModel [mutable], [protected], [inherited]  
Stores the assignment of the current satisfiable result, if existent.

**0.15.170.5.16 mModelComputed** bool smtrat::Module::mModelComputed [mutable], [protected],  
[inherited]  
True, if the model has already been computed.

**0.15.170.5.17 mNumOfBranchVarsToStore** std::size\_t smtrat::Module::mNumOfBranchVarsToStore = 5 [static], [inherited]  
The number of different variables to consider for a probable infinite loop of branchings.

**0.15.170.5.18 mObjectiveVariable** carl::Variable smtrat::Module::mObjectiveVariable [protected],  
[inherited]  
Objective variable to be minimized. If set to NO\_VARIABLE, a normal sat check should be performed.

**0.15.170.5.19 mOldSplittingVariables** std::vector< [FormulaT](#) > smtrat::Module::mOldSplittingVariables [static], [inherited]  
Reusable splitting variables.

**0.15.170.5.20 mpManager** [Manager](#)\* const smtrat::Module::mpManager [protected], [inherited]  
A reference to the manager.

**0.15.170.5.21 mSmallerMusesCheckCounter** unsigned smtrat::Module::mSmallerMusesCheckCounter [mutable], [protected], [inherited]  
Counter used for the generation of the smt2 files to check for smaller muses.

**0.15.170.5.22 mSolverState** std::atomic<[Answer](#)> smrat::Module::mSolverState [protected], [inherited]

States whether the received formula is known to be satisfiable or unsatisfiable otherwise it is set to unknown.

**0.15.170.5.23 mTheoryPropagations** std::vector<[TheoryPropagation](#)> smrat::Module::mTheory← Propagations [protected], [inherited]

**0.15.170.5.24 mUsedBackends** std::vector<[Module\\*](#)> smrat::Module::mUsedBackends [protected], [inherited]

The backends of this module which are currently used (conditions to use this module are fulfilled for the passed formula).

**0.15.170.5.25 mVariableCounters** std::vector<std::size\_t> smrat::Module::mVariableCounters [protected], [inherited]

Maps variables to the number of their occurrences.

## 0.15.171 smrat::subtropical::Encoding Class Reference

```
#include <Subtropical.h>
```

### Public Member Functions

- [FormulaT encode\\_separator](#) (const [Separator](#) &separator, const [Direction](#) direction, const [SeparatorType](#) separator\_type)
 

*Creates the formula for the hyperplane that linearly separates at least one variant positive frame vertex from all variant negative frame vertices.*
- [FormulaT encode\\_integer](#) (carl::Variable var)
- [Model construct\\_assignment](#) (const [Model](#) &lra\_model, const [FormulaT](#) &f) const

### 0.15.171.1 Member Function Documentation

**0.15.171.1.1 construct\_assignment()** [Model](#) smrat::subtropical::Encoding::construct\_assignment (const [Model](#) & lra\_model, const [FormulaT](#) & f ) const [inline]

Stores all informations retrieved from the LRA solver to construct the model

**0.15.171.1.2 encode\_integer()** [FormulaT](#) smrat::subtropical::Encoding::encode\_integer (carl::Variable var ) [inline]

**0.15.171.1.3 encode\_separator()** [FormulaT](#) smrat::subtropical::Encoding::encode\_separator (const [Separator](#) & separator, const [Direction](#) direction, const [SeparatorType](#) separator\_type ) [inline]

Creates the formula for the hyperplane that linearly separates at least one variant positive frame vertex from all variant negative frame vertices.

If a weak separator is searched, the corresponding rating is included.

### Parameters

|                  |                                                                                                                                               |
|------------------|-----------------------------------------------------------------------------------------------------------------------------------------------|
| <i>separator</i> | The separator object that stores the construction information.                                                                                |
| <i>negated</i>   | True, if the formula for the negated polynomial shall be constructed. False, if the formula for the original polynomial shall be constructed. |

**Returns**

Formula that is satisfiable iff such a separating hyperplane exists.

Create the hyperplane and sign change formula

Create the rating case distinction formula

Create the strict/weak linear separating hyperplane

- bool **is\_minimizing** () const
- void **excludeNotReceivedVariablesFromModel** () const  
*Excludes all variables from the current model, which do not occur in the received formula.*
- void **updateLemmas** ()

- Stores all lemmas of any backend of this module in its own lemma vector.
- void `collectTheoryPropagations ()`  
Collects the formulas in the given formula, which are part of the received formula.
- void `collectOrigins (const FormulaT &_formula, FormulasT &_origins) const`  
Checks the given infeasible subset for minimality by storing all subsets of it, which have a smaller size which differs from the size of the infeasible subset not more than the given threshold.
- void `checkInSubsetForMinimality (std::vector< FormulaSetT >::const_iterator _insubset, const std::string &_filename="smaller_muses", unsigned _maxSizeDifference=1) const`
- virtual std::pair< bool, FormulaT > `getReceivedFormulaSimplified ()`
- void `print (const std::string &_initiation="***") const`  
Prints everything relevant of the solver.
- void `printReceivedFormula (const std::string &_initiation="***") const`  
Prints the vector of the received formula.
- void `printPassedFormula (const std::string &_initiation="***") const`  
Prints the vector of passed formula.
- void `printInfeasibleSubsets (const std::string &_initiation="***") const`  
Prints the infeasible subsets.
- void `printModel (std::ostream &_out=std::cout) const`  
Prints the assignment of this module satisfying its received formula if it satisfiable and this module could find an assignment.
- void `printAllModels (std::ostream &_out=std::cout)`  
Prints all assignments of this module satisfying its received formula if it satisfiable and this module could find an assignment.

### Static Public Member Functions

- static void `freeSplittingVariable (const FormulaT &_splittingVariable)`

### Static Public Attributes

- static size\_t `mNumOfBranchVarsToStore` = 5  
The number of different variables to consider for a probable infinite loop of branchings.
- static std::vector< Branching > `mLastBranches` = std::vector<Branching>(mNumOfBranchVarsToStore, Branching(typename Poly::PolyType(), 0))  
Stores the last branches in a cycle buffer.
- static size\_t `mFirstPosInLastBranches` = 0  
The beginning of the cyclic buffer storing the last branches.
- static std::vector< FormulaT > `mOldSplittingVariables`  
Reusable splitting variables.

### Protected Member Functions

- virtual void `deinformCore (const FormulaT &_constraint)`  
The inverse of informing about a constraint.
- bool `anAnswerFound () const`  
Checks for all antecedent modules and those which run in parallel with the same antecedent modules, whether one of them has determined a result.
- void `clearModel () const`  
Clears the assignment, if any was found.
- void `clearModels () const`  
Clears all assignments, if any was found.
- void `cleanModel () const`

*Substitutes variable occurrences by its model value in the model values of other variables.*

- `ModuleInput::iterator passedFormulaBegin ()`
- `ModuleInput::iterator passedFormulaEnd ()`
- `void addOrigin (ModuleInput::iterator _formula, const FormulaT &_origin)`

*Adds the given set of formulas in the received formula to the origins of the given passed formula.*
- `const FormulaT & getOrigins (ModuleInput::const_iterator _formula) const`

*Gets the origins of the passed formula at the given position.*
- `void getOrigins (const FormulaT &_formula, FormulasT &_origins) const`
- `void getOrigins (const FormulaT &_formula, FormulaSetT &_origins) const`
- `std::pair< ModuleInput::iterator, bool > removeOrigin (ModuleInput::iterator _formula, const FormulaT &_origin)`
- `std::pair< ModuleInput::iterator, bool > removeOrigins (ModuleInput::iterator _formula, const std::shared_ptr< std::vector< FormulaT >> &_origins)`
- `void informBackends (const FormulaT &_constraint)`

*Informs all backends of this module about the given constraint.*
- `virtual void addConstraintToInform (const FormulaT &_constraint)`

*Adds a constraint to the collection of constraints of this module, which are informed to a freshly generated backend.*
- `std::pair< ModuleInput::iterator, bool > addReceivedSubformulaToPassedFormula (ModuleInput::const_iterator _subformula)`

*Copies the given sub-formula of the received formula to the passed formula.*
- `bool originInReceivedFormula (const FormulaT &_origin) const`
- `std::pair< ModuleInput::iterator, bool > addSubformulaToPassedFormula (const FormulaT &_formula)`

*Adds the given formula to the passed formula with no origin.*
- `std::pair< ModuleInput::iterator, bool > addSubformulaToPassedFormula (const FormulaT &_formula, const std::shared_ptr< std::vector< FormulaT >> &_origins)`

*Adds the given formula to the passed formula.*
- `std::pair< ModuleInput::iterator, bool > addSubformulaToPassedFormula (const FormulaT &_formula, const FormulaT &_origin)`

*Adds the given formula to the passed formula.*
- `void generateTrivialInfeasibleSubset ()`

*Stores the trivial infeasible subset being the set of received formulas.*
- `void receivedFormulasAsInfeasibleSubset (ModuleInput::const_iterator _subformula)`

*Stores an infeasible subset consisting only of the given received formula.*
- `std::vector< FormulaT >::const_iterator findBestOrigin (const std::vector< FormulaT > &_origins) const`
- `void getInfeasibleSubsets ()`

*Copies the infeasible subsets of the passed formula.*
- `std::vector< FormulaSetT > getInfeasibleSubsets (const Model & backend) const`

*Get the infeasible subsets the given backend provides.*
- `const Model & backendsModel () const`

*Stores the model of a backend which determined satisfiability of the passed formula in the model of this module.*
- `void getBackendsModel () const`
- `void getBackendsAllModels () const`

*Stores all models of a backend in the list of all models of this module.*
- `virtual Answer runBackends (bool _final, bool _full, carl::Variable _objective)`

*Runs the backend solvers on the passed formula.*
- `virtual Answer runBackends ()`
- `virtual ModuleInput::iterator eraseSubformulaFromPassedFormula (ModuleInput::iterator _subformula, bool _ignoreOrigins=false)`

*Removes everything related to the sub-formula to remove from the passed formula in the backends of this module.*
- `void clearPassedFormula ()`
- `std::vector< FormulaT > merge (const std::vector< FormulaT > &, const std::vector< FormulaT > &) const`

*Merges the two vectors of sets into the first one.*

- size\_t `determine_smallest_origin` (const std::vector< `FormulaT` > &origins) const
- bool `probablyLooping` (const typename `Poly::PolyType` &\_branchingPolynomial, const `Rational` &\_← branchingValue) const
 

*Checks whether given the current branching value and branching variable/polynomial it is (highly) probable that this branching is part of an infinite loop of branchings.*
- bool `branchAt` (const `Poly` &\_polynomial, bool \_integral, const `Rational` &\_value, std::vector< `FormulaT` > &&\_premise, bool \_leftCaseWeak=true, bool \_preferLeftCase=true, bool \_useReceivedFormulaAsPremise=false)
 

*Adds a lemmas which provoke a branching for the given variable at the given value, if this module returns Unknown and there exists a preceding `SATModule`.*
- bool `branchAt` (const `Poly` &\_polynomial, bool \_integral, const `Rational` &\_value, bool \_leftCaseWeak=true, bool \_preferLeftCase=true, bool \_useReceivedFormulaAsPremise=false, const std::vector< `FormulaT` > &← \_premise=std::vector< `FormulaT` >())
 

*Adds a lemmas which provoke a branching for the given variable at the given value, if this module returns Unknown and there exists a preceding `SATModule`.*
- bool `branchAt` (carl::Variable::Arg \_var, const `Rational` &\_value, std::vector< `FormulaT` > &&\_premise, bool \_leftCaseWeak=true, bool \_preferLeftCase=true, bool \_useReceivedFormulaAsPremise=false)
 

*Adds a lemmas which provoke a branching for the given variable at the given value, if this module returns Unknown and there exists a preceding `SATModule`.*
- bool `branchAt` (carl::Variable::Arg \_var, const `Rational` &\_value, bool \_leftCaseWeak=true, bool \_preferLeftCase=true, bool \_useReceivedFormulaAsPremise=false, const std::vector< `FormulaT` > &\_premise=std::vector< `FormulaT` >())
 

*Adds a lemmas which provoke a branching for the given variable at the given value, if this module returns Unknown and there exists a preceding `SATModule`.*
- void `splitUnequalConstraint` (const `FormulaT` &)
 

*Adds the following lemmas for the given constraint p!=0.*
- unsigned `checkModel` () const
- void `addInformationRelevantFormula` (const `FormulaT` &formula)
 

*Adds a formula to the `InformationRelevantFormula`.*
- const std::set< `FormulaT` > & `getInformationRelevantFormulas` ()
 

*Gets all `InformationRelevantFormulas`.*
- bool `isLemmaLevel` (`LemmaLevel` level)
 

*Checks if current lemma level is greater or equal to given level.*

## Static Protected Member Functions

- static bool `modelsDisjoint` (const `Model` &\_modelA, const `Model` &\_modelB)
 

*Checks whether there is no variable assigned by both models.*

## Protected Attributes

- std::vector< `FormulaSetT` > `mInfeasibleSubsets`

*Stores the infeasible subsets.*
- `Manager` \*const `mpManager`

*A reference to the manager.*
- `Model` `mModel`

*Stores the assignment of the current satisfiable result, if existent.*
- std::vector< `Model` > `mAllModels`

*Stores all satisfying assignments.*
- bool `mModelComputed`

*True, if the model has already been computed.*
- bool `mFinalCheck`

*true, if the check procedure should perform a final check which especially means not to postpone splitting decisions*
- bool `mFullCheck`

*false, if this module should avoid too expensive procedures and rather return unknown instead.*
- carl::Variable `mObjectiveVariable`

*Objective variable to be minimized. If set to NO\_VARIABLE, a normal sat check should be performed.*
- std::vector< `TheoryPropagation` > `mTheoryPropagations`
- std::atomic< `Answer` > `mSolverState`

*States whether the received formula is known to be satisfiable or unsatisfiable otherwise it is set to unknown.*

- `std::atomic_bool * mBackendsFoundAnswer`  
*This flag is passed to any backend and if it determines an answer to a prior check call, this flag is fired.*
- `Conditionals mFoundAnswer`  
*Vector of Booleans: If any of them is true, we have to terminate a running check procedure.*
- `std::vector< Module * > mUsedBackends`  
*The backends of this module which are currently used (conditions to use this module are fulfilled for the passed formula).*
- `std::vector< Module * > mAllBackends`  
*The backends of this module which have been used.*
- `std::vector< Lemma > mLemmas`  
*Stores the lemmas being valid formulas this module or its backends made.*
- `ModuleInput::iterator mFirstSubformulaToPass`  
*Stores the position of the first sub-formula in the passed formula, which has not yet been considered for a consistency check of the backends.*
- `carl::FastSet< FormulaT > mConstraintsToInform`  
*Stores the constraints which the backends must be informed about.*
- `carl::FastSet< FormulaT > mInformedConstraints`  
*Stores the position of the first constraint of which no backend has been informed about.*
- `ModuleInput::const_iterator mFirstUncheckedReceivedSubformula`  
*Stores the position of the first (by this module) unchecked sub-formula of the received formula.*
- `unsigned mSmallerMusesCheckCounter`  
*Counter used for the generation of the smt2 files to check for smaller muses.*
- `std::vector< std::size_t > mVariableCounters`  
*Maps variables to the number of their occurrences.*

#### 0.15.173.4 Member Function Documentation

**0.15.173.4.1 add()** bool smtrat::Module::add (   
    ModuleInput::const\_iterator \_subformula ) [inherited]

The module has to take the given sub-formula of the received formula into account.

##### Parameters

|             |                                                    |
|-------------|----------------------------------------------------|
| _subformula | The sub-formula to take additionally into account. |
|-------------|----------------------------------------------------|

##### Returns

false, if it can be easily decided that this sub-formula causes a conflict with the already considered sub-formulas; true, otherwise.

**0.15.173.4.2 addConstraintToInform()** void smtrat::Module::addConstraintToInform (   
    const FormulaT & \_constraint ) [protected], [virtual], [inherited]

Adds a constraint to the collection of constraints of this module, which are informed to a freshly generated backend.

##### Parameters

|             |                        |
|-------------|------------------------|
| _constraint | The constraint to add. |
|-------------|------------------------|

Reimplemented in [smtrat::SATModule< Settings >](#).

**0.15.173.4.3 addCore()** template<typename Settings >  
bool smtrat::EQModule< Settings >::addCore (   
    ModuleInput::const\_iterator \_subformula ) [virtual]

The module has to take the given sub-formula of the received formula into account.

##### Parameters

|             |                                                    |
|-------------|----------------------------------------------------|
| _subformula | The sub-formula to take additionally into account. |
|-------------|----------------------------------------------------|

##### Returns

false, if it can be easily decided that this sub-formula causes a conflict with the already considered sub-formulas; true, otherwise.

Reimplemented from [smtrat::Module](#).

**0.15.173.4.4 addInformationRelevantFormula()** void smtrat::Module::addInformationRelevantFormula (   
    const FormulaT & formula ) [protected], [inherited]

Adds a formula to the InformationRelevantFormula.

##### Parameters

|         |                |
|---------|----------------|
| formula | Formula to add |
|---------|----------------|

```
0.15.173.4.5 addLemma() void smtrat::Module::addLemma (
 const FormulaT & _lemma,
 const LemmaType & _lt = LemmaType::NORMAL,
 const FormulaT & _preferredFormula = FormulaT(carl::FormulaType::TRUE)) [inline],
[inherited]
```

Stores a lemma being a valid formula.

#### Parameters

|                          |                                                                       |
|--------------------------|-----------------------------------------------------------------------|
| <i>_lemma</i>            | The eduction/lemma to store.                                          |
| <i>_lt</i>               | The type of the lemma.                                                |
| <i>_preferredFormula</i> | Hint for the next decision, which formula should be assigned to true. |

```
0.15.173.4.6 addOrigin() void smtrat::Module::addOrigin (
```

```
 ModuleInput::iterator _formula,
 const FormulaT & _origin) [inline], [protected], [inherited]
```

Adds the given set of formulas in the received formula to the origins of the given passed formula.

#### Parameters

|                 |                                                           |
|-----------------|-----------------------------------------------------------|
| <i>_formula</i> | The passed formula to set the origins for.                |
| <i>_origin</i>  | A set of formulas in the received formula of this module. |

```
0.15.173.4.7 addReceivedSubformulaToPassedFormula() std::pair<ModuleInput::iterator,bool>
smtrat::Module::addReceivedSubformulaToPassedFormula (
```

```
 ModuleInput::const_iterator _subformula) [inline], [protected], [inherited]
```

Copies the given sub-formula of the received formula to the passed formula.

Note, that there is always a link between sub-formulas of the passed formulas to sub-formulas of the received formulas, which are responsible for its occurrence.

#### Parameters

|                    |                                                  |
|--------------------|--------------------------------------------------|
| <i>_subformula</i> | The sub-formula of the received formula to copy. |
|--------------------|--------------------------------------------------|

```
0.15.173.4.8 addSubformulaToPassedFormula() [1/3] std::pair<ModuleInput::iterator,bool> smtrat<-
::Module::addSubformulaToPassedFormula (
 const FormulaT & _formula) [inline], [protected], [inherited]
```

Adds the given formula to the passed formula with no origin.

Note that in the next call of this module's removeSubformula, all formulas in the passed formula without origins will be removed.

#### Parameters

|                 |                                           |
|-----------------|-------------------------------------------|
| <i>_formula</i> | The formula to add to the passed formula. |
|-----------------|-------------------------------------------|

**Returns**

A pair to the position where the formula to add has been inserted (or its first sub-formula which has not yet been in the passed formula, in case the formula to add is a conjunction), and a Boolean stating whether anything has been added to the passed formula.

**0.15.173.4.9 addSubformulaToPassedFormula()** [2/3] std::pair<ModuleInput::iterator,bool> smrat::Module::addSubformulaToPassedFormula (

```
 const FormulaT & _formula,
 const FormulaT & _origin) [inline], [protected], [inherited]
```

Adds the given formula to the passed formula.

**Parameters**

|                 |                                                                                                                           |
|-----------------|---------------------------------------------------------------------------------------------------------------------------|
| <i>_formula</i> | The formula to add to the passed formula.                                                                                 |
| <i>_origin</i>  | The sub-formula of the received formula being responsible for the occurrence of the formula to add to the passed formula. |

**Returns**

A pair to the position where the formula to add has been inserted (or its first sub-formula which has not yet been in the passed formula, in case the formula to add is a conjunction), and a Boolean stating whether anything has been added to the passed formula.

**0.15.173.4.10 addSubformulaToPassedFormula()** [3/3] std::pair<ModuleInput::iterator,bool> smrat::Module::addSubformulaToPassedFormula (

```
 const FormulaT & _formula,
 const std::shared_ptr< std::vector< FormulaT >> & _origins) [inline], [protected],
[inherited]
```

Adds the given formula to the passed formula.

**Parameters**

|                 |                                                                                                                                         |
|-----------------|-----------------------------------------------------------------------------------------------------------------------------------------|
| <i>_formula</i> | The formula to add to the passed formula.                                                                                               |
| <i>_origins</i> | The link of the formula to add to the passed formula to sub-formulas of the received formulas, which are responsible for its occurrence |

**Returns**

A pair to the position where the formula to add has been inserted (or its first sub-formula which has not yet been in the passed formula, in case the formula to add is a conjunction), and a Boolean stating whether anything has been added to the passed formula.

**0.15.173.4.11 allModels()** const std::vector<Model>& smrat::Module::allModels () const [inline], [inherited]

**Returns**

All satisfying assignments, if existent.

**0.15.173.4.12 `anAnswerFound()`** `bool smrat::Module::anAnswerFound () const [inline], [protected], [inherited]`

Checks for all antecedent modules and those which run in parallel with the same antecedent modules, whether one of them has determined a result.

**Returns**

True, if one of them has determined a result.

**0.15.173.4.13 `answerFound()`** `const smrat::Conditionals& smrat::Module::answerFound () const [inline], [inherited]`

**Returns**

A vector of Booleans: If any of them is true, we have to terminate a running check procedure.

**0.15.173.4.14 `backendsModel()`** `const Model & smrat::Module::backendsModel () const [protected], [inherited]`

Stores the model of a backend which determined satisfiability of the passed formula in the model of this module.

**0.15.173.4.15 `branchAt() [1/4]`** `bool smrat::Module::branchAt ( carl::Variable::Arg _var, const Rational & _value, bool _leftCaseWeak = true, bool _preferLeftCase = true, bool _useReceivedFormulaAsPremise = false, const std::vector< FormulaT > & _premise = std::vector<FormulaT>() ) [inline], [protected], [inherited]`

**0.15.173.4.16 `branchAt() [2/4]`** `bool smrat::Module::branchAt ( carl::Variable::Arg _var, const Rational & _value, std::vector< FormulaT > && _premise, bool _leftCaseWeak = true, bool _preferLeftCase = true, bool _useReceivedFormulaAsPremise = false ) [inline], [protected], [inherited]`

**0.15.173.4.17 `branchAt() [3/4]`** `bool smrat::Module::branchAt ( const Poly & _polynomial, bool _integral, const Rational & _value, bool _leftCaseWeak = true, bool _preferLeftCase = true, bool _useReceivedFormulaAsPremise = false, const std::vector< FormulaT > & _premise = std::vector<FormulaT>() ) [inline], [protected], [inherited]`

**0.15.173.4.18 `branchAt() [4/4]`** `bool smrat::Module::branchAt ( const Poly & _polynomial, bool _integral, const Rational & _value,`

```
 std::vector< FormulaT > && _premise,
 bool _leftCaseWeak = true,
 bool _preferLeftCase = true,
 bool _useReceivedFormulaAsPremise = false) [protected], [inherited]
```

Adds a lemmas which provoke a branching for the given variable at the given value, if this module returns Unknown and there exists a preceding [SATModule](#).

Note that the given value is rounded down and up, if the given variable is integer-valued.

#### Parameters

|                                              |                                                                                                                                                                                                                |
|----------------------------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <a href="#">_polynomial</a>                  | The variable to branch for.                                                                                                                                                                                    |
| <a href="#">_integral</a>                    | A flag being true, if all variables in the polynomial to branch for are integral.                                                                                                                              |
| <a href="#">_value</a>                       | The value to branch at.                                                                                                                                                                                        |
| <a href="#">_premise</a>                     | The sub-formulas of the received formula from which the branch is followed. Note, that a premise is not necessary, as every branch is a valid formula. But a premise can prevent from branching unnecessarily. |
| <a href="#">_leftCaseWeak</a>                | true, if a branching in the form of (or ( $\leq p b$ ) ( $> p b$ )) is desired. false, if a branching in the form of (or ( $< p b$ ) ( $\geq p b$ )) is desired.                                               |
| <a href="#">_preferLeftCase</a>              | true, if the left case (polynomial less(or equal) 0 shall be chosen first. false, otherwise.                                                                                                                   |
| <a href="#">_useReceivedFormulaAsPremise</a> | true, if the whole received formula should be used as premise                                                                                                                                                  |

#### 0.15.173.4.19 [check\(\)](#) Answer [smtrat::Module](#)::check (

```
 bool _final = false,
 bool _full = true,
 carl::Variable _objective = carl::Variable::NO_VARIABLE) [virtual], [inherited]
```

Checks the received formula for consistency.

Note, that this is an implementation of the satisfiability check of the conjunction of the so far received formulas, which does actually nothing but passing the problem to its backends. This implementation is only used internally and must be overwritten by any derived module.

#### Parameters

|                            |                                                                                                                                       |
|----------------------------|---------------------------------------------------------------------------------------------------------------------------------------|
| <a href="#">_final</a>     | true, if this satisfiability check will be the last one (for a global sat-check), if its result is SAT                                |
| <a href="#">_full</a>      | false, if this module should avoid too expensive procedures and rather return unknown instead.                                        |
| <a href="#">_objective</a> | if not set to NO_VARIABLE, the module should find an assignment minimizing this objective variable; otherwise any assignment is good. |

#### Returns

True, if the received formula is satisfiable; False, if the received formula is not satisfiable; Unknown, otherwise.

Reimplemented in [smtrat::PModule](#).

#### 0.15.173.4.20 [checkCore\(\)](#) template<typename Settings >

```
Answer smtrat::EQModule< Settings >::checkCore () [virtual]
```

Checks the received formula for consistency.

#### Returns

SAT, if the received formula is satisfiable; UNSAT, if the received formula is not satisfiable; Unknown, otherwise.

Reimplemented from [smtrat::Module](#).

```
0.15.173.4.21 checkInfSubsetForMinimality() void smtrat::Module::checkInfSubsetForMinimality (
 std::vector< FormulaSetT >::const_iterator _infssubset,
 const std::string & _filename = "smaller_muses",
 unsigned _maxSizeDifference = 1) const [inherited]
```

Checks the given infeasible subset for minimality by storing all subsets of it, which have a smaller size which differs from the size of the infeasible subset not more than the given threshold.

#### Parameters

|                                 |                                                                                                        |
|---------------------------------|--------------------------------------------------------------------------------------------------------|
| <code>_infssubset</code>        | The infeasible subset to check for minimality.                                                         |
| <code>_filename</code>          | The name of the file to store the infeasible subsets in order to be able to check their infeasibility. |
| <code>_maxSizeDifference</code> | The maximal difference between the sizes of the subsets compared to the size of the infeasible subset. |

```
0.15.173.4.22 checkModel() unsigned smtrat::Module::checkModel () const [protected], [inherited]
```

#### Returns

false, if the current model of this module does not satisfy the current given formula; true, if it cannot be said whether the model satisfies the given formula.

```
0.15.173.4.23 cleanModel() void smtrat::Module::cleanModel () const [inline], [protected], [inherited]
```

Substitutes variable occurrences by its model value in the model values of other variables.

```
0.15.173.4.24 clearLemmas() void smtrat::Module::clearLemmas () [inline], [inherited]
```

Deletes all yet found lemmas.

```
0.15.173.4.25 clearModel() void smtrat::Module::clearModel () const [inline], [protected], [inherited]
```

Clears the assignment, if any was found.

```
0.15.173.4.26 clearModels() void smtrat::Module::clearModels () const [inline], [protected], [inherited]
```

Clears all assignments, if any was found.

```
0.15.173.4.27 clearPassedFormula() void smtrat::Module::clearPassedFormula () [protected], [inherited]
```

```
0.15.173.4.28 collectOrigins() [1/2] void smtrat::Module::collectOrigins (
 const FormulaT & _formula,
 FormulaSetT & _origins) const [inherited]
```

```
0.15.173.4.29 collectOrigins() [2/2] void smtrat::Module::collectOrigins (
 const FormulaT & _formula,
 FormulasT & _origins) const [inherited]
```

Collects the formulas in the given formula, which are part of the received formula.

If the given formula directly occurs in the received formula, it is inserted into the given set. Otherwise, the given formula must be of type AND and all its sub-formulas part of the received formula. Hence, they will be added to the given set.

#### Parameters

|                       |                                                                                                      |
|-----------------------|------------------------------------------------------------------------------------------------------|
| <code>_formula</code> | The formula from which to collect the formulas being sub-formulas of the received formula (origins). |
| <code>_origins</code> | The set in which to store the origins.                                                               |

```
0.15.173.4.30 collectTheoryPropagations() void smtrat::Module::collectTheoryPropagations () [inherited]
```

```
0.15.173.4.31 constraintsToInform() const carl::FastSet<FormulaT>& smtrat::Module::constraints←ToInform () const [inline], [inherited]
```

#### Returns

The constraints which the backends must be informed about.

```
0.15.173.4.32 currentlySatisfied() virtual unsigned smtrat::Module::currentlySatisfied (
 const FormulaT &) const [inline], [virtual], [inherited]
```

#### Returns

0, if the given formula is conflicted by the current model; 1, if the given formula is satisfied by the current model; 2, otherwise; 3, if we do not know anything (default)

Reimplemented in [smtrat::LRAbstractModule< Settings >](#), [smtrat::LRAbstractModule< LRASettingsICP >](#), and [smtrat::LRAbstractModule< LRASettings >](#)

```
0.15.173.4.33 currentlySatisfiedByBackend() unsigned smtrat::Module::currentlySatisfiedByBackend (
 const FormulaT & _formula) const [inherited]
```

#### Returns

0, if the given formula is conflicted by the current model; 1, if the given formula is satisfied by the current model; 2, otherwise 3, if we do not know anything (default)

```
0.15.173.4.34 deinform() void smtrat::Module::deinform (
 const FormulaT & _constraint) [inherited]
```

The inverse of informing about a constraint.

All data structures which were kept regarding this constraint are going to be removed. Note, that this makes only sense if it is not likely enough that a formula with this constraint must be solved again.

#### Parameters

|                          |                                                         |
|--------------------------|---------------------------------------------------------|
| <code>_constraint</code> | The constraint to remove from internal data structures. |
|--------------------------|---------------------------------------------------------|

**0.15.173.4.35 `deinformCore()`** `virtual void smtrat::Module::deinformCore (`  
 `const FormulaT & _constraint )` [inline], [protected], [virtual], [inherited]

The inverse of informing about a constraint.

All data structures which were kept regarding this constraint are going to be removed. Note, that this makes only sense if it is not likely enough that a formula with this constraint must be solved again.

#### Parameters

|                          |                                                         |
|--------------------------|---------------------------------------------------------|
| <code>_constraint</code> | The constraint to remove from internal data structures. |
|--------------------------|---------------------------------------------------------|

Reimplemented in [smtrat::LRAbstractModule< Settings >](#), [smtrat::LRAbstractModule< LRASettingsICP >](#), and [smtrat::LRAbstractModule< LRASettings1 >](#).

**0.15.173.4.36 `determine_smallest_origin()`** `size_t smtrat::Module::determine_smallest_origin (`  
 `const std::vector< FormulaT > & origins ) const` [protected], [inherited]

#### Parameters

|                      |                              |
|----------------------|------------------------------|
| <code>origins</code> | A vector of sets of origins. |
|----------------------|------------------------------|

#### Returns

The index of the smallest (regarding the size of the sets) element of origins

**0.15.173.4.37 `eraseSubformulaFromPassedFormula()`** `ModuleInput::iterator smtrat::Module::eraseSubformulaFromPassedFormula (`  
 `ModuleInput::iterator _subformula,`  
 `bool _ignoreOrigins = false )` [protected], [virtual], [inherited]

Removes everything related to the sub-formula to remove from the passed formula in the backends of this module.  
Afterwards the sub-formula is removed from the passed formula.

#### Parameters

|                             |                                                                                                              |
|-----------------------------|--------------------------------------------------------------------------------------------------------------|
| <code>_subformula</code>    | The sub-formula to remove from the passed formula.                                                           |
| <code>_ignoreOrigins</code> | True, if the sub-formula shall be removed regardless of its origins (should only be applied with expertise). |

#### Returns

Reimplemented in [smtrat::ICPModule< Settings >](#), [smtrat::ICPModule< ICPSettings4 >](#), and [smtrat::ICPModule< ICPSettings1 >](#).

**0.15.173.4.38 `excludeNotReceivedVariablesFromModel()`** `void smtrat::Module::excludeNotReceivedVariablesFromModel ( ) const` [inherited]

Excludes all variables from the current model, which do not occur in the received formula.

**0.15.173.4.39 `find_representative()`** `template<typename Settings >`  
`const term_type* smtrat::EQModule< Settings >::find_representative (`  
 `const term_type & term )`  
find a "canonical" representative for some term

```
0.15.173.4.40 findBestOrigin() std::vector< FormulaT >::const_iterator smrat::Module::findBestOrigin (const std::vector< FormulaT > & _origins) const [protected], [inherited]
```

**Parameters**

|                 |
|-----------------|
| <i>_origins</i> |
|-----------------|

**Returns**

```
0.15.173.4.41 firstSubformulaToPass() ModuleInput::const_iterator smrat::Module::firstSubformulaToPass () const [inline], [inherited]
```

**Returns**

The position of the first sub-formula in the passed formula, which has not yet been considered for a consistency check of the backends.

```
0.15.173.4.42 firstUncheckedReceivedSubformula() ModuleInput::const_iterator smrat::Module::firstUncheckedReceivedSubformula () const [inline], [inherited]
```

**Returns**

The position of the first (by this module) unchecked sub-formula of the received formula.

```
0.15.173.4.43 freeSplittingVariable() static void smrat::Module::freeSplittingVariable (const FormulaT & _splittingVariable) [inline], [static], [inherited]
```

```
0.15.173.4.44 generateTrivialInfeasibleSubset() void smrat::Module::generateTrivialInfeasibleSubset () [inline], [protected], [inherited]
```

Stores the trivial infeasible subset being the set of received formulas.

```
0.15.173.4.45 get_class() template<typename Settings > std::size_t smrat::EQModule< Settings >::get_class (const term_type & term)
```

returns the component-component-level class of some term

```
0.15.173.4.46 getBackendsAllModels() void smrat::Module::getBackendsAllModels () const [protected], [inherited]
```

Stores all models of a backend in the list of all models of this module.

```
0.15.173.4.47 getBackendsModel() void smrat::Module::getBackendsModel () const [protected], [inherited]
```

**0.15.173.4.48 getInfeasibleSubsets()** [1/2] void smtrat::Module::getInfeasibleSubsets ( ) [protected], [inherited]  
Copies the infeasible subsets of the passed formula.

**0.15.173.4.49 getInfeasibleSubsets()** [2/2] std::vector< [FormulaSetT](#) > smtrat::Module::getInfeasibleSubsets ( ) [protected], [inherited]

Get the infeasible subsets the given backend provides.

Note, that an infeasible subset in a backend contains sub formulas of the passed formula and an infeasible subset of this module contains sub formulas of the received formula. In this method the LATTER is returned.

#### Parameters

|                       |                                                          |
|-----------------------|----------------------------------------------------------|
| <code>_backend</code> | The backend from which to obtain the infeasible subsets. |
|-----------------------|----------------------------------------------------------|

#### Returns

The infeasible subsets the given backend provides.

**0.15.173.4.50 getInformationRelevantFormulas()** const std::set< [FormulaT](#) > & smtrat::Module::getInformationRelevantFormulas ( ) [protected], [inherited]  
Gets all InformationRelevantFormulas.

#### Returns

Set of all formulas

**0.15.173.4.51 getModelEqualities()** std::list< std::vector< carl::Variable > > smtrat::Module::getModelEqualities ( ) const [virtual], [inherited]  
Partition the variables from the current model into equivalence classes according to their assigned value.  
The result is a set of equivalence classes of variables where all variables within one class are assigned the same value. Note that the number of classes may not be minimal, i.e. two classes may actually be equivalent.

#### Returns

Equivalence classes.

**0.15.173.4.52 getOrigins()** [1/3] void smtrat::Module::getOrigins ( ) const [inline], [protected], [inherited]  
const [FormulaT](#) & `_formula`,  
[FormulaSetT](#) & `_origins` ) const [inline], [protected], [inherited]

#### Parameters

|                       |  |
|-----------------------|--|
| <code>_formula</code> |  |
| <code>_origins</code> |  |

**0.15.173.4.53 getOrigins()** [2/3] void smtrat::Module::getOrigins ( ) const [inline], [protected], [inherited]  
const [FormulaT](#) & `_formula`,  
[FormulasT](#) & `_origins` ) const [inline], [protected], [inherited]

**Parameters**

|                 |  |
|-----------------|--|
| <i>_formula</i> |  |
| <i>_origins</i> |  |

**0.15.173.4.54 `getOrigins()` [3/3]** const `FormulaT&` `smtrat::Module::getOrigins (ModuleInput::const_iterator _formula )` const [inline], [protected], [inherited]  
Gets the origins of the passed formula at the given position.

**Parameters**

|                 |                                                   |
|-----------------|---------------------------------------------------|
| <i>_formula</i> | The position of a formula in the passed formulas. |
|-----------------|---------------------------------------------------|

**Returns**

The origins of the passed formula at the given position.

**0.15.173.4.55 `getReceivedFormulaSimplified()`** std::pair< bool, `FormulaT` > `smtrat::Module::get←ReceivedFormulaSimplified ( )` [virtual], [inherited]

**Returns**

A pair of a Boolean and a formula, where the Boolean is true, if the received formula could be simplified to an equisatisfiable formula. The formula is equisatisfiable to this module's received formula, if the Boolean is true.

Reimplemented in [smtrat::PModule](#).

**0.15.173.4.56 `hasLemmas()`** bool `smtrat::Module::hasLemmas ( )` [inline], [inherited]  
Checks whether this module or any of its backends provides any lemmas.

**0.15.173.4.57 `hasValidInfeasibleSubset()`** bool `smtrat::Module::hasValidInfeasibleSubset ( )` const [inherited]

**Returns**

true, if the module has at least one valid infeasible subset, that is all its elements are sub-formulas of the received formula (pointer must be equal).

**0.15.173.4.58 `id()`** std::size\_t `smtrat::Module::id ( )` const [inline], [inherited]

**Returns**

A unique ID to identify this module instance.

**0.15.173.4.59 `infeasibleSubsets()`** const std::vector<`FormulaSetT`>& `smtrat::Module::infeasible←Subsets ( )` const [inline], [inherited]

**Returns**

The infeasible subsets of the set of received formulas (empty, if this module has not detected unsatisfiability of the conjunction of received formulas).

```
0.15.173.4.60 inform() bool smrat::Module::inform (
 const FormulaT & _constraint) [inherited]
```

Informs the module about the given constraint.

It should be tried to inform this module about any constraint it could receive eventually before assertSubformula is called (preferably for the first time, but at least before adding a formula containing that constraint).

#### Parameters

|                    |                                 |
|--------------------|---------------------------------|
| <i>_constraint</i> | The constraint to inform about. |
|--------------------|---------------------------------|

#### Returns

false, if it can be easily decided whether the given constraint is inconsistent; true, otherwise.

```
0.15.173.4.61 informBackends() void smrat::Module::informBackends (
```

```
 const FormulaT & _constraint) [inline], [protected], [inherited]
```

Informs all backends of this module about the given constraint.

#### Parameters

|                    |                                 |
|--------------------|---------------------------------|
| <i>_constraint</i> | The constraint to inform about. |
|--------------------|---------------------------------|

```
0.15.173.4.62 informCore() template<typename Settings >
```

```
bool smrat::EQModule< Settings >::informCore (
```

```
 const FormulaT & _constraint) [virtual]
```

Informs the module about the given constraint.

It should be tried to inform this module about any constraint it could receive eventually before assertSubformula is called (preferably for the first time, but at least before adding a formula containing that constraint).

#### Parameters

|                    |                                 |
|--------------------|---------------------------------|
| <i>_constraint</i> | The constraint to inform about. |
|--------------------|---------------------------------|

#### Returns

false, if it can be easily decided whether the given constraint is inconsistent; true, otherwise.

Reimplemented from [smrat::Module](#).

```
0.15.173.4.63 informedConstraints() const carl::FastSet<FormulaT>& smrat::Module::informedConstraints () const [inline], [inherited]
```

#### Returns

The position of the first constraint of which no backend has been informed about.

```
0.15.173.4.64 init() template<typename Settings >
```

```
void smrat::EQModule< Settings >::init () [virtual]
```

Informs all backends about the so far encountered constraints, which have not yet been communicated.

This method must not and will not be called more than once and only before the first runBackends call.

Reimplemented from [smrat::Module](#).

**0.15.173.4.65 `is_minimizing()`** `bool smtrat::Module::is_minimizing () const [inline], [inherited]`

**0.15.173.4.66 `isLemmaLevel()`** `bool smtrat::Module::isLemmaLevel (`

`LemmaLevel level ) [protected], [inherited]`

Checks if current lemma level is greater or equal to given level.

Parameters

|                    |                 |
|--------------------|-----------------|
| <code>level</code> | Level to check. |
|--------------------|-----------------|

**0.15.173.4.67 `isPreprocessor()`** `bool smtrat::Module::isPreprocessor () const [inline], [inherited]`

Returns

true, if this module is a preprocessor that is a module, which simplifies its received formula to an equisatisfiable formula being passed to its backends. The simplified formula can be obtained with [getReceivedFormulaSimplified\(\)](#).

**0.15.173.4.68 `lemmas()`** `const std::vector<Lemma>& smtrat::Module::lemmas () const [inline], [inherited]`

Returns

A constant reference to the lemmas being valid formulas this module or its backends made.

**0.15.173.4.69 `merge()`** `std::vector< FormulaT > smtrat::Module::merge (`

`const std::vector< FormulaT > & _vecSetA,`

`const std::vector< FormulaT > & _vecSetB ) const [protected], [inherited]`

Merges the two vectors of sets into the first one.

({a,b},{a,c}) and ({b,d},{b}) -> ({a,b,d},{a,b},{a,b,c,d},{a,b,c})

Parameters

|                       |                                  |
|-----------------------|----------------------------------|
| <code>_vecSetA</code> | A vector of sets of constraints. |
| <code>_vecSetB</code> | A vector of sets of constraints. |

Returns

The vector being the two given vectors merged.

**0.15.173.4.70 `model()`** `const Model& smtrat::Module::model () const [inline], [inherited]`

Returns

The assignment of the current satisfiable result, if existent.

**0.15.173.4.71 `modelsDisjoint()`** `bool smtrat::Module::modelsDisjoint (`

`const Model & _modelA,`

`const Model & _modelB ) [static], [protected], [inherited]`

Checks whether there is no variable assigned by both models.

**Parameters**

|                      |                                |
|----------------------|--------------------------------|
| <code>_modelA</code> | The first model to check for.  |
| <code>_modelB</code> | The second model to check for. |

**Returns**

true, if there is no variable assigned by both models; false, otherwise.

**0.15.173.4.72 `moduleName()`** `template<typename Settings >`  
`std::string smtrat::EQModule< Settings >::moduleName ( ) const [inline], [virtual]`

**Returns**

The name of the given module type as name.

Reimplemented from [smtrat::Module](#).

**0.15.173.4.73 `objective()`** `carl::Variable smtrat::Module::objective ( ) const [inline], [inherited]`

**0.15.173.4.74 `originInReceivedFormula()`** `bool smtrat::Module::originInReceivedFormula (`  
`const FormulaT & _origin ) const [protected], [inherited]`

**0.15.173.4.75 `passedFormulaBegin()`** `ModuleInput::iterator smtrat::Module::passedFormulaBegin (`  
`) [inline], [protected], [inherited]`

**Returns**

An iterator to the end of the passed formula. TODO: disable this method

**0.15.173.4.76 `passedFormulaEnd()`** `ModuleInput::iterator smtrat::Module::passedFormulaEnd ( )`  
`[inline], [protected], [inherited]`

**Returns**

An iterator to the end of the passed formula.

**0.15.173.4.77 `pPassedFormula()`** `const ModuleInput* smtrat::Module::pPassedFormula ( ) const`  
`[inline], [inherited]`

**Returns**

A pointer to the formula passed to the backends of this module.

**0.15.173.4.78 `pReceivedFormula()`** `const ModuleInput* smtrat::Module::pReceivedFormula ( ) const`  
`[inline], [inherited]`

**Returns**

A pointer to the formula passed to this module.

**0.15.173.4.79 `print()`** `void smtrat::Module::print (`  
`const std::string & _initiation = "***" ) const [inherited]`

Prints everything relevant of the solver.

**Parameters**

|                    |                      |
|--------------------|----------------------|
| <i>_initiation</i> | The line initiation. |
|--------------------|----------------------|

**0.15.173.4.80 printAllModels()** void smtrat::Module::printAllModels ( std::ostream & *\_out* = std::cout ) const [inherited]

Prints all assignments of this module satisfying its received formula if it satisfiable and this module could find an assignment.

**Parameters**

|             |                                        |
|-------------|----------------------------------------|
| <i>_out</i> | The stream to print the assignment on. |
|-------------|----------------------------------------|

**0.15.173.4.81 printInfeasibleSubsets()** void smtrat::Module::printInfeasibleSubsets ( const std::string & *\_initiation* = "\*\*\*" ) const [inherited]

Prints the infeasible subsets.

**Parameters**

|                    |                      |
|--------------------|----------------------|
| <i>_initiation</i> | The line initiation. |
|--------------------|----------------------|

**0.15.173.4.82 printModel()** void smtrat::Module::printModel ( std::ostream & *\_out* = std::cout ) const [inherited]

Prints the assignment of this module satisfying its received formula if it satisfiable and this module could find an assignment.

**Parameters**

|             |                                        |
|-------------|----------------------------------------|
| <i>_out</i> | The stream to print the assignment on. |
|-------------|----------------------------------------|

**0.15.173.4.83 printPassedFormula()** void smtrat::Module::printPassedFormula ( const std::string & *\_initiation* = "\*\*\*" ) const [inherited]

Prints the vector of passed formula.

**Parameters**

|                    |                      |
|--------------------|----------------------|
| <i>_initiation</i> | The line initiation. |
|--------------------|----------------------|

**0.15.173.4.84 printReceivedFormula()** void smtrat::Module::printReceivedFormula ( const std::string & *\_initiation* = "\*\*\*" ) const [inherited]

Prints the vector of the received formula.

**Parameters**

|                    |                      |
|--------------------|----------------------|
| <i>_initiation</i> | The line initiation. |
|--------------------|----------------------|

```
0.15.173.4.85 probablyLooping() bool smtrat::Module::probablyLooping (
 const typename Poly::PolyType & _branchingPolynomial,
 const Rational & _branchingValue) const [protected], [inherited]
```

Checks whether given the current branching value and branching variable/polynomial it is (highly) probable that this branching is part of an infinite loop of branchings.

#### Parameters

|                      |                                                                                     |
|----------------------|-------------------------------------------------------------------------------------|
| _branchingPolynomial | The polynomial to branch at (in most branching strategies this is just a variable). |
| _branchingValue      | The value to branch at.                                                             |

#### Returns

true, if this branching is probably part of an infinite loop of branchings; false, otherwise.

```
0.15.173.4.86 process_merge_lists() template<typename Settings >
void smtrat::EQModule< Settings >::process_merge_lists ()
parts of the public interface that are not part of the general module interface
```

```
0.15.173.4.87 receivedFormulaChecked() void smtrat::Module::receivedFormulaChecked () [inline],
[inherited]
```

Notifies that the received formulas has been checked.

```
0.15.173.4.88 receivedFormulasAsInfeasibleSubset() void smtrat::Module::receivedFormulasAs<=
InfeasibleSubset (
 ModuleInput::const_iterator _subformula) [inline], [protected], [inherited]
```

Stores an infeasible subset consisting only of the given received formula.

```
0.15.173.4.89 receivedVariable() bool smtrat::Module::receivedVariable (
 carl::Variable::Arg _var) const [inline], [inherited]
```

```
0.15.173.4.90 remove() void smtrat::Module::remove (
 ModuleInput::const_iterator _subformula) [virtual], [inherited]
```

Removes everything related to the given sub-formula of the received formula.

However, it is desired not to lose track of search spaces where no satisfying assignment can be found for the remaining sub-formulas.

#### Parameters

|             |                                                    |
|-------------|----------------------------------------------------|
| _subformula | The sub formula of the received formula to remove. |
|-------------|----------------------------------------------------|

Reimplemented in [smtrat::PModule](#).

```
0.15.173.4.91 removeCore() template<typename Settings >
void smtrat::EQModule< Settings >::removeCore (
 ModuleInput::const_iterator _subformula) [virtual]
```

Removes the subformula of the received formula at the given position to the considered ones of this module.

Note that this includes every stored calculation which depended on this subformula, but should keep the other stored calculation, if possible, untouched.

#### Parameters

|                          |                                           |
|--------------------------|-------------------------------------------|
| <code>_subformula</code> | The position of the subformula to remove. |
|--------------------------|-------------------------------------------|

Reimplemented from [smrat::Module](#).

**0.15.173.4.92 `removeOrigin()`** `std::pair<ModuleInput::iterator, bool> smrat::Module::removeOrigin (`

```
 ModuleInput::iterator _formula,
 const FormulaT & _origin) [inline], [protected], [inherited]
```

**0.15.173.4.93 `removeOrigins()`** `std::pair<ModuleInput::iterator, bool> smrat::Module::removeOrigins (`

```
 ModuleInput::iterator _formula,
 const std::shared_ptr< std::vector< FormulaT >> & _origins) [inline], [protected],
[inherited]
```

**0.15.173.4.94 `rPassedFormula()`** `const ModuleInput& smrat::Module::rPassedFormula ( ) const`  
[inline], [inherited]

#### Returns

A reference to the formula passed to the backends of this module.

**0.15.173.4.95 `rReceivedFormula()`** `const ModuleInput& smrat::Module::rReceivedFormula ( ) const`  
[inline], [inherited]

#### Returns

A reference to the formula passed to this module.

**0.15.173.4.96 `runBackends() [1/2]`** `virtual Answer smrat::Module::runBackends ( ) [inline],`  
[protected], [virtual], [inherited]

Reimplemented in [smrat::PModule](#).

**0.15.173.4.97 `runBackends() [2/2]`** `Answer smrat::Module::runBackends (`

```
 bool _final,
 bool _full,
 carl::Variable _objective) [protected], [virtual], [inherited]
```

Runs the backend solvers on the passed formula.

#### Parameters

|                         |                                                                                                                                       |
|-------------------------|---------------------------------------------------------------------------------------------------------------------------------------|
| <code>_final</code>     | true, if this satisfiability check will be the last one (for a global sat-check), if its result is SAT                                |
| <code>_full</code>      | false, if this module should avoid too expensive procedures and rather return unknown instead.                                        |
| <code>_objective</code> | if not set to NO_VARIABLE, the module should find an assignment minimizing this objective variable; otherwise any assignment is good. |

**Returns**

True, if the passed formula is consistent; False, if the passed formula is inconsistent; Unknown, otherwise.

Reimplemented in [smtrat::PModule](#).

**0.15.173.4.98 setId()** `void smtrat::Module::setId ( std::size_t _id ) [inline], [inherited]`  
 Sets this modules unique ID to identify itself.

**Parameters**

|              |                                    |
|--------------|------------------------------------|
| $\leftarrow$ | The id to set this module's id to. |
| $\_id$       |                                    |

**0.15.173.4.99 setThreadPriority()** `void smtrat::Module::setThreadPriority ( thread_priority _threadPriority ) [inline], [inherited]`  
 Sets the priority of this module to get a thread for running its check procedure.

**Parameters**

|                    |                                                       |
|--------------------|-------------------------------------------------------|
| $\_threadPriority$ | The priority to set this module's thread priority to. |
|--------------------|-------------------------------------------------------|

**0.15.173.4.100 solverState()** [Answer](#) `smtrat::Module::solverState ( ) const [inline], [inherited]`

**Returns**

True, if this module is in a state, such that it has found a solution for its received formula; False, if this module is in a state, such that it has determined that there is no solution for its received formula; Unknown, otherwise.

**0.15.173.4.101 splitUnequalConstraint()** `void smtrat::Module::splitUnequalConstraint ( const FormulaT & _unequalConstraint ) [protected], [inherited]`  
 Adds the following lemmas for the given constraint  $p \neq 0$ .

$(p \neq 0 \leftrightarrow (p < 0 \text{ or } p > 0))$

and  $\neg(p < 0 \text{ and } p > 0)$

**Parameters**

|                       |                                                  |
|-----------------------|--------------------------------------------------|
| $\_unequalConstraint$ | A constraint having the relation symbol $\neq$ . |
|-----------------------|--------------------------------------------------|

**0.15.173.4.102 threadPriority()** [thread\\_priority](#) `smtrat::Module::threadPriority ( ) const [inline], [inherited]`

**Returns**

The priority of this module to get a thread for running its check procedure.

**0.15.173.4.103 updateAllModels()** void smtrat::Module::updateAllModels () [virtual], [inherited]  
Updates all satisfying models, if the solver has detected the consistency of the received formula, beforehand.  
Reimplemented in [smtrat::SATModule< Settings >](#).

**0.15.173.4.104 updateLemmas()** void smtrat::Module::updateLemmas () [inherited]  
Stores all lemmas of any backend of this module in its own lemma vector.

**0.15.173.4.105 updateModel()** template<typename Settings >  
void [smtrat::EQModule< Settings >](#)::updateModel () const [virtual]  
Updates the current assignment into the model.  
Note, that this is a unique but possibly symbolic assignment maybe containing newly introduced variables.  
Reimplemented from [smtrat::Module](#).

**0.15.173.4.106 usedBackends()** const std::vector<[Module](#)\*>& smtrat::Module::usedBackends ()  
const [inline], [inherited]

**Returns**

The backends of this module which are currently used (conditions to use this module are fulfilled for the passed formula).

## 0.15.173.5 Field Documentation

**0.15.173.5.1 mAllBackends** std::vector<[Module](#)\*> smtrat::Module::mAllBackends [protected],  
[inherited]  
The backends of this module which have been used.

**0.15.173.5.2 mAllModels** std::vector<[Model](#)> smtrat::Module::mAllModels [mutable], [protected],  
[inherited]  
Stores all satisfying assignments.

**0.15.173.5.3 mBackendsFoundAnswer** std::atomic\_bool\* smtrat::Module::mBackendsFoundAnswer  
[protected], [inherited]  
This flag is passed to any backend and if it determines an answer to a prior check call, this flag is fired.

**0.15.173.5.4 mConstraintsToInform** carl::FastSet<[FormulaT](#)> smtrat::Module::mConstraintsToInform  
[protected], [inherited]  
Stores the constraints which the backends must be informed about.

**0.15.173.5.5 mFinalCheck** bool smtrat::Module::mFinalCheck [protected], [inherited]  
true, if the check procedure should perform a final check which especially means not to postpone splitting decisions

**0.15.173.5.6 mFirstPosInLastBranches** std::size\_t smtrat::Module::mFirstPosInLastBranches = 0  
[static], [inherited]  
The beginning of the cyclic buffer storing the last branches.

**0.15.173.5.7 mFirstSubformulaToPass** `ModuleInput::iterator smrat::Module::mFirstSubformulaToPass` [protected], [inherited]

Stores the position of the first sub-formula in the passed formula, which has not yet been considered for a consistency check of the backends.

**0.15.173.5.8 mFirstUncheckedReceivedSubformula** `ModuleInput::const_iterator smrat::Module::mFirstUncheckedReceivedSubformula` [protected], [inherited]

Stores the position of the first (by this module) unchecked sub-formula of the received formula.

**0.15.173.5.9 mFoundAnswer** `Conditionals smrat::Module::mFoundAnswer` [protected], [inherited]

Vector of Booleans: If any of them is true, we have to terminate a running check procedure.

**0.15.173.5.10 mFullCheck** `bool smrat::Module::mFullCheck` [protected], [inherited]

false, if this module should avoid too expensive procedures and rather return unknown instead.

**0.15.173.5.11 mInfeasibleSubsets** `std::vector<FormulaSetT> smrat::Module::mInfeasibleSubsets`

[protected], [inherited]

Stores the infeasible subsets.

**0.15.173.5.12 mInformedConstraints** `carl::FastSet<FormulaT> smrat::Module::mInformedConstraints`

[protected], [inherited]

Stores the position of the first constraint of which no backend has been informed about.

**0.15.173.5.13 mLastBranches** `std::vector< Branching > smrat::Module::mLastBranches = std::vector<Branching> (mNumOfBranchVarsToStore, Branching(typename Poly::PolyType(), 0))` [static], [inherited]

Stores the last branches in a cycle buffer.

**0.15.173.5.14 mLemmas** `std::vector<Lemma> smrat::Module::mLemmas` [protected], [inherited]

Stores the lemmas being valid formulas this module or its backends made.

**0.15.173.5.15 mModel** `Model smrat::Module::mModel` [mutable], [protected], [inherited]

Stores the assignment of the current satisfiable result, if existent.

**0.15.173.5.16 mModelComputed** `bool smrat::Module::mModelComputed` [mutable], [protected], [inherited]

True, if the model has already been computed.

**0.15.173.5.17 mNumOfBranchVarsToStore** `std::size_t smrat::Module::mNumOfBranchVarsToStore = 5` [static], [inherited]

The number of different variables to consider for a probable infinite loop of branchings.

**0.15.173.5.18 mObjectiveVariable** `carl::Variable smtrat::Module::mObjectiveVariable [protected], [inherited]`  
Objective variable to be minimized. If set to NO\_VARIABLE, a normal sat check should be performed.

**0.15.173.5.19 mOldSplittingVariables** `std::vector< FormulaT > smtrat::Module::mOldSplitting [static], [inherited]`  
Reusable splitting variables.

**0.15.173.5.20 mpManager** `Manager* const smtrat::Module::mpManager [protected], [inherited]`  
A reference to the manager.

**0.15.173.5.21 mSmallerMusesCheckCounter** `unsigned smtrat::Module::mSmallerMusesCheckCounter [mutable], [protected], [inherited]`  
Counter used for the generation of the smt2 files to check for smaller muses.

**0.15.173.5.22 mSolverState** `std::atomic<Answer> smtrat::Module::mSolverState [protected], [inherited]`  
States whether the received formula is known to be satisfiable or unsatisfiable otherwise it is set to unknown.

**0.15.173.5.23 mTheoryPropagations** `std::vector<TheoryPropagation> smtrat::Module::mTheoryPropagations [protected], [inherited]`

**0.15.173.5.24 mUsedBackends** `std::vector<Module*> smtrat::Module::mUsedBackends [protected], [inherited]`  
The backends of this module which are currently used (conditions to use this module are fulfilled for the passed formula).

**0.15.173.5.25 mVariableCounters** `std::vector<std::size_t> smtrat::Module::mVariableCounters [protected], [inherited]`  
Maps variables to the number of their occurrences.

## 0.15.174 smtrat::EQPreprocessingModule< Settings > Class Template Reference

#include <EQPreprocessingModule.h>

### Public Types

- `typedef Settings SettingsType`
- `enum class LemmaType : unsigned { NORMAL = 0 , PERMANENT = 1 }`

### Public Member Functions

- `std::string moduleName () const`
- `EQPreprocessingModule (const ModuleInput *_formula, Conditionals &_conditionals, Manager *_manager=NULL)`
- `~EQPreprocessingModule ()`
- `void updateModel () const`  
*Updates the model, if the solver has detected the consistency of the received formula, beforehand.*
- `Answer checkCore ()`

- Checks the received formula for consistency.
- bool `inform` (const `FormulaT` &\_constraint)
  - Informs the module about the given constraint.
- void `deinform` (const `FormulaT` &\_constraint)
  - The inverse of informing about a constraint.
- virtual void `init` ()
  - Informs all backends about the so far encountered constraints, which have not yet been communicated.
- bool `add` (`ModuleInput::const_iterator` \_subformula)
  - The module has to take the given sub-formula of the received formula into account.
- virtual `Answer check` (bool \_final=false, bool \_full=true, `carl::Variable` \_objective=`carl::Variable::NO_VARIABLE`)
  - Checks the received formula for consistency.
- virtual void `remove` (`ModuleInput::const_iterator` \_subformula)
  - Removes everything related to the given sub-formula of the received formula.
- virtual void `updateAllModels` ()
  - Updates all satisfying models, if the solver has detected the consistency of the received formula, beforehand.
- virtual `std::list< std::vector< carl::Variable > > getModelEqualities` () const
  - Partition the variables from the current model into equivalence classes according to their assigned value.
- unsigned `currentlySatisfiedByBackend` (const `FormulaT` &\_formula) const
- virtual unsigned `currentlySatisfied` (const `FormulaT` &) const
- bool `receivedVariable` (`carl::Variable::Arg` \_var) const
- `Answer solverState` () const
- `std::size_t id` () const
- void `setId` (`std::size_t` \_id)
  - Sets this modules unique ID to identify itself.
- `thread_priority threadPriority` () const
- void `setThreadPriority` (`thread_priority` \_threadPriority)
  - Sets the priority of this module to get a thread for running its check procedure.
- const `ModuleInput * pReceivedFormula` () const
- const `ModuleInput & rReceivedFormula` () const
- const `ModuleInput * pPassedFormula` () const
- const `ModuleInput & rPassedFormula` () const
- const `Model & model` () const
- const `std::vector< Model > & allModels` () const
- const `std::vector< FormulaSetT > & infeasibleSubsets` () const
- const `std::vector< Module * > & usedBackends` () const
- const `carl::FastSet< FormulaT > & constraintsToInform` () const
- const `carl::FastSet< FormulaT > & informedConstraints` () const
- void `addLemma` (const `FormulaT` &\_lemma, const `LemmaType` &\_lt=`LemmaType::NORMAL`, const `FormulaT` &\_preferredFormula=`FormulaT(carl::FormulaType::TRUE)`)
  - Stores a lemma being a valid formula.
- bool `hasLemmas` ()
  - Checks whether this module or any of its backends provides any lemmas.
- void `clearLemmas` ()
  - Deletes all yet found lemmas.
- const `std::vector< Lemma > & lemmas` () const
- `ModuleInput::const_iterator firstUncheckedReceivedSubformula` () const
- `ModuleInput::const_iterator firstSubformulaToPass` () const
- void `receivedFormulaChecked` ()
  - Notifies that the received formulas has been checked.
- const `smrat::Conditionals & answerFound` () const
- bool `isPreprocessor` () const

- `carl::Variable objective () const`
- `bool is_minimizing () const`
- `void excludeNotReceivedVariablesFromModel () const`

*Excludes all variables from the current model, which do not occur in the received formula.*
- `void updateLemmas ()`

*Stores all lemmas of any backend of this module in its own lemma vector.*
- `void collectTheoryPropagations ()`
- `void collectOrigins (const FormulaT &_formula, FormulasT &_origins) const`

*Collects the formulas in the given formula, which are part of the received formula.*
- `void collectOrigins (const FormulaT &_formula, FormulaSetT &_origins) const`
- `bool hasValidInfeasibleSubset () const`
- `void checkInfeasibleSubsetForMinimality (std::vector<FormulaSetT>::const_iterator _insubset, const std::string &filename="smaller_muses", unsigned _maxSizeDifference=1) const`

*Checks the given infeasible subset for minimality by storing all subsets of it, which have a smaller size which differs from the size of the infeasible subset not more than the given threshold.*
- `virtual std::pair< bool, FormulaT > getReceivedFormulaSimplified ()`
- `void print (const std::string &_initiation="***") const`

*Prints everything relevant of the solver.*
- `void printReceivedFormula (const std::string &_initiation="***") const`

*Prints the vector of the received formula.*
- `void printPassedFormula (const std::string &_initiation="***") const`

*Prints the vector of passed formula.*
- `void printInfeasibleSubsets (const std::string &_initiation="***") const`

*Prints the infeasible subsets.*
- `void printModel (std::ostream &_out=std::cout) const`

*Prints the assignment of this module satisfying its received formula if it satisfiable and this module could find an assignment.*
- `void printAllModels (std::ostream &_out=std::cout)`

*Prints all assignments of this module satisfying its received formula if it satisfiable and this module could find an assignment.*

## Static Public Member Functions

- `static void freeSplittingVariable (const FormulaT &_splittingVariable)`

## Static Public Attributes

- `static size_t mNumOfBranchVarsToStore = 5`

*The number of different variables to consider for a probable infinite loop of branchings.*
- `static std::vector< Branching > mLastBranches = std::vector<Branching>(mNumOfBranchVarsToStore, Branching(typename Poly::PolyType(), 0))`

*Stores the last branches in a cycle buffer.*
- `static size_t mFirstPosInLastBranches = 0`

*The beginning of the cyclic buffer storing the last branches.*
- `static std::vector< FormulaT > mOldSplittingVariables`

*Reusable splitting variables.*

## Protected Member Functions

- virtual bool `informCore` (const `FormulaT` &\_constraint)
 

*Informs the module about the given constraint.*
- virtual void `deinformCore` (const `FormulaT` &\_constraint)
 

*The inverse of informing about a constraint.*
- virtual bool `addCore` (`ModuleInput::const_iterator` formula)
 

*The module has to take the given sub-formula of the received formula into account.*
- virtual void `removeCore` (`ModuleInput::const_iterator` formula)
 

*Removes everything related to the given sub-formula of the received formula.*
- bool `anAnswerFound` () const
 

*Checks for all antecedent modules and those which run in parallel with the same antecedent modules, whether one of them has determined a result.*
- void `clearModel` () const
 

*Clears the assignment, if any was found.*
- void `clearModels` () const
 

*Clears all assignments, if any was found.*
- void `cleanModel` () const
 

*Substitutes variable occurrences by its model value in the model values of other variables.*
- `ModuleInput::iterator` `passedFormulaBegin` ()
- `ModuleInput::iterator` `passedFormulaEnd` ()
- void `addOrigin` (`ModuleInput::iterator` \_formula, const `FormulaT` &\_origin)
 

*Adds the given set of formulas in the received formula to the origins of the given passed formula.*
- const `FormulaT` & `getOrigins` (`ModuleInput::const_iterator` \_formula) const
 

*Gets the origins of the passed formula at the given position.*
- void `getOrigins` (const `FormulaT` &\_formula, `FormulasT` &\_origins) const
- void `getOrigins` (const `FormulaT` &\_formula, `FormulaSetT` &\_origins) const
- std::pair< `ModuleInput::iterator`, bool > `removeOrigin` (`ModuleInput::iterator` \_formula, const `FormulaT` &\_origin)
- std::pair< `ModuleInput::iterator`, bool > `removeOrigins` (`ModuleInput::iterator` \_formula, const std::shared\_ptr< std::vector< `FormulaT` >> &\_origins)
- void `informBackends` (const `FormulaT` &\_constraint)
 

*Informs all backends of this module about the given constraint.*
- virtual void `addConstraintToInform` (const `FormulaT` &\_constraint)
 

*Adds a constraint to the collection of constraints of this module, which are informed to a freshly generated backend.*
- std::pair< `ModuleInput::iterator`, bool > `addReceivedSubformulaToPassedFormula` (`ModuleInput::const_iterator` \_subformula)
 

*Copies the given sub-formula of the received formula to the passed formula.*
- bool `originInReceivedFormula` (const `FormulaT` &\_origin) const
- std::pair< `ModuleInput::iterator`, bool > `addSubformulaToPassedFormula` (const `FormulaT` &\_formula)
 

*Adds the given formula to the passed formula with no origin.*
- std::pair< `ModuleInput::iterator`, bool > `addSubformulaToPassedFormula` (const `FormulaT` &\_formula, const std::shared\_ptr< std::vector< `FormulaT` >> &\_origins)
 

*Adds the given formula to the passed formula.*
- std::pair< `ModuleInput::iterator`, bool > `addSubformulaToPassedFormula` (const `FormulaT` &\_formula, const `FormulaT` &\_origin)
 

*Adds the given formula to the passed formula.*
- void `generateTrivialInfeasibleSubset` ()
 

*Stores the trivial infeasible subset being the set of received formulas.*
- void `receivedFormulasAsInfeasibleSubset` (`ModuleInput::const_iterator` \_subformula)
 

*Stores an infeasible subset consisting only of the given received formula.*
- std::vector< `FormulaT` >::const\_iterator `findBestOrigin` (const std::vector< `FormulaT` > &\_origins) const
- void `getInfeasibleSubsets` ()

- Copies the infeasible subsets of the passed formula.
  - std::vector< [FormulaSetT](#) > [getInfeasibleSubsets](#) (const [Module](#) &\_backend) const
    - Get the infeasible subsets the given backend provides.
  - const [Model](#) & [backendsModel](#) () const
    - Stores the model of a backend which determined satisfiability of the passed formula in the model of this module.
  - void [getBackendsModel](#) () const
  - void [getBackendsAllModels](#) () const
    - Stores all models of a backend in the list of all models of this module.
- virtual [Answer](#) [runBackends](#) (bool \_final, bool \_full, carl::Variable \_objective)
  - Runs the backend solvers on the passed formula.
- virtual [Answer](#) [runBackends](#) ()
- virtual [ModuleInput](#)::iterator [eraseSubformulaFromPassedFormula](#) ([ModuleInput](#)::iterator \_subformula, bool \_ignoreOrigins=false)
  - Removes everything related to the sub-formula to remove from the passed formula in the backends of this module.
- void [clearPassedFormula](#) ()
- std::vector< [FormulaT](#) > [merge](#) (const std::vector< [FormulaT](#) > &, const std::vector< [FormulaT](#) > &) const
  - Merges the two vectors of sets into the first one.
- size\_t [determine\\_smallest\\_origin](#) (const std::vector< [FormulaT](#) > &origins) const
- bool [probablyLooping](#) (const typename Poly::PolyType &\_branchingPolynomial, const [Rational](#) &\_branchingValue) const
  - Checks whether given the current branching value and branching variable/polynomial it is (highly) probable that this branching is part of an infinite loop of branchings.
- bool [branchAt](#) (const [Poly](#) &\_polynomial, bool \_integral, const [Rational](#) &\_value, std::vector< [FormulaT](#) > &&\_premise, bool \_leftCaseWeak=true, bool \_preferLeftCase=true, bool \_useReceivedFormulaAsPremise=false)
  - Adds a lemmas which provoke a branching for the given variable at the given value, if this module returns Unknown and there exists a preceding [SATModule](#).
- bool [branchAt](#) (const [Poly](#) &\_polynomial, bool \_integral, const [Rational](#) &\_value, bool \_leftCaseWeak=true, bool \_preferLeftCase=true, bool \_useReceivedFormulaAsPremise=false, const std::vector< [FormulaT](#) > &&\_premise=std::vector< [FormulaT](#) >())
- bool [branchAt](#) (carl::Variable::Arg \_var, const [Rational](#) &\_value, std::vector< [FormulaT](#) > &&\_premise, bool \_leftCaseWeak=true, bool \_preferLeftCase=true, bool \_useReceivedFormulaAsPremise=false)
- bool [branchAt](#) (carl::Variable::Arg \_var, const [Rational](#) &\_value, bool \_leftCaseWeak=true, bool \_preferLeftCase=true, bool \_useReceivedFormulaAsPremise=false, const std::vector< [FormulaT](#) > &\_premise=std::vector< [FormulaT](#) >())
- void [splitUnequalConstraint](#) (const [FormulaT](#) &)
  - Adds the following lemmas for the given constraint  $p \neq 0$ .
- unsigned [checkModel](#) () const
- void [addInformationRelevantFormula](#) (const [FormulaT](#) &formula)
  - Adds a formula to the InformationRelevantFormula.
- const std::set< [FormulaT](#) > & [getInformationRelevantFormulas](#) ()
  - Gets all InformationRelevantFormulas.
- bool [isLemmaLevel](#) ([LemmaLevel](#) level)
  - Checks if current lemma level is greater or equal to given level.

## Static Protected Member Functions

- static bool [modelsDisjoint](#) (const [Model](#) &\_modelA, const [Model](#) &\_modelB)
  - Checks whether there is no variable assigned by both models.

## Protected Attributes

- std::vector< [FormulaSetT](#) > mInfeasibleSubsets  
*Stores the infeasible subsets.*
- Manager \*const mpManager  
*A reference to the manager.*
- Model mModel  
*Stores the assignment of the current satisfiable result, if existent.*
- std::vector< [Model](#) > mAllModels  
*Stores all satisfying assignments.*
- bool mModelComputed  
*True, if the model has already been computed.*
- bool mFinalCheck  
*true, if the check procedure should perform a final check which especially means not to postpone splitting decisions*
- bool mFullCheck  
*false, if this module should avoid too expensive procedures and rather return unknown instead.*
- carl::Variable mObjectiveVariable  
*Objective variable to be minimized. If set to NO\_VARIABLE, a normal sat check should be performed.*
- std::vector< [TheoryPropagation](#) > mTheoryPropagations
- std::atomic< [Answer](#) > mSolverState  
*States whether the received formula is known to be satisfiable or unsatisfiable otherwise it is set to unknown.*
- std::atomic\_bool \* mBackendsFoundAnswer  
*This flag is passed to any backend and if it determines an answer to a prior check call, this flag is fired.*
- Conditionals mFoundAnswer  
*Vector of Booleans: If any of them is true, we have to terminate a running check procedure.*
- std::vector< [Module](#) \* > mUsedBackends  
*The backends of this module which are currently used (conditions to use this module are fulfilled for the passed formula).*
- std::vector< [Module](#) \* > mAllBackends  
*The backends of this module which have been used.*
- std::vector< [Lemma](#) > mLemmas  
*Stores the lemmas being valid formulas this module or its backends made.*
- ModuleInput::iterator mFirstSubformulaToPass  
*Stores the position of the first sub-formula in the passed formula, which has not yet been considered for a consistency check of the backends.*
- carl::FastSet< [FormulaT](#) > mConstraintsToInform  
*Stores the constraints which the backends must be informed about.*
- carl::FastSet< [FormulaT](#) > mInformedConstraints  
*Stores the position of the first constraint of which no backend has been informed about.*
- ModuleInput::const\_iterator mFirstUncheckedReceivedSubformula  
*Stores the position of the first (by this module) unchecked sub-formula of the received formula.*
- unsigned mSmallerMusesCheckCounter  
*Counter used for the generation of the smt2 files to check for smaller muses.*
- std::vector< std::size\_t > mVariableCounters  
*Maps variables to the number of their occurrences.*

smtrat::EQPreprocessingModule<Settings>::~EQPreprocessingModule()
```

## 0.15.174.4 Member Function Documentation

```
0.15.174.4.1 add() bool smtrat::Module::add(
 ModuleInput::const_iterator _subformula) [inherited]
```

The module has to take the given sub-formula of the received formula into account.

Parameters

|             |                                                    |
|-------------|----------------------------------------------------|
| _subformula | The sub-formula to take additionally into account. |
|-------------|----------------------------------------------------|

Returns

false, if it can be easily decided that this sub-formula causes a conflict with the already considered sub-formulas; true, otherwise.

```
0.15.174.4.2 addConstraintToInform() void smtrat::Module::addConstraintToInform(
 const FormulaT & _constraint) [protected], [virtual], [inherited]
```

Adds a constraint to the collection of constraints of this module, which are informed to a freshly generated backend.

Parameters

|             |                        |
|-------------|------------------------|
| _constraint | The constraint to add. |
|-------------|------------------------|

Reimplemented in `smtrat::SATModule<Settings>`.

```
0.15.174.4.3 addCore() virtual bool smtrat::Module::addCore(
```

```
ModuleInput::const_iterator formula) [inline], [protected], [virtual], [inherited]
```

The module has to take the given sub-formula of the received formula into account.

#### Parameters

|                      |                                                    |
|----------------------|----------------------------------------------------|
| <code>formula</code> | The sub-formula to take additionally into account. |
|----------------------|----------------------------------------------------|

#### Returns

false, if it can be easily decided that this sub-formula causes a conflict with the already considered sub-formulas; true, otherwise.

Reimplemented in [smrat::VSModule< Settings >](#), [smrat::SATModule< Settings >](#), [smrat::PFEModule< Settings >](#), [smrat::ICPModule< Settings >](#), [smrat::ICPModule< ICPSettings4 >](#), [smrat::ICPModule< ICPSettings1 >](#), [smrat::UnionFindModule< Settings >](#), [smrat::UFCegarModule< Settings >](#), [smrat::STropModule< Settings >](#), [smrat::PBPPModule< Settings >](#), [smrat::PBGaussModule< Settings >](#), [smrat::NRAILModule< Settings >](#), [smrat::NewCoveringModule< Settings >](#), [smrat::NewCADModule< Settings >](#), [smrat::LRAModule< Settings >](#), [smrat::LRAModule< LRASettingsICP >](#), [smrat::LRAModule< LRASettings1 >](#), [smrat::IntEqModule< Settings >](#), [smrat::IntBlastModule< Settings >](#), [smrat::IncWidthModule< Settings >](#), [smrat::ICEModule< Settings >](#), [smrat::FPPModule< Settings >](#), [smrat::FouMoModule< Settings >](#), [smrat::EQModule< Settings >](#), [smrat::CurryModule< Settings >](#), [smrat::CubeLIAModule< Settings >](#), [smrat::CSplitModule< Settings >](#), [smrat::BVMModule< Settings >](#), and [smrat::GBModule< Settings >](#).

#### 0.15.174.4.4 addInformationRelevantFormula()

```
void smrat::Module::addInformationRelevantFormula(
```

```
 const FormulaT & formula) [protected], [inherited]
```

Adds a formula to the InformationRelevantFormula.

#### Parameters

|                      |                |
|----------------------|----------------|
| <code>formula</code> | Formula to add |
|----------------------|----------------|

#### 0.15.174.4.5 addLemma()

```
void smrat::Module::addLemma(
```

```
 const FormulaT & _lemma,
```

```
 const LemmaType & _lt = LemmaType::NORMAL,
```

```
 const FormulaT & _preferredFormula = FormulaT(carl::FormulaType::TRUE)) [inline],
```

[inherited]

Stores a lemma being a valid formula.

#### Parameters

|                                |                                                                       |
|--------------------------------|-----------------------------------------------------------------------|
| <code>_lemma</code>            | The eduction/lemma to store.                                          |
| <code>_lt</code>               | The type of the lemma.                                                |
| <code>_preferredFormula</code> | Hint for the next decision, which formula should be assigned to true. |

#### 0.15.174.4.6 addOrigin()

```
void smrat::Module::addOrigin(
```

```
 ModuleInput::iterator _formula,
```

```
 const FormulaT & _origin) [inline], [protected], [inherited]
```

Adds the given set of formulas in the received formula to the origins of the given passed formula.

**Parameters**

|                       |                                                           |
|-----------------------|-----------------------------------------------------------|
| <code>_formula</code> | The passed formula to set the origins for.                |
| <code>_origin</code>  | A set of formulas in the received formula of this module. |

**0.15.174.4.7 addReceivedSubformulaToPassedFormula()** `std::pair<ModuleInput::iterator,bool>`

```
smrat::Module::addReceivedSubformulaToPassedFormula (
 ModuleInput::const_iterator _subformula) [inline], [protected], [inherited]
```

Copies the given sub-formula of the received formula to the passed formula.

Note, that there is always a link between sub-formulas of the passed formulas to sub-formulas of the received formulas, which are responsible for its occurrence.

**Parameters**

|                          |                                                  |
|--------------------------|--------------------------------------------------|
| <code>_subformula</code> | The sub-formula of the received formula to copy. |
|--------------------------|--------------------------------------------------|

**0.15.174.4.8 addSubformulaToPassedFormula() [1/3]** `std::pair<ModuleInput::iterator,bool>`

```
smrat::Module::addSubformulaToPassedFormula (
 const FormulaT & _formula) [inline], [protected], [inherited]
```

Adds the given formula to the passed formula with no origin.

Note that in the next call of this module's removeSubformula, all formulas in the passed formula without origins will be removed.

**Parameters**

|                       |                                           |
|-----------------------|-------------------------------------------|
| <code>_formula</code> | The formula to add to the passed formula. |
|-----------------------|-------------------------------------------|

**Returns**

A pair to the position where the formula to add has been inserted (or its first sub-formula which has not yet been in the passed formula, in case the formula to add is a conjunction), and a Boolean stating whether anything has been added to the passed formula.

**0.15.174.4.9 addSubformulaToPassedFormula() [2/3]** `std::pair<ModuleInput::iterator,bool>`

```
smrat::Module::addSubformulaToPassedFormula (
 const FormulaT & _formula,
 const FormulaT & _origin) [inline], [protected], [inherited]
```

Adds the given formula to the passed formula.

**Parameters**

|                       |                                                                                                                           |
|-----------------------|---------------------------------------------------------------------------------------------------------------------------|
| <code>_formula</code> | The formula to add to the passed formula.                                                                                 |
| <code>_origin</code>  | The sub-formula of the received formula being responsible for the occurrence of the formula to add to the passed formula. |

**Returns**

A pair to the position where the formula to add has been inserted (or its first sub-formula which has not yet been in the passed formula, in case the formula to add is a conjunction), and a Boolean stating whether anything has been added to the passed formula.

```
0.15.174.4.10 addSubformulaToPassedFormula() [3/3] std::pair<ModuleInput::iterator,bool>
smrat::Module::addSubformulaToPassedFormula (
 const FormulaT & _formula,
 const std::shared_ptr< std::vector< FormulaT >> & _origins) [inline], [protected],
[inherited]
```

Adds the given formula to the passed formula.

#### Parameters

|                 |                                                                                                                                         |
|-----------------|-----------------------------------------------------------------------------------------------------------------------------------------|
| <i>_formula</i> | The formula to add to the passed formula.                                                                                               |
| <i>_origins</i> | The link of the formula to add to the passed formula to sub-formulas of the received formulas, which are responsible for its occurrence |

#### Returns

A pair to the position where the formula to add has been inserted (or its first sub-formula which has not yet been in the passed formula, in case the formula to add is a conjunction), and a Boolean stating whether anything has been added to the passed formula.

```
0.15.174.4.11 allModels() const std::vector<Model>& smrat::Module::allModels () const [inline],
[inherited]
```

#### Returns

All satisfying assignments, if existent.

```
0.15.174.4.12 anAnswerFound() bool smrat::Module::anAnswerFound () const [inline], [protected],
[inherited]
```

Checks for all antecedent modules and those which run in parallel with the same antecedent modules, whether one of them has determined a result.

#### Returns

True, if one of them has determined a result.

```
0.15.174.4.13 answerFound() const smrat::Conditionals& smrat::Module::answerFound () const
[inline], [inherited]
```

#### Returns

A vector of Booleans: If any of them is true, we have to terminate a running check procedure.

```
0.15.174.4.14 backendsModel() const Model & smrat::Module::backendsModel () const [protected],
[inherited]
```

Stores the model of a backend which determined satisfiability of the passed formula in the model of this module.

---

**0.15.174.4.15** **branchAt()** [1/4] `bool smrat::Module::branchAt (`

```
carl::Variable::Arg _var,
const Rational & _value,
bool _leftCaseWeak = true,
bool _preferLeftCase = true,
bool _useReceivedFormulaAsPremise = false,
const std::vector< FormulaT > & _premise = std::vector<FormulaT>()) [inline],
[protected], [inherited]
```

**0.15.174.4.16** **branchAt()** [2/4] `bool smrat::Module::branchAt (`

```
carl::Variable::Arg _var,
const Rational & _value,
std::vector< FormulaT > && _premise,
bool _leftCaseWeak = true,
bool _preferLeftCase = true,
bool _useReceivedFormulaAsPremise = false) [inline], [protected], [inherited]
```

**0.15.174.4.17** **branchAt()** [3/4] `bool smrat::Module::branchAt (`

```
const Poly & _polynomial,
bool _integral,
const Rational & _value,
bool _leftCaseWeak = true,
bool _preferLeftCase = true,
bool _useReceivedFormulaAsPremise = false,
const std::vector< FormulaT > & _premise = std::vector<FormulaT>()) [inline],
[protected], [inherited]
```

**0.15.174.4.18** **branchAt()** [4/4] `bool smrat::Module::branchAt (`

```
const Poly & _polynomial,
bool _integral,
const Rational & _value,
std::vector< FormulaT > && _premise,
bool _leftCaseWeak = true,
bool _preferLeftCase = true,
bool _useReceivedFormulaAsPremise = false) [protected], [inherited]
```

Adds a lemmas which provoke a branching for the given variable at the given value, if this module returns Unknown and there exists a preceding [SATModule](#).

Note that the given value is rounded down and up, if the given variable is integer-valued.

#### Parameters

|                                           |                                                                                                                                                                                                                |
|-------------------------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>_polynomial</code>                  | The variable to branch for.                                                                                                                                                                                    |
| <code>_integral</code>                    | A flag being true, if all variables in the polynomial to branch for are integral.                                                                                                                              |
| <code>_value</code>                       | The value to branch at.                                                                                                                                                                                        |
| <code>_premise</code>                     | The sub-formulas of the received formula from which the branch is followed. Note, that a premise is not necessary, as every branch is a valid formula. But a premise can prevent from branching unnecessarily. |
| <code>_leftCaseWeak</code>                | true, if a branching in the form of (or ( $\leq p b$ ) ( $> p b$ )) is desired. false, if a branching in the form of (or ( $< p b$ ) ( $\geq p b$ )) is desired.                                               |
| <code>_preferLeftCase</code>              | true, if the left case (polynomial less(or equal) 0 shall be chosen first. false, otherwise.                                                                                                                   |
| <code>_useReceivedFormulaAsPremise</code> | true, if the whole received formula should be used as premise                                                                                                                                                  |

```
0.15.174.4.19 check() Answer smtrat::Module::check (
 bool _final = false,
 bool _full = true,
 carl::Variable _objective = carl::Variable::NO_VARIABLE) [virtual], [inherited]
```

Checks the received formula for consistency.

Note, that this is an implementation of the satisfiability check of the conjunction of the so far received formulas, which does actually nothing but passing the problem to its backends. This implementation is only used internally and must be overwritten by any derived module.

#### Parameters

|                   |                                                                                                                                       |
|-------------------|---------------------------------------------------------------------------------------------------------------------------------------|
| <i>_final</i>     | true, if this satisfiability check will be the last one (for a global sat-check), if its result is SAT                                |
| <i>_full</i>      | false, if this module should avoid too expensive procedures and rather return unknown instead.                                        |
| <i>_objective</i> | if not set to NO_VARIABLE, the module should find an assignment minimizing this objective variable; otherwise any assignment is good. |

#### Returns

True, if the received formula is satisfiable; False, if the received formula is not satisfiable; Unknown, otherwise.

Reimplemented in [smtrat::PModule](#).

```
0.15.174.4.20 checkCore() template<typename Settings >
Answer smtrat::EQPreprocessingModule< Settings >::checkCore () [virtual]
```

Checks the received formula for consistency.

#### Returns

SAT, if the received formula is satisfiable; UNSAT, if the received formula is not satisfiable; Unknown, otherwise.

Reimplemented from [smtrat::Module](#).

```
0.15.174.4.21 checkInfeasibleSubsetForMinimality() void smtrat::Module::checkInfeasibleSubsetForMinimality (
 std::vector< FormulaSetT >::const_iterator _infssubset,
 const std::string & _filename = "smaller_muses",
 unsigned _maxSizeDifference = 1) const [inherited]
```

Checks the given infeasible subset for minimality by storing all subsets of it, which have a smaller size which differs from the size of the infeasible subset not more than the given threshold.

#### Parameters

|                           |                                                                                                        |
|---------------------------|--------------------------------------------------------------------------------------------------------|
| <i>_infssubset</i>        | The infeasible subset to check for minimality.                                                         |
| <i>_filename</i>          | The name of the file to store the infeasible subsets in order to be able to check their infeasibility. |
| <i>_maxSizeDifference</i> | The maximal difference between the sizes of the subsets compared to the size of the infeasible subset. |

```
0.15.174.4.22 checkModel() unsigned smtrat::Module::checkModel () const [protected], [inherited]
```

**Returns**

false, if the current model of this module does not satisfy the current given formula; true, if it cannot be said whether the model satisfies the given formula.

**0.15.174.4.23 cleanModel()** void smtrat::Module::cleanModel ( ) const [inline], [protected], [inherited]

Substitutes variable occurrences by its model value in the model values of other variables.

**0.15.174.4.24 clearLemmas()** void smtrat::Module::clearLemmas ( ) [inline], [inherited]

Deletes all yet found lemmas.

**0.15.174.4.25 clearModel()** void smtrat::Module::clearModel ( ) const [inline], [protected], [inherited]

Clears the assignment, if any was found.

**0.15.174.4.26 clearModels()** void smtrat::Module::clearModels ( ) const [inline], [protected], [inherited]

Clears all assignments, if any was found.

**0.15.174.4.27 clearPassedFormula()** void smtrat::Module::clearPassedFormula ( ) [protected], [inherited]

**0.15.174.4.28 collectOrigins() [1/2]** void smtrat::Module::collectOrigins ( const `FormulaT` & `_formula`, `FormulaSetT` & `_origins` ) const [inherited]

**0.15.174.4.29 collectOrigins() [2/2]** void smtrat::Module::collectOrigins ( const `FormulaT` & `_formula`, `FormulasT` & `_origins` ) const [inherited]

Collects the formulas in the given formula, which are part of the received formula.

If the given formula directly occurs in the received formula, it is inserted into the given set. Otherwise, the given formula must be of type AND and all its sub-formulas part of the received formula. Hence, they will be added to the given set.

**Parameters**

|                       |                                                                                                      |
|-----------------------|------------------------------------------------------------------------------------------------------|
| <code>_formula</code> | The formula from which to collect the formulas being sub-formulas of the received formula (origins). |
| <code>_origins</code> | The set in which to store the origins.                                                               |

**0.15.174.4.30 collectTheoryPropagations()** void smtrat::Module::collectTheoryPropagations ( ) [inherited]

**0.15.174.4.31 constraintsToInform()** const carl::FastSet<`FormulaT`>& smtrat::Module::constraintsToInform ( ) const [inline], [inherited]

**Returns**

The constraints which the backends must be informed about.

**0.15.174.4.32 currentlySatisfied()** `virtual unsigned smtrat::Module::currentlySatisfied ( const FormulaT & ) const [inline], [virtual], [inherited]`

**Returns**

0, if the given formula is conflicted by the current model; 1, if the given formula is satisfied by the current model; 2, otherwise; 3, if we do not know anything (default)

Reimplemented in [smtrat::LRAModule< Settings >](#), [smtrat::LRAModule< LRASettingsICP >](#), and [smtrat::LRAModule< LRASettings >](#)

**0.15.174.4.33 currentlySatisfiedByBackend()** `unsigned smtrat::Module::currentlySatisfiedByBackend ( const FormulaT & _formula ) const [inherited]`

**Returns**

0, if the given formula is conflicted by the current model; 1, if the given formula is satisfied by the current model; 2, otherwise 3, if we do not know anything (default)

**0.15.174.4.34 deinform()** `void smtrat::Module::deinform ( const FormulaT & _constraint ) [inherited]`

The inverse of informing about a constraint.

All data structures which were kept regarding this constraint are going to be removed. Note, that this makes only sense if it is not likely enough that a formula with this constraint must be solved again.

**Parameters**

|                          |                                                         |
|--------------------------|---------------------------------------------------------|
| <code>_constraint</code> | The constraint to remove from internal data structures. |
|--------------------------|---------------------------------------------------------|

**0.15.174.4.35 deinformCore()** `virtual void smtrat::Module::deinformCore ( const FormulaT & _constraint ) [inline], [protected], [virtual], [inherited]`

The inverse of informing about a constraint.

All data structures which were kept regarding this constraint are going to be removed. Note, that this makes only sense if it is not likely enough that a formula with this constraint must be solved again.

**Parameters**

|                          |                                                         |
|--------------------------|---------------------------------------------------------|
| <code>_constraint</code> | The constraint to remove from internal data structures. |
|--------------------------|---------------------------------------------------------|

Reimplemented in [smtrat::LRAModule< Settings >](#), [smtrat::LRAModule< LRASettingsICP >](#), and [smtrat::LRAModule< LRASettings >](#)

**0.15.174.4.36 determine\_smallest\_origin()** `size_t smtrat::Module::determine_smallest_origin ( const std::vector< FormulaT > & origins ) const [protected], [inherited]`

**Parameters**

|                      |                              |
|----------------------|------------------------------|
| <code>origins</code> | A vector of sets of origins. |
|----------------------|------------------------------|

**Returns**

The index of the smallest (regarding the size of the sets) element of origins

**0.15.174.4.37 eraseSubformulaFromPassedFormula()** `ModuleInput::iterator smtrat::Module::eraseSubformulaFromPassedFormula (`

```
 ModuleInput::iterator _subformula,
 bool _ignoreOrigins = false) [protected], [virtual], [inherited]
```

Removes everything related to the sub-formula to remove from the passed formula in the backends of this module. Afterwards the sub-formula is removed from the passed formula.

**Parameters**

|                             |                                                                                                              |
|-----------------------------|--------------------------------------------------------------------------------------------------------------|
| <code>_subformula</code>    | The sub-formula to remove from the passed formula.                                                           |
| <code>_ignoreOrigins</code> | True, if the sub-formula shall be removed regardless of its origins (should only be applied with expertise). |

**Returns**

Reimplemented in `smtrat::ICPModule< Settings >`, `smtrat::ICPModule< ICPSettings4 >`, and `smtrat::ICPModule< ICPSettings1 >`.

**0.15.174.4.38 excludeNotReceivedVariablesFromModel()** `void smtrat::Module::excludeNotReceivedVariablesFromModel ( ) const [inherited]`

Excludes all variables from the current model, which do not occur in the received formula.

**0.15.174.4.39 findBestOrigin()** `std::vector< FormulaT >::const_iterator smtrat::Module::findBestOrigin (`

```
 const std::vector< FormulaT > & _origins) const [protected], [inherited]
```

**Parameters**

|                       |
|-----------------------|
| <code>_origins</code> |
|-----------------------|

**Returns****0.15.174.4.40 firstSubformulaToPass()** `ModuleInput::const_iterator smtrat::Module::firstSubformulaToPass ( ) const [inline], [inherited]`**Returns**

The position of the first sub-formula in the passed formula, which has not yet been considered for a consistency check of the backends.

**0.15.174.4.41 firstUncheckedReceivedSubformula()** `ModuleInput::const_iterator smtrat::Module::firstUncheckedReceivedSubformula ( ) const [inline], [inherited]`**Returns**

The position of the first (by this module) unchecked sub-formula of the received formula.

**0.15.174.4.42 freeSplittingVariable()** static void smtrat::Module::freeSplittingVariable ( const `FormulaT` & `_splittingVariable` ) [inline], [static], [inherited]

**0.15.174.4.43 generateTrivialInfeasibleSubset()** void smtrat::Module::generateTrivialInfeasibleSubset ( ) [inline], [protected], [inherited]  
Stores the trivial infeasible subset being the set of received formulas.

**0.15.174.4.44 getBackendsAllModels()** void smtrat::Module::getBackendsAllModels ( ) const [protected], [inherited]  
Stores all models of a backend in the list of all models of this module.

**0.15.174.4.45 getBackendsModel()** void smtrat::Module::getBackendsModel ( ) const [protected], [inherited]

**0.15.174.4.46 getInfeasibleSubsets() [1/2]** void smtrat::Module::getInfeasibleSubsets ( ) [protected], [inherited]  
Copies the infeasible subsets of the passed formula.

**0.15.174.4.47 getInfeasibleSubsets() [2/2]** std::vector< `FormulaSetT` > smtrat::Module::getInfeasibleSubsets ( const `Module` & `_backend` ) const [protected], [inherited]

Get the infeasible subsets the given backend provides.  
Note, that an infeasible subset in a backend contains sub formulas of the passed formula and an infeasible subset of this module contains sub formulas of the received formula. In this method the LATTER is returned.

#### Parameters

|                       |                                                          |
|-----------------------|----------------------------------------------------------|
| <code>_backend</code> | The backend from which to obtain the infeasible subsets. |
|-----------------------|----------------------------------------------------------|

#### Returns

The infeasible subsets the given backend provides.

**0.15.174.4.48 getInformationRelevantFormulas()** const std::set< `FormulaT` > & smtrat::Module::getInformationRelevantFormulas ( ) [protected], [inherited]  
Gets all InformationRelevantFormulas.

#### Returns

Set of all formulas

**0.15.174.4.49 getModelEqualities()** std::list< std::vector< `carl::Variable` > > smtrat::Module::getModelEqualities ( ) const [virtual], [inherited]

Partition the variables from the current model into equivalence classes according to their assigned value.  
The result is a set of equivalence classes of variables where all variables within one class are assigned the same value. Note that the number of classes may not be minimal, i.e. two classes may actually be equivalent.

#### Returns

Equivalence classes.

**0.15.174.4.50 getOrigins() [1/3]** void smtrat::Module::getOrigins ( const FormulaT & \_formula, FormulaSetT & \_origins ) const [inline], [protected], [inherited]

**Parameters**

|          |  |
|----------|--|
| _formula |  |
| _origins |  |

**0.15.174.4.51 getOrigins() [2/3]** void smtrat::Module::getOrigins ( const FormulaT & \_formula, FormulasT & \_origins ) const [inline], [protected], [inherited]

**Parameters**

|          |  |
|----------|--|
| _formula |  |
| _origins |  |

**0.15.174.4.52 getOrigins() [3/3]** const FormulaT& smtrat::Module::getOrigins ( ModuleInput::const\_iterator \_formula ) const [inline], [protected], [inherited]

Gets the origins of the passed formula at the given position.

**Parameters**

|          |                                                   |
|----------|---------------------------------------------------|
| _formula | The position of a formula in the passed formulas. |
|----------|---------------------------------------------------|

**Returns**

The origins of the passed formula at the given position.

**0.15.174.4.53 getReceivedFormulaSimplified()** std::pair< bool, FormulaT > smtrat::Module::getReceivedFormulaSimplified ( ) [virtual], [inherited]

**Returns**

A pair of a Boolean and a formula, where the Boolean is true, if the received formula could be simplified to an equisatisfiable formula. The formula is equisatisfiable to this module's received formula, if the Boolean is true.

Reimplemented in [smtrat::PModule](#).

**0.15.174.4.54 hasLemmas()** bool smtrat::Module::hasLemmas ( ) [inline], [inherited]

Checks whether this module or any of its backends provides any lemmas.

**0.15.174.4.55 hasValidInfeasibleSubset()** bool smtrat::Module::hasValidInfeasibleSubset ( ) const [inherited]

**Returns**

true, if the module has at least one valid infeasible subset, that is all its elements are sub-formulas of the received formula (pointer must be equal).

**0.15.174.4.56 `id()`** `std::size_t smtrat::Module::id () const [inline], [inherited]`

**Returns**

A unique ID to identify this module instance.

**0.15.174.4.57 `infeasibleSubsets()`** `const std::vector<FormulaSetT>& smtrat::Module::infeasibleSubsets () const [inline], [inherited]`

**Returns**

The infeasible subsets of the set of received formulas (empty, if this module has not detected unsatisfiability of the conjunction of received formulas).

**0.15.174.4.58 `inform()`** `bool smtrat::Module::inform (const FormulaT & _constraint) [inherited]`

Informs the module about the given constraint.

It should be tried to inform this module about any constraint it could receive eventually before assertSubformula is called (preferably for the first time, but at least before adding a formula containing that constraint).

**Parameters**

|                          |                                 |
|--------------------------|---------------------------------|
| <code>_constraint</code> | The constraint to inform about. |
|--------------------------|---------------------------------|

**Returns**

false, if it can be easily decided whether the given constraint is inconsistent; true, otherwise.

**0.15.174.4.59 `informBackends()`** `void smtrat::Module::informBackends (const FormulaT & _constraint) [inline], [protected], [inherited]`

Informs all backends of this module about the given constraint.

**Parameters**

|                          |                                 |
|--------------------------|---------------------------------|
| <code>_constraint</code> | The constraint to inform about. |
|--------------------------|---------------------------------|

**0.15.174.4.60 `informCore()`** `virtual bool smtrat::Module::informCore (const FormulaT & _constraint) [inline], [protected], [virtual], [inherited]`

Informs the module about the given constraint.

It should be tried to inform this module about any constraint it could receive eventually before assertSubformula is called (preferably for the first time, but at least before adding a formula containing that constraint).

**Parameters**

|                          |                                 |
|--------------------------|---------------------------------|
| <code>_constraint</code> | The constraint to inform about. |
|--------------------------|---------------------------------|

**Returns**

false, if it can be easily decided whether the given constraint is inconsistent; true, otherwise.

Reimplemented in [smtrat::UnionFindModule< Settings >](#), [smtrat::PBPPModule< Settings >](#), [smtrat::PBGaussModule< Settings >](#), [smtrat::NRAILModule< Settings >](#), [smtrat::NewCoveringModule< Settings >](#), [smtrat::NewCADModule< Settings >](#),

`smrat::LRAModule< Settings >, smrat::LRAModule< LRASettingsICP >, smrat::LRAModule< LRASettings1 >, smrat::IntBlastModule< Settings >, smrat::FPPModule< Settings >, smrat::EQModule< Settings >, smrat::CurryModule< Settings >, smrat::BVMModule< Settings >, smrat::ICPModule< Settings >, smrat::ICPModule< ICPSettings4 >, and smrat::ICPModule< ICPSettings1 >.`

**0.15.174.4.61 informedConstraints()** `const carl::FastSet<FormulaT>& smrat::Module::informedConstraints( ) const [inline], [inherited]`

**Returns**

The position of the first constraint of which no backend has been informed about.

**0.15.174.4.62 init()** `void smrat::Module::init( ) [virtual], [inherited]`

Informs all backends about the so far encountered constraints, which have not yet been communicated.

This method must not be called twice and only before the first runBackends call.

Reimplemented in `smrat::PBPPModule< Settings >, smrat::PBGaussModule< Settings >, smrat::NRAILModule< Settings >, smrat::NewCoveringModule< Settings >, smrat::NewCADModule< Settings >, smrat::LRAModule< Settings >, smrat::LRAModule< LRASettingsICP >, smrat::LRAModule< LRASettings1 >, smrat::IntBlastModule< Settings >, smrat::FPPModule< Settings >, smrat::EQModule< Settings >, smrat::CurryModule< Settings >, and smrat::BVMModule< Settings >.`

**0.15.174.4.63 is\_minimizing()** `bool smrat::Module::is_minimizing( ) const [inline], [inherited]`

**0.15.174.4.64 isLemmaLevel()** `bool smrat::Module::isLemmaLevel( LemmaLevel level ) [protected], [inherited]`

Checks if current lemma level is greater or equal to given level.

**Parameters**

|                    |                 |
|--------------------|-----------------|
| <code>level</code> | Level to check. |
|--------------------|-----------------|

**0.15.174.4.65 isPreprocessor()** `bool smrat::Module::isPreprocessor( ) const [inline], [inherited]`

**Returns**

true, if this module is a preprocessor that is a module, which simplifies its received formula to an equisatisfiable formula being passed to its backends. The simplified formula can be obtained with `getReceivedFormulaSimplified()`.

**0.15.174.4.66 lemmas()** `const std::vector<Lemma>& smrat::Module::lemmas( ) const [inline], [inherited]`

**Returns**

A constant reference to the lemmas being valid formulas this module or its backends made.

**0.15.174.4.67 merge()** `std::vector< FormulaT > smrat::Module::merge( const std::vector< FormulaT > & _vecSetA, const std::vector< FormulaT > & _vecSetB ) const [protected], [inherited]`

Merges the two vectors of sets into the first one.

({a,b},{a,c}) and ({b,d},{b}) -> ({a,b,d},{a,b},{a,b,c,d},{a,b,c})

**Parameters**

|                       |                                  |
|-----------------------|----------------------------------|
| <code>_vecSetA</code> | A vector of sets of constraints. |
| <code>_vecSetB</code> | A vector of sets of constraints. |

**Returns**

The vector being the two given vectors merged.

**0.15.174.4.68 `model()`** `const Model& smtrat::Module::model () const [inline], [inherited]`**Returns**

The assignment of the current satisfiable result, if existent.

**0.15.174.4.69 `modelsDisjoint()`** `bool smtrat::Module::modelsDisjoint (const Model & _modelA, const Model & _modelB ) [static], [protected], [inherited]`

Checks whether there is no variable assigned by both models.

**Parameters**

|                      |                                |
|----------------------|--------------------------------|
| <code>_modelA</code> | The first model to check for.  |
| <code>_modelB</code> | The second model to check for. |

**Returns**

true, if there is no variable assigned by both models; false, otherwise.

**0.15.174.4.70 `moduleName()`** `template<typename Settings > std::string smtrat::EQPreprocessingModule< Settings >::moduleName () const [inline], [virtual]`**Returns**

The name of the given module type as name.

Reimplemented from [smtrat::Module](#).

**0.15.174.4.71 `objective()`** `carl::Variable smtrat::Module::objective () const [inline], [inherited]`**0.15.174.4.72 `originInReceivedFormula()`** `bool smtrat::Module::originInReceivedFormula (const FormulaT & _origin ) const [protected], [inherited]`**0.15.174.4.73 `passedFormulaBegin()`** `ModuleInput::iterator smtrat::Module::passedFormulaBegin () [inline], [protected], [inherited]`**Returns**

An iterator to the end of the passed formula. TODO: disable this method

**0.15.174.4.74 passedFormulaEnd()** `ModuleInput::iterator smtrat::Module::passedFormulaEnd ()`  
[inline], [protected], [inherited]

**Returns**

An iterator to the end of the passed formula.

**0.15.174.4.75 pPassedFormula()** `const ModuleInput* smtrat::Module::pPassedFormula () const`  
[inline], [inherited]

**Returns**

A pointer to the formula passed to the backends of this module.

**0.15.174.4.76 pReceivedFormula()** `const ModuleInput* smtrat::Module::pReceivedFormula () const`  
[inline], [inherited]

**Returns**

A pointer to the formula passed to this module.

**0.15.174.4.77 print()** `void smtrat::Module::print (`  
`const std::string & _initiation = "***" ) const` [inherited]  
Prints everything relevant of the solver.

**Parameters**

|                          |                      |
|--------------------------|----------------------|
| <code>_initiation</code> | The line initiation. |
|--------------------------|----------------------|

**0.15.174.4.78 printAllModels()** `void smtrat::Module::printAllModels (`  
`std::ostream & _out = std::cout )` [inherited]

Prints all assignments of this module satisfying its received formula if it satisfiable and this module could find an assignment.

**Parameters**

|                   |                                        |
|-------------------|----------------------------------------|
| <code>_out</code> | The stream to print the assignment on. |
|-------------------|----------------------------------------|

**0.15.174.4.79 printInfeasibleSubsets()** `void smtrat::Module::printInfeasibleSubsets (`  
`const std::string & _initiation = "***" ) const` [inherited]

Prints the infeasible subsets.

**Parameters**

|                          |                      |
|--------------------------|----------------------|
| <code>_initiation</code> | The line initiation. |
|--------------------------|----------------------|

**0.15.174.4.80 printModel()** `void smtrat::Module::printModel (`  
`std::ostream & _out = std::cout ) const` [inherited]

Prints the assignment of this module satisfying its received formula if it satisfiable and this module could find an assignment.

Parameters

|                   |                                        |
|-------------------|----------------------------------------|
| <code>_out</code> | The stream to print the assignment on. |
|-------------------|----------------------------------------|

**0.15.174.4.81 `printPassedFormula()`** `void smtrat::Module::printPassedFormula ( const std::string & _initiation = "***" ) const [inherited]`

Prints the vector of passed formula.

Parameters

|                          |                      |
|--------------------------|----------------------|
| <code>_initiation</code> | The line initiation. |
|--------------------------|----------------------|

**0.15.174.4.82 `printReceivedFormula()`** `void smtrat::Module::printReceivedFormula ( const std::string & _initiation = "***" ) const [inherited]`

Prints the vector of the received formula.

Parameters

|                          |                      |
|--------------------------|----------------------|
| <code>_initiation</code> | The line initiation. |
|--------------------------|----------------------|

**0.15.174.4.83 `probablyLooping()`** `bool smtrat::Module::probablyLooping ( const typename Poly::PolyType & _branchingPolynomial, const Rational & _branchingValue ) const [protected], [inherited]`

Checks whether given the current branching value and branching variable/polynomial it is (highly) probable that this branching is part of an infinite loop of branchings.

Parameters

|                                   |                                                                                     |
|-----------------------------------|-------------------------------------------------------------------------------------|
| <code>_branchingPolynomial</code> | The polynomial to branch at (in most branching strategies this is just a variable). |
| <code>_branchingValue</code>      | The value to branch at.                                                             |

Returns

true, if this branching is probably part of an infinite loop of branchings; false, otherwise.

**0.15.174.4.84 `receivedFormulaChecked()`** `void smtrat::Module::receivedFormulaChecked ( ) [inline], [inherited]`

Notifies that the received formulas has been checked.

**0.15.174.4.85 `receivedFormulasAsInfeasibleSubset()`** `void smtrat::Module::receivedFormulasAsInfeasibleSubset ( ModuleInput::const_iterator _subformula ) [inline], [protected], [inherited]`

Stores an infeasible subset consisting only of the given received formula.

```
0.15.174.4.86 receivedVariable() bool smrat::Module::receivedVariable (
 carl::Variable::Arg _var) const [inline], [inherited]
```

```
0.15.174.4.87 remove() void smrat::Module::remove (
 ModuleInput::const_iterator _subformula) [virtual], [inherited]
```

Removes everything related to the given sub-formula of the received formula.

However, it is desired not to lose track of search spaces where no satisfying assignment can be found for the remaining sub-formulas.

#### Parameters

|             |                                                    |
|-------------|----------------------------------------------------|
| _subformula | The sub formula of the received formula to remove. |
|-------------|----------------------------------------------------|

Reimplemented in [smrat::PModule](#).

```
0.15.174.4.88 removeCore() virtual void smrat::Module::removeCore (
 ModuleInput::const_iterator formula) [inline], [protected], [virtual], [inherited]
```

Removes everything related to the given sub-formula of the received formula.

However, it is desired not to lose track of search spaces where no satisfying assignment can be found for the remaining sub-formulas.

#### Parameters

|         |                                                    |
|---------|----------------------------------------------------|
| formula | The sub formula of the received formula to remove. |
|---------|----------------------------------------------------|

Reimplemented in [smrat::VSModule< Settings >](#), [smrat::SATModule< Settings >](#), [smrat::PFEModule< Settings >](#), [smrat::ICPModule< Settings >](#), [smrat::ICPModule< ICPSettings4 >](#), [smrat::ICPModule< ICPSettings1 >](#), [smrat::UnionFindModule< Settings >](#), [smrat::UFCegarModule< Settings >](#), [smrat::STropModule< Settings >](#), [smrat::PBPPModule< Settings >](#), [smrat::PBGaussModule< Settings >](#), [smrat::NRAILModule< Settings >](#), [smrat::NewCoveringModule< Settings >](#), [smrat::NewCADModule< Settings >](#), [smrat::LRAModule< Settings >](#), [smrat::LRAModule< LRASettingsICP >](#), [smrat::LRAModule< LRASettings1 >](#), [smrat::IntEqModule< Settings >](#), [smrat::IntBlastModule< Settings >](#), [smrat::IncWidthModule< Settings >](#), [smrat::ICEModule< Settings >](#), [smrat::FPPModule< Settings >](#), [smrat::FouMoModule< Settings >](#), [smrat::EQModule< Settings >](#), [smrat::CurryModule< Settings >](#), [smrat::CubeLIAModule< Settings >](#), [smrat::CSplitModule< Settings >](#), [smrat::BVMModule< Settings >](#), and [smrat::GBModule< Settings >](#).

```
0.15.174.4.89 removeOrigin() std::pair<ModuleInput::iterator,bool> smrat::Module::remove<-
Origin (
 ModuleInput::iterator _formula,
 const FormulaT & _origin) [inline], [protected], [inherited]
```

```
0.15.174.4.90 removeOrigins() std::pair<ModuleInput::iterator,bool> smrat::Module::remove<-
Origins (
 ModuleInput::iterator _formula,
 const std::shared_ptr< std::vector< FormulaT >> & _origins) [inline], [protected],
[inherited]
```

```
0.15.174.4.91 rPassedFormula() const ModuleInput& smrat::Module::rPassedFormula () const
[inline], [inherited]
```

**Returns**

A reference to the formula passed to the backends of this module.

**0.15.174.4.92 rReceivedFormula()** `const ModuleInput& smtrat::Module::rReceivedFormula () const [inline], [inherited]`

**Returns**

A reference to the formula passed to this module.

**0.15.174.4.93 runBackends() [1/2]** `virtual Answer smtrat::Module::runBackends () [inline], [protected], [virtual], [inherited]`

Reimplemented in [smtrat::PModule](#).

**0.15.174.4.94 runBackends() [2/2]** `Answer smtrat::Module::runBackends (`

`bool _final,`

`bool _full,`

`carl::Variable _objective ) [protected], [virtual], [inherited]`

Runs the backend solvers on the passed formula.

**Parameters**

|                         |                                                                                                                                       |
|-------------------------|---------------------------------------------------------------------------------------------------------------------------------------|
| <code>_final</code>     | true, if this satisfiability check will be the last one (for a global sat-check), if its result is SAT                                |
| <code>_full</code>      | false, if this module should avoid too expensive procedures and rather return unknown instead.                                        |
| <code>_objective</code> | if not set to NO_VARIABLE, the module should find an assignment minimizing this objective variable; otherwise any assignment is good. |

**Returns**

True, if the passed formula is consistent; False, if the passed formula is inconsistent; Unknown, otherwise.

Reimplemented in [smtrat::PModule](#).

**0.15.174.4.95 setId()** `void smtrat::Module::setId (`

`std::size_t _id ) [inline], [inherited]`

Sets this modules unique ID to identify itself.

**Parameters**

|                 |                                    |
|-----------------|------------------------------------|
| <code>id</code> | The id to set this module's id to. |
|-----------------|------------------------------------|

**0.15.174.4.96 setThreadPriority()** `void smtrat::Module::setThreadPriority (`

`thread_priority _threadPriority ) [inline], [inherited]`

Sets the priority of this module to get a thread for running its check procedure.

**Parameters**

|                              |                                                       |
|------------------------------|-------------------------------------------------------|
| <code>_threadPriority</code> | The priority to set this module's thread priority to. |
|------------------------------|-------------------------------------------------------|

**0.15.174.4.97 `solverState()`** `Answer smtrat::Module::solverState () const [inline], [inherited]`**Returns**

True, if this module is in a state, such that it has found a solution for its received formula; False, if this module is in a state, such that it has determined that there is no solution for its received formula; Unknown, otherwise.

**0.15.174.4.98 `splitUnequalConstraint()`** `void smtrat::Module::splitUnequalConstraint (const FormulaT & _unequalConstraint ) [protected], [inherited]`

Adds the following lemmas for the given constraint  $p \neq 0$ .

$(p \neq 0 \Leftrightarrow (p < 0 \text{ or } p > 0))$

and  $\neg(p < 0 \text{ and } p > 0)$

**Parameters**

|                                 |                                                  |
|---------------------------------|--------------------------------------------------|
| <code>_unequalConstraint</code> | A constraint having the relation symbol $\neq$ . |
|---------------------------------|--------------------------------------------------|

**0.15.174.4.99 `threadPriority()`** `thread_priority smtrat::Module::threadPriority () const [inline], [inherited]`**Returns**

The priority of this module to get a thread for running its check procedure.

**0.15.174.4.100 `updateAllModels()`** `void smtrat::Module::updateAllModels () [virtual], [inherited]`

Updates all satisfying models, if the solver has detected the consistency of the received formula, beforehand.

Reimplemented in [smtrat::SATModule< Settings >](#).

**0.15.174.4.101 `updateLemmas()`** `void smtrat::Module::updateLemmas () [inherited]`

Stores all lemmas of any backend of this module in its own lemma vector.

**0.15.174.4.102 `updateModel()`** `template<typename Settings > void smtrat::EQPreprocessingModule< Settings >::updateModel () const [virtual]`

Updates the model, if the solver has detected the consistency of the received formula, beforehand.

Reimplemented from [smtrat::Module](#).

**0.15.174.4.103 `usedBackends()`** `const std::vector<Module*>& smtrat::Module::usedBackends () const [inline], [inherited]`**Returns**

The backends of this module which are currently used (conditions to use this module are fulfilled for the passed formula).

**0.15.174.5 Field Documentation**

**0.15.174.5.1 mAllBackends** `std::vector<Module*> smrat::Module::mAllBackends [protected], [inherited]`

The backends of this module which have been used.

**0.15.174.5.2 mAllModels** `std::vector<Model> smrat::Module::mAllModels [mutable], [protected], [inherited]`

Stores all satisfying assignments.

**0.15.174.5.3 mBackendsFoundAnswer** `std::atomic_bool* smrat::Module::mBackendsFoundAnswer [protected], [inherited]`

This flag is passed to any backend and if it determines an answer to a prior check call, this flag is fired.

**0.15.174.5.4 mConstraintsToInform** `carl::FastSet<FormulaT> smrat::Module::mConstraintsToInform [protected], [inherited]`

Stores the constraints which the backends must be informed about.

**0.15.174.5.5 mFinalCheck** `bool smrat::Module::mFinalCheck [protected], [inherited]`  
true, if the check procedure should perform a final check which especially means not to postpone splitting decisions

**0.15.174.5.6 mFirstPosInLastBranches** `std::size_t smrat::Module::mFirstPosInLastBranches = 0 [static], [inherited]`

The beginning of the cyclic buffer storing the last branches.

**0.15.174.5.7 mFirstSubformulaToPass** `ModuleInput::iterator smrat::Module::mFirstSubformulaToPass [protected], [inherited]`

Stores the position of the first sub-formula in the passed formula, which has not yet been considered for a consistency check of the backends.

**0.15.174.5.8 mFirstUncheckedReceivedSubformula** `ModuleInput::const_iterator smrat::Module::mFirstUncheckedReceivedSubformula [protected], [inherited]`

Stores the position of the first (by this module) unchecked sub-formula of the received formula.

**0.15.174.5.9 mFoundAnswer** `Conditionals smrat::Module::mFoundAnswer [protected], [inherited]`  
Vector of Booleans: If any of them is true, we have to terminate a running check procedure.

**0.15.174.5.10 mFullCheck** `bool smrat::Module::mFullCheck [protected], [inherited]`  
false, if this module should avoid too expensive procedures and rather return unknown instead.

**0.15.174.5.11 mInfeasibleSubsets** `std::vector<FormulaSetT> smrat::Module::mInfeasibleSubsets [protected], [inherited]`

Stores the infeasible subsets.

**0.15.174.5.12 mInformedConstraints** `carl::FastSet<FormulaT> smtrat::Module::mInformedConstraints` [protected], [inherited]  
Stores the position of the first constraint of which no backend has been informed about.

**0.15.174.5.13 mLastBranches** `std::vector<Branching> smtrat::Module::mLastBranches = std::vector<Branching>(mNumOfBranchVarsToStore, Branching(typename Poly::PolyType(), 0))` [static], [inherited]  
Stores the last branches in a cycle buffer.

**0.15.174.5.14 mLemmas** `std::vector<Lemma> smtrat::Module::mLemmas` [protected], [inherited]  
Stores the lemmas being valid formulas this module or its backends made.

**0.15.174.5.15 mModel** `Model smtrat::Module::mModel` [mutable], [protected], [inherited]  
Stores the assignment of the current satisfiable result, if existent.

**0.15.174.5.16 mModelComputed** `bool smtrat::Module::mModelComputed` [mutable], [protected], [inherited]  
True, if the model has already been computed.

**0.15.174.5.17 mNumOfBranchVarsToStore** `std::size_t smtrat::Module::mNumOfBranchVarsToStore = 5` [static], [inherited]  
The number of different variables to consider for a probable infinite loop of branchings.

**0.15.174.5.18 mObjectiveVariable** `carl::Variable smtrat::Module::mObjectiveVariable` [protected], [inherited]  
Objective variable to be minimized. If set to NO\_VARIABLE, a normal sat check should be performed.

**0.15.174.5.19 mOldSplittingVariables** `std::vector<FormulaT> smtrat::Module::mOldSplittingVariables` [static], [inherited]  
Reusable splitting variables.

**0.15.174.5.20 mpManager** `Manager* const smtrat::Module::mpManager` [protected], [inherited]  
A reference to the manager.

**0.15.174.5.21 mSmallerMusesCheckCounter** `unsigned smtrat::Module::mSmallerMusesCheckCounter` [mutable], [protected], [inherited]  
Counter used for the generation of the smt2 files to check for smaller muses.

**0.15.174.5.22 mSolverState** `std::atomic<Answer> smtrat::Module::mSolverState` [protected], [inherited]  
States whether the received formula is known to be satisfiable or unsatisfiable otherwise it is set to unknown.

**0.15.174.5.23 mTheoryPropagations** `std::vector<TheoryPropagation> smtrat::Module::mTheoryPropagations` [protected], [inherited]

**0.15.174.5.24 mUsedBackends** std::vector<[Module](#)\*> smtrat::Module::mUsedBackends [protected], [inherited]

The backends of this module which are currently used (conditions to use this module are fulfilled for the passed formula).

**0.15.174.5.25 mVariableCounters** std::vector<std::size\_t> smtrat::Module::mVariableCounters [protected], [inherited]

Maps variables to the number of their occurrences.

### 0.15.178.4 Member Function Documentation

**0.15.178.4.1 add()** `bool smrat::PModule::add (`  
`ModuleInput::const_iterator _subformula ) [inherited]`

The module has to take the given sub-formula of the received formula into account.

**Parameters**

|                          |                                                    |
|--------------------------|----------------------------------------------------|
| <code>_subformula</code> | The sub-formula to take additionally into account. |
|--------------------------|----------------------------------------------------|

**Returns**

false, if it can be easily decided that this sub-formula causes a conflict with the already considered sub-formulas; true, otherwise.

**0.15.178.4.2 `addConstraintToInform()`** `void smtrat::Module::addConstraintToInform ( const FormulaT & _constraint )` [protected], [virtual], [inherited]

Adds a constraint to the collection of constraints of this module, which are informed to a freshly generated backend.

**Parameters**

|                          |                        |
|--------------------------|------------------------|
| <code>_constraint</code> | The constraint to add. |
|--------------------------|------------------------|

Reimplemented in [smtrat::SATModule< Settings >](#).

**0.15.178.4.3 `addCore()`** `virtual bool smtrat::Module::addCore ( ModuleInput::const_iterator formula )` [inline], [protected], [virtual], [inherited]

The module has to take the given sub-formula of the received formula into account.

**Parameters**

|                      |                                                    |
|----------------------|----------------------------------------------------|
| <code>formula</code> | The sub-formula to take additionally into account. |
|----------------------|----------------------------------------------------|

**Returns**

false, if it can be easily decided that this sub-formula causes a conflict with the already considered sub-formulas; true, otherwise.

Reimplemented in [smtrat::VSModule< Settings >](#), [smtrat::SATModule< Settings >](#), [smtrat::PFEModule< Settings >](#), [smtrat::ICPModule< Settings >](#), [smtrat::ICPModule< ICPSettings4 >](#), [smtrat::ICPModule< ICPSettings1 >](#), [smtrat::UnionFindModule< Settings >](#), [smtrat::UFCegarModule< Settings >](#), [smtrat::STropModule< Settings >](#), [smtrat::PBPPModule< Settings >](#), [smtrat::PBGaussModule< Settings >](#), [smtrat::NRAILModule< Settings >](#), [smtrat::NewCoveringModule< Settings >](#), [smtrat::NewCADModule< Settings >](#), [smtrat::LRAModule< Settings >](#), [smtrat::LRAModule< LRASettingsICP >](#), [smtrat::LRAModule< LRASettings1 >](#), [smtrat::IntEqModule< Settings >](#), [smtrat::IntBlastModule< Settings >](#), [smtrat::IncWidthModule< Settings >](#), [smtrat::ICEModule< Settings >](#), [smtrat::FPPModule< Settings >](#), [smtrat::FouMoModule< Settings >](#), [smtrat::EQModule< Settings >](#), [smtrat::CurryModule< Settings >](#), [smtrat::CubeLIAModule< Settings >](#), [smtrat::CSplitModule< Settings >](#), [smtrat::BVMModule< Settings >](#), and [smtrat::GBModule< Settings >](#).

**0.15.178.4.4 `addInformationRelevantFormula()`** `void smtrat::Module::addInformationRelevantFormula ( const FormulaT & formula )` [protected], [inherited]

Adds a formula to the InformationRelevantFormula.

**Parameters**

|                      |                |
|----------------------|----------------|
| <code>formula</code> | Formula to add |
|----------------------|----------------|

```
0.15.178.4.5 addLemma() void smtrat::Module::addLemma (
 const FormulaT & _lemma,
 const LemmaType & _lt = LemmaType::NORMAL,
 const FormulaT & _preferredFormula = FormulaT(carl::FormulaType::TRUE)) [inline],
[inherited]
```

Stores a lemma being a valid formula.

#### Parameters

|                   |                                                                       |
|-------------------|-----------------------------------------------------------------------|
| _lemma            | The eduction/lemma to store.                                          |
| _lt               | The type of the lemma.                                                |
| _preferredFormula | Hint for the next decision, which formula should be assigned to true. |

```
0.15.178.4.6 addOrigin() void smtrat::Module::addOrigin (
 ModuleInput::iterator _formula,
 const FormulaT & _origin) [inline], [protected], [inherited]
```

Adds the given set of formulas in the received formula to the origins of the given passed formula.

#### Parameters

|          |                                                           |
|----------|-----------------------------------------------------------|
| _formula | The passed formula to set the origins for.                |
| _origin  | A set of formulas in the received formula of this module. |

```
0.15.178.4.7 addReceivedSubformulaToPassedFormula() std::pair<ModuleInput::iterator,bool>
smtrat::Module::addReceivedSubformulaToPassedFormula (
```

```
 ModuleInput::const_iterator _subformula) [inline], [protected], [inherited]
```

Copies the given sub-formula of the received formula to the passed formula.

Note, that there is always a link between sub-formulas of the passed formulas to sub-formulas of the received formulas, which are responsible for its occurrence.

#### Parameters

|             |                                                  |
|-------------|--------------------------------------------------|
| _subformula | The sub-formula of the received formula to copy. |
|-------------|--------------------------------------------------|

```
0.15.178.4.8 addSubformulaToPassedFormula() [1/3] std::pair<ModuleInput::iterator,bool> smtrat<-
::Module::addSubformulaToPassedFormula (
```

```
 const FormulaT & _formula) [inline], [protected], [inherited]
```

Adds the given formula to the passed formula with no origin.

Note that in the next call of this module's removeSubformula, all formulas in the passed formula without origins will be removed.

#### Parameters

|          |                                           |
|----------|-------------------------------------------|
| _formula | The formula to add to the passed formula. |
|----------|-------------------------------------------|

#### Returns

A pair to the position where the formula to add has been inserted (or its first sub-formula which has not yet been in the passed formula, in case the formula to add is a conjunction), and a Boolean stating whether anything has been added to the passed formula.

**0.15.178.4.9 addSubformulaToPassedFormula()** [2/3] std::pair<ModuleInput::iterator,bool> smrat→  
::Module::addSubformulaToPassedFormula ( const FormulaT & \_formula,  
const FormulaT & \_origin ) [inline], [protected], [inherited]  
Adds the given formula to the passed formula.

#### Parameters

|          |                                                                                                                           |
|----------|---------------------------------------------------------------------------------------------------------------------------|
| _formula | The formula to add to the passed formula.                                                                                 |
| _origin  | The sub-formula of the received formula being responsible for the occurrence of the formula to add to the passed formula. |

#### Returns

A pair to the position where the formula to add has been inserted (or its first sub-formula which has not yet been in the passed formula, in case the formula to add is a conjunction), and a Boolean stating whether anything has been added to the passed formula.

**0.15.178.4.10 addSubformulaToPassedFormula()** [3/3] std::pair<ModuleInput::iterator,bool>  
smrat::Module::addSubformulaToPassedFormula ( const FormulaT & \_formula,  
const std::shared\_ptr<std::vector<FormulaT>> & \_origins ) [inline], [protected],  
[inherited]  
Adds the given formula to the passed formula.

#### Parameters

|          |                                                                                                                                         |
|----------|-----------------------------------------------------------------------------------------------------------------------------------------|
| _formula | The formula to add to the passed formula.                                                                                               |
| _origins | The link of the formula to add to the passed formula to sub-formulas of the received formulas, which are responsible for its occurrence |

#### Returns

A pair to the position where the formula to add has been inserted (or its first sub-formula which has not yet been in the passed formula, in case the formula to add is a conjunction), and a Boolean stating whether anything has been added to the passed formula.

**0.15.178.4.11 allModels()** const std::vector<Model>& smrat::Module::allModels () const [inline],  
[inherited]

#### Returns

All satisfying assignments, if existent.

**0.15.178.4.12 anAnswerFound()** bool smrat::Module::anAnswerFound () const [inline], [protected],  
[inherited]

Checks for all antecedent modules and those which run in parallel with the same antecedent modules, whether one of them has determined a result.

#### Returns

True, if one of them has determined a result.

**0.15.178.4.13 answerFound()** const `smtrat::Conditionals`& `smtrat::Module::answerFound` ( ) const [inline], [inherited]

#### Returns

A vector of Booleans: If any of them is true, we have to terminate a running check procedure.

**0.15.178.4.14 appliedPreprocessing()** bool `smtrat::PModule::appliedPreprocessing` ( ) const [inline], [inherited]

#### Returns

true, if the current received formula has been simplified and the result of this simplification is stored in the passed formula.

**0.15.178.4.15 backendsModel()** const `Model` & `smtrat::Module::backendsModel` ( ) const [protected], [inherited]

Stores the model of a backend which determined satisfiability of the passed formula in the model of this module.

**0.15.178.4.16 branchAt() [1/4]** bool `smtrat::Module::branchAt` (

```
carl::Variable::Arg _var,
const Rational & _value,
bool _leftCaseWeak = true,
bool _preferLeftCase = true,
bool _useReceivedFormulaAsPremise = false,
const std::vector< FormulaT > & _premise = std::vector<FormulaT>()) [inline],
[protected], [inherited]
```

**0.15.178.4.17 branchAt() [2/4]** bool `smtrat::Module::branchAt` (

```
carl::Variable::Arg _var,
const Rational & _value,
std::vector< FormulaT > && _premise,
bool _leftCaseWeak = true,
bool _preferLeftCase = true,
bool _useReceivedFormulaAsPremise = false) [inline], [protected], [inherited]
```

**0.15.178.4.18 branchAt() [3/4]** bool `smtrat::Module::branchAt` (

```
const Poly & _polynomial,
bool _integral,
const Rational & _value,
bool _leftCaseWeak = true,
bool _preferLeftCase = true,
bool _useReceivedFormulaAsPremise = false,
const std::vector< FormulaT > & _premise = std::vector<FormulaT>()) [inline],
[protected], [inherited]
```

**0.15.178.4.19 branchAt() [4/4]** bool `smtrat::Module::branchAt` (

```
const Poly & _polynomial,
bool _integral,
const Rational & _value,
std::vector< FormulaT > && _premise,
```

```

 bool _leftCaseWeak = true,
 bool _preferLeftCase = true,
 bool _useReceivedFormulaAsPremise = false) [protected], [inherited]

```

Adds a lemmas which provoke a branching for the given variable at the given value, if this module returns Unknown and there exists a preceding [SATModule](#).

Note that the given value is rounded down and up, if the given variable is integer-valued.

#### Parameters

|                                           |                                                                                                                                                                                                                |
|-------------------------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>_polynomial</code>                  | The variable to branch for.                                                                                                                                                                                    |
| <code>_integral</code>                    | A flag being true, if all variables in the polynomial to branch for are integral.                                                                                                                              |
| <code>_value</code>                       | The value to branch at.                                                                                                                                                                                        |
| <code>_premise</code>                     | The sub-formulas of the received formula from which the branch is followed. Note, that a premise is not necessary, as every branch is a valid formula. But a premise can prevent from branching unnecessarily. |
| <code>_leftCaseWeak</code>                | true, if a branching in the form of (or ( $\leq p b$ ) ( $> p b$ )) is desired. false, if a branching in the form of (or ( $< p b$ ) ( $\geq p b$ )) is desired.                                               |
| <code>_preferLeftCase</code>              | true, if the left case (polynomial less(or equal) 0 shall be chosen first. false, otherwise.                                                                                                                   |
| <code>_useReceivedFormulaAsPremise</code> | true, if the whole received formula should be used as premise                                                                                                                                                  |

#### 0.15.178.4.20 `check()`

```

Answer smtrat::PModule::check (
 bool _final = false,
 bool _full = true,
 carl::Variable _objective = carl::Variable::NO_VARIABLE) [virtual], [inherited]

```

Checks the received formula for consistency.

Note, that this is an implementation of the satisfiability check of the conjunction of the so far received formulas, which does actually nothing but passing the problem to its backends. This implementation is only used internally and must be overwritten by any derived module.

#### Parameters

|                         |                                                                                                                                       |
|-------------------------|---------------------------------------------------------------------------------------------------------------------------------------|
| <code>_final</code>     | true, if this satisfiability check will be the last one (for a global sat-check), if its result is SAT                                |
| <code>_full</code>      | false, if this module should avoid too expensive procedures and rather return unknown instead.                                        |
| <code>_objective</code> | if not set to NO_VARIABLE, the module should find an assignment minimizing this objective variable; otherwise any assignment is good. |

#### Returns

True, if the received formula is satisfiable; False, if the received formula is not satisfiable; Unknown, otherwise.

Reimplemented from [smtrat::Module](#).

#### 0.15.178.4.21 `checkCore()`

```
template<typename Settings >
Answer smtrat::ESModule< Settings >::checkCore () [virtual]
```

Checks the received formula for consistency.

#### Returns

SAT, if the received formula is satisfiable; UNSAT, if the received formula is not satisfiable; Unknown, otherwise.

Reimplemented from [smtrat::Module](#).

```
0.15.178.4.22 checkInfSubsetForMinimality() void smtrat::Module::checkInfSubsetForMinimality (
 std::vector< FormulaSetT >::const_iterator _infssubset,
 const std::string & _filename = "smaller_muses",
 unsigned _maxSizeDifference = 1) const [inherited]
```

Checks the given infeasible subset for minimality by storing all subsets of it, which have a smaller size which differs from the size of the infeasible subset not more than the given threshold.

#### Parameters

|                                 |                                                                                                        |
|---------------------------------|--------------------------------------------------------------------------------------------------------|
| <code>_infssubset</code>        | The infeasible subset to check for minimality.                                                         |
| <code>_filename</code>          | The name of the file to store the infeasible subsets in order to be able to check their infeasibility. |
| <code>_maxSizeDifference</code> | The maximal difference between the sizes of the subsets compared to the size of the infeasible subset. |

```
0.15.178.4.23 checkModel() unsigned smtrat::Module::checkModel () const [protected], [inherited]
```

#### Returns

false, if the current model of this module does not satisfy the current given formula; true, if it cannot be said whether the model satisfies the given formula.

```
0.15.178.4.24 cleanModel() void smtrat::Module::cleanModel () const [inline], [protected], [inherited]
```

Substitutes variable occurrences by its model value in the model values of other variables.

```
0.15.178.4.25 clearLemmas() void smtrat::Module::clearLemmas () [inline], [inherited]
```

Deletes all yet found lemmas.

```
0.15.178.4.26 clearModel() void smtrat::Module::clearModel () const [inline], [protected], [inherited]
```

Clears the assignment, if any was found.

```
0.15.178.4.27 clearModels() void smtrat::Module::clearModels () const [inline], [protected], [inherited]
```

Clears all assignments, if any was found.

```
0.15.178.4.28 clearPassedFormula() void smtrat::Module::clearPassedFormula () [protected], [inherited]
```

```
0.15.178.4.29 collectOrigins() [1/2] void smtrat::Module::collectOrigins (
 const FormulaT & _formula,
 FormulaSetT & _origins) const [inherited]
```

```
0.15.178.4.30 collectOrigins() [2/2] void smtrat::Module::collectOrigins (
 const FormulaT & _formula,
 FormulasT & _origins) const [inherited]
```

Collects the formulas in the given formula, which are part of the received formula.

If the given formula directly occurs in the received formula, it is inserted into the given set. Otherwise, the given formula must be of type AND and all its sub-formulas part of the received formula. Hence, they will be added to the given set.

#### Parameters

|                       |                                                                                                      |
|-----------------------|------------------------------------------------------------------------------------------------------|
| <code>_formula</code> | The formula from which to collect the formulas being sub-formulas of the received formula (origins). |
| <code>_origins</code> | The set in which to store the origins.                                                               |

```
0.15.178.4.31 collectTheoryPropagations() void smtrat::Module::collectTheoryPropagations () [inherited]
```

```
0.15.178.4.32 constraintsToInform() const carl::FastSet<FormulaT>& smtrat::Module::constraintsToInform () const [inline], [inherited]
```

#### Returns

The constraints which the backends must be informed about.

```
0.15.178.4.33 currentlySatisfied() virtual unsigned smtrat::Module::currentlySatisfied (
 const FormulaT &) const [inline], [virtual], [inherited]
```

#### Returns

0, if the given formula is conflicted by the current model; 1, if the given formula is satisfied by the current model; 2, otherwise; 3, if we do not know anything (default)

Reimplemented in [smtrat::LRAModule< Settings >](#), [smtrat::LRAModule< LRASettingsICP >](#), and [smtrat::LRAModule< LRASettings >](#)

```
0.15.178.4.34 currentlySatisfiedByBackend() unsigned smtrat::Module::currentlySatisfiedByBackend (
 const FormulaT & _formula) const [inherited]
```

#### Returns

0, if the given formula is conflicted by the current model; 1, if the given formula is satisfied by the current model; 2, otherwise 3, if we do not know anything (default)

```
0.15.178.4.35 deinform() void smtrat::Module::deinform (
 const FormulaT & _constraint) [inherited]
```

The inverse of informing about a constraint.

All data structures which were kept regarding this constraint are going to be removed. Note, that this makes only sense if it is not likely enough that a formula with this constraint must be solved again.

#### Parameters

|                          |                                                         |
|--------------------------|---------------------------------------------------------|
| <code>_constraint</code> | The constraint to remove from internal data structures. |
|--------------------------|---------------------------------------------------------|

**0.15.178.4.36 `deinformCore()`** `virtual void smtrat::Module::deinformCore (`  
 `const FormulaT & _constraint )` [inline], [protected], [virtual], [inherited]

The inverse of informing about a constraint.

All data structures which were kept regarding this constraint are going to be removed. Note, that this makes only sense if it is not likely enough that a formula with this constraint must be solved again.

#### Parameters

|                          |                                                         |
|--------------------------|---------------------------------------------------------|
| <code>_constraint</code> | The constraint to remove from internal data structures. |
|--------------------------|---------------------------------------------------------|

Reimplemented in [smtrat::LRAModule< Settings >](#), [smtrat::LRAModule< LRASettingsICP >](#), and [smtrat::LRAModule< LRASettings1 >](#).

**0.15.178.4.37 `determine_smallest_origin()`** `size_t smtrat::Module::determine_smallest_origin (`  
 `const std::vector< FormulaT > & origins )` const [protected], [inherited]

#### Parameters

|                      |                              |
|----------------------|------------------------------|
| <code>origins</code> | A vector of sets of origins. |
|----------------------|------------------------------|

#### Returns

The index of the smallest (regarding the size of the sets) element of origins

**0.15.178.4.38 `eraseSubformulaFromPassedFormula()`** `ModuleInput::iterator smtrat::Module::eraseSubformulaFromPassedFormula (`  
 `ModuleInput::iterator _subformula,`  
 `bool _ignoreOrigins = false )` [protected], [virtual], [inherited]

Removes everything related to the sub-formula to remove from the passed formula in the backends of this module.  
Afterwards the sub-formula is removed from the passed formula.

#### Parameters

|                             |                                                                                                              |
|-----------------------------|--------------------------------------------------------------------------------------------------------------|
| <code>_subformula</code>    | The sub-formula to remove from the passed formula.                                                           |
| <code>_ignoreOrigins</code> | True, if the sub-formula shall be removed regardless of its origins (should only be applied with expertise). |

#### Returns

Reimplemented in [smtrat::ICPModule< Settings >](#), [smtrat::ICPModule< ICPSettings4 >](#), and [smtrat::ICPModule< ICPSettings1 >](#).

**0.15.178.4.39 `excludeNotReceivedVariablesFromModel()`** `void smtrat::Module::excludeNotReceivedVariablesFromModel ( )` const [inherited]

Excludes all variables from the current model, which do not occur in the received formula.

**0.15.178.4.40 `findBestOrigin()`** `std::vector< FormulaT >::const_iterator smtrat::Module::findBestOrigin (`  
 `const std::vector< FormulaT > & _origins )` const [protected], [inherited]

**Parameters**

|                 |  |
|-----------------|--|
| <i>_origins</i> |  |
|-----------------|--|

**Returns**

**0.15.178.4.41 `firstSubformulaToPass()`** `ModuleInput::const_iterator smtrat::Module::firstSubformulaToPass () const [inline], [inherited]`

**Returns**

The position of the first sub-formula in the passed formula, which has not yet been considered for a consistency check of the backends.

**0.15.178.4.42 `firstUncheckedReceivedSubformula()`** `ModuleInput::const_iterator smtrat::Module::firstUncheckedReceivedSubformula () const [inline], [inherited]`

**Returns**

The position of the first (by this module) unchecked sub-formula of the received formula.

**0.15.178.4.43 `freeSplittingVariable()`** `static void smtrat::Module::freeSplittingVariable (const FormulaT & _splittingVariable) [inline], [static], [inherited]`

**0.15.178.4.44 `generateTrivialInfeasibleSubset()`** `void smtrat::Module::generateTrivialInfeasibleSubset () [inline], [protected], [inherited]`

Stores the trivial infeasible subset being the set of received formulas.

**0.15.178.4.45 `getBackendsAllModels()`** `void smtrat::Module::getBackendsAllModels () const [protected], [inherited]`

Stores all models of a backend in the list of all models of this module.

**0.15.178.4.46 `getBackendsModel()`** `void smtrat::Module::getBackendsModel () const [protected], [inherited]`

**0.15.178.4.47 `getInfeasibleSubsets()` [1/2]** `void smtrat::Module::getInfeasibleSubsets () [protected], [inherited]`

Copies the infeasible subsets of the passed formula.

**0.15.178.4.48 `getInfeasibleSubsets()` [2/2]** `std::vector< FormulaSetT > smtrat::Module::getInfeasibleSubsets (const Module & _backend) const [protected], [inherited]`

Get the infeasible subsets the given backend provides.

Note, that an infeasible subset in a backend contains sub formulas of the passed formula and an infeasible subset of this module contains sub formulas of the received formula. In this method the LATTER is returned.

**Parameters**

|                       |                                                          |
|-----------------------|----------------------------------------------------------|
| <code>_backend</code> | The backend from which to obtain the infeasible subsets. |
|-----------------------|----------------------------------------------------------|

**Returns**

The infeasible subsets the given backend provides.

**0.15.178.4.49 `getInformationRelevantFormulas()`** `const std::set< FormulaT > & smtrat::Module::getInformationRelevantFormulas ( ) [protected], [inherited]`  
Gets all InformationRelevantFormulas.

**Returns**

Set of all formulas

**0.15.178.4.50 `getModelEqualities()`** `std::list< std::vector< carl::Variable > > smtrat::Module::getModelEqualities ( ) const [virtual], [inherited]`  
Partition the variables from the current model into equivalence classes according to their assigned value.  
The result is a set of equivalence classes of variables where all variables within one class are assigned the same value. Note that the number of classes may not be minimal, i.e. two classes may actually be equivalent.

**Returns**

Equivalence classes.

**0.15.178.4.51 `getOrigins()` [1/3]** `void smtrat::Module::getOrigins ( const FormulaT & _formula, FormulaSetT & _origins ) const [inline], [protected], [inherited]`

**Parameters**

|                       |  |
|-----------------------|--|
| <code>_formula</code> |  |
| <code>_origins</code> |  |

**0.15.178.4.52 `getOrigins()` [2/3]** `void smtrat::Module::getOrigins ( const FormulaT & _formula, FormulasT & _origins ) const [inline], [protected], [inherited]`

**Parameters**

|                       |  |
|-----------------------|--|
| <code>_formula</code> |  |
| <code>_origins</code> |  |

**0.15.178.4.53 `getOrigins()` [3/3]** `const FormulaT& smtrat::Module::getOrigins ( ModuleInput::const_iterator _formula ) const [inline], [protected], [inherited]`  
Gets the origins of the passed formula at the given position.

**Parameters**

|                       |                                                   |
|-----------------------|---------------------------------------------------|
| <code>_formula</code> | The position of a formula in the passed formulas. |
|-----------------------|---------------------------------------------------|

**Returns**

The origins of the passed formula at the given position.

**0.15.178.4.54 `getReceivedFormulaSimplified()`** `std::pair< bool, FormulaT >` `smtrat::PModule::getReceivedFormulaSimplified( )` [virtual], [inherited]

**Returns**

A pair of a Boolean and a formula, where the Boolean is true, if the received formula could be simplified to an equisatisfiable formula. The formula is equisatisfiable to this module's received formula, if the Boolean is true.

Reimplemented from [smtrat::Module](#).

**0.15.178.4.55 `hasLemmas()`** `bool smtrat::Module::hasLemmas( )` [inline], [inherited]

Checks whether this module or any of its backends provides any lemmas.

**0.15.178.4.56 `hasValidInfeasibleSubset()`** `bool smtrat::Module::hasValidInfeasibleSubset( ) const` [inherited]

**Returns**

true, if the module has at least one valid infeasible subset, that is all its elements are sub-formulas of the received formula (pointer must be equal).

**0.15.178.4.57 `id()`** `std::size_t smtrat::Module::id( ) const` [inline], [inherited]

**Returns**

A unique ID to identify this module instance.

**0.15.178.4.58 `infeasibleSubsets()`** `const std::vector<FormulaSetT>& smtrat::Module::infeasibleSubsets( ) const` [inline], [inherited]

**Returns**

The infeasible subsets of the set of received formulas (empty, if this module has not detected unsatisfiability of the conjunction of received formulas).

**0.15.178.4.59 `inform()`** `bool smtrat::Module::inform( const FormulaT & _constraint )` [inherited]

Informs the module about the given constraint.

It should be tried to inform this module about any constraint it could receive eventually before `assertSubformula` is called (preferably for the first time, but at least before adding a formula containing that constraint).

**Parameters**

|                          |                                 |
|--------------------------|---------------------------------|
| <code>_constraint</code> | The constraint to inform about. |
|--------------------------|---------------------------------|

**Returns**

false, if it can be easily decided whether the given constraint is inconsistent; true, otherwise.

**0.15.178.4.60 informBackends()** void smrat::Module::informBackends ( const FormulaT & \_constraint ) [inline], [protected], [inherited]

Informs all backends of this module about the given constraint.

**Parameters**

|                    |                                 |
|--------------------|---------------------------------|
| <i>_constraint</i> | The constraint to inform about. |
|--------------------|---------------------------------|

**0.15.178.4.61 informCore()** virtual bool smrat::Module::informCore (

const FormulaT & \_constraint ) [inline], [protected], [virtual], [inherited]

Informs the module about the given constraint.

It should be tried to inform this module about any constraint it could receive eventually before assertSubformula is called (preferably for the first time, but at least before adding a formula containing that constraint).

**Parameters**

|                    |                                 |
|--------------------|---------------------------------|
| <i>_constraint</i> | The constraint to inform about. |
|--------------------|---------------------------------|

**Returns**

false, if it can be easily decided whether the given constraint is inconsistent; true, otherwise.

Reimplemented in [smrat::UnionFindModule< Settings >](#), [smrat::PBPPModule< Settings >](#), [smrat::PBGaussModule< Settings >](#), [smrat::NRAILModule< Settings >](#), [smrat::NewCoveringModule< Settings >](#), [smrat::NewCADModule< Settings >](#), [smrat::LRAModule< Settings >](#), [smrat::LRAModule< LRASettingsICP >](#), [smrat::LRAModule< LRASettings1 >](#), [smrat::IntBlastModule< Settings >](#), [smrat::FPPModule< Settings >](#), [smrat::EQModule< Settings >](#), [smrat::CurryModule< Settings >](#), [smrat::BVMModule< Settings >](#), [smrat::ICPModule< Settings >](#), [smrat::ICPModule< ICPSettings4 >](#), and [smrat::ICPModule< ICPSettings1 >](#).

**0.15.178.4.62 informedConstraints()** const carl::FastSet<FormulaT>& smrat::Module::informedConstraints ( ) const [inline], [inherited]

**Returns**

The position of the first constraint of which no backend has been informed about.

**0.15.178.4.63 init()** void smrat::Module::init ( ) [virtual], [inherited]

Informs all backends about the so far encountered constraints, which have not yet been communicated.

This method must not be called twice and only before the first runBackends call.

Reimplemented in [smrat::PBPPModule< Settings >](#), [smrat::PBGaussModule< Settings >](#), [smrat::NRAILModule< Settings >](#), [smrat::NewCoveringModule< Settings >](#), [smrat::NewCADModule< Settings >](#), [smrat::LRAModule< Settings >](#), [smrat::LRAModule< LRASettingsICP >](#), [smrat::LRAModule< LRASettings1 >](#), [smrat::IntBlastModule< Settings >](#), [smrat::FPPModule< Settings >](#), [smrat::EQModule< Settings >](#), [smrat::CurryModule< Settings >](#), and [smrat::BVMModule< Settings >](#).

**0.15.178.4.64 is\_minimizing()** bool smrat::Module::is\_minimizing ( ) const [inline], [inherited]

**0.15.178.4.65 `isLemmaLevel()`** `bool smtrat::Module::isLemmaLevel (``LemmaLevel level ) [protected], [inherited]`

Checks if current lemma level is greater or equal to given level.

**Parameters**

|                    |                 |
|--------------------|-----------------|
| <code>level</code> | Level to check. |
|--------------------|-----------------|

**0.15.178.4.66 `isPreprocessor()`** `bool smtrat::PModule::isPreprocessor ( ) const [inline], [inherited]`**Returns**

true, if this module is a preprocessor that is a module, which simplifies its received formula to an equisatisfiable formula being passed to its backends. The simplified formula can be obtained with [getReceivedFormulaSimplified\(\)](#).

**0.15.178.4.67 `lemmas()`** `const std::vector<Lemma>& smtrat::Module::lemmas ( ) const [inline], [inherited]`**Returns**

A constant reference to the lemmas being valid formulas this module or its backends made.

**0.15.178.4.68 `merge()`** `std::vector< FormulaT > smtrat::Module::merge (``const std::vector< FormulaT > & _vecSetA,``const std::vector< FormulaT > & _vecSetB ) const [protected], [inherited]`

Merges the two vectors of sets into the first one.

({a,b},{a,c}) and ({b,d},{b}) -> ({a,b,d},{a,b},{a,b,c,d},{a,b,c})

**Parameters**

|                       |                                  |
|-----------------------|----------------------------------|
| <code>_vecSetA</code> | A vector of sets of constraints. |
| <code>_vecSetB</code> | A vector of sets of constraints. |

**Returns**

The vector being the two given vectors merged.

**0.15.178.4.69 `model()`** `const Model& smtrat::Module::model ( ) const [inline], [inherited]`**Returns**

The assignment of the current satisfiable result, if existent.

**0.15.178.4.70 `modelsDisjoint()`** `bool smtrat::Module::modelsDisjoint (``const Model & _modelA,``const Model & _modelB ) [static], [protected], [inherited]`

Checks whether there is no variable assigned by both models.

**Parameters**

|                      |                                |
|----------------------|--------------------------------|
| <code>_modelA</code> | The first model to check for.  |
| <code>_modelB</code> | The second model to check for. |

**Returns**

true, if there is no variable assigned by both models; false, otherwise.

**0.15.178.4.71 `moduleName()`** `virtual std::string smtrat::Module::moduleName( ) const [inline], [virtual], [inherited]`

**Returns**

The name of the given module type as name.

Reimplemented in `smtrat::VSModule< Settings >`, `smtrat::UnionFindModule< Settings >`, `smtrat::UFCegarModule< Settings >`, `smtrat::STropModule< Settings >`, `smtrat::SplitSOSModule< Settings >`, `smtrat::PBPPModule< Settings >`, `smtrat::PBGaussModule< Settings >`, `smtrat::NRAILModule< Settings >`, `smtrat::NewCADModule< Settings >`, `smtrat::LVEModule< Settings >`, `smtrat::LRAModule< Settings >`, `smtrat::LRAModule< LRASettingsICP >`, `smtrat::LRAModule< LRASettings1 >`, `smtrat::IntEqModule< Settings >`, `smtrat::IntBlastModule< Settings >`, `smtrat::IncWidthModule< Settings >`, `smtrat::ICPModule< Settings >`, `smtrat::ICPModule< ICPSettings4 >`, `smtrat::ICPModule< ICPSettings1 >`, `smtrat::GBModule< Settings >`, `smtrat::FouMoModule< Settings >`, `smtrat::EQPreprocessingModule< Settings >`, `smtrat::EQModule< Settings >`, `smtrat::CurryModule< Settings >`, `smtrat::CubeLIAModule< Settings >`, `smtrat::CSplitModule< Settings >`, `smtrat::BVMModule< Settings >`, and `smtrat::BEModule< Settings >`.

**0.15.178.4.72 `objective()`** `carl::Variable smtrat::Module::objective( ) const [inline], [inherited]`

**0.15.178.4.73 `originInReceivedFormula()`** `bool smtrat::Module::originInReceivedFormula( const FormulaT & _origin ) const [protected], [inherited]`

**0.15.178.4.74 `passedFormulaBegin()`** `ModuleInput::iterator smtrat::Module::passedFormulaBegin( ) [inline], [protected], [inherited]`

**Returns**

An iterator to the end of the passed formula. TODO: disable this method

**0.15.178.4.75 `passedFormulaEnd()`** `ModuleInput::iterator smtrat::Module::passedFormulaEnd( ) [inline], [protected], [inherited]`

**Returns**

An iterator to the end of the passed formula.

**0.15.178.4.76 `pPassedFormula()`** `const ModuleInput* smtrat::Module::pPassedFormula( ) const [inline], [inherited]`

**Returns**

A pointer to the formula passed to the backends of this module.

**0.15.178.4.77 pReceivedFormula()** const `ModuleInput*` smtrat::Module::pReceivedFormula ( ) const [inline], [inherited]

**Returns**

A pointer to the formula passed to this module.

**0.15.178.4.78 print()** void smtrat::Module::print ( const std::string & `_initiation` = "\*\*\*" ) const [inherited]  
Prints everything relevant of the solver.

**Parameters**

|                          |                      |
|--------------------------|----------------------|
| <code>_initiation</code> | The line initiation. |
|--------------------------|----------------------|

**0.15.178.4.79 printAllModels()** void smtrat::Module::printAllModels ( std::ostream & `_out` = `std::cout` ) [inherited]

Prints all assignments of this module satisfying its received formula if it satisfiable and this module could find an assignment.

**Parameters**

|                   |                                        |
|-------------------|----------------------------------------|
| <code>_out</code> | The stream to print the assignment on. |
|-------------------|----------------------------------------|

**0.15.178.4.80 printInfeasibleSubsets()** void smtrat::Module::printInfeasibleSubsets ( const std::string & `_initiation` = "\*\*\*" ) const [inherited]

Prints the infeasible subsets.

**Parameters**

|                          |                      |
|--------------------------|----------------------|
| <code>_initiation</code> | The line initiation. |
|--------------------------|----------------------|

**0.15.178.4.81 printModel()** void smtrat::Module::printModel ( std::ostream & `_out` = `std::cout` ) const [inherited]

Prints the assignment of this module satisfying its received formula if it satisfiable and this module could find an assignment.

**Parameters**

|                   |                                        |
|-------------------|----------------------------------------|
| <code>_out</code> | The stream to print the assignment on. |
|-------------------|----------------------------------------|

**0.15.178.4.82 printPassedFormula()** void smtrat::Module::printPassedFormula ( const std::string & `_initiation` = "\*\*\*" ) const [inherited]

Prints the vector of passed formula.

**Parameters**

|                          |                      |
|--------------------------|----------------------|
| <code>_initiation</code> | The line initiation. |
|--------------------------|----------------------|

**0.15.178.4.83 printReceivedFormula()** void smtrat::Module::printReceivedFormula ( const std::string & *\_initiation* = "\*\*\*" ) const [inherited]

Prints the vector of the received formula.

#### Parameters

|                    |                      |
|--------------------|----------------------|
| <i>_initiation</i> | The line initiation. |
|--------------------|----------------------|

**0.15.178.4.84 probablyLooping()** bool smtrat::Module::probablyLooping (

const typename Poly::PolyType & *\_branchingPolynomial*,  
const Rational & *\_branchingValue* ) const [protected], [inherited]

Checks whether given the current branching value and branching variable/polynomial it is (highly) probable that this branching is part of an infinite loop of branchings.

#### Parameters

|                             |                                                                                     |
|-----------------------------|-------------------------------------------------------------------------------------|
| <i>_branchingPolynomial</i> | The polynomial to branch at (in most branching strategies this is just a variable). |
| <i>_branchingValue</i>      | The value to branch at.                                                             |

#### Returns

true, if this branching is probably part of an infinite loop of branchings; false, otherwise.

**0.15.178.4.85 receivedFormulaChecked()** void smtrat::Module::receivedFormulaChecked ( ) [inline], [inherited]

Notifies that the received formulas has been checked.

**0.15.178.4.86 receivedFormulasAsInfeasibleSubset()** void smtrat::Module::receivedFormulasAsInfeasibleSubset (

ModuleInput::const\_iterator *\_subformula* ) [inline], [protected], [inherited]

Stores an infeasible subset consisting only of the given received formula.

**0.15.178.4.87 receivedVariable()** bool smtrat::Module::receivedVariable ( carl::Variable::Arg *\_var* ) const [inline], [inherited]

**0.15.178.4.88 remove()** void smtrat::PModule::remove (

ModuleInput::const\_iterator *\_subformula* ) [virtual], [inherited]

Removes everything related to the given sub-formula of the received formula.

However, it is desired not to lose track of search spaces where no satisfying assignment can be found for the remaining sub-formulas.

#### Parameters

|                    |                                                    |
|--------------------|----------------------------------------------------|
| <i>_subformula</i> | The sub formula of the received formula to remove. |
|--------------------|----------------------------------------------------|

Reimplemented from [smtrat::Module](#).

**0.15.178.4.89 removeCore()** `virtual void smrat::Module::removeCore (`  
    `ModuleInput::const_iterator formula ) [inline], [protected], [virtual], [inherited]`

Removes everything related to the given sub-formula of the received formula.

However, it is desired not to lose track of search spaces where no satisfying assignment can be found for the remaining sub-formulas.

#### Parameters

|                      |                                                    |
|----------------------|----------------------------------------------------|
| <code>formula</code> | The sub formula of the received formula to remove. |
|----------------------|----------------------------------------------------|

Reimplemented in [smrat::VSModule< Settings >](#), [smrat::SATModule< Settings >](#), [smrat::PFEModule< Settings >](#), [smrat::ICPModule< Settings >](#), [smrat::ICPModule< ICPSettings4 >](#), [smrat::ICPModule< ICPSettings1 >](#), [smrat::UnionFindModule< Settings >](#), [smrat::UFCegarModule< Settings >](#), [smrat::STropModule< Settings >](#), [smrat::PBPPModule< Settings >](#), [smrat::PBGaussModule< Settings >](#), [smrat::NRAILModule< Settings >](#), [smrat::NewCoveringModule< Settings >](#), [smrat::NewCADModule< Settings >](#), [smrat::LRAModule< Settings >](#), [smrat::LRAModule< LRASettingsICP >](#), [smrat::LRAModule< LRASettings1 >](#), [smrat::IntEqModule< Settings >](#), [smrat::IntBlastModule< Settings >](#), [smrat::IncWidthModule< Settings >](#), [smrat::ICEModule< Settings >](#), [smrat::FPPModule< Settings >](#), [smrat::FouMoModule< Settings >](#), [smrat::EQModule< Settings >](#), [smrat::CurryModule< Settings >](#), [smrat::CubeLIAModule< Settings >](#), [smrat::CSplitModule< Settings >](#), [smrat::BVModule< Settings >](#), and [smrat::GBModule< Settings >](#).

**0.15.178.4.90 removeOrigin()** `std::pair<ModuleInput::iterator,bool> smrat::Module::removeOrigin (`  
    `ModuleInput::iterator _formula,`  
    `const FormulaT & _origin ) [inline], [protected], [inherited]`

**0.15.178.4.91 removeOrigins()** `std::pair<ModuleInput::iterator,bool> smrat::Module::removeOrigins (`  
    `ModuleInput::iterator _formula,`  
    `const std::shared_ptr< std::vector< FormulaT >> & _origins ) [inline], [protected],`  
    `[inherited]`

**0.15.178.4.92 rPassedFormula()** `const ModuleInput& smrat::Module::rPassedFormula ( ) const`  
    `[inline], [inherited]`

#### Returns

A reference to the formula passed to the backends of this module.

**0.15.178.4.93 rReceivedFormula()** `const ModuleInput& smrat::Module::rReceivedFormula ( ) const`  
    `[inline], [inherited]`

#### Returns

A reference to the formula passed to this module.

**0.15.178.4.94 runBackends() [1/2]** `virtual Answer smrat::PModule::runBackends ( ) [inline],`  
    `[virtual], [inherited]`

Reimplemented from [smrat::Module](#).

**0.15.178.4.95 runBackends()** [2/2] [Answer](#) smtrat::PModule::runBackends (

```
 bool _final,
 bool _full,
 carl::Variable _objective) [virtual], [inherited]
```

Runs the backend solvers on the passed formula.

#### Parameters

|                         |                                                                                                                                       |
|-------------------------|---------------------------------------------------------------------------------------------------------------------------------------|
| <code>_final</code>     | true, if this satisfiability check will be the last one (for a global sat-check), if its result is SAT.                               |
| <code>_full</code>      | false, if this module should avoid too expensive procedures and rather return unknown instead.                                        |
| <code>_objective</code> | if not set to NO_VARIABLE, the module should find an assignment minimizing this objective variable; otherwise any assignment is good. |

#### Returns

True, if the passed formula is consistent; False, if the passed formula is inconsistent; Unknown, otherwise.

Reimplemented from [smtrat::Module](#).

**0.15.178.4.96 setId()** void smtrat::Module::setId (

```
 std::size_t _id) [inline], [inherited]
```

Sets this modules unique ID to identify itself.

#### Parameters

|                 |                                    |
|-----------------|------------------------------------|
| <code>id</code> | The id to set this module's id to. |
|-----------------|------------------------------------|

**0.15.178.4.97 setThreadPriority()** void smtrat::Module::setThreadPriority (

```
 thread_priority _threadPriority) [inline], [inherited]
```

Sets the priority of this module to get a thread for running its check procedure.

#### Parameters

|                              |                                                       |
|------------------------------|-------------------------------------------------------|
| <code>_threadPriority</code> | The priority to set this module's thread priority to. |
|------------------------------|-------------------------------------------------------|

**0.15.178.4.98 solverState()** [Answer](#) smtrat::Module::solverState ( ) const [inline], [inherited]

#### Returns

True, if this module is in a state, such that it has found a solution for its received formula; False, if this module is in a state, such that it has determined that there is no solution for its received formula; Unknown, otherwise.

**0.15.178.4.99 splitUnequalConstraint()** void smtrat::Module::splitUnequalConstraint (

```
 const FormulaT & _unequalConstraint) [protected], [inherited]
```

Adds the following lemmas for the given constraint p!=0.

$(p \neq 0 \leftrightarrow (p < 0 \text{ or } p > 0))$

and  $\neg(p < 0 \text{ and } p > 0)$

**Parameters**

|                                 |                                             |
|---------------------------------|---------------------------------------------|
| <code>_unequalConstraint</code> | A constraint having the relation symbol !=. |
|---------------------------------|---------------------------------------------|

**0.15.178.4.100 `threadPriority()`** `thread_priority` `smtrat::Module::threadPriority () const [inline], [inherited]`

**Returns**

The priority of this module to get a thread for running its check procedure.

**0.15.178.4.101 `updateAllModels()`** `void smtrat::Module::updateAllModels () [virtual], [inherited]`  
Updates all satisfying models, if the solver has detected the consistency of the received formula, beforehand.  
Reimplemented in `smtrat::SATModule< Settings >`.

**0.15.178.4.102 `updateLemmas()`** `void smtrat::Module::updateLemmas () [inherited]`  
Stores all lemmas of any backend of this module in its own lemma vector.

**0.15.178.4.103 `updateModel()`** `template<typename Settings > void smtrat::ESModule< Settings >::updateModel () const [virtual]`  
Updates the current assignment into the model.

Note, that this is a unique but possibly symbolic assignment maybe containing newly introduced variables.  
Reimplemented from `smtrat::Module`.

**0.15.178.4.104 `usedBackends()`** `const std::vector<Module*>& smtrat::Module::usedBackends () const [inline], [inherited]`

**Returns**

The backends of this module which are currently used (conditions to use this module are fulfilled for the passed formula).

## 0.15.178.5 Field Documentation

**0.15.178.5.1 `mAllBackends`** `std::vector<Module*> smtrat::Module::mAllBackends [protected], [inherited]`  
The backends of this module which have been used.

**0.15.178.5.2 `mAllModels`** `std::vector<Model> smtrat::Module::mAllModels [mutable], [protected], [inherited]`  
Stores all satisfying assignments.

**0.15.178.5.3 `mBackendsFoundAnswer`** `std::atomic_bool* smtrat::Module::mBackendsFoundAnswer [protected], [inherited]`  
This flag is passed to any backend and if it determines an answer to a prior check call, this flag is fired.

**0.15.178.5.4 mConstraintsToInform** `carl::FastSet<FormulaT> smrat::Module::mConstraintsToInform` [protected], [inherited]  
Stores the constraints which the backends must be informed about.

**0.15.178.5.5 mFinalCheck** `bool smrat::Module::mFinalCheck` [protected], [inherited]  
true, if the check procedure should perform a final check which especially means not to postpone splitting decisions

**0.15.178.5.6 mFirstPosInLastBranches** `std::size_t smrat::Module::mFirstPosInLastBranches = 0` [static], [inherited]  
The beginning of the cyclic buffer storing the last branches.

**0.15.178.5.7 mFirstSubformulaToPass** `ModuleInput::iterator smrat::Module::mFirstSubformulaToPass` [protected], [inherited]  
Stores the position of the first sub-formula in the passed formula, which has not yet been considered for a consistency check of the backends.

**0.15.178.5.8 mFirstUncheckedReceivedSubformula** `ModuleInput::const_iterator smrat::Module::mFirstUncheckedReceivedSubformula` [protected], [inherited]  
Stores the position of the first (by this module) unchecked sub-formula of the received formula.

**0.15.178.5.9 mFoundAnswer** `Conditionals smrat::Module::mFoundAnswer` [protected], [inherited]  
Vector of Booleans: If any of them is true, we have to terminate a running check procedure.

**0.15.178.5.10 mFullCheck** `bool smrat::Module::mFullCheck` [protected], [inherited]  
false, if this module should avoid too expensive procedures and rather return unknown instead.

**0.15.178.5.11 mInfeasibleSubsets** `std::vector<FormulaSet> smrat::Module::mInfeasibleSubsets` [protected], [inherited]  
Stores the infeasible subsets.

**0.15.178.5.12 mInformedConstraints** `carl::FastSet<FormulaT> smrat::Module::mInformedConstraints` [protected], [inherited]  
Stores the position of the first constraint of which no backend has been informed about.

**0.15.178.5.13 mLastBranches** `std::vector<Branching> smrat::Module::mLastBranches = std::vector<Branching>(mNumOfBranchVarsToStore, Branching(typename Poly::PolyType(), 0))` [static], [inherited]  
Stores the last branches in a cycle buffer.

**0.15.178.5.14 mLemmas** `std::vector<Lemma> smrat::Module::mLemmas` [protected], [inherited]  
Stores the lemmas being valid formulas this module or its backends made.

**0.15.178.5.15 mModel** `Model smrat::Module::mModel` [mutable], [protected], [inherited]  
Stores the assignment of the current satisfiable result, if existent.

**0.15.178.5.16 mModelComputed** bool smtrat::Module::mModelComputed [mutable], [protected], [inherited]  
True, if the model has already been computed.

**0.15.178.5.17 mNumOfBranchVarsToStore** std::size\_t smtrat::Module::mNumOfBranchVarsToStore = 5 [static], [inherited]  
The number of different variables to consider for a probable infinite loop of branchings.

**0.15.178.5.18 mObjectiveVariable** carl::Variable smtrat::Module::mObjectiveVariable [protected], [inherited]  
Objective variable to be minimized. If set to NO\_VARIABLE, a normal sat check should be performed.

**0.15.178.5.19 mOldSplittingVariables** std::vector<FormulaT> smtrat::Module::mOldSplittingVariables [static], [inherited]  
Reusable splitting variables.

**0.15.178.5.20 mpManager** Manager\* const smtrat::Module::mpManager [protected], [inherited]  
A reference to the manager.

**0.15.178.5.21 mSmallerMusesCheckCounter** unsigned smtrat::Module::mSmallerMusesCheckCounter [mutable], [protected], [inherited]  
Counter used for the generation of the smt2 files to check for smaller muses.

**0.15.178.5.22 mSolverState** std::atomic<Answer> smtrat::Module::mSolverState [protected], [inherited]  
States whether the received formula is known to be satisfiable or unsatisfiable otherwise it is set to unknown.

**0.15.178.5.23 mTheoryPropagations** std::vector<TheoryPropagation> smtrat::Module::mTheoryPropagations [protected], [inherited]

**0.15.178.5.24 mUsedBackends** std::vector<Module\*> smtrat::Module::mUsedBackends [protected], [inherited]  
The backends of this module which are currently used (conditions to use this module are fulfilled for the passed formula).

**0.15.178.5.25 mVariableCounters** std::vector<std::size\_t> smtrat::Module::mVariableCounters [protected], [inherited]  
Maps variables to the number of their occurrences.

## 0.15.179 smtrat::uf\_impl::estimator< IteratorType, IsRandomAccess > Struct Template Reference

Distance estimation for a range delimited by iterators; if the given iterators are random access, returns the result of std::distance in the estimate\_distance function.

```
#include <union_find.h>
```

### Static Public Member Functions

- static std::size\_t `estimate_distance` (IteratorType begin, IteratorType end) noexcept

#### 0.15.179.1 Detailed Description

```
template<typename IteratorType, bool IsRandomAccess = std::is_convertible< typename std::iterator_traits<IteratorType>::iterator_category, std::random_access_iterator_tag >::value>
struct smtrat::uf_impl::estimator< IteratorType, IsRandomAccess >
```

Distance estimation for a range delimited by iterators; if the given iterators are random access, returns the result of `std::distance` in the `estimate_distance` function.

Otherwise, it simply returns 0.

#### 0.15.179.2 Member Function Documentation

```
0.15.179.2.1 estimate_distance() template<typename IteratorType , bool IsRandomAccess = std::is_convertible< typename std::iterator_traits<IteratorType>::iterator_category, std::random_access_iterator_tag >::value>
static std::size_t smtrat::uf_impl::estimator< IteratorType, IsRandomAccess >::estimate_distance (
 IteratorType begin,
 IteratorType end) [inline], [static], [noexcept]
```

### 0.15.180 smtrat::uf\_impl::estimator< IteratorType, false > Struct Template Reference

```
#include <union_find.h>
```

### Static Public Member Functions

- static constexpr std::size\_t `estimate_distance` (IteratorType, IteratorType) noexcept

#### 0.15.180.1 Member Function Documentation

```
0.15.180.1.1 estimate_distance() template<typename IteratorType >
static constexpr std::size_t smtrat::uf_impl::estimator< IteratorType, false >::estimate_distance (
 IteratorType ,
 IteratorType) [inline], [static], [constexpr], [noexcept]
```

### 0.15.181 smtrat::ExactlyOneCommanderEncoder Class Reference

```
#include <ExactlyOneCommanderEncoder.h>
```

### Public Member Functions

- `ExactlyOneCommanderEncoder ()`
- `Rational encodingSize (const ConstraintT &constraint)`
- `bool canEncode (const ConstraintT &constraint)`

### 0.15.186 smtrat::mcsat::nlsat::Explanation Struct Reference

```
#include <Explanation.h>
```

#### Public Member Functions

- std::optional< mcsat::Explanation > operator() (const mcsat::Bookkeeping &data, carl::Variable var, const FormulasT &reason, bool) const

We construct a formula ' $E \rightarrow I$ ', i.e.

#### 0.15.186.1 Member Function Documentation

```
0.15.186.1.1 operator() std::optional< mcsat::Explanation > smtrat::mcsat::nlsat::Explanation<->::operator() (
 const mcsat::Bookkeeping & data,
 carl::Variable var,
 const FormulasT & reason,
 bool) const
```

We construct a formula ' $E \rightarrow I$ ', i.e.

'e1 & e2 ... en -> i', called "Explanation", in its clausal form ' $-e_1 \vee -e_2 \dots \vee -e_n \vee i$ ', where e1, e2.. are reason Atoms and CAD cell bound atoms, and i is the implication. It "explains" why the assignment point in data is inconsistent with the reason atoms/constraints and the implication in that it constructs a whole region of assignments points, which the assignment point in data is a part of.

#### Parameters

|                         |                                                                                                                                                                                                                                                                                                                                                          |
|-------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <i>variableOrdering</i> | Determine the order of variables, e.g. x1, x2, .. x10                                                                                                                                                                                                                                                                                                    |
| <i>data</i>             | Represent the assigned variables and their assigned values in different representations. These are a prefix of the <i>variableOrdering</i> , e.g. x1, x2, .. x5                                                                                                                                                                                          |
| <i>var</i>              | The smallest/first variable in the <i>variableOrdering</i> that is not assigned by <i>data</i> , e.g. x6                                                                                                                                                                                                                                                 |
| <i>reason</i>           | A collection of atoms that are inconsistent together or imply the <i>implication</i> . These atoms mention only variables x1, x2.. x6 (some atom definitely mentions x6) and possibly x7..x10 if they are irrelevant and "vanish" under the assignment in <i>data</i> , e.g. x1*x7+x6=0 (for x1 := 0) or x6*(x7^2+1)>0 (equiv to x6>0, since x7^2+1 > 0) |

```

#### 0.15.191.2 Member Function Documentation

```
0.15.191.2.1 generateExplanation() void smtrat::mcsat::nlsat::ExplanationGenerator::generate<Explanation (
```

```
 const FormulaT & impliedAtom,
 std::vector< FormulasT > & explainAtomsInLvl) const [inline]
```

Construct explanation in non-clausal form (without the impliedAtom/implication).

It consists of atomic formulas as expressions for cell component bounds and the constraintAtoms for which a CAD was constructed. Each cell component creates zero, one or two explanation atoms. The impliedAtom is not added to facilitate conversion into a clausal form afterwards.

```
0.15.191.2.2 getExplanation() mcsat::Explanation smtrat::mcsat::nlsat::ExplanationGenerator< ::getExplanation (
```

```
 const FormulaT & impliedAtom) const [inline]
```

Compute explanation in clausal form.

- `Valuation valuateVariable (const Objects &o, carl::Variable v) const`
- `std::vector< carl::Variable > sortVariables (const Objects &o, std::vector< carl::Variable > vars) const`

### Data Fields

- `std::vector< std::tuple< Extractor, std::size_t, double > > mFeatures`

#### 0.15.202.1 Detailed Description

```
template<typename Objects>
struct smtrat::mcsat::variableordering::detail::FeatureCollector< Objects >
```

This class manages features that are used to valuate variables on objects.

Each feature consists of a valuation function, a level and a weight. All feature valuations of a certain level are combined linearly using the respective weights. Valuations are then compared lexicographically.

#### 0.15.202.2 Member Typedef Documentation

```
0.15.202.2.1 Extractor template<typename Objects >
using smtrat::mcsat::variableordering::detail::FeatureCollector< Objects >::Extractor = std::function<double(Objects, carl::Variable)>
```

- [template<typename T2 > CONSTEXPR bool operator!=\(const fixedsize\\_allocator< T2 > &\) const NOEXCEPT](#)

### 0.15.203.1 Detailed Description

```
template<typename T>
class smtrat::fixedsize_allocator< T >
```

An allocator meant to be used for containers that typically allocate single objects or nodes, such as sets, maps and linked lists.

For any allocation that allocates more than one element at once, this falls back to std::allocator. With this allocator, free consists of two single pointer operations only. Allocate is almost always as cheap as free.

### 0.15.203.2 Constructor & Destructor Documentation

```
0.15.203.2.1 fixedsize_allocator() [1/3] template<typename T >
smtrat::fixedsize_allocator< T >::fixedsize_allocator () [inline]
```

```
0.15.203.2.2 fixedsize_allocator() [2/3] template<typename T >
smtrat::fixedsize_allocator< T >::fixedsize_allocator (

## 0.15.208 smtrat::impl::fixedsize\_allocator\_size\_helper< T, Size > Class Template Reference

```
#include <alloc.h>
```

## 0.15.209 smtrat::fixedsize\_freelist< ChunkSizeShift > Class Template Reference

Implements a fixed-(at-compile-time)-size allocator based on a free list embedded in the space of currently unused objects.

```
#include <alloc.h>
```

### Public Member Functions

- **fixedsize\_freelist ()**
- **~fixedsize\_freelist ()**
- **void \* alloc ()**  
*Allocate an object of size 1<<ChunkSizeShift.*
- **void free (void \*ptr) NOEXCEPT**  
*Freeing means just prepending the free'd element to the front of the freelist.*

### 0.15.209.1 Detailed Description

```
template<std::size_t ChunkSizeShift>
class smtrat::fixedsize_freelist< ChunkSizeShift >
```

Implements a fixed-(at-compile-time)-size allocator based on a free list embedded in the space of currently unused objects.

### 0.15.209.2 Constructor & Destructor Documentation

```
0.15.209.2.1 fixedsize_freelist() template<std::size_t ChunkSizeShift>
smtrat::fixedsize_freelist< ChunkSizeShift >::fixedsize_freelist () [inline], [explicit]
```

```
0.15.209.2.2 ~fixedsize_freelist() template<std::size_t ChunkSizeShift>
smtrat::fixedsize_freelist< ChunkSizeShift >::~fixedsize_freelist () [inline]
```

### 0.15.209.3 Member Function Documentation

**0.15.209.3.1 alloc()** template<std::size\_t ChunkSizeShift>  
void\* smtrat::fixedsize\_freelist< ChunkSizeShift >::alloc ( ) [inline]  
Allocate an object of size  $1 \ll \text{ChunkSizeShift}$ .  
First, try to return the first entry on the freelist.  
If that is empty, try forward-allocation (allocating the next element on the current page that has never been allocated before.)  
Otherwise, go to the next page.  
If there is no next page, allocate a new page with malloc. This page has twice the space of the previous page.  
Start forward-allocation phase on the new page.

**0.15.209.3.2 free()** template<std::size\_t ChunkSizeShift>  
void smtrat::fixedsize\_freelist< ChunkSizeShift >::free ( void \* ptr ) [inline]

Freeling means just prepending the free'd element to the front of the freelist.

## 0.15.210 smtrat::impl::fixedsize\_freelists< SizeCurrent, SizeMax, LowEnough > Class Template Reference

Publicly derive from all [fixedsize\\_freelist](#) types with chunk sizes between SizeCurrent and SizeMax.

```
#include <alloc.h>
```

### 0.15.210.1 Detailed Description

```
template<std::size_t SizeCurrent, std::size_t SizeMax, bool LowEnough = (SizeCurrent < SizeMax)>
class smtrat::impl::fixedsize_freelists< SizeCurrent, SizeMax, LowEnough >
```

Publicly derive from all [fixedsize\\_freelist](#) types with chunk sizes between SizeCurrent and SizeMax.

## 0.15.211 smtrat::impl::fixedsize\_freelists< SizeCurrent, SizeMax, true > Class Template Reference

```
#include <alloc.h>
```

## 0.15.212 smtrat::parser::FixedWidthConstant< T > Struct Template Reference

Represents a constant of a fixed width.

### 0.15.216.1 Detailed Description

```
template<typename VertexProperty, typename EdgeProperty, bool UniqueVertices = true>
class smrat::ForwardHyperGraph< VertexProperty, EdgeProperty, UniqueVertices >
```

This class implements a forward hypergraph.

We define a hypergraph to be a graph structure \$(V,E)\$ where \$V\$ is a set of vertices and \$E \subseteq 2^V\$ a set of hyperedges. A hyperedge can connect an arbitrary number of vertices.

If a hypergraph is directed if every edge \$e \in E\$ is partitioned into \$I(e)\$ and \$O(e)\$ that are sets of incoming vertices and outgoing vertices, respectively. A forward hypergraph is directed and every edge has only a single incoming vertices, that is \$|I(e)| = 1\$. Note that we store edges as a mapping from the incoming vertex to a set of outgoing vertices and thus do not have an explicit incoming vertex in our edge representation.

This implementation of a forward hypergraph accepts arbitrary labels (called properties) for both vertices and edges. It relies on a dense list of vertices that are internally labeled starting from zero. Therefore, removal of vertices is not supported.

If the third template parameter UniqueVertices is set to true (being the default), we make sure that every vertex is unique with respect to its property. To make this possible, a vertex property may not be changed in this case which is enforced using a static assertion. No requirements are imposed on the edge properties.

This class supports both printing a simple text representation and writing a description to a dot file.

### 0.15.216.2 Member Typedef Documentation

**0.15.216.2.1 Vertex** `template<typename VertexProperty , typename EdgeProperty , bool UniqueVertices = true>`  
`using smrat::ForwardHyperGraph< VertexProperty, EdgeProperty, UniqueVertices >::Vertex =`  
`std::size_t`  
Internal type of a vertex.

### 0.15.216.3 Member Function Documentation

**0.15.216.3.1 begin()** `template<typename VertexProperty , typename EdgeProperty , bool UniqueVertices = true>`  
`Vertex smrat::ForwardHyperGraph< VertexProperty, EdgeProperty, UniqueVertices >::begin ()`  
const [inline]  
Returns the first vertex.

**0.15.216.3.2 end()** `template<typename VertexProperty , typename EdgeProperty , bool UniqueVertices = true>`  
`Vertex smrat::ForwardHyperGraph< VertexProperty, EdgeProperty, UniqueVertices >::end ()`  
const [inline]  
Returns the past-the-last vertex.

**0.15.216.3.3 newEdge() [1/2]** `template<typename VertexProperty , typename EdgeProperty , bool UniqueVertices = true>`  
`Edge& smrat::ForwardHyperGraph< VertexProperty, EdgeProperty, UniqueVertices >::newEdge (`  
const VertexProperty & source,  
const EdgeProperty & ep ) [inline]  
Creates a new edge where the given vertex is the incoming vertex that is labeled with the given edge property.

```
0.15.216.3.4 newEdge() [2/2] template<typename VertexProperty , typename EdgeProperty , bool UniqueVertices = true>
Edge& smtrat::ForwardHyperGraph< VertexProperty, EdgeProperty, UniqueVertices >::newEdge (
 Vertex source,
 const EdgeProperty & ep) [inline]
```

Creates a new edge where the given vertex is the incoming vertex that is labeled with the given edge property.

```
0.15.216.3.5 newVertex() template<typename VertexProperty , typename EdgeProperty , bool UniqueVertices = true>
Vertex smtrat::ForwardHyperGraph< VertexProperty, EdgeProperty, UniqueVertices >::newVertex (
 const VertexProperty & vp) [inline]
```

Returns a new vertex that is labeled with the given vertex property.

If UniqueVertices is set to true and a vector with the given property already exists, this vector is returned.

```
0.15.216.3.6 operator[]() [1/2] template<typename VertexProperty , typename EdgeProperty , bool UniqueVertices = true>
VertexProperty& smtrat::ForwardHyperGraph< VertexProperty, EdgeProperty, UniqueVertices >::operator[] (
 Vertex v) [inline]
```

Retrieves the vertex property for the given vertex.

This method is disabled if UniqueVertices is set to true.

```
0.15.216.3.7 operator[]() [2/2] template<typename VertexProperty , typename EdgeProperty , bool UniqueVertices = true>
const VertexProperty& smtrat::ForwardHyperGraph< VertexProperty, EdgeProperty, UniqueVertices >::operator[] (
 Vertex v) const [inline]
```

Retrieves the vertex property for the given vertex.

```
0.15.216.3.8 out() [1/2] template<typename VertexProperty , typename EdgeProperty , bool UniqueVertices = true>
const std::vector<Edge>& smtrat::ForwardHyperGraph< VertexProperty, EdgeProperty, UniqueVertices >::out (
 const VertexProperty & v) const [inline]
```

Retrieves all outgoing edges for the given vertex.

```
0.15.216.3.9 out() [2/2] template<typename VertexProperty , typename EdgeProperty , bool UniqueVertices = true>
const std::vector<Edge>& smtrat::ForwardHyperGraph< VertexProperty, EdgeProperty, UniqueVertices >::out (
 Vertex v) const [inline]
```

Retrieves all outgoing edges for the given vertex.

```
0.15.216.3.10 size() template<typename VertexProperty , typename EdgeProperty , bool UniqueVertices = true>
std::size_t smtrat::ForwardHyperGraph< VertexProperty, EdgeProperty, UniqueVertices >::size (
) const [inline]
```

Returns the number of vertices.

```
0.15.216.3.11 toDot() template<typename VertexProperty , typename EdgeProperty , bool UniqueVertices = true>
```

```
void smtrat::ForwardHyperGraph< VertexProperty, EdgeProperty, UniqueVertices >::toDot (
 const std::string & filename) const
Writes a representation of this graph to the given file.
```

#### 0.15.216.4 Friends And Related Function Documentation

```
0.15.216.4.1 operator<< template<typename VertexProperty , typename EdgeProperty , bool UniqueVertices = true>
template<typename VP , typename EP >
std::ostream& operator<< (
 std::ostream & os,
 const ForwardHyperGraph< VP, EP > & fhg) [friend]
Writes a textual representation of this graph to the given stream.
```

### 0.15.217 smtrat::FouMoModule< Settings > Class Template Reference

A module which applies the Fourier-Motzkin algorithm.

```
#include <FouMoModule.h>
```

#### Public Types

- **typedef Settings SettingsType**
- **enum class LemmaType : unsigned { NORMAL = 0 , PERMANENT = 1 }**

#### Public Member Functions

- **std::string moduleName () const**  
*The module has to take the given sub-formula of the received formula into account.*
- **FouMoModule (const ModuleInput \*\_formula, Conditionals &\_conditionals, Manager \*\_manager=NULL)**  
*Removes the subformula of the received formula at the given position to the considered ones of this module.*
- **~FouMoModule ()**
- **bool addCore (ModuleInput::const\_iterator \_subformula)**  
*The module has to take the given sub-formula of the received formula into account.*
- **void removeCore (ModuleInput::const\_iterator \_subformula)**  
*Updates the current assignment into the model.*
- **void updateModel () const**  
*Updates the current assignment into the model.*
- **Answer checkCore ()**  
*Checks the received formula for consistency.*
- **bool inform (const FormulaT &\_constraint)**  
*Informs the module about the given constraint.*
- **void deinform (const FormulaT &\_constraint)**  
*The inverse of informing about a constraint.*
- **virtual void init ()**  
*Informs all backends about the so far encountered constraints, which have not yet been communicated.*
- **bool add (ModuleInput::const\_iterator \_subformula)**  
*The module has to take the given sub-formula of the received formula into account.*
- **virtual Answer check (bool \_final=false, bool \_full=true, carl::Variable \_objective=carl::Variable::NO\_VARIABLE)**  
*Checks the received formula for consistency.*
- **virtual void remove (ModuleInput::const\_iterator \_subformula)**  
*Removes everything related to the given sub-formula of the received formula.*
- **virtual void updateAllModels ()**  
*Updates all satisfying models, if the solver has detected the consistency of the received formula, beforehand.*
- **virtual std::list< std::vector< carl::Variable > > getModelEqualities () const**

*Partition the variables from the current model into equivalence classes according to their assigned value.*

- `unsigned currentlySatisfiedByBackend (const FormulaT &_formula) const`
- `virtual unsigned currentlySatisfied (const FormulaT &) const`
- `bool receivedVariable (carl::Variable::Arg _var) const`
- `Answer solverState () const`
- `std::size_t id () const`
- `void setId (std::size_t _id)`

*Sets this modules unique ID to identify itself.*

- `thread_priority threadPriority () const`
- `void setThreadPriority (thread_priority _threadPriority)`

*Sets the priority of this module to get a thread for running its check procedure.*

- `const ModuleInput * pReceivedFormula () const`
- `const ModuleInput & rReceivedFormula () const`
- `const ModuleInput * pPassedFormula () const`
- `const ModuleInput & rPassedFormula () const`
- `const Model & model () const`
- `const std::vector< Model > & allModels () const`
- `const std::vector< FormulaSetT > & infeasibleSubsets () const`
- `const std::vector< Module * > & usedBackends () const`
- `const carl::FastSet< FormulaT > & constraintsToInform () const`
- `const carl::FastSet< FormulaT > & informedConstraints () const`
- `void addLemma (const FormulaT &_lemma, const LemmaType &_lt=LemmaType::NORMAL, const FormulaT &_preferredFormula=FormulaT(carl::FormulaType::TRUE))`

*Stores a lemma being a valid formula.*

- `bool hasLemmas ()`

*Checks whether this module or any of its backends provides any lemmas.*

- `void clearLemmas ()`

*Deletes all yet found lemmas.*

- `const std::vector< Lemma > & lemmas () const`
- `ModuleInput::const_iterator firstUncheckedReceivedSubformula () const`
- `ModuleInput::const_iterator firstSubformulaToPass () const`
- `void receivedFormulaChecked ()`

*Notifies that the received formulas has been checked.*

- `const smrat::Conditionals & answerFound () const`
- `bool isPreprocessor () const`
- `carl::Variable objective () const`
- `bool is_minimizing () const`
- `void excludeNotReceivedVariablesFromModel () const`

*Excludes all variables from the current model, which do not occur in the received formula.*

- `void updateLemmas ()`

*Stores all lemmas of any backend of this module in its own lemma vector.*

- `void collectTheoryPropagations ()`
- `void collectOrigins (const FormulaT &_formula, FormulasT &_origins) const`

*Collects the formulas in the given formula, which are part of the received formula.*

- `void collectOrigins (const FormulaT &_formula, FormulaSetT &_origins) const`
- `bool hasValidInfeasibleSubset () const`
- `void checkInfSubsetForMinimality (std::vector< FormulaSetT >::const_iterator _infsSubset, const std::string &filename="smaller_muses", unsigned _maxSizeDifference=1) const`

*Checks the given infeasible subset for minimality by storing all subsets of it, which have a smaller size which differs from the size of the infeasible subset not more than the given threshold.*

- `virtual std::pair< bool, FormulaT > getReceivedFormulaSimplified ()`
- `void print (const std::string &_initiation="***") const`

*Prints everything relevant of the solver.*

- void `printReceivedFormula` (const std::string &\_initiation="\*\*\*") const  
*Prints the vector of the received formula.*
- void `printPassedFormula` (const std::string &\_initiation="\*\*\*") const  
*Prints the vector of passed formula.*
- void `printInfeasibleSubsets` (const std::string &\_initiation="\*\*\*") const  
*Prints the infeasible subsets.*
- void `printModel` (std::ostream &\_out=std::cout) const  
*Prints the assignment of this module satisfying its received formula if it satisfiable and this module could find an assignment.*
- void `printAllModels` (std::ostream &\_out=std::cout)  
*Prints all assignments of this module satisfying its received formula if it satisfiable and this module could find an assignment.*

### Static Public Member Functions

- static void `freeSplittingVariable` (const `FormulaT` &\_splittingVariable)

### Static Public Attributes

- static size\_t `mNumOfBranchVarsToStore` = 5  
*The number of different variables to consider for a probable infinite loop of branchings.*
- static std::vector<`Branching`> `mLastBranches` = std::vector<`Branching`>(mNumOfBranchVarsToStore, `Branching`(typename Poly::PolyType(), 0))  
*Stores the last branches in a cycle buffer.*
- static size\_t `mFirstPosInLastBranches` = 0  
*The beginning of the cyclic buffer storing the last branches.*
- static std::vector<`FormulaT`> `mOldSplittingVariables`  
*Reusable splitting variables.*

### Protected Member Functions

- virtual bool `informCore` (const `FormulaT` &\_constraint)  
*Informs the module about the given constraint.*
- virtual void `deinformCore` (const `FormulaT` &\_constraint)  
*The inverse of informing about a constraint.*
- bool `anAnswerFound` () const  
*Checks for all antecedent modules and those which run in parallel with the same antecedent modules, whether one of them has determined a result.*
- void `clearModel` () const  
*Clears the assignment, if any was found.*
- void `clearModels` () const  
*Clears all assignments, if any was found.*
- void `cleanModel` () const  
*Substitutes variable occurrences by its model value in the model values of other variables.*
- `ModuleInput::iterator` `passedFormulaBegin` ()
- `ModuleInput::iterator` `passedFormulaEnd` ()
- void `addOrigin` (`ModuleInput::iterator` \_formula, const `FormulaT` &\_origin)  
*Adds the given set of formulas in the received formula to the origins of the given passed formula.*
- const `FormulaT` & `getOrigins` (`ModuleInput::const_iterator` \_formula) const  
*Gets the origins of the passed formula at the given position.*
- void `getOrigins` (const `FormulaT` &\_formula, `FormulasT` &\_origins) const
- void `getOrigins` (const `FormulaT` &\_formula, `FormulaSetT` &\_origins) const
- std::pair<`ModuleInput::iterator`, bool> `removeOrigin` (`ModuleInput::iterator` \_formula, const `FormulaT` &\_origin)

- std::pair< [ModuleInput::iterator](#), bool > [removeOrigins](#) ([ModuleInput::iterator](#) \_formula, const std::shared\_ptr< std::vector< [FormulaT](#) >> &\_origins)
- void [informBackends](#) (const [FormulaT](#) &\_constraint)
 

*Informs all backends of this module about the given constraint.*
- virtual void [addConstraintToInform](#) (const [FormulaT](#) &\_constraint)
 

*Adds a constraint to the collection of constraints of this module, which are informed to a freshly generated backend.*
- std::pair< [ModuleInput::iterator](#), bool > [addReceivedSubformulaToPassedFormula](#) ([ModuleInput::const\\_iterator](#) \_subformula)
 

*Copies the given sub-formula of the received formula to the passed formula.*
- bool [originInReceivedFormula](#) (const [FormulaT](#) &\_origin) const
 

*Adds the given formula to the passed formula with no origin.*
- std::pair< [ModuleInput::iterator](#), bool > [addSubformulaToPassedFormula](#) (const [FormulaT](#) &\_formula)
 

*Adds the given formula to the passed formula with no origin.*
- std::pair< [ModuleInput::iterator](#), bool > [addSubformulaToPassedFormula](#) (const [FormulaT](#) &\_formula, const std::shared\_ptr< std::vector< [FormulaT](#) >> &\_origins)
 

*Adds the given formula to the passed formula.*
- std::pair< [ModuleInput::iterator](#), bool > [addSubformulaToPassedFormula](#) (const [FormulaT](#) &\_formula, const [FormulaT](#) &\_origin)
 

*Adds the given formula to the passed formula.*
- void [generateTrivialInfeasibleSubset](#) ()
 

*Stores the trivial infeasible subset being the set of received formulas.*
- void [receivedFormulasAsInfeasibleSubset](#) ([ModuleInput::const\\_iterator](#) \_subformula)
 

*Stores an infeasible subset consisting only of the given received formula.*
- std::vector< [FormulaT](#) >::const\_iterator [findBestOrigin](#) (const std::vector< [FormulaT](#) > &\_origins) const
 

*Finds the best origin from the given set of origins.*
- void [getInfeasibleSubsets](#) ()
 

*Copies the infeasible subsets of the passed formula.*
- std::vector< [FormulaSetT](#) > [getInfeasibleSubsets](#) (const [Module](#) &\_backend) const
 

*Get the infeasible subsets the given backend provides.*
- const [Model](#) & [backendsModel](#) () const
 

*Stores the model of a backend which determined satisfiability of the passed formula in the model of this module.*
- void [getBackendsModel](#) () const
 

*Get the model of a backend which determined satisfiability of the passed formula in the model of this module.*
- void [getBackendsAllModels](#) () const
 

*Stores all models of a backend in the list of all models of this module.*
- virtual [Answer](#) [runBackends](#) (bool \_final, bool \_full, carl::Variable \_objective)
 

*Runs the backend solvers on the passed formula.*
- virtual [Answer](#) [runBackends](#) ()
 

*Runs the backend solvers on the passed formula.*
- virtual [ModuleInput::iterator](#) [eraseSubformulaFromPassedFormula](#) ([ModuleInput::iterator](#) \_subformula, bool \_ignoreOrigins=false)
 

*Removes everything related to the sub-formula to remove from the passed formula in the backends of this module.*
- void [clearPassedFormula](#) ()
 

*Clears the passed formula.*
- std::vector< [FormulaT](#) > [merge](#) (const std::vector< [FormulaT](#) > &, const std::vector< [FormulaT](#) > &) const
 

*Merges the two vectors of sets into the first one.*
- size\_t [determine\\_smallest\\_origin](#) (const std::vector< [FormulaT](#) > &origins) const
 

*Determines the smallest origin in the given vector.*
- bool [probablyLooping](#) (const typename Poly::PolyType &\_branchingPolynomial, const Rational &\_branchingValue) const
 

*Checks whether given the current branching value and branching variable/polynomial it is (highly) probable that this branching is part of an infinite loop of branchings.*
- bool [branchAt](#) (const [Poly](#) &\_polynomial, bool \_integral, const Rational &\_value, std::vector< [FormulaT](#) > &&\_premise, bool \_leftCaseWeak=true, bool \_preferLeftCase=true, bool \_useReceivedFormulaAsPremise=false)
 

*Adds a lemmas which provoke a branching for the given variable at the given value, if this module returns Unknown and there exists a preceding [SATModule](#).*

- bool `branchAt` (const `Poly` &\_polynomial, bool \_integral, const `Rational` &\_value, bool \_leftCaseWeak=true, bool \_preferLeftCase=true, bool \_useReceivedFormulaAsPremise=false, const std::vector<`FormulaT`> &\_premise=std::vector<`FormulaT`>())
- bool `branchAt` (carl::Variable::Arg \_var, const `Rational` &\_value, std::vector<`FormulaT`> &&\_premise, bool \_leftCaseWeak=true, bool \_preferLeftCase=true, bool \_useReceivedFormulaAsPremise=false)
- bool `branchAt` (carl::Variable::Arg \_var, const `Rational` &\_value, bool \_leftCaseWeak=true, bool \_preferLeftCase=true, bool \_useReceivedFormulaAsPremise=false, const std::vector<`FormulaT`> &\_premise=std::vector<`FormulaT`>())
- void `splitUnequalConstraint` (const `FormulaT` &)
 

*Adds the following lemmas for the given constraint p!=0.*
- unsigned `checkModel` () const
- void `addInformationRelevantFormula` (const `FormulaT` &formula)
 

*Adds a formula to the InformationRelevantFormula.*
- const std::set<`FormulaT`> & `getInformationRelevantFormulas` ()
 

*Gets all InformationRelevantFormulas.*
- bool `isLemmaLevel` (`LemmaLevel` level)
 

*Checks if current lemma level is greater or equal to given level.*

## Static Protected Member Functions

- static bool `modelsDisjoint` (const `Model` &\_modelA, const `Model` &\_modelB)
 

*Checks whether there is no variable assigned by both models.*

## Protected Attributes

- std::vector<`FormulaSetT`> `mInfeasibleSubsets`

*Stores the infeasible subsets.*
- `Manager` \*const `mpManager`

*A reference to the manager.*
- `Model` `mModel`

*Stores the assignment of the current satisfiable result, if existent.*
- std::vector<`Model`> `mAllModels`

*Stores all satisfying assignments.*
- bool `mModelComputed`

*True, if the model has already been computed.*
- bool `mFinalCheck`

*true, if the check procedure should perform a final check which especially means not to postpone splitting decisions*
- bool `mFullCheck`

*false, if this module should avoid too expensive procedures and rather return unknown instead.*
- carl::Variable `mObjectiveVariable`

*Objective variable to be minimized. If set to NO\_VARIABLE, a normal sat check should be performed.*
- std::vector<`TheoryPropagation`> `mTheoryPropagations`
- std::atomic<`Answer`> `mSolverState`

*States whether the received formula is known to be satisfiable or unsatisfiable otherwise it is set to unknown.*
- std::atomic\_bool \* `mBackendsFoundAnswer`

*This flag is passed to any backend and if it determines an answer to a prior check call, this flag is fired.*
- `Conditionals` `mFoundAnswer`

*Vector of Booleans: If any of them is true, we have to terminate a running check procedure.*
- std::vector<`Module` \*> `mUsedBackends`

*The backends of this module which are currently used (conditions to use this module are fulfilled for the passed formula).*
- std::vector<`Module` \*> `mAllBackends`

*The backends of this module which have been used.*

- `std::vector< Lemma > mLemmas`  
*Stores the lemmas being valid formulas this module or its backends made.*
- `ModuleInput::iterator mFirstSubformulaToPass`  
*Stores the position of the first sub-formula in the passed formula, which has not yet been considered for a consistency check of the backends.*
- `carl::FastSet< FormulaT > mConstraintsToInform`  
*Stores the constraints which the backends must be informed about.*
- `carl::FastSet< FormulaT > mInformedConstraints`  
*Stores the position of the first constraint of which no backend has been informed about.*
- `ModuleInput::const_iterator mFirstUncheckedReceivedSubformula`  
*Stores the position of the first (by this module) unchecked sub-formula of the received formula.*
- `unsigned mSmallerMusesCheckCounter`  
*Counter used for the generation of the smt2 files to check for smaller muses.*
- `std::vector< std::size_t > mVariableCounters`  
*Maps variables to the number of their occurrences.*

### 0.15.217.1 Detailed Description

```
template<typename Settings>
class smrat::FouMoModule< Settings >
```

A module which applies the Fourier-Motzkin algorithm.

### 0.15.217.2 Member Typedef Documentation

```
0.15.217.2.1 SettingsType template<typename Settings >
typedef Settings smrat::FouMoModule< Settings >::SettingsType
```

### 0.15.217.3 Member Enumeration Documentation

```
0.15.217.3.1 LemmaType enum smrat::Module::LemmaType : unsigned [strong], [inherited]
```

Enumerator

|           |  |
|-----------|--|
| NORMAL    |  |
| PERMANENT |  |

### 0.15.217.4 Constructor & Destructor Documentation

```
0.15.217.4.1 FouMoModule() template<typename Settings >
smrat::FouMoModule< Settings >::FouMoModule (
 const ModuleInput * _formula,
 Conditionals & _conditionals,
 Manager * _manager = NULL)
```

```
0.15.217.4.2 ~FouMoModule() template<typename Settings >
smrat::FouMoModule< Settings >::~FouMoModule () [inline]
```

### 0.15.217.5 Member Function Documentation

**0.15.217.5.1 add()** `bool smtrat::Module::add (`  
    `ModuleInput::const_iterator _subformula ) [inherited]`

The module has to take the given sub-formula of the received formula into account.

#### Parameters

|                          |                                                    |
|--------------------------|----------------------------------------------------|
| <code>_subformula</code> | The sub-formula to take additionally into account. |
|--------------------------|----------------------------------------------------|

#### Returns

false, if it can be easily decided that this sub-formula causes a conflict with the already considered sub-formulas; true, otherwise.

**0.15.217.5.2 addConstraintToInform()** `void smtrat::Module::addConstraintToInform (`  
    `const FormulaT & _constraint ) [protected], [virtual], [inherited]`

Adds a constraint to the collection of constraints of this module, which are informed to a freshly generated backend.

#### Parameters

|                          |                        |
|--------------------------|------------------------|
| <code>_constraint</code> | The constraint to add. |
|--------------------------|------------------------|

Reimplemented in [smtrat::SATModule< Settings >](#).

**0.15.217.5.3 addCore()** `template<typename Settings >`  
`bool smtrat::FouMoModule< Settings >::addCore (`  
    `ModuleInput::const_iterator _subformula ) [virtual]`

The module has to take the given sub-formula of the received formula into account.

#### Parameters

|                          |                                                    |
|--------------------------|----------------------------------------------------|
| <code>_subformula</code> | The sub-formula to take additionally into account. |
|--------------------------|----------------------------------------------------|

#### Returns

false, if it can be easily decided that this sub-formula causes a conflict with the already considered sub-formulas; true, otherwise.

Reimplemented from [smtrat::Module](#).

**0.15.217.5.4 addInformationRelevantFormula()** `void smtrat::Module::addInformationRelevantFormula (`  
    `const FormulaT & formula ) [protected], [inherited]`

Adds a formula to the InformationRelevantFormula.

#### Parameters

|                      |                |
|----------------------|----------------|
| <code>formula</code> | Formula to add |
|----------------------|----------------|

```
0.15.217.5.5 addLemma() void smtrat::Module::addLemma (
 const FormulaT & _lemma,
 const LemmaType & _lt = LemmaType::NORMAL,
 const FormulaT & _preferredFormula = FormulaT(carl::FormulaType::TRUE)) [inline],
[inherited]
```

Stores a lemma being a valid formula.

#### Parameters

|                   |                                                                       |
|-------------------|-----------------------------------------------------------------------|
| _lemma            | The eduction/lemma to store.                                          |
| _lt               | The type of the lemma.                                                |
| _preferredFormula | Hint for the next decision, which formula should be assigned to true. |

```
0.15.217.5.6 addOrigin() void smtrat::Module::addOrigin (
 ModuleInput::iterator _formula,
 const FormulaT & _origin) [inline], [protected], [inherited]
```

Adds the given set of formulas in the received formula to the origins of the given passed formula.

#### Parameters

|          |                                                           |
|----------|-----------------------------------------------------------|
| _formula | The passed formula to set the origins for.                |
| _origin  | A set of formulas in the received formula of this module. |

```
0.15.217.5.7 addReceivedSubformulaToPassedFormula() std::pair<ModuleInput::iterator,bool>
smtrat::Module::addReceivedSubformulaToPassedFormula (
```

```
 ModuleInput::const_iterator _subformula) [inline], [protected], [inherited]
```

Copies the given sub-formula of the received formula to the passed formula.

Note, that there is always a link between sub-formulas of the passed formulas to sub-formulas of the received formulas, which are responsible for its occurrence.

#### Parameters

|             |                                                  |
|-------------|--------------------------------------------------|
| _subformula | The sub-formula of the received formula to copy. |
|-------------|--------------------------------------------------|

```
0.15.217.5.8 addSubformulaToPassedFormula() [1/3] std::pair<ModuleInput::iterator,bool> smtrat::Module::addSubformulaToPassedFormula (
```

```
 const FormulaT & _formula) [inline], [protected], [inherited]
```

Adds the given formula to the passed formula with no origin.

Note that in the next call of this module's removeSubformula, all formulas in the passed formula without origins will be removed.

#### Parameters

|          |                                           |
|----------|-------------------------------------------|
| _formula | The formula to add to the passed formula. |
|----------|-------------------------------------------|

#### Returns

A pair to the position where the formula to add has been inserted (or its first sub-formula which has not yet been in the passed formula, in case the formula to add is a conjunction), and a Boolean stating whether anything has been added to the passed formula.

**0.15.217.5.9 addSubformulaToPassedFormula()** [2/3] std::pair<ModuleInput::iterator,bool> smrat→  
::Module::addSubformulaToPassedFormula ( const FormulaT & \_formula,  
const FormulaT & \_origin ) [inline], [protected], [inherited]

Adds the given formula to the passed formula.

#### Parameters

|          |                                                                                                                           |
|----------|---------------------------------------------------------------------------------------------------------------------------|
| _formula | The formula to add to the passed formula.                                                                                 |
| _origin  | The sub-formula of the received formula being responsible for the occurrence of the formula to add to the passed formula. |

#### Returns

A pair to the position where the formula to add has been inserted (or its first sub-formula which has not yet been in the passed formula, in case the formula to add is a conjunction), and a Boolean stating whether anything has been added to the passed formula.

**0.15.217.5.10 addSubformulaToPassedFormula()** [3/3] std::pair<ModuleInput::iterator,bool>  
smrat::Module::addSubformulaToPassedFormula ( const FormulaT & \_formula,  
const std::shared\_ptr<std::vector<FormulaT>> & \_origins ) [inline], [protected],  
[inherited]

Adds the given formula to the passed formula.

#### Parameters

|          |                                                                                                                                         |
|----------|-----------------------------------------------------------------------------------------------------------------------------------------|
| _formula | The formula to add to the passed formula.                                                                                               |
| _origins | The link of the formula to add to the passed formula to sub-formulas of the received formulas, which are responsible for its occurrence |

#### Returns

A pair to the position where the formula to add has been inserted (or its first sub-formula which has not yet been in the passed formula, in case the formula to add is a conjunction), and a Boolean stating whether anything has been added to the passed formula.

**0.15.217.5.11 allModels()** const std::vector<Model>& smrat::Module::allModels () const [inline],  
[inherited]

#### Returns

All satisfying assignments, if existent.

**0.15.217.5.12 anAnswerFound()** bool smrat::Module::anAnswerFound () const [inline], [protected],  
[inherited]

Checks for all antecedent modules and those which run in parallel with the same antecedent modules, whether one of them has determined a result.

#### Returns

True, if one of them has determined a result.

**0.15.217.5.13 answerFound()** const `smtrat::Conditionals`& `smtrat::Module::answerFound` ( ) const [inline], [inherited]

#### Returns

A vector of Booleans: If any of them is true, we have to terminate a running check procedure.

**0.15.217.5.14 backendsModel()** const `Model` & `smtrat::Module::backendsModel` ( ) const [protected], [inherited]

Stores the model of a backend which determined satisfiability of the passed formula in the model of this module.

**0.15.217.5.15 branchAt() [1/4]** bool `smtrat::Module::branchAt` ( carl::Variable::Arg `_var`, const `Rational` & `_value`, bool `_leftCaseWeak` = `true`, bool `_preferLeftCase` = `true`, bool `_useReceivedFormulaAsPremise` = `false`, const std::vector< `FormulaT` > & `_premise` = std::vector<`FormulaT`>() ) [inline], [protected], [inherited]

**0.15.217.5.16 branchAt() [2/4]** bool `smtrat::Module::branchAt` ( carl::Variable::Arg `_var`, const `Rational` & `_value`, std::vector< `FormulaT` > && `_premise`, bool `_leftCaseWeak` = `true`, bool `_preferLeftCase` = `true`, bool `_useReceivedFormulaAsPremise` = `false` ) [inline], [protected], [inherited]

**0.15.217.5.17 branchAt() [3/4]** bool `smtrat::Module::branchAt` ( const `Poly` & `_polynomial`, bool `_integral`, const `Rational` & `_value`, bool `_leftCaseWeak` = `true`, bool `_preferLeftCase` = `true`, bool `_useReceivedFormulaAsPremise` = `false`, const std::vector< `FormulaT` > & `_premise` = std::vector<`FormulaT`>() ) [inline], [protected], [inherited]

**0.15.217.5.18 branchAt() [4/4]** bool `smtrat::Module::branchAt` ( const `Poly` & `_polynomial`, bool `_integral`, const `Rational` & `_value`, std::vector< `FormulaT` > && `_premise`, bool `_leftCaseWeak` = `true`, bool `_preferLeftCase` = `true`, bool `_useReceivedFormulaAsPremise` = `false` ) [protected], [inherited]

Adds a lemmas which provoke a branching for the given variable at the given value, if this module returns Unknown and there exists a preceding `SATModule`.

Note that the given value is rounded down and up, if the given variable is integer-valued.

#### Parameters

|                          |                             |
|--------------------------|-----------------------------|
| <code>_polynomial</code> | The variable to branch for. |
|--------------------------|-----------------------------|

## Parameters

|                                           |                                                                                                                                                                                                                |
|-------------------------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>_integral</code>                    | A flag being true, if all variables in the polynomial to branch for are integral.                                                                                                                              |
| <code>_value</code>                       | The value to branch at.                                                                                                                                                                                        |
| <code>_premise</code>                     | The sub-formulas of the received formula from which the branch is followed. Note, that a premise is not necessary, as every branch is a valid formula. But a premise can prevent from branching unnecessarily. |
| <code>_leftCaseWeak</code>                | true, if a branching in the form of (or ( $\leq p b$ ) ( $> p b$ )) is desired. false, if a branching in the form of (or ( $< p b$ ) ( $\geq p b$ )) is desired.                                               |
| <code>_preferLeftCase</code>              | true, if the left case (polynomial less(or equal) 0 shall be chosen first. false, otherwise.                                                                                                                   |
| <code>_useReceivedFormulaAsPremise</code> | true, if the whole received formula should be used as premise                                                                                                                                                  |

### 0.15.217.5.19 `check()`

```
Answer smrat::Module::check (
 bool _final = false,
 bool _full = true,
 carl::Variable _objective = carl::Variable::NO_VARIABLE) [virtual], [inherited]
```

Checks the received formula for consistency.

Note, that this is an implementation of the satisfiability check of the conjunction of the so far received formulas, which does actually nothing but passing the problem to its backends. This implementation is only used internally and must be overwritten by any derived module.

## Parameters

|                         |                                                                                                                                       |
|-------------------------|---------------------------------------------------------------------------------------------------------------------------------------|
| <code>_final</code>     | true, if this satisfiability check will be the last one (for a global sat-check), if its result is SAT                                |
| <code>_full</code>      | false, if this module should avoid too expensive procedures and rather return unknown instead.                                        |
| <code>_objective</code> | if not set to NO_VARIABLE, the module should find an assignment minimizing this objective variable; otherwise any assignment is good. |

## Returns

True, if the received formula is satisfiable; False, if the received formula is not satisfiable; Unknown, otherwise.

Reimplemented in [smrat::PModule](#).

### 0.15.217.5.20 `checkCore()`

```
template<typename Settings >
Answer smrat::FouMoModule< Settings >::checkCore () [virtual]
```

Checks the received formula for consistency.

## Returns

SAT, if the received formula is satisfiable; UNSAT, if the received formula is not satisfiable; Unknown, otherwise.

Reimplemented from [smrat::Module](#).

### 0.15.217.5.21 `checkInfSubsetForMinimality()`

```
void smrat::Module::checkInfSubsetForMinimality (
 std::vector< FormulaSetT >::const_iterator _infssubset,
 const std::string & _filename = "smaller_muses",
 unsigned _maxSizeDifference = 1) const [inherited]
```

Checks the given infeasible subset for minimality by storing all subsets of it, which have a smaller size which differs from the size of the infeasible subset not more than the given threshold.

## Parameters

|                                 |                                                                                                        |
|---------------------------------|--------------------------------------------------------------------------------------------------------|
| <code>_infsSubset</code>        | The infeasible subset to check for minimality.                                                         |
| <code>_filename</code>          | The name of the file to store the infeasible subsets in order to be able to check their infeasibility. |
| <code>_maxSizeDifference</code> | The maximal difference between the sizes of the subsets compared to the size of the infeasible subset. |

**0.15.217.5.22 `checkModel()`** `unsigned smrat::Module::checkModel ( ) const [protected], [inherited]`

## Returns

false, if the current model of this module does not satisfy the current given formula; true, if it cannot be said whether the model satisfies the given formula.

**0.15.217.5.23 `cleanModel()`** `void smrat::Module::cleanModel ( ) const [inline], [protected], [inherited]`

Substitutes variable occurrences by its model value in the model values of other variables.

**0.15.217.5.24 `clearLemmas()`** `void smrat::Module::clearLemmas ( ) [inline], [inherited]`  
Deletes all yet found lemmas.

**0.15.217.5.25 `clearModel()`** `void smrat::Module::clearModel ( ) const [inline], [protected], [inherited]`  
Clears the assignment, if any was found.

**0.15.217.5.26 `clearModels()`** `void smrat::Module::clearModels ( ) const [inline], [protected], [inherited]`  
Clears all assignments, if any was found.

**0.15.217.5.27 `clearPassedFormula()`** `void smrat::Module::clearPassedFormula ( ) [protected], [inherited]`

**0.15.217.5.28 `collectOrigins() [1/2]`** `void smrat::Module::collectOrigins ( const FormulaT & _formula, FormulasT & _origins ) const [inherited]`

**0.15.217.5.29 `collectOrigins() [2/2]`** `void smrat::Module::collectOrigins ( const FormulaT & _formula, FormulasT & _origins ) const [inherited]`

Collects the formulas in the given formula, which are part of the received formula.

If the given formula directly occurs in the received formula, it is inserted into the given set. Otherwise, the given formula must be of type AND and all its sub-formulas part of the received formula. Hence, they will be added to the given set.

**Parameters**

|                       |                                                                                                      |
|-----------------------|------------------------------------------------------------------------------------------------------|
| <code>_formula</code> | The formula from which to collect the formulas being sub-formulas of the received formula (origins). |
| <code>_origins</code> | The set in which to store the origins.                                                               |

**0.15.217.5.30 `collectTheoryPropagations()`** `void smtrat::Module::collectTheoryPropagations ( )`  
[inherited]

**0.15.217.5.31 `constraintsToInform()`** `const carl::FastSet<FormulaT>& smtrat::Module::constraintsToInform ( ) const [inline], [inherited]`

**Returns**

The constraints which the backends must be informed about.

**0.15.217.5.32 `currentlySatisfied()`** `virtual unsigned smtrat::Module::currentlySatisfied ( const FormulaT & ) const [inline], [virtual], [inherited]`

**Returns**

0, if the given formula is conflicted by the current model; 1, if the given formula is satisfied by the current model; 2, otherwise; 3, if we do not know anything (default)

Reimplemented in [smtrat::LRAModule< Settings >](#), [smtrat::LRAModule< LRASettingsICP >](#), and [smtrat::LRAModule< LRASettings >](#)

**0.15.217.5.33 `currentlySatisfiedByBackend()`** `unsigned smtrat::Module::currentlySatisfiedByBackend ( const FormulaT & _formula ) const [inherited]`

**Returns**

0, if the given formula is conflicted by the current model; 1, if the given formula is satisfied by the current model; 2, otherwise 3, if we do not know anything (default)

**0.15.217.5.34 `deinform()`** `void smtrat::Module::deinform ( const FormulaT & _constraint ) [inherited]`

The inverse of informing about a constraint.

All data structures which were kept regarding this constraint are going to be removed. Note, that this makes only sense if it is not likely enough that a formula with this constraint must be solved again.

**Parameters**

|                          |                                                         |
|--------------------------|---------------------------------------------------------|
| <code>_constraint</code> | The constraint to remove from internal data structures. |
|--------------------------|---------------------------------------------------------|

**0.15.217.5.35 `deinformCore()`** `virtual void smtrat::Module::deinformCore ( const FormulaT & _constraint ) [inline], [protected], [virtual], [inherited]`

The inverse of informing about a constraint.

All data structures which were kept regarding this constraint are going to be removed. Note, that this makes only sense if it is not likely enough that a formula with this constraint must be solved again.

## Parameters

|                          |                                                         |
|--------------------------|---------------------------------------------------------|
| <code>_constraint</code> | The constraint to remove from internal data structures. |
|--------------------------|---------------------------------------------------------|

Reimplemented in [smtrat::LRAbstractModule< Settings >](#), [smtrat::LRAbstractModule< LRASettingsICP >](#), and [smtrat::LRAbstractModule< LRASettings4 >](#).

**0.15.217.5.36 `determine_smallest_origin()`** `size_t smtrat::Module::determine_smallest_origin (const std::vector< FormulaT > & origins) const [protected], [inherited]`

## Parameters

|                      |                              |
|----------------------|------------------------------|
| <code>origins</code> | A vector of sets of origins. |
|----------------------|------------------------------|

## Returns

The index of the smallest (regarding the size of the sets) element of `origins`

**0.15.217.5.37 `eraseSubformulaFromPassedFormula()`** `ModuleInput::iterator smtrat::Module::eraseSubformulaFromPassedFormula (ModuleInput::iterator _subformula, bool _ignoreOrigins = false) [protected], [virtual], [inherited]`

Removes everything related to the sub-formula to remove from the passed formula in the backends of this module. Afterwards the sub-formula is removed from the passed formula.

## Parameters

|                             |                                                                                                              |
|-----------------------------|--------------------------------------------------------------------------------------------------------------|
| <code>_subformula</code>    | The sub-formula to remove from the passed formula.                                                           |
| <code>_ignoreOrigins</code> | True, if the sub-formula shall be removed regardless of its origins (should only be applied with expertise). |

## Returns

Reimplemented in [smtrat::ICPModule< Settings >](#), [smtrat::ICPModule< ICPSettings4 >](#), and [smtrat::ICPModule< ICPSettings1 >](#).

**0.15.217.5.38 `excludeNotReceivedVariablesFromModel()`** `void smtrat::Module::excludeNotReceivedVariablesFromModel () const [inherited]`

Excludes all variables from the current model, which do not occur in the received formula.

**0.15.217.5.39 `findBestOrigin()`** `std::vector< FormulaT >::const_iterator smtrat::Module::findBestOrigin (const std::vector< FormulaT > & _origins) const [protected], [inherited]`

## Parameters

|                       |  |
|-----------------------|--|
| <code>_origins</code> |  |
|-----------------------|--|

Returns

**0.15.217.5.40 firstSubformulaToPass()** `ModuleInput::const_iterator smtrat::Module::firstSubformulaToPass () const [inline], [inherited]`

Returns

The position of the first sub-formula in the passed formula, which has not yet been considered for a consistency check of the backends.

**0.15.217.5.41 firstUncheckedReceivedSubformula()** `ModuleInput::const_iterator smtrat::Module::firstUncheckedReceivedSubformula () const [inline], [inherited]`

Returns

The position of the first (by this module) unchecked sub-formula of the received formula.

**0.15.217.5.42 freeSplittingVariable()** `static void smtrat::Module::freeSplittingVariable (const FormulaT & _splittingVariable ) [inline], [static], [inherited]`

**0.15.217.5.43 generateTrivialInfeasibleSubset()** `void smtrat::Module::generateTrivialInfeasibleSubset () [inline], [protected], [inherited]`  
Stores the trivial infeasible subset being the set of received formulas.

**0.15.217.5.44 getBackendsAllModels()** `void smtrat::Module::getBackendsAllModels () const [protected], [inherited]`

Stores all models of a backend in the list of all models of this module.

**0.15.217.5.45 getBackendsModel()** `void smtrat::Module::getBackendsModel () const [protected], [inherited]`

**0.15.217.5.46 getInfeasibleSubsets() [1/2]** `void smtrat::Module::getInfeasibleSubsets () [protected], [inherited]`  
Copies the infeasible subsets of the passed formula.

**0.15.217.5.47 getInfeasibleSubsets() [2/2]** `std::vector<FormulaSetT> smtrat::Module::getInfeasibleSubsets (const Module & _backend ) const [protected], [inherited]`

Get the infeasible subsets the given backend provides.

Note, that an infeasible subset in a backend contains sub formulas of the passed formula and an infeasible subset of this module contains sub formulas of the received formula. In this method the LATTER is returned.

Parameters

|                       |                                                          |
|-----------------------|----------------------------------------------------------|
| <code>_backend</code> | The backend from which to obtain the infeasible subsets. |
|-----------------------|----------------------------------------------------------|

**Returns**

The infeasible subsets the given backend provides.

**0.15.217.5.48 getInformationRelevantFormulas()** `const std::set< FormulaT > & smtrat::Module::getInformationRelevantFormulas () [protected], [inherited]`  
Gets all InformationRelevantFormulas.

**Returns**

Set of all formulas

**0.15.217.5.49 getModelEqualities()** `std::list< std::vector< carl::Variable > > smtrat::Module::getModelEqualities () const [virtual], [inherited]`  
Partition the variables from the current model into equivalence classes according to their assigned value.  
The result is a set of equivalence classes of variables where all variables within one class are assigned the same value. Note that the number of classes may not be minimal, i.e. two classes may actually be equivalent.

**Returns**

Equivalence classes.

**0.15.217.5.50 getOrigins() [1/3]** `void smtrat::Module::getOrigins ( const FormulaT & _formula, FormulaSetT & _origins ) const [inline], [protected], [inherited]`

**Parameters**

|                       |  |
|-----------------------|--|
| <code>_formula</code> |  |
| <code>_origins</code> |  |

**0.15.217.5.51 getOrigins() [2/3]** `void smtrat::Module::getOrigins ( const FormulaT & _formula, FormulasT & _origins ) const [inline], [protected], [inherited]`

**Parameters**

|                       |  |
|-----------------------|--|
| <code>_formula</code> |  |
| <code>_origins</code> |  |

**0.15.217.5.52 getOrigins() [3/3]** `const FormulaT& smtrat::Module::getOrigins ( ModuleInput::const_iterator _formula ) const [inline], [protected], [inherited]`  
Gets the origins of the passed formula at the given position.

**Parameters**

|                       |                                                   |
|-----------------------|---------------------------------------------------|
| <code>_formula</code> | The position of a formula in the passed formulas. |
|-----------------------|---------------------------------------------------|

**Returns**

The origins of the passed formula at the given position.

**0.15.217.5.53 `getReceivedFormulaSimplified()`** `std::pair< bool, FormulaT > smtrat::Module::getReceivedFormulaSimplified( ) [virtual], [inherited]`

**Returns**

A pair of a Boolean and a formula, where the Boolean is true, if the received formula could be simplified to an equisatisfiable formula. The formula is equisatisfiable to this module's received formula, if the Boolean is true.

Reimplemented in [smtrat::PModule](#).

**0.15.217.5.54 `hasLemmas()`** `bool smtrat::Module::hasLemmas( ) [inline], [inherited]`

Checks whether this module or any of its backends provides any lemmas.

**0.15.217.5.55 `hasValidInfeasibleSubset()`** `bool smtrat::Module::hasValidInfeasibleSubset( ) const [inherited]`

**Returns**

true, if the module has at least one valid infeasible subset, that is all its elements are sub-formulas of the received formula (pointer must be equal).

**0.15.217.5.56 `id()`** `std::size_t smtrat::Module::id( ) const [inline], [inherited]`

**Returns**

A unique ID to identify this module instance.

**0.15.217.5.57 `infeasibleSubsets()`** `const std::vector<FormulaSetT>& smtrat::Module::infeasibleSubsets( ) const [inline], [inherited]`

**Returns**

The infeasible subsets of the set of received formulas (empty, if this module has not detected unsatisfiability of the conjunction of received formulas).

**0.15.217.5.58 `inform()`** `bool smtrat::Module::inform( const FormulaT & _constraint ) [inherited]`

Informs the module about the given constraint.

It should be tried to inform this module about any constraint it could receive eventually before assertSubformula is called (preferably for the first time, but at least before adding a formula containing that constraint).

**Parameters**

|                          |                                 |
|--------------------------|---------------------------------|
| <code>_constraint</code> | The constraint to inform about. |
|--------------------------|---------------------------------|

**Returns**

false, if it can be easily decided whether the given constraint is inconsistent; true, otherwise.

**0.15.217.5.59 informBackends()** void smrat::Module::informBackends ( const FormulaT & \_constraint ) [inline], [protected], [inherited]

Informs all backends of this module about the given constraint.

**Parameters**

|                    |                                 |
|--------------------|---------------------------------|
| <i>_constraint</i> | The constraint to inform about. |
|--------------------|---------------------------------|

**0.15.217.5.60 informCore()** virtual bool smrat::Module::informCore (

const FormulaT & \_constraint ) [inline], [protected], [virtual], [inherited]

Informs the module about the given constraint.

It should be tried to inform this module about any constraint it could receive eventually before assertSubformula is called (preferably for the first time, but at least before adding a formula containing that constraint).

**Parameters**

|                    |                                 |
|--------------------|---------------------------------|
| <i>_constraint</i> | The constraint to inform about. |
|--------------------|---------------------------------|

**Returns**

false, if it can be easily decided whether the given constraint is inconsistent; true, otherwise.

Reimplemented in [smrat::UnionFindModule< Settings >](#), [smrat::PBPPModule< Settings >](#), [smrat::PBGaussModule< Settings >](#), [smrat::NRAILModule< Settings >](#), [smrat::NewCoveringModule< Settings >](#), [smrat::NewCADModule< Settings >](#), [smrat::LRAModule< Settings >](#), [smrat::LRAModule< LRASettingsICP >](#), [smrat::LRAModule< LRASettings1 >](#), [smrat::IntBlastModule< Settings >](#), [smrat::FPPModule< Settings >](#), [smrat::EQModule< Settings >](#), [smrat::CurryModule< Settings >](#), [smrat::BVMModule< Settings >](#), [smrat::ICPModule< Settings >](#), [smrat::ICPModule< ICPSettings4 >](#), and [smrat::ICPModule< ICPSettings1 >](#).

**0.15.217.5.61 informedConstraints()** const carl::FastSet<FormulaT>& smrat::Module::informedConstraints ( ) const [inline], [inherited]

**Returns**

The position of the first constraint of which no backend has been informed about.

**0.15.217.5.62 init()** void smrat::Module::init ( ) [virtual], [inherited]

Informs all backends about the so far encountered constraints, which have not yet been communicated.

This method must not be called twice and only before the first runBackends call.

Reimplemented in [smrat::PBPPModule< Settings >](#), [smrat::PBGaussModule< Settings >](#), [smrat::NRAILModule< Settings >](#), [smrat::NewCoveringModule< Settings >](#), [smrat::NewCADModule< Settings >](#), [smrat::LRAModule< Settings >](#), [smrat::LRAModule< LRASettingsICP >](#), [smrat::LRAModule< LRASettings1 >](#), [smrat::IntBlastModule< Settings >](#), [smrat::FPPModule< Settings >](#), [smrat::EQModule< Settings >](#), [smrat::CurryModule< Settings >](#), and [smrat::BVMModule< Settings >](#).

**0.15.217.5.63 is\_minimizing()** bool smrat::Module::is\_minimizing ( ) const [inline], [inherited]

**0.15.217.5.64 `isLemmaLevel()`** `bool smtrat::Module::isLemmaLevel (``LemmaLevel level ) [protected], [inherited]`

Checks if current lemma level is greater or equal to given level.

**Parameters**

|                    |                 |
|--------------------|-----------------|
| <code>level</code> | Level to check. |
|--------------------|-----------------|

**0.15.217.5.65 `isPreprocessor()`** `bool smtrat::Module::isPreprocessor ( ) const [inline], [inherited]`**Returns**

true, if this module is a preprocessor that is a module, which simplifies its received formula to an equisatisfiable formula being passed to its backends. The simplified formula can be obtained with [getReceivedFormulaSimplified\(\)](#).

**0.15.217.5.66 `lemmas()`** `const std::vector<Lemma>& smtrat::Module::lemmas ( ) const [inline], [inherited]`**Returns**

A constant reference to the lemmas being valid formulas this module or its backends made.

**0.15.217.5.67 `merge()`** `std::vector< FormulaT > smtrat::Module::merge (``const std::vector< FormulaT > & _vecSetA,``const std::vector< FormulaT > & _vecSetB ) const [protected], [inherited]`

Merges the two vectors of sets into the first one.

({a,b},{a,c}) and ({b,d},{b}) -> ({a,b,d},{a,b},{a,b,c,d},{a,b,c})

**Parameters**

|                       |                                  |
|-----------------------|----------------------------------|
| <code>_vecSetA</code> | A vector of sets of constraints. |
| <code>_vecSetB</code> | A vector of sets of constraints. |

**Returns**

The vector being the two given vectors merged.

**0.15.217.5.68 `model()`** `const Model& smtrat::Module::model ( ) const [inline], [inherited]`**Returns**

The assignment of the current satisfiable result, if existent.

**0.15.217.5.69 `modelsDisjoint()`** `bool smtrat::Module::modelsDisjoint (``const Model & _modelA,``const Model & _modelB ) [static], [protected], [inherited]`

Checks whether there is no variable assigned by both models.

**Parameters**

|                      |                                |
|----------------------|--------------------------------|
| <code>_modelA</code> | The first model to check for.  |
| <code>_modelB</code> | The second model to check for. |

**Returns**

true, if there is no variable assigned by both models; false, otherwise.

**0.15.217.5.70 `moduleName()`** template<typename Settings >  
`std::string smtrat::FouMoModule< Settings >::moduleName ( ) const [inline], [virtual]`

**Returns**

The name of the given module type as name.

Reimplemented from [smtrat::Module](#).

**0.15.217.5.71 `objective()`** carl::Variable `smtrat::Module::objective ( ) const [inline], [inherited]`

**0.15.217.5.72 `originInReceivedFormula()`** bool `smtrat::Module::originInReceivedFormula ( const FormulaT & _origin ) const [protected], [inherited]`

**0.15.217.5.73 `passedFormulaBegin()`** [ModuleInput::iterator](#) `smtrat::Module::passedFormulaBegin ( ) [inline], [protected], [inherited]`

**Returns**

An iterator to the end of the passed formula. TODO: disable this method

**0.15.217.5.74 `passedFormulaEnd()`** [ModuleInput::iterator](#) `smtrat::Module::passedFormulaEnd ( ) [inline], [protected], [inherited]`

**Returns**

An iterator to the end of the passed formula.

**0.15.217.5.75 `pPassedFormula()`** const [ModuleInput\\*](#) `smtrat::Module::pPassedFormula ( ) const [inline], [inherited]`

**Returns**

A pointer to the formula passed to the backends of this module.

**0.15.217.5.76 `pReceivedFormula()`** const [ModuleInput\\*](#) `smtrat::Module::pReceivedFormula ( ) const [inline], [inherited]`

**Returns**

A pointer to the formula passed to this module.

**0.15.217.5.77 `print()`** void `smtrat::Module::print ( const std::string & _initiation = "***" ) const [inherited]`

Prints everything relevant of the solver.

**Parameters**

|                    |                      |
|--------------------|----------------------|
| <i>_initiation</i> | The line initiation. |
|--------------------|----------------------|

**0.15.217.5.78 printAllModels()** void smtrat::Module::printAllModels ( std::ostream & *\_out* = std::cout ) const [inherited]

Prints all assignments of this module satisfying its received formula if it satisfiable and this module could find an assignment.

**Parameters**

|             |                                        |
|-------------|----------------------------------------|
| <i>_out</i> | The stream to print the assignment on. |
|-------------|----------------------------------------|

**0.15.217.5.79 printInfeasibleSubsets()** void smtrat::Module::printInfeasibleSubsets ( const std::string & *\_initiation* = "\*\*\*" ) const [inherited]

Prints the infeasible subsets.

**Parameters**

|                    |                      |
|--------------------|----------------------|
| <i>_initiation</i> | The line initiation. |
|--------------------|----------------------|

**0.15.217.5.80 printModel()** void smtrat::Module::printModel ( std::ostream & *\_out* = std::cout ) const [inherited]

Prints the assignment of this module satisfying its received formula if it satisfiable and this module could find an assignment.

**Parameters**

|             |                                        |
|-------------|----------------------------------------|
| <i>_out</i> | The stream to print the assignment on. |
|-------------|----------------------------------------|

**0.15.217.5.81 printPassedFormula()** void smtrat::Module::printPassedFormula ( const std::string & *\_initiation* = "\*\*\*" ) const [inherited]

Prints the vector of passed formula.

**Parameters**

|                    |                      |
|--------------------|----------------------|
| <i>_initiation</i> | The line initiation. |
|--------------------|----------------------|

**0.15.217.5.82 printReceivedFormula()** void smtrat::Module::printReceivedFormula ( const std::string & *\_initiation* = "\*\*\*" ) const [inherited]

Prints the vector of the received formula.

**Parameters**

|                    |                      |
|--------------------|----------------------|
| <i>_initiation</i> | The line initiation. |
|--------------------|----------------------|

```
0.15.217.5.83 probablyLooping() bool smtrat::Module::probablyLooping (
 const typename Poly::PolyType & _branchingPolynomial,
 const Rational & _branchingValue) const [protected], [inherited]
```

Checks whether given the current branching value and branching variable/polynomial it is (highly) probable that this branching is part of an infinite loop of branchings.

#### Parameters

|                                   |                                                                                     |
|-----------------------------------|-------------------------------------------------------------------------------------|
| <code>_branchingPolynomial</code> | The polynomial to branch at (in most branching strategies this is just a variable). |
| <code>_branchingValue</code>      | The value to branch at.                                                             |

#### Returns

true, if this branching is probably part of an infinite loop of branchings; false, otherwise.

```
0.15.217.5.84 receivedFormulaChecked() void smtrat::Module::receivedFormulaChecked () [inline], [inherited]
```

Notifies that the received formulas has been checked.

```
0.15.217.5.85 receivedFormulasAsInfeasibleSubset() void smtrat::Module::receivedFormulasAs< InfeasibleSubset (
```

```
 ModuleInput::const_iterator _subformula) [inline], [protected], [inherited]
```

Stores an infeasible subset consisting only of the given received formula.

```
0.15.217.5.86 receivedVariable() bool smtrat::Module::receivedVariable (
 carl::Variable::Arg _var) const [inline], [inherited]
```

```
0.15.217.5.87 remove() void smtrat::Module::remove (
```

```
 ModuleInput::const_iterator _subformula) [virtual], [inherited]
```

Removes everything related to the given sub-formula of the received formula.

However, it is desired not to lose track of search spaces where no satisfying assignment can be found for the remaining sub-formulas.

#### Parameters

|                          |                                                    |
|--------------------------|----------------------------------------------------|
| <code>_subformula</code> | The sub formula of the received formula to remove. |
|--------------------------|----------------------------------------------------|

Reimplemented in [smtrat::PModule](#).

```
0.15.217.5.88 removeCore() template<typename Settings >
void smtrat::FouMoModule< Settings >::removeCore (
 ModuleInput::const_iterator _subformula) [virtual]
```

Removes the subformula of the received formula at the given position to the considered ones of this module.

Note that this includes every stored calculation which depended on this subformula, but should keep the other stored calculation, if possible, untouched.

#### Parameters

|                          |                                           |
|--------------------------|-------------------------------------------|
| <code>_subformula</code> | The position of the subformula to remove. |
|--------------------------|-------------------------------------------|

Reimplemented from [smtrat::Module](#).

**0.15.217.5.89 `removeOrigin()`** `std::pair<ModuleInput::iterator, bool> smtrat::Module::removeOrigin (`

`ModuleInput::iterator _formula,`  
`const FormulaT & _origin ) [inline], [protected], [inherited]`

**0.15.217.5.90 `removeOrigins()`** `std::pair<ModuleInput::iterator, bool> smtrat::Module::removeOrigins (`

`ModuleInput::iterator _formula,`  
`const std::shared_ptr< std::vector< FormulaT >> & _origins ) [inline], [protected],`  
`[inherited]`

**0.15.217.5.91 `rPassedFormula()`** `const ModuleInput& smtrat::Module::rPassedFormula ( ) const`  
[inline], [inherited]

**Returns**

A reference to the formula passed to the backends of this module.

**0.15.217.5.92 `rReceivedFormula()`** `const ModuleInput& smtrat::Module::rReceivedFormula ( ) const`  
[inline], [inherited]

**Returns**

A reference to the formula passed to this module.

**0.15.217.5.93 `runBackends() [1/2]`** `virtual Answer smtrat::Module::runBackends ( ) [inline],`  
[protected], [virtual], [inherited]

Reimplemented in [smtrat::PModule](#).

**0.15.217.5.94 `runBackends() [2/2]`** `Answer smtrat::Module::runBackends (`

`bool _final,`  
`bool _full,`  
`carl::Variable _objective ) [protected], [virtual], [inherited]`

Runs the backend solvers on the passed formula.

**Parameters**

|                         |                                                                                                                                       |
|-------------------------|---------------------------------------------------------------------------------------------------------------------------------------|
| <code>_final</code>     | true, if this satisfiability check will be the last one (for a global sat-check), if its result is SAT                                |
| <code>_full</code>      | false, if this module should avoid too expensive procedures and rather return unknown instead.                                        |
| <code>_objective</code> | if not set to NO_VARIABLE, the module should find an assignment minimizing this objective variable; otherwise any assignment is good. |

**Returns**

True, if the passed formula is consistent; False, if the passed formula is inconsistent; Unknown, otherwise.

Reimplemented in [smtrat::PModule](#).

**0.15.217.5.95 setId()** void smtrat::Module::setId ( std::size\_t \_id ) [inline], [inherited]  
 Sets this modules unique ID to identify itself.

#### Parameters

|                                                 |                                    |
|-------------------------------------------------|------------------------------------|
| $\leftarrow$<br>$\overline{\leftarrow}$<br>$id$ | The id to set this module's id to. |
|-------------------------------------------------|------------------------------------|

**0.15.217.5.96 setThreadPriority()** void smtrat::Module::setThreadPriority ( thread\_priority \_threadPriority ) [inline], [inherited]  
 Sets the priority of this module to get a thread for running its check procedure.

#### Parameters

|                   |                                                       |
|-------------------|-------------------------------------------------------|
| $_threadPriority$ | The priority to set this module's thread priority to. |
|-------------------|-------------------------------------------------------|

**0.15.217.5.97 solverState()** Answer smtrat::Module::solverState ( ) const [inline], [inherited]

#### Returns

True, if this module is in a state, such that it has found a solution for its received formula; False, if this module is in a state, such that it has determined that there is no solution for its received formula; Unknown, otherwise.

**0.15.217.5.98 splitUnequalConstraint()** void smtrat::Module::splitUnequalConstraint ( const FormulaT & \_unequalConstraint ) [protected], [inherited]  
 Adds the following lemmas for the given constraint  $p \neq 0$ .

$(p \neq 0 \leftrightarrow (p < 0 \text{ or } p > 0))$

and  $\neg(p < 0 \text{ and } p > 0)$

#### Parameters

|                      |                                                  |
|----------------------|--------------------------------------------------|
| $_unequalConstraint$ | A constraint having the relation symbol $\neq$ . |
|----------------------|--------------------------------------------------|

**0.15.217.5.99 threadPriority()** thread\_priority smtrat::Module::threadPriority ( ) const [inline], [inherited]

#### Returns

The priority of this module to get a thread for running its check procedure.

**0.15.217.5.100 updateAllModels()** void smtrat::Module::updateAllModels ( ) [virtual], [inherited]  
 Updates all satisfying models, if the solver has detected the consistency of the received formula, beforehand.  
 Reimplemented in [smtrat::SATModule< Settings >](#).

**0.15.217.5.101 updateLemmas()** void smtrat::Module::updateLemmas () [inherited]  
Stores all lemmas of any backend of this module in its own lemma vector.

**0.15.217.5.102 updateModel()** template<typename Settings >  
void smtrat::FouMoModule< Settings >::updateModel () const [virtual]

Updates the current assignment into the model.

Note, that this is a unique but possibly symbolic assignment maybe containing newly introduced variables.  
Reimplemented from [smtrat::Module](#).

**0.15.217.5.103 usedBackends()** const std::vector<[Module](#)\*>& smtrat::Module::usedBackends ()  
const [inline], [inherited]

#### Returns

The backends of this module which are currently used (conditions to use this module are fulfilled for the passed formula).

## 0.15.217.6 Field Documentation

**0.15.217.6.1 mAllBackends** std::vector<[Module](#)\*> smtrat::Module::mAllBackends [protected],  
[inherited]

The backends of this module which have been used.

**0.15.217.6.2 mAllModels** std::vector<[Model](#)> smtrat::Module::mAllModels [mutable], [protected],  
[inherited]

Stores all satisfying assignments.

**0.15.217.6.3 mBackendsFoundAnswer** std::atomic\_bool\* smtrat::Module::mBackendsFoundAnswer  
[protected], [inherited]

This flag is passed to any backend and if it determines an answer to a prior check call, this flag is fired.

**0.15.217.6.4 mConstraintsToInform** carl::FastSet<[FormulaT](#)> smtrat::Module::mConstraintsToInform  
[protected], [inherited]

Stores the constraints which the backends must be informed about.

**0.15.217.6.5 mFinalCheck** bool smtrat::Module::mFinalCheck [protected], [inherited]  
true, if the check procedure should perform a final check which especially means not to postpone splitting decisions

**0.15.217.6.6 mFirstPosInLastBranches** std::size\_t smtrat::Module::mFirstPosInLastBranches = 0  
[static], [inherited]

The beginning of the cyclic buffer storing the last branches.

**0.15.217.6.7 mFirstSubformulaToPass** [ModuleInput](#)::iterator smtrat::Module::mFirstSubformulaToPass  
[protected], [inherited]

Stores the position of the first sub-formula in the passed formula, which has not yet been considered for a consistency check of the backends.

**0.15.217.6.8 mFirstUncheckedReceivedSubformula** `ModuleInput::const_iterator smtrat::Module::mFirstUncheckedReceivedSubformula [protected], [inherited]`  
Stores the position of the first (by this module) unchecked sub-formula of the received formula.

**0.15.217.6.9 mFoundAnswer** `Conditionals smtrat::Module::mFoundAnswer [protected], [inherited]`  
Vector of Booleans: If any of them is true, we have to terminate a running check procedure.

**0.15.217.6.10 mFullCheck** `bool smtrat::Module::mFullCheck [protected], [inherited]`  
false, if this module should avoid too expensive procedures and rather return unknown instead.

**0.15.217.6.11 mInfeasibleSubsets** `std::vector<FormulaSetT> smtrat::Module::mInfeasibleSubsets [protected], [inherited]`  
Stores the infeasible subsets.

**0.15.217.6.12 mInformedConstraints** `carl::FastSet<FormulaT> smtrat::Module::mInformedConstraints [protected], [inherited]`  
Stores the position of the first constraint of which no backend has been informed about.

**0.15.217.6.13 mLastBranches** `std::vector<Branching> smtrat::Module::mLastBranches = std::vector<Branching>(mNumOfBranchVarsToStore, Branching(typename Poly::PolyType(), 0)) [static], [inherited]`  
Stores the last branches in a cycle buffer.

**0.15.217.6.14 mLemmas** `std::vector<Lemma> smtrat::Module::mLemmas [protected], [inherited]`  
Stores the lemmas being valid formulas this module or its backends made.

**0.15.217.6.15 mModel** `Model smtrat::Module::mModel [mutable], [protected], [inherited]`  
Stores the assignment of the current satisfiable result, if existent.

**0.15.217.6.16 mModelComputed** `bool smtrat::Module::mModelComputed [mutable], [protected], [inherited]`  
True, if the model has already been computed.

**0.15.217.6.17 mNumOfBranchVarsToStore** `std::size_t smtrat::Module::mNumOfBranchVarsToStore = 5 [static], [inherited]`  
The number of different variables to consider for a probable infinite loop of branchings.

**0.15.217.6.18 mObjectiveVariable** `carl::Variable smtrat::Module::mObjectiveVariable [protected], [inherited]`  
Objective variable to be minimized. If set to NO\_VARIABLE, a normal sat check should be performed.

**0.15.217.6.19 mOldSplittingVariables** `std::vector<FormulaT> smtrat::Module::mOldSplittingVariables [static], [inherited]`  
Reusable splitting variables.

**0.15.217.6.20 mpManager** `Manager* const smtrat::Module::mpManager [protected], [inherited]`  
A reference to the manager.

**0.15.217.6.21 mSmallerMusesCheckCounter** `unsigned smtrat::Module::mSmallerMusesCheckCounter [mutable], [protected], [inherited]`  
Counter used for the generation of the smt2 files to check for smaller muses.

**0.15.217.6.22 mSolverState** `std::atomic<Answer> smtrat::Module::mSolverState [protected], [inherited]`  
States whether the received formula is known to be satisfiable or unsatisfiable otherwise it is set to unknown.

**0.15.217.6.23 mTheoryPropagations** `std::vector<TheoryPropagation> smtrat::Module::mTheory->Propagations [protected], [inherited]`

**0.15.217.6.24 mUsedBackends** `std::vector<Module*> smtrat::Module::mUsedBackends [protected], [inherited]`  
The backends of this module which are currently used (conditions to use this module are fulfilled for the passed formula).

**0.15.217.6.25 mVariableCounters** `std::vector<std::size_t> smtrat::Module::mVariableCounters [protected], [inherited]`  
Maps variables to the number of their occurrences.

## 0.15.218 smtrat::qe::fm::FourierMotzkinQE Class Reference

Provides a simple implementation for Fourier Motzkin variable elimination for linear, existentially quantified constraints.

```
#include <FourierMotzkinQE.h>
```

### Public Types

- using `FormulaPartition = std::vector< std::vector< FormulaT > >`

### Public Member Functions

- `FourierMotzkinQE (const FormulaT &qfree, const QEQuery &quantifiers)`
- `FormulaT eliminateQuantifiers ()`

#### 0.15.218.1 Detailed Description

Provides a simple implementation for Fourier Motzkin variable elimination for linear, existentially quantified constraints.

#### 0.15.218.2 Member Typedef Documentation

**0.15.218.2.1 FormulaPartition** using `smtrat::qe::fm::FourierMotzkinQE::FormulaPartition = std::vector< std::vector< FormulaT > >`

#### 0.15.218.3 Constructor & Destructor Documentation

```
0.15.218.3.1 FourierMotzkinQE() smtrat::qe::fm::FourierMotzkinQE::FourierMotzkinQE (
 const FormulaT & qfree,
 const QEQuery & quantifiers) [inline]
```

#### 0.15.218.4 Member Function Documentation

**0.15.218.4.1 eliminateQuantifiers()** FormulaT smtrat::qe::fm::FourierMotzkinQE::eliminateQuantifiers( )

### 0.15.219 smtrat::FPPModule< Settings > Class Template Reference

```
#include <FPPModule.h>
```

#### Public Types

- **typedef Settings SettingsType**
- **enum class LemmaType : unsigned { NORMAL = 0 , PERMANENT = 1 }**

#### Public Member Functions

- **FPPModule (const ModuleInput \*\_formula, Conditionals &\_conditionals, Manager \*\_manager=NULL)**
- **~FPPModule ()**

*Prints the infeasible subsets.*
- void `printModel` (std::ostream &\_out=std::cout) const  
*Prints the assignment of this module satisfying its received formula if it satisfiable and this module could find an assignment.*
- void `printAllModels` (std::ostream &\_out=std::cout)  
*Prints all assignments of this module satisfying its received formula if it satisfiable and this module could find an assignment.*

### Static Public Member Functions

- static void `freeSplittingVariable` (const `FormulaT` &\_splittingVariable)

### Static Public Attributes

- static size\_t `mNumOfBranchVarsToStore` = 5  
*The number of different variables to consider for a probable infinite loop of branchings.*
- static std::vector< `Branching` > `mLastBranches` = std::vector<`Branching`>(mNumOfBranchVarsToStore, `Branching`(typename Poly::PolyType(), 0))  
*Stores the last branches in a cycle buffer.*
- static size\_t `mFirstPosInLastBranches` = 0  
*The beginning of the cyclic buffer storing the last branches.*
- static std::vector< `FormulaT` > `mOldSplittingVariables`  
*Reusable splitting variables.*

### Protected Member Functions

- virtual void `deinformCore` (const `FormulaT` &\_constraint)  
*The inverse of informing about a constraint.*
- bool `anAnswerFound` () const  
*Checks for all antecedent modules and those which run in parallel with the same antecedent modules, whether one of them has determined a result.*
- void `clearModel` () const  
*Clears the assignment, if any was found.*
- void `clearModels` () const  
*Clears all assignments, if any was found.*
- void `cleanModel` () const  
*Substitutes variable occurrences by its model value in the model values of other variables.*
- `ModuleInput::iterator` `passedFormulaBegin` ()
- `ModuleInput::iterator` `passedFormulaEnd` ()
- void `addOrigin` (`ModuleInput::iterator` \_formula, const `FormulaT` &\_origin)  
*Adds the given set of formulas in the received formula to the origins of the given passed formula.*
- const `FormulaT` & `getOrigins` (`ModuleInput::const_iterator` \_formula) const  
*Gets the origins of the passed formula at the given position.*
- void `getOrigins` (const `FormulaT` &\_formula, `FormulasT` &\_origins) const
- void `getOrigins` (const `FormulaT` &\_formula, `FormulaSetT` &\_origins) const
- std::pair< `ModuleInput::iterator`, bool > `removeOrigin` (`ModuleInput::iterator` \_formula, const `FormulaT` &\_origin)
- std::pair< `ModuleInput::iterator`, bool > `removeOrigins` (`ModuleInput::iterator` \_formula, const std::shared\_ptr< std::vector< `FormulaT` >> &\_origins)

- void `informBackends` (const `FormulaT` &\_constraint)
 

*Informs all backends of this module about the given constraint.*
- virtual void `addConstraintToInform` (const `FormulaT` &\_constraint)
 

*Adds a constraint to the collection of constraints of this module, which are informed to a freshly generated backend.*
- std::pair< `ModuleInput::iterator`, bool > `addReceivedSubformulaToPassedFormula` (`ModuleInput::const_iterator` \_subformula)
 

*Copies the given sub-formula of the received formula to the passed formula.*
- bool `originInReceivedFormula` (const `FormulaT` &\_origin) const
 

*Adds the given formula to the passed formula with no origin.*
- std::pair< `ModuleInput::iterator`, bool > `addSubformulaToPassedFormula` (const `FormulaT` &\_formula)
 

*Adds the given formula to the passed formula with no origin.*
- std::pair< `ModuleInput::iterator`, bool > `addSubformulaToPassedFormula` (const `FormulaT` &\_formula, const std::shared\_ptr< std::vector< `FormulaT` >> &\_origins)
 

*Adds the given formula to the passed formula.*
- std::pair< `ModuleInput::iterator`, bool > `addSubformulaToPassedFormula` (const `FormulaT` &\_formula, const `FormulaT` &\_origin)
 

*Adds the given formula to the passed formula.*
- void `generateTrivialInfeasibleSubset` ()
 

*Stores the trivial infeasible subset being the set of received formulas.*
- void `receivedFormulasAsInfeasibleSubset` (`ModuleInput::const_iterator` \_subformula)
 

*Stores an infeasible subset consisting only of the given received formula.*
- std::vector< `FormulaT` >::const\_iterator `findBestOrigin` (const std::vector< `FormulaT` > &\_origins) const
 

*Get the infeasible subsets the given backend provides.*
- const `Model` & `backendsModel` () const
 

*Stores the model of a backend which determined satisfiability of the passed formula in the model of this module.*
- void `getBackendsModel` () const
 

*Stores all models of a backend in the list of all models of this module.*
- void `getBackendsAllModels` () const
 

*Merges the two vectors of sets into the first one.*
- size\_t `determine_smallest_origin` (const std::vector< `FormulaT` > &origins) const
 

*Checks whether given the current branching value and branching variable/polynomial it is (highly) probable that this branching is part of an infinite loop of branchings.*
- bool `probablyLooping` (const typename `Poly::PolyType` &\_branchingPolynomial, const `Rational` &\_branchingValue) const
 

*Adds a lemmas which provoke a branching for the given variable at the given value, if this module returns Unknown and there exists a preceding SATModule.*
- bool `branchAt` (const `Poly` &\_polynomial, bool \_integral, const `Rational` &\_value, std::vector< `FormulaT` > &&\_premise, bool \_leftCaseWeak=true, bool \_preferLeftCase=true, bool \_useReceivedFormulaAsPremise=false, const std::vector< `FormulaT` > &←\_premise=std::vector< `FormulaT` >())
 

*Adds a lemmas which provoke a branching for the given variable at the given value, if this module returns Unknown and there exists a preceding SATModule.*
- bool `branchAt` (carl::Variable::Arg \_var, const `Rational` &\_value, std::vector< `FormulaT` > &&\_premise, bool \_leftCaseWeak=true, bool \_preferLeftCase=true, bool \_useReceivedFormulaAsPremise=false)
 

*Adds a lemmas which provoke a branching for the given variable at the given value, if this module returns Unknown and there exists a preceding SATModule.*
- bool `branchAt` (carl::Variable::Arg \_var, const `Rational` &\_value, bool \_leftCaseWeak=true, bool \_preferLeftCase=true, bool \_useReceivedFormulaAsPremise=false, const std::vector< `FormulaT` > &\_premise=std::vector< `FormulaT` >())
 

*Adds a lemmas which provoke a branching for the given variable at the given value, if this module returns Unknown and there exists a preceding SATModule.*

- void `splitUnequalConstraint` (const `FormulaT` &)
 

*Adds the following lemmas for the given constraint  $p \neq 0$ .*
- unsigned `checkModel` () const
- void `addInformationRelevantFormula` (const `FormulaT` &`formula`)
 

*Adds a formula to the InformationRelevantFormula.*
- const std::set< `FormulaT` > & `getInformationRelevantFormulas` ()
 

*Gets all InformationRelevantFormulas.*
- bool `isLemmaLevel` (`LemmaLevel` level)
 

*Checks if current lemma level is greater or equal to given level.*

### Static Protected Member Functions

- static bool `modelsDisjoint` (const `Model` &`_modelA`, const `Model` &`_modelB`)
 

*Checks whether there is no variable assigned by both models.*

### Protected Attributes

- std::vector< `FormulaSetT` > `mInfeasibleSubsets`

*Stores the infeasible subsets.*
- `Manager` \*const `mpManager`

*A reference to the manager.*
- `Model` `mModel`

*Stores the assignment of the current satisfiable result, if existent.*
- std::vector< `Model` > `mAllModels`

*Stores all satisfying assignments.*
- bool `mModelComputed`

*True, if the model has already been computed.*
- bool `mFinalCheck`

*true, if the check procedure should perform a final check which especially means not to postpone splitting decisions*
- bool `mFullCheck`

*false, if this module should avoid too expensive procedures and rather return unknown instead.*
- carl::Variable `mObjectiveVariable`

*Objective variable to be minimized. If set to NO\_VARIABLE, a normal sat check should be performed.*
- std::vector< `TheoryPropagation` > `mTheoryPropagations`
- std::atomic< `Answer` > `mSolverState`

*States whether the received formula is known to be satisfiable or unsatisfiable otherwise it is set to unknown.*
- std::atomic\_bool \* `mBackendsFoundAnswer`

*This flag is passed to any backend and if it determines an answer to a prior check call, this flag is fired.*
- Conditionals `mFoundAnswer`

*Vector of Booleans: If any of them is true, we have to terminate a running check procedure.*
- std::vector< `Module` \* > `mUsedBackends`

*The backends of this module which are currently used (conditions to use this module are fulfilled for the passed formula).*
- std::vector< `Module` \* > `mAllBackends`

*The backends of this module which have been used.*
- std::vector< `Lemma` > `mLemmas`

*Stores the lemmas being valid formulas this module or its backends made.*
- `ModuleInput`::iterator `mFirstSubformulaToPass`

*Stores the position of the first sub-formula in the passed formula, which has not yet been considered for a consistency check of the backends.*
- carl::FastSet< `FormulaT` > `mConstraintsToInform`

*Stores the constraints which the backends must be informed about.*

- `carl::FastSet< FormulaT > mInformedConstraints`  
*Stores the position of the first constraint of which no backend has been informed about.*
- `ModuleInput::const_iterator mFirstUncheckedReceivedSubformula`  
*Stores the position of the first (by this module) unchecked sub-formula of the received formula.*
- `unsigned mSmallerMusesCheckCounter`  
*Counter used for the generation of the smt2 files to check for smaller muses.*
- `std::vector< std::size_t > mVariableCounters`  
*Maps variables to the number of their occurrences.*

### 0.15.219.4 Member Function Documentation

**0.15.219.4.1 add()** `bool smrat::PModule::add (`  
`ModuleInput::const_iterator _subformula ) [inherited]`

The module has to take the given sub-formula of the received formula into account.

Parameters

|                          |                                                    |
|--------------------------|----------------------------------------------------|
| <code>_subformula</code> | The sub-formula to take additionally into account. |
|--------------------------|----------------------------------------------------|

**Returns**

false, if it can be easily decided that this sub-formula causes a conflict with the already considered sub-formulas; true, otherwise.

**0.15.219.4.2 addConstraintToInform()** `void smtrat::Module::addConstraintToInform (`

```
const FormulaT & _constraint) [protected], [virtual], [inherited]
```

Adds a constraint to the collection of constraints of this module, which are informed to a freshly generated backend.

**Parameters**

|                          |                        |
|--------------------------|------------------------|
| <code>_constraint</code> | The constraint to add. |
|--------------------------|------------------------|

Reimplemented in [smtrat::SATModule< Settings >](#).

**0.15.219.4.3 addCore()** `template<typename Settings >`

```
bool smtrat::FPPModule< Settings >::addCore (
 ModuleInput::const_iterator _subformula) [virtual]
```

The module has to take the given sub-formula of the received formula into account.

**Parameters**

|                          |                                                    |
|--------------------------|----------------------------------------------------|
| <code>_subformula</code> | The sub-formula to take additionally into account. |
|--------------------------|----------------------------------------------------|

**Returns**

false, if it can be easily decided that this sub-formula causes a conflict with the already considered sub-formulas; true, otherwise.

Reimplemented from [smtrat::Module](#).

**0.15.219.4.4 addInformationRelevantFormula()** `void smtrat::Module::addInformationRelevantFormula`

```
(
```

```
const FormulaT & formula) [protected], [inherited]
```

Adds a formula to the InformationRelevantFormula.

**Parameters**

|                      |                |
|----------------------|----------------|
| <code>formula</code> | Formula to add |
|----------------------|----------------|

**0.15.219.4.5 addLemma()** `void smtrat::Module::addLemma (`

```
const FormulaT & _lemma,
```

```
const LemmaType & _lt = LemmaType::NORMAL,
```

```
const FormulaT & _preferredFormula = FormulaT(carl::FormulaType::TRUE)) [inline],
```

```
[inherited]
```

Stores a lemma being a valid formula.

**Parameters**

|                                |                                                                       |
|--------------------------------|-----------------------------------------------------------------------|
| <code>_lemma</code>            | The eduction/lemma to store.                                          |
| <code>_lt</code>               | The type of the lemma.                                                |
| <code>_preferredFormula</code> | Hint for the next decision, which formula should be assigned to true. |

**0.15.219.4.6 addOrigin()** void smtrat::Module::addOrigin (

```
 ModuleInput::iterator _formula,
 const FormulaT & _origin) [inline], [protected], [inherited]
```

Adds the given set of formulas in the received formula to the origins of the given passed formula.

**Parameters**

|                       |                                                           |
|-----------------------|-----------------------------------------------------------|
| <code>_formula</code> | The passed formula to set the origins for.                |
| <code>_origin</code>  | A set of formulas in the received formula of this module. |

**0.15.219.4.7 addReceivedSubformulaToPassedFormula()** std::pair<ModuleInput::iterator, bool>

```
smtrat::Module::addReceivedSubformulaToPassedFormula (
```

```
 ModuleInput::const_iterator _subformula) [inline], [protected], [inherited]
```

Copies the given sub-formula of the received formula to the passed formula.

Note, that there is always a link between sub-formulas of the passed formulas to sub-formulas of the received formulas, which are responsible for its occurrence.

**Parameters**

|                          |                                                  |
|--------------------------|--------------------------------------------------|
| <code>_subformula</code> | The sub-formula of the received formula to copy. |
|--------------------------|--------------------------------------------------|

**0.15.219.4.8 addSubformulaToPassedFormula() [1/3]** std::pair<ModuleInput::iterator, bool> smtrat::Module::addSubformulaToPassedFormula (

```
 const FormulaT & _formula) [inline], [protected], [inherited]
```

Adds the given formula to the passed formula with no origin.

Note that in the next call of this module's removeSubformula, all formulas in the passed formula without origins will be removed.

**Parameters**

|                       |                                           |
|-----------------------|-------------------------------------------|
| <code>_formula</code> | The formula to add to the passed formula. |
|-----------------------|-------------------------------------------|

**Returns**

A pair to the position where the formula to add has been inserted (or its first sub-formula which has not yet been in the passed formula, in case the formula to add is a conjunction), and a Boolean stating whether anything has been added to the passed formula.

**0.15.219.4.9 addSubformulaToPassedFormula() [2/3]** std::pair<ModuleInput::iterator, bool> smtrat::Module::addSubformulaToPassedFormula (

```
 const FormulaT & _formula,
 const FormulaT & _origin) [inline], [protected], [inherited]
```

Adds the given formula to the passed formula.

**Parameters**

|                       |                                                                                                                           |
|-----------------------|---------------------------------------------------------------------------------------------------------------------------|
| <code>_formula</code> | The formula to add to the passed formula.                                                                                 |
| <code>_origin</code>  | The sub-formula of the received formula being responsible for the occurrence of the formula to add to the passed formula. |

**Returns**

A pair to the position where the formula to add has been inserted (or its first sub-formula which has not yet been in the passed formula, in case the formula to add is a conjunction), and a Boolean stating whether anything has been added to the passed formula.

**0.15.219.4.10 addSubformulaToPassedFormula() [3/3] std::pair<ModuleInput::iterator,bool>**

```
smrat::Module::addSubformulaToPassedFormula (
 const FormulaT & _formula,
 const std::shared_ptr< std::vector< FormulaT >> & _origins) [inline], [protected],
[inherited]
```

Adds the given formula to the passed formula.

**Parameters**

|                       |                                                                                                                                         |
|-----------------------|-----------------------------------------------------------------------------------------------------------------------------------------|
| <code>_formula</code> | The formula to add to the passed formula.                                                                                               |
| <code>_origins</code> | The link of the formula to add to the passed formula to sub-formulas of the received formulas, which are responsible for its occurrence |

**Returns**

A pair to the position where the formula to add has been inserted (or its first sub-formula which has not yet been in the passed formula, in case the formula to add is a conjunction), and a Boolean stating whether anything has been added to the passed formula.

**0.15.219.4.11 allModels() const std::vector<Model>& smrat::Module::allModels () const [inline], [inherited]****Returns**

All satisfying assignments, if existent.

**0.15.219.4.12 anAnswerFound() bool smrat::Module::anAnswerFound () const [inline], [protected], [inherited]**

Checks for all antecedent modules and those which run in parallel with the same antecedent modules, whether one of them has determined a result.

**Returns**

True, if one of them has determined a result.

**0.15.219.4.13 answerFound() const smrat::Conditionals& smrat::Module::answerFound () const [inline], [inherited]****Returns**

A vector of Booleans: If any of them is true, we have to terminate a running check procedure.

**0.15.219.4.14 appliedPreprocessing() bool smrat::PModule::appliedPreprocessing () const [inline], [inherited]****Returns**

true, if the current received formula has been simplified and the result of this simplification is stored in the passed formula.

---

**0.15.219.4.15 `backendsModel()`** const `Model` & smtrat::Module::backendsModel () const [protected], [inherited]

Stores the model of a backend which determined satisfiability of the passed formula in the model of this module.

**0.15.219.4.16 `branchAt() [1/4]`** bool smtrat::Module::branchAt ( carl::Variable::Arg \_var, const Rational & \_value, bool \_leftCaseWeak = true, bool \_preferLeftCase = true, bool \_useReceivedFormulaAsPremise = false, const std::vector< `FormulaT` > & \_premise = std::vector<`FormulaT`>() ) [inline], [protected], [inherited]

**0.15.219.4.17 `branchAt() [2/4]`** bool smtrat::Module::branchAt ( carl::Variable::Arg \_var, const Rational & \_value, std::vector< `FormulaT` > && \_premise, bool \_leftCaseWeak = true, bool \_preferLeftCase = true, bool \_useReceivedFormulaAsPremise = false ) [inline], [protected], [inherited]

**0.15.219.4.18 `branchAt() [3/4]`** bool smtrat::Module::branchAt ( const Poly & \_polynomial, bool \_integral, const Rational & \_value, bool \_leftCaseWeak = true, bool \_preferLeftCase = true, bool \_useReceivedFormulaAsPremise = false, const std::vector< `FormulaT` > & \_premise = std::vector<`FormulaT`>() ) [inline], [protected], [inherited]

**0.15.219.4.19 `branchAt() [4/4]`** bool smtrat::Module::branchAt ( const Poly & \_polynomial, bool \_integral, const Rational & \_value, std::vector< `FormulaT` > && \_premise, bool \_leftCaseWeak = true, bool \_preferLeftCase = true, bool \_useReceivedFormulaAsPremise = false ) [protected], [inherited]

Adds a lemmas which provoke a branching for the given variable at the given value, if this module returns Unknown and there exists a preceding `SATModule`.

Note that the given value is rounded down and up, if the given variable is integer-valued.

#### Parameters

|                            |                                                                                                                                                                                                                |
|----------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>_polynomial</code>   | The variable to branch for.                                                                                                                                                                                    |
| <code>_integral</code>     | A flag being true, if all variables in the polynomial to branch for are integral.                                                                                                                              |
| <code>_value</code>        | The value to branch at.                                                                                                                                                                                        |
| <code>_premise</code>      | The sub-formulas of the received formula from which the branch is followed. Note, that a premise is not necessary, as every branch is a valid formula. But a premise can prevent from branching unnecessarily. |
| <code>_leftCaseWeak</code> | true, if a branching in the form of (or ( $\leq p b$ ) ( $> p b$ )) is desired. false, if a branching in the form of (or ( $< p b$ ) ( $\geq p b$ )) is desired.                                               |

## Parameters

|                                           |                                                                                              |
|-------------------------------------------|----------------------------------------------------------------------------------------------|
| <code>_preferLeftCase</code>              | true, if the left case (polynomial less(or equal) 0 shall be chosen first. false, otherwise. |
| <code>_useReceivedFormulaAsPremise</code> | true, if the whole received formula should be used as premise                                |

**0.15.219.4.20 `check()`** `Answer smtrat::PModule::check (`

```
 bool _final = false,
 bool _full = true,
 carl::Variable _objective = carl::Variable::NO_VARIABLE) [virtual], [inherited]
```

Checks the received formula for consistency.

Note, that this is an implementation of the satisfiability check of the conjunction of the so far received formulas, which does actually nothing but passing the problem to its backends. This implementation is only used internally and must be overwritten by any derived module.

## Parameters

|                         |                                                                                                                                       |
|-------------------------|---------------------------------------------------------------------------------------------------------------------------------------|
| <code>_final</code>     | true, if this satisfiability check will be the last one (for a global sat-check), if its result is SAT                                |
| <code>_full</code>      | false, if this module should avoid too expensive procedures and rather return unknown instead.                                        |
| <code>_objective</code> | if not set to NO_VARIABLE, the module should find an assignment minimizing this objective variable; otherwise any assignment is good. |

## Returns

True, if the received formula is satisfiable; False, if the received formula is not satisfiable; Unknown, otherwise.

Reimplemented from [smtrat::Module](#).

**0.15.219.4.21 `checkCore()`** `template<typename Settings >`

```
Answer smtrat::FPPModule< Settings >::checkCore () [virtual]
```

Checks the received formula for consistency.

## Returns

SAT, if the received formula is satisfiable; UNSAT, if the received formula is not satisfiable; Unknown, otherwise.

Reimplemented from [smtrat::Module](#).

**0.15.219.4.22 `checkInfeasibleSubsetForMinimality()`** `void smtrat::Module::checkInfeasibleSubsetForMinimality (`

```
 std::vector< FormulaSet >::const_iterator _infssubset,
 const std::string & _filename = "smaller_muses",
 unsigned _maxSizeDifference = 1) const [inherited]
```

Checks the given infeasible subset for minimality by storing all subsets of it, which have a smaller size which differs from the size of the infeasible subset not more than the given threshold.

## Parameters

|                                 |                                                                                                        |
|---------------------------------|--------------------------------------------------------------------------------------------------------|
| <code>_infssubset</code>        | The infeasible subset to check for minimality.                                                         |
| <code>_filename</code>          | The name of the file to store the infeasible subsets in order to be able to check their infeasibility. |
| <code>_maxSizeDifference</code> | The maximal difference between the sizes of the subsets compared to the size of the infeasible subset. |

**0.15.219.4.23 checkModel()** `unsigned smtrat::Module::checkModel ( ) const [protected], [inherited]`

**Returns**

false, if the current model of this module does not satisfy the current given formula; true, if it cannot be said whether the model satisfies the given formula.

**0.15.219.4.24 cleanModel()** `void smtrat::Module::cleanModel ( ) const [inline], [protected], [inherited]`

Substitutes variable occurrences by its model value in the model values of other variables.

**0.15.219.4.25 clearLemmas()** `void smtrat::Module::clearLemmas ( ) [inline], [inherited]`  
Deletes all yet found lemmas.

**0.15.219.4.26 clearModel()** `void smtrat::Module::clearModel ( ) const [inline], [protected], [inherited]`

Clears the assignment, if any was found.

**0.15.219.4.27 clearModels()** `void smtrat::Module::clearModels ( ) const [inline], [protected], [inherited]`

Clears all assignments, if any was found.

**0.15.219.4.28 clearPassedFormula()** `void smtrat::Module::clearPassedFormula ( ) [protected], [inherited]`

**0.15.219.4.29 collectOrigins() [1/2]** `void smtrat::Module::collectOrigins ( const FormulaT & _formula, FormulaSetT & _origins ) const [inherited]`

**0.15.219.4.30 collectOrigins() [2/2]** `void smtrat::Module::collectOrigins ( const FormulaT & _formula, FormulasT & _origins ) const [inherited]`

Collects the formulas in the given formula, which are part of the received formula.

If the given formula directly occurs in the received formula, it is inserted into the given set. Otherwise, the given formula must be of type AND and all its sub-formulas part of the received formula. Hence, they will be added to the given set.

**Parameters**

|                       |                                                                                                      |
|-----------------------|------------------------------------------------------------------------------------------------------|
| <code>_formula</code> | The formula from which to collect the formulas being sub-formulas of the received formula (origins). |
| <code>_origins</code> | The set in which to store the origins.                                                               |

**0.15.219.4.31 collectTheoryPropagations()** `void smtrat::Module::collectTheoryPropagations ( ) [inherited]`

**0.15.219.4.32 constraintsToInform()** const carl::FastSet<[FormulaT](#)>& smtrat::Module::constraintsToInform( ) const [inline], [inherited]

**Returns**

The constraints which the backends must be informed about.

**0.15.219.4.33 currentlySatisfied()** virtual unsigned smtrat::Module::currentlySatisfied( const [FormulaT](#) & ) const [inline], [virtual], [inherited]

**Returns**

0, if the given formula is conflicted by the current model; 1, if the given formula is satisfied by the current model; 2, otherwise; 3, if we do not know anything (default)

Reimplemented in [smtrat::LRAModule< Settings >](#), [smtrat::LRAModule< LRASettingsICP >](#), and [smtrat::LRAModule< LRASettings >](#)

**0.15.219.4.34 currentlySatisfiedByBackend()** unsigned smtrat::Module::currentlySatisfiedByBackend( const [FormulaT](#) & \_formula ) const [inherited]

**Returns**

0, if the given formula is conflicted by the current model; 1, if the given formula is satisfied by the current model; 2, otherwise 3, if we do not know anything (default)

**0.15.219.4.35 deinform()** void smtrat::Module::deinform( const [FormulaT](#) & \_constraint ) [inherited]

The inverse of informing about a constraint.

All data structures which were kept regarding this constraint are going to be removed. Note, that this makes only sense if it is not likely enough that a formula with this constraint must be solved again.

**Parameters**

|                          |                                                         |
|--------------------------|---------------------------------------------------------|
| <code>_constraint</code> | The constraint to remove from internal data structures. |
|--------------------------|---------------------------------------------------------|

**0.15.219.4.36 deinformCore()** virtual void smtrat::Module::deinformCore( const [FormulaT](#) & \_constraint ) [inline], [protected], [virtual], [inherited]

The inverse of informing about a constraint.

All data structures which were kept regarding this constraint are going to be removed. Note, that this makes only sense if it is not likely enough that a formula with this constraint must be solved again.

**Parameters**

|                          |                                                         |
|--------------------------|---------------------------------------------------------|
| <code>_constraint</code> | The constraint to remove from internal data structures. |
|--------------------------|---------------------------------------------------------|

Reimplemented in [smtrat::LRAModule< Settings >](#), [smtrat::LRAModule< LRASettingsICP >](#), and [smtrat::LRAModule< LRASettings >](#)

**0.15.219.4.37 determine\_smallest\_origin()** size\_t smtrat::Module::determine\_smallest\_origin( const std::vector< [FormulaT](#) > & origins ) const [protected], [inherited]

**Parameters**

|                |                              |
|----------------|------------------------------|
| <i>origins</i> | A vector of sets of origins. |
|----------------|------------------------------|

**Returns**

The index of the smallest (regarding the size of the sets) element of origins

**0.15.219.4.38 `eraseSubformulaFromPassedFormula()`** `ModuleInput::iterator smtrat::Module::erase<SubformulaFromPassedFormula (`

`ModuleInput::iterator _subformula,`  
`bool _ignoreOrigins = false ) [protected], [virtual], [inherited]`

Removes everything related to the sub-formula to remove from the passed formula in the backends of this module.  
Afterwards the sub-formula is removed from the passed formula.

**Parameters**

|                       |                                                                                                              |
|-----------------------|--------------------------------------------------------------------------------------------------------------|
| <i>_subformula</i>    | The sub-formula to remove from the passed formula.                                                           |
| <i>_ignoreOrigins</i> | True, if the sub-formula shall be removed regardless of its origins (should only be applied with expertise). |

**Returns**

Reimplemented in `smtrat::ICPModule< Settings >`, `smtrat::ICPModule< ICPSettings4 >`, and `smtrat::ICPModule< ICPSettings1 >`.

**0.15.219.4.39 `excludeNotReceivedVariablesFromModel()`** `void smtrat::Module::excludeNotReceived<VariablesFromModel ( ) const [inherited]`

Excludes all variables from the current model, which do not occur in the received formula.

**0.15.219.4.40 `findBestOrigin()`** `std::vector< FormulaT >::const_iterator smtrat::Module::find<BestOrigin (`

`const std::vector< FormulaT > & _origins ) const [protected], [inherited]`

**Parameters**

|                 |  |
|-----------------|--|
| <i>_origins</i> |  |
|-----------------|--|

**Returns**

**0.15.219.4.41 `firstSubformulaToPass()`** `ModuleInput::const_iterator smtrat::Module::firstSubformula<ToPass ( ) const [inline], [inherited]`

**Returns**

The position of the first sub-formula in the passed formula, which has not yet been considered for a consistency check of the backends.

**0.15.219.4.42 firstUncheckedReceivedSubformula()** `ModuleInput::const_iterator smtrat::Module::firstUncheckedReceivedSubformula ( ) const [inline], [inherited]`

#### Returns

The position of the first (by this module) unchecked sub-formula of the received formula.

**0.15.219.4.43 freeSplittingVariable()** `static void smtrat::Module::freeSplittingVariable ( const FormulaT & _splittingVariable ) [inline], [static], [inherited]`

**0.15.219.4.44 generateTrivialInfeasibleSubset()** `void smtrat::Module::generateTrivialInfeasibleSubset ( ) [inline], [protected], [inherited]`

Stores the trivial infeasible subset being the set of received formulas.

**0.15.219.4.45 getBackendsAllModels()** `void smtrat::Module::getBackendsAllModels ( ) const [protected], [inherited]`

Stores all models of a backend in the list of all models of this module.

**0.15.219.4.46 getBackendsModel()** `void smtrat::Module::getBackendsModel ( ) const [protected], [inherited]`

**0.15.219.4.47 getInfeasibleSubsets() [1/2]** `void smtrat::Module::getInfeasibleSubsets ( ) [protected], [inherited]`

Copies the infeasible subsets of the passed formula.

**0.15.219.4.48 getInfeasibleSubsets() [2/2]** `std::vector< FormulaSetT > smtrat::Module::getInfeasibleSubsets (`

`const Module & _backend ) const [protected], [inherited]`

Get the infeasible subsets the given backend provides.

Note, that an infeasible subset in a backend contains sub formulas of the passed formula and an infeasible subset of this module contains sub formulas of the received formula. In this method the LATTER is returned.

#### Parameters

|                       |                                                          |
|-----------------------|----------------------------------------------------------|
| <code>_backend</code> | The backend from which to obtain the infeasible subsets. |
|-----------------------|----------------------------------------------------------|

#### Returns

The infeasible subsets the given backend provides.

**0.15.219.4.49 getInformationRelevantFormulas()** `const std::set< FormulaT > & smtrat::Module::getInformationRelevantFormulas ( ) [protected], [inherited]`

Gets all InformationRelevantFormulas.

#### Returns

Set of all formulas

**0.15.219.4.50 getModelEqualities()** `std::list< std::vector< carl::Variable > > smtrat::Module::getModelEqualities ( ) const [virtual], [inherited]`

Partition the variables from the current model into equivalence classes according to their assigned value.

The result is a set of equivalence classes of variables where all variables within one class are assigned the same value. Note that the number of classes may not be minimal, i.e. two classes may actually be equivalent.

#### Returns

Equivalence classes.

**0.15.219.4.51 getOrigins() [1/3]** `void smtrat::Module::getOrigins (`

```
const FormulaT & _formula,
FormulaSetT & _origins) const [inline], [protected], [inherited]
```

#### Parameters

|                       |  |
|-----------------------|--|
| <code>_formula</code> |  |
| <code>_origins</code> |  |

**0.15.219.4.52 getOrigins() [2/3]** `void smtrat::Module::getOrigins (`

```
const FormulaT & _formula,
FormulasT & _origins) const [inline], [protected], [inherited]
```

#### Parameters

|                       |  |
|-----------------------|--|
| <code>_formula</code> |  |
| <code>_origins</code> |  |

**0.15.219.4.53 getOrigins() [3/3]** `const FormulaT& smtrat::Module::getOrigins (`

```
ModuleInput::const_iterator _formula) const [inline], [protected], [inherited]
```

Gets the origins of the passed formula at the given position.

#### Parameters

|                       |                                                   |
|-----------------------|---------------------------------------------------|
| <code>_formula</code> | The position of a formula in the passed formulas. |
|-----------------------|---------------------------------------------------|

#### Returns

The origins of the passed formula at the given position.

**0.15.219.4.54 getReceivedFormulaSimplified()** `std::pair< bool, FormulaT > smtrat::PModule::getReceivedFormulaSimplified ( ) [virtual], [inherited]`

#### Returns

A pair of a Boolean and a formula, where the Boolean is true, if the received formula could be simplified to an equisatisfiable formula. The formula is equisatisfiable to this module's received formula, if the Boolean is true.

Reimplemented from [smtrat::Module](#).

**0.15.219.4.55 hasLemmas()** `bool smtrat::Module::hasLemmas () [inline], [inherited]`  
 Checks whether this module or any of its backends provides any lemmas.

**0.15.219.4.56 hasValidInfeasibleSubset()** `bool smtrat::Module::hasValidInfeasibleSubset () const [inherited]`

**Returns**

true, if the module has at least one valid infeasible subset, that is all its elements are sub-formulas of the received formula (pointer must be equal).

**0.15.219.4.57 id()** `std::size_t smtrat::Module::id () const [inline], [inherited]`

**Returns**

A unique ID to identify this module instance.

**0.15.219.4.58 infeasibleSubsets()** `const std::vector<FormulaSetT>& smtrat::Module::infeasibleSubsets () const [inline], [inherited]`

**Returns**

The infeasible subsets of the set of received formulas (empty, if this module has not detected unsatisfiability of the conjunction of received formulas).

**0.15.219.4.59 inform()** `bool smtrat::Module::inform (const FormulaT & _constraint) [inherited]`

Informs the module about the given constraint.

It should be tried to inform this module about any constraint it could receive eventually before assertSubformula is called (preferably for the first time, but at least before adding a formula containing that constraint).

**Parameters**

|                          |                                 |
|--------------------------|---------------------------------|
| <code>_constraint</code> | The constraint to inform about. |
|--------------------------|---------------------------------|

**Returns**

false, if it can be easily decided whether the given constraint is inconsistent; true, otherwise.

**0.15.219.4.60 informBackends()** `void smtrat::Module::informBackends (const FormulaT & _constraint) [inline], [protected], [inherited]`

Informs all backends of this module about the given constraint.

**Parameters**

|                          |                                 |
|--------------------------|---------------------------------|
| <code>_constraint</code> | The constraint to inform about. |
|--------------------------|---------------------------------|

**0.15.219.4.61 informCore()** `template<typename Settings > bool smtrat::FPPModule< Settings >::informCore (`

```
 const FormulaT & _constraint) [virtual]
```

Informs the module about the given constraint.

It should be tried to inform this module about any constraint it could receive eventually before assertSubformula is called (preferably for the first time, but at least before adding a formula containing that constraint).

#### Parameters

|                          |                                 |
|--------------------------|---------------------------------|
| <code>_constraint</code> | The constraint to inform about. |
|--------------------------|---------------------------------|

#### Returns

`false`, if it can be easily decided whether the given constraint is inconsistent; `true`, otherwise.

Reimplemented from [smtrat::Module](#).

**0.15.219.4.62 informedConstraints()** `const carl::FastSet<FormulaT>& smtrat::Module::informedConstraints ( ) const [inline], [inherited]`

#### Returns

The position of the first constraint of which no backend has been informed about.

**0.15.219.4.63 init()** `template<typename Settings > void smtrat::FPPModule< Settings >::init ( ) [virtual]`

Informs all backends about the so far encountered constraints, which have not yet been communicated.

This method must not and will not be called more than once and only before the first runBackends call.

Reimplemented from [smtrat::Module](#).

**0.15.219.4.64 is\_minimizing()** `bool smtrat::Module::is_minimizing ( ) const [inline], [inherited]`

**0.15.219.4.65 isLemmaLevel()** `bool smtrat::Module::isLemmaLevel (`

```
 LemmaLevel level) [protected], [inherited]
```

Checks if current lemma level is greater or equal to given level.

#### Parameters

|                    |                 |
|--------------------|-----------------|
| <code>level</code> | Level to check. |
|--------------------|-----------------|

**0.15.219.4.66 isPreprocessor()** `bool smtrat::PModule::isPreprocessor ( ) const [inline], [inherited]`

#### Returns

`true`, if this module is a preprocessor that is a module, which simplifies its received formula to an equisatisfiable formula being passed to its backends. The simplified formula can be obtained with [getReceivedFormulaSimplified\(\)](#).

**0.15.219.4.67 lemmas()** `const std::vector<Lemma>& smtrat::Module::lemmas ( ) const [inline], [inherited]`

**Returns**

A constant reference to the lemmas being valid formulas this module or its backends made.

**0.15.219.4.68 merge()** `std::vector< FormulaT > smtrat::Module::merge ( const std::vector< FormulaT > & _vecSetA, const std::vector< FormulaT > & _vecSetB ) const [protected], [inherited]`  
Merges the two vectors of sets into the first one.  
 $\{\{a,b\},\{a,c\}\}$  and  $\{\{b,d\},\{b\}\} \rightarrow \{\{a,b,d\},\{a,b\},\{a,b,c,d\},\{a,b,c\}\}$

**Parameters**

|                       |                                  |
|-----------------------|----------------------------------|
| <code>_vecSetA</code> | A vector of sets of constraints. |
| <code>_vecSetB</code> | A vector of sets of constraints. |

**Returns**

The vector being the two given vectors merged.

**0.15.219.4.69 model()** `const Model& smtrat::Module::model ( ) const [inline], [inherited]`

**Returns**

The assignment of the current satisfiable result, if existent.

**0.15.219.4.70 modelsDisjoint()** `bool smtrat::Module::modelsDisjoint ( const Model & _modelA, const Model & _modelB ) [static], [protected], [inherited]`  
Checks whether there is no variable assigned by both models.

**Parameters**

|                      |                                |
|----------------------|--------------------------------|
| <code>_modelA</code> | The first model to check for.  |
| <code>_modelB</code> | The second model to check for. |

**Returns**

true, if there is no variable assigned by both models; false, otherwise.

**0.15.219.4.71 moduleName()** `virtual std::string smtrat::Module::moduleName ( ) const [inline], [virtual], [inherited]`

**Returns**

The name of the given module type as name.

Reimplemented in [smtrat::VSModule< Settings >](#), [smtrat::UnionFindModule< Settings >](#), [smtrat::UFCegarModule< Settings >](#), [smtrat::STropModule< Settings >](#), [smtrat::SplitSOSModule< Settings >](#), [smtrat::PBPPModule< Settings >](#), [smtrat::PBGaussModule< Settings >](#), [smtrat::NRAILModule< Settings >](#), [smtrat::NewCADModule< Settings >](#), [smtrat::LVEModule< Settings >](#), [smtrat::LRAModule< Settings >](#), [smtrat::LRAModule< LRASettingsICP >](#), [smtrat::LRAModule< LRASettings1 >](#), [smtrat::IntEqModule< Settings >](#), [smtrat::IntBlastModule< Settings >](#), [smtrat::IncWidthModule< Settings >](#), [smtrat::ICPModule< Settings >](#), [smtrat::ICPModule< ICPSettings4 >](#),

smrat::ICPModule< ICPSettings1 >, smrat::GBModule< Settings >, smrat::FouMoModule< Settings >, smrat::EQPreprocessingModule< Settings >, smrat::EQModule< Settings >, smrat::CurryModule< Settings >, smrat::CubeLIAModule< Settings >, smrat::CSplitModule< Settings >, smrat::BVMModule< Settings >, and smrat::BEModule< Settings >.

**0.15.219.4.72 objective()** carl::Variable smrat::Module::objective ( ) const [inline], [inherited]

**0.15.219.4.73 originInReceivedFormula()** bool smrat::Module::originInReceivedFormula ( const FormulaT & \_origin ) const [protected], [inherited]

**0.15.219.4.74 passedFormulaBegin()** ModuleInput::iterator smrat::Module::passedFormulaBegin ( ) [inline], [protected], [inherited]

**Returns**

An iterator to the end of the passed formula. TODO: disable this method

**0.15.219.4.75 passedFormulaEnd()** ModuleInput::iterator smrat::Module::passedFormulaEnd ( ) [inline], [protected], [inherited]

**Returns**

An iterator to the end of the passed formula.

**0.15.219.4.76 pPassedFormula()** const ModuleInput\* smrat::Module::pPassedFormula ( ) const [inline], [inherited]

**Returns**

A pointer to the formula passed to the backends of this module.

**0.15.219.4.77 pReceivedFormula()** const ModuleInput\* smrat::Module::pReceivedFormula ( ) const [inline], [inherited]

**Returns**

A pointer to the formula passed to this module.

**0.15.219.4.78 print()** void smrat::Module::print ( const std::string & \_initiation = "\*\*\*" ) const [inherited]

Prints everything relevant of the solver.

**Parameters**

|                    |                      |
|--------------------|----------------------|
| <i>_initiation</i> | The line initiation. |
|--------------------|----------------------|

**0.15.219.4.79 printAllModels()** void smrat::Module::printAllModels ( std::ostream & \_out = std::cout ) [inherited]

Prints all assignments of this module satisfying its received formula if it satisfiable and this module could find an assignment.

**Parameters**

|                   |                                        |
|-------------------|----------------------------------------|
| <code>_out</code> | The stream to print the assignment on. |
|-------------------|----------------------------------------|

**0.15.219.4.80 `printInfeasibleSubsets()`** `void smtrat::Module::printInfeasibleSubsets ( const std::string & _initiation = "***" ) const [inherited]`

Prints the infeasible subsets.

**Parameters**

|                          |                      |
|--------------------------|----------------------|
| <code>_initiation</code> | The line initiation. |
|--------------------------|----------------------|

**0.15.219.4.81 `printModel()`** `void smtrat::Module::printModel ( std::ostream & _out = std::cout ) const [inherited]`

Prints the assignment of this module satisfying its received formula if it satisfiable and this module could find an assignment.

**Parameters**

|                   |                                        |
|-------------------|----------------------------------------|
| <code>_out</code> | The stream to print the assignment on. |
|-------------------|----------------------------------------|

**0.15.219.4.82 `printPassedFormula()`** `void smtrat::Module::printPassedFormula ( const std::string & _initiation = "***" ) const [inherited]`

Prints the vector of passed formula.

**Parameters**

|                          |                      |
|--------------------------|----------------------|
| <code>_initiation</code> | The line initiation. |
|--------------------------|----------------------|

**0.15.219.4.83 `printReceivedFormula()`** `void smtrat::Module::printReceivedFormula ( const std::string & _initiation = "***" ) const [inherited]`

Prints the vector of the received formula.

**Parameters**

|                          |                      |
|--------------------------|----------------------|
| <code>_initiation</code> | The line initiation. |
|--------------------------|----------------------|

**0.15.219.4.84 `probablyLooping()`** `bool smtrat::Module::probablyLooping ( const typename Poly::PolyType & _branchingPolynomial, const Rational & _branchingValue ) const [protected], [inherited]`

Checks whether given the current branching value and branching variable/polynomial it is (highly) probable that this branching is part of an infinite loop of branchings.

#### Parameters

|                             |                                                                                     |
|-----------------------------|-------------------------------------------------------------------------------------|
| <i>_branchingPolynomial</i> | The polynomial to branch at (in most branching strategies this is just a variable). |
| <i>_branchingValue</i>      | The value to branch at.                                                             |

#### Returns

true, if this branching is probably part of an infinite loop of branchings; false, otherwise.

**0.15.219.4.85 receivedFormulaChecked()** void smrat::Module::receivedFormulaChecked ( ) [inline], [inherited]

Notifies that the received formulas has been checked.

**0.15.219.4.86 receivedFormulasAsInfeasibleSubset()** void smrat::Module::receivedFormulasAsInfeasibleSubset (

`ModuleInput::const_iterator _subformula`) [inline], [protected], [inherited]

Stores an infeasible subset consisting only of the given received formula.

**0.15.219.4.87 receivedVariable()** bool smrat::Module::receivedVariable (

`carl::Variable::Arg _var`) const [inline], [inherited]

**0.15.219.4.88 remove()** void smrat::PModule::remove (

`ModuleInput::const_iterator _subformula`) [virtual], [inherited]

Removes everything related to the given sub-formula of the received formula.

However, it is desired not to lose track of search spaces where no satisfying assignment can be found for the remaining sub-formulas.

#### Parameters

|                    |                                                    |
|--------------------|----------------------------------------------------|
| <i>_subformula</i> | The sub formula of the received formula to remove. |
|--------------------|----------------------------------------------------|

Reimplemented from [smrat::Module](#).

**0.15.219.4.89 removeCore()** template<typename Settings >

void smrat::FPPModule< Settings >::removeCore (

`ModuleInput::const_iterator _subformula`) [virtual]

Removes the subformula of the received formula at the given position to the considered ones of this module.

Note that this includes every stored calculation which depended on this subformula, but should keep the other stored calculation, if possible, untouched.

#### Parameters

|                    |                                           |
|--------------------|-------------------------------------------|
| <i>_subformula</i> | The position of the subformula to remove. |
|--------------------|-------------------------------------------|

Reimplemented from [smrat::Module](#).

**0.15.219.4.90 removeOrigin()** std::pair<[ModuleInput::iterator](#),bool> smrat::Module::removeOrigin (

`ModuleInput::iterator _formula,`

```
const FormulaT & _origin) [inline], [protected], [inherited]
```

**0.15.219.4.91 removeOrigins()** std::pair<[ModuleInput](#)::iterator, bool> smtrat::Module::removeOrigins (

```
 ModuleInput::iterator _formula,
 const std::shared_ptr< std::vector< FormulaT >> & _origins) [inline], [protected],
[inherited]
```

**0.15.219.4.92 rPassedFormula()** const [ModuleInput](#)& smtrat::Module::rPassedFormula () const [inline], [inherited]

#### Returns

A reference to the formula passed to the backends of this module.

**0.15.219.4.93 rReceivedFormula()** const [ModuleInput](#)& smtrat::Module::rReceivedFormula () const [inline], [inherited]

#### Returns

A reference to the formula passed to this module.

**0.15.219.4.94 runBackends() [1/2]** virtual [Answer](#) smtrat::PModule::runBackends () [inline], [virtual], [inherited]

Reimplemented from [smtrat::Module](#).

**0.15.219.4.95 runBackends() [2/2]** [Answer](#) smtrat::PModule::runBackends (

```
 bool _final,
 bool _full,
 carl::Variable _objective) [virtual], [inherited]
```

Runs the backend solvers on the passed formula.

#### Parameters

|                   |                                                                                                                                       |
|-------------------|---------------------------------------------------------------------------------------------------------------------------------------|
| <i>_final</i>     | true, if this satisfiability check will be the last one (for a global sat-check), if its result is SAT.                               |
| <i>_full</i>      | false, if this module should avoid too expensive procedures and rather return unknown instead.                                        |
| <i>_objective</i> | if not set to NO_VARIABLE, the module should find an assignment minimizing this objective variable; otherwise any assignment is good. |

#### Returns

True, if the passed formula is consistent; False, if the passed formula is inconsistent; Unknown, otherwise.

Reimplemented from [smtrat::Module](#).

**0.15.219.4.96 setId()** void smtrat::Module::setId (

```
 std::size_t _id) [inline], [inherited]
```

Sets this modules unique ID to identify itself.

**Parameters**

|                               |                                    |
|-------------------------------|------------------------------------|
| $\leftrightarrow$             | The id to set this module's id to. |
| $\underline{\leftrightarrow}$ |                                    |

**0.15.219.4.97 `setThreadPriority()`** `void smtrat::Module::setThreadPriority ( thread_priority _threadPriority )` [inline], [inherited]

Sets the priority of this module to get a thread for running its check procedure.

**Parameters**

|                              |                                                       |
|------------------------------|-------------------------------------------------------|
| <code>_threadPriority</code> | The priority to set this module's thread priority to. |
|------------------------------|-------------------------------------------------------|

**0.15.219.4.98 `solverState()`** `Answer smtrat::Module::solverState ( ) const` [inline], [inherited]

**Returns**

True, if this module is in a state, such that it has found a solution for its received formula; False, if this module is in a state, such that it has determined that there is no solution for its received formula; Unknown, otherwise.

**0.15.219.4.99 `splitUnequalConstraint()`** `void smtrat::Module::splitUnequalConstraint ( const FormulaT & _unequalConstraint )` [protected], [inherited]

Adds the following lemmas for the given constraint  $p \neq 0$ .

$(p \neq 0 \leftrightarrow (p < 0 \text{ or } p > 0))$

and  $\neg(p < 0 \text{ and } p > 0)$

**Parameters**

|                                 |                                                  |
|---------------------------------|--------------------------------------------------|
| <code>_unequalConstraint</code> | A constraint having the relation symbol $\neq$ . |
|---------------------------------|--------------------------------------------------|

**0.15.219.4.100 `threadPriority()`** `thread_priority smtrat::Module::threadPriority ( ) const` [inline], [inherited]

**Returns**

The priority of this module to get a thread for running its check procedure.

**0.15.219.4.101 `updateAllModels()`** `void smtrat::Module::updateAllModels ( )` [virtual], [inherited]

Updates all satisfying models, if the solver has detected the consistency of the received formula, beforehand.

Reimplemented in [smtrat::SATModule< Settings >](#).

**0.15.219.4.102 `updateLemmas()`** `void smtrat::Module::updateLemmas ( )` [inherited]

Stores all lemmas of any backend of this module in its own lemma vector.

**0.15.219.4.103 updateModel()** template<typename Settings>  
void smrat::FPPModule<Settings>::updateModel() const [virtual]

Updates the current assignment into the model.

Note, that this is a unique but possibly symbolic assignment maybe containing newly introduced variables.

Reimplemented from [smrat::Module](#).

**0.15.219.4.104 usedBackends()** const std::vector<[Module](#)\*>& smrat::Module::usedBackends() const [inline], [inherited]

#### Returns

The backends of this module which are currently used (conditions to use this module are fulfilled for the passed formula).

### 0.15.219.5 Field Documentation

**0.15.219.5.1 mAllBackends** std::vector<[Module](#)\*> smrat::Module::mAllBackends [protected], [inherited]

The backends of this module which have been used.

**0.15.219.5.2 mAllModels** std::vector<[Model](#)> smrat::Module::mAllModels [mutable], [protected], [inherited]

Stores all satisfying assignments.

**0.15.219.5.3 mBackendsFoundAnswer** std::atomic\_bool\* smrat::Module::mBackendsFoundAnswer [protected], [inherited]

This flag is passed to any backend and if it determines an answer to a prior check call, this flag is fired.

**0.15.219.5.4 mConstraintsToInform** carl::FastSet<[FormulaT](#)> smrat::Module::mConstraintsToInform [protected], [inherited]

Stores the constraints which the backends must be informed about.

**0.15.219.5.5 mFinalCheck** bool smrat::Module::mFinalCheck [protected], [inherited]  
true, if the check procedure should perform a final check which especially means not to postpone splitting decisions

**0.15.219.5.6 mFirstPosInLastBranches** std::size\_t smrat::Module::mFirstPosInLastBranches = 0 [static], [inherited]

The beginning of the cyclic buffer storing the last branches.

**0.15.219.5.7 mFirstSubformulaToPass** [ModuleInput](#)::iterator smrat::Module::mFirstSubformulaToPass [protected], [inherited]
