Stores the position of the first sub-formula in the passed formula, which has not yet been considered for a consistency check of the backends.

**0.15.219.5.8 mFirstUncheckedReceivedSubformula** [ModuleInput](#)::const\_iterator smrat::Module::mFirstUncheckedReceivedSubformula [protected], [inherited]

Stores the position of the first (by this module) unchecked sub-formula of the received formula.

**0.15.219.5.9 mFoundAnswer** `Conditionals` `smtrat::Module::mFoundAnswer` [protected], [inherited]  
Vector of Booleans: If any of them is true, we have to terminate a running check procedure.

**0.15.219.5.10 mFullCheck** `bool` `smtrat::Module::mFullCheck` [protected], [inherited]  
false, if this module should avoid too expensive procedures and rather return unknown instead.

**0.15.219.5.11 mInfeasibleSubsets** `std::vector<FormulaSetT>` `smtrat::Module::mInfeasibleSubsets` [protected], [inherited]  
Stores the infeasible subsets.

**0.15.219.5.12 mInformedConstraints** `carl::FastSet<FormulaT>` `smtrat::Module::mInformedConstraints` [protected], [inherited]  
Stores the position of the first constraint of which no backend has been informed about.

**0.15.219.5.13 mLastBranches** `std::vector<Branching>` `smtrat::Module::mLastBranches` = `std::vector<Branching>(mNumOfBranchVarsToStore, Branching(typename Poly::PolyType(), 0))` [static], [inherited]  
Stores the last branches in a cycle buffer.

**0.15.219.5.14 mLemmas** `std::vector<Lemma>` `smtrat::Module::mLemmas` [protected], [inherited]  
Stores the lemmas being valid formulas this module or its backends made.

**0.15.219.5.15 mModel** `Model` `smtrat::Module::mModel` [mutable], [protected], [inherited]  
Stores the assignment of the current satisfiable result, if existent.

**0.15.219.5.16 mModelComputed** `bool` `smtrat::Module::mModelComputed` [mutable], [protected], [inherited]  
True, if the model has already been computed.

**0.15.219.5.17 mNumOfBranchVarsToStore** `std::size_t` `smtrat::Module::mNumOfBranchVarsToStore` = 5 [static], [inherited]  
The number of different variables to consider for a probable infinite loop of branchings.

**0.15.219.5.18 mObjectiveVariable** `carl::Variable` `smtrat::Module::mObjectiveVariable` [protected], [inherited]  
Objective variable to be minimized. If set to NO\_VARIABLE, a normal sat check should be performed.

**0.15.219.5.19 mOldSplittingVariables** `std::vector<FormulaT>` `smtrat::Module::mOldSplittingVariables` [static], [inherited]  
Reusable splitting variables.

**0.15.219.5.20 mpManager** `Manager*` `const smtrat::Module::mpManager` [protected], [inherited]  
A reference to the manager.

**0.15.219.5.21 mSmallerMusesCheckCounter** `unsigned smtrat::Module::mSmallerMusesCheckCounter`  
 [mutable], [protected], [inherited]  
 Counter used for the generation of the smt2 files to check for smaller muses.

**0.15.219.5.22 mSolverState** `std::atomic<Answer> smtrat::Module::mSolverState` [protected],  
 [inherited]

States whether the received formula is known to be satisfiable or unsatisfiable otherwise it is set to unknown.

**0.15.219.5.23 mTheoryPropagations** `std::vector<TheoryPropagation> smtrat::Module::mTheory←Propagations` [protected], [inherited]

**0.15.219.5.24 mUsedBackends** `std::vector<Module*> smtrat::Module::mUsedBackends` [protected],  
 [inherited]  
 The backends of this module which are currently used (conditions to use this module are fulfilled for the passed formula).

**0.15.219.5.25 mVariableCounters** `std::vector<std::size_t> smtrat::Module::mVariableCounters`  
 [protected], [inherited]  
 Maps variables to the number of their occurrences.

## 0.15.220 smtrat::freelist< T > Class Template Reference

Implements a fixed-(at-runtime)-size allocator based on a free list embedded in the space of currently unused objects.

```
#include <alloc.h>
```

### Public Member Functions

- `freelist ()`
- `freelist (std::size_t chunk_size_)`
- `~freelist ()`
- template<typename... Args>  
`T & emplace (Args &&... args)`
- `void * alloc ()`  
*Allocate an object of size 1<<mSizeShift.*
- `void free (void *ptr) NOEXCEPT`  
*Freeing means just prepending the free'd element to the front of the freelist.*
- `void clear () NOEXCEPT`  
*Invalidate ALL entries allocated using this allocator.*

### 0.15.220.1 Detailed Description

```
template<typename T>
class smtrat::freelist< T >
```

Implements a fixed-(at-runtime)-size allocator based on a free list embedded in the space of currently unused objects.

Caution: Do not use this with types that need their destructor to be called, only for trivial types (like pointers, iterators, scalar values, ...). Otherwise, do not use the `clear()` method and call the destructor before `free()`.

### 0.15.220.2 Constructor & Destructor Documentation

**0.15.220.2.1 freelist() [1/2]** template<typename T >  
smtrat::freelist< T >::freelist ( ) [inline], [explicit]

**0.15.220.2.2 freelist() [2/2]** template<typename T >  
smtrat::freelist< T >::freelist ( std::size\_t chunk\_size\_ ) [inline], [explicit]

**0.15.220.2.3 ~freelist()** template<typename T >  
smtrat::freelist< T >::~freelist ( ) [inline]

### 0.15.220.3 Member Function Documentation

**0.15.220.3.1 alloc()** template<typename T >  
void\* smtrat::freelist< T >::alloc ( ) [inline]

Allocate an object of size  $1 \ll \text{mSizeShift}$ .

First, try to return the first entry on the freelist.

If that is empty, try forward-allocation (allocating the next element on the current page that has never been allocated before.)

Otherwise, go to the next page.

If there is no next page, allocate a new page with malloc. This page has twice the space of the previous page.

Start forward-allocation phase on the new page.

**0.15.220.3.2 clear()** template<typename T >  
void smtrat::freelist< T >::clear ( ) [inline]

Invalidate ALL entries allocated using this allocator.

Note that this does not call the destructor of any elements, and does not return any memory to the OS.

**0.15.220.3.3 emplace()** template<typename T >  
template<typename... Args>  
T& smtrat::freelist< T >::emplace ( Args &&... args ) [inline]

**0.15.220.3.4 free()** template<typename T >  
void smtrat::freelist< T >::free ( void \* ptr ) [inline]

Freeling means just prepending the free'd element to the front of the freelist.

## 0.15.221 smtrat::mcsat::FullParallelExplanation< Backends > Struct Template Reference

This explanation executes all given explanation parallel in multiple threads and waits until every single one has finished, returning the result of the first listed explanation.

```
#include <FullParallelExplanation.h>
```

### 0.15.221.1 Detailed Description

```
template<typename... Backends>
struct smtrat::mcsat::FullParallelExplanation< Backends >
```

This explanation executes all given explanation parallel in multiple threads and waits until every single one has finished, returning the result of the first listed explanation.

## 0.15.227 smtrat::GBModule< Settings > Class Template Reference

A solver module based on Groebner basis.

```
#include <GBModule.h>
```

### Public Types

- `typedef Settings SettingsType`
- `typedef Settings::Order Order`
- `typedef Settings::PolynomialWithReasons GBPolynomial`
- `typedef Settings::Multivariateideal Ideal`
- `enum class LemmaType : unsigned { NORMAL = 0 , PERMANENT = 1 }`

### Public Member Functions

- `std::string moduleName () const`
  - The module has to take the given sub-formula of the received formula into account.*
- `GBModule (const ModuleInput *const, Conditionals &, Manager *const =NULL)`
- `virtual ~GBModule ()`
- `bool addCore (ModuleInput::const_iterator _formula)`
  - Checks the received formula for consistency.*
- `virtual Answer checkCore ()`
  - Removes everything related to the given sub-formula of the received formula.*
- `void removeCore (ModuleInput::const_iterator _formula)`
  - Informs the module about the given constraint.*
- `void printStateHistory ()`
- `void printRewriteRules ()`
- `bool inform (const FormulaT &_constraint)`
  - The inverse of informing about a constraint.*
- `void deinform (const FormulaT &_constraint)`
  - Informs all backends about the so far encountered constraints, which have not yet been communicated.*
- `bool add (ModuleInput::const_iterator _subformula)`
  - Checks the received formula for consistency.*
- `virtual Answer check (bool _final=false, bool _full=true, carl::Variable _objective=carl::Variable::NO_VARIABLE)`
  - Removes everything related to the given sub-formula of the received formula.*
- `virtual void remove (ModuleInput::const_iterator _subformula)`
  - Updates the model, if the solver has detected the consistency of the received formula, beforehand.*
- `virtual void updateModel () const`
  - Updates all satisfying models, if the solver has detected the consistency of the received formula, beforehand.*
- `virtual std::list< std::vector< carl::Variable > > getModelEqualities () const`
  - Partition the variables from the current model into equivalence classes according to their assigned value.*
- `unsigned currentlySatisfiedByBackend (const FormulaT &_formula) const`
- `virtual unsigned currentlySatisfied (const FormulaT &) const`
- `bool receivedVariable (carl::Variable::Arg _var) const`
- `Answer solverState () const`

- std::size\_t `id () const`
- void `setId (std::size_t _id)`

*Sets this module's unique ID to identify itself.*
- `thread_priority threadPriority () const`
- void `setThreadPriority (thread_priority _threadPriority)`

*Sets the priority of this module to get a thread for running its check procedure.*
- const `ModuleInput * pReceivedFormula () const`
- const `ModuleInput & rReceivedFormula () const`
- const `ModuleInput * pPassedFormula () const`
- const `ModuleInput & rPassedFormula () const`
- const `Model & model () const`
- const std::vector< `Model` > & `allModels () const`
- const std::vector< `FormulaSetT` > & `infeasibleSubsets () const`
- const std::vector< `Module` \* > & `usedBackends () const`
- const carl::FastSet< `FormulaT` > & `constraintsToInform () const`
- const carl::FastSet< `FormulaT` > & `informedConstraints () const`
- void `addLemma (const FormulaT &_lemma, const LemmaType &_lt=LemmaType::NORMAL, const FormulaT &_preferredFormula=FormulaT(carl::FormulaType::TRUE))`

*Stores a lemma being a valid formula.*
- bool `hasLemmas ()`

*Checks whether this module or any of its backends provides any lemmas.*
- void `clearLemmas ()`

*Deletes all yet found lemmas.*
- const std::vector< `Lemma` > & `lemmas () const`
- `ModuleInput::const_iterator firstUncheckedReceivedSubformula () const`
- `ModuleInput::const_iterator firstSubformulaToPass () const`
- void `receivedFormulaChecked ()`

*Notifies that the received formulas has been checked.*
- const `smrat::Conditionals & answerFound () const`
- bool `isPreprocessor () const`
- carl::Variable `objective () const`
- bool `is_minimizing () const`
- void `excludeNotReceivedVariablesFromModel () const`

*Excludes all variables from the current model, which do not occur in the received formula.*
- void `updateLemmas ()`

*Stores all lemmas of any backend of this module in its own lemma vector.*
- void `collectTheoryPropagations ()`
- void `collectOrigins (const FormulaT &_formula, FormulasT &_origins) const`

*Collects the formulas in the given formula, which are part of the received formula.*
- void `collectOrigins (const FormulaT &_formula, FormulaSetT &_origins) const`
- bool `hasValidInfeasibleSubset () const`
- void `checkInfSubsetForMinimality (std::vector< FormulaSetT >::const_iterator _infsSubset, const std::string &_filename="smaller_muses", unsigned _maxSizeDifference=1) const`

*Checks the given infeasible subset for minimality by storing all subsets of it, which have a smaller size which differs from the size of the infeasible subset not more than the given threshold.*
- virtual std::pair< bool, `FormulaT` > `getReceivedFormulaSimplified ()`
- void `print (const std::string &_initiation="***") const`

*Prints everything relevant of the solver.*
- void `printReceivedFormula (const std::string &_initiation="***") const`

*Prints the vector of the received formula.*
- void `printPassedFormula (const std::string &_initiation="***") const`

*Prints the vector of passed formula.*
- void `printInfeasibleSubsets (const std::string &_initiation="***") const`

- Prints the infeasible subsets.
  - void **printModel** (std::ostream &\_out=std::cout) const
    - Prints the assignment of this module satisfying its received formula if it satisfiable and this module could find an assignment.
  - void **printAllModels** (std::ostream &\_out=std::cout)
    - Prints all assignments of this module satisfying its received formula if it satisfiable and this module could find an assignment.

## Static Public Member Functions

- static void **freeSplittingVariable** (const **FormulaT** &\_splittingVariable)

## Static Public Attributes

- static size\_t **mNumOfBranchVarsToStore** = 5
  - The number of different variables to consider for a probable infinite loop of branchings.
- static std::vector< **Branching** > **mLastBranches** = std::vector<**Branching**>(mNumOfBranchVarsToStore, **Branching**(typename Poly::PolyType(), 0))
  - Stores the last branches in a cycle buffer.
- static size\_t **mFirstPosInLastBranches** = 0
  - The beginning of the cyclic buffer storing the last branches.
- static std::vector< **FormulaT** > **mOldSplittingVariables**
  - Reusable splitting variables.

## Protected Member Functions

- bool **constraintByGB** (carl::Relation cr)

- **GBPolynomial** **rewriteVariable** (const **GBPolynomial** &, const carl::Variable &, const **TermT** &, const BitVector &)
- bool **validityCheck** ()
- virtual bool **informCore** (const **FormulaT** &\_constraint)
  - Informs the module about the given constraint.
- virtual void **deinformCore** (const **FormulaT** &\_constraint)
  - The inverse of informing about a constraint.
- bool **anAnswerFound** () const

- Checks for all antecedent modules and those which run in parallel with the same antecedent modules, whether one of them has determined a result.*
- void `clearModel () const`

*Clears the assignment, if any was found.*
  - void `clearModels () const`

*Clears all assignments, if any was found.*
  - void `cleanModel () const`

*Substitutes variable occurrences by its model value in the model values of other variables.*
  - `ModuleInput::iterator passedFormulaBegin ()`
  - `ModuleInput::iterator passedFormulaEnd ()`
  - void `addOrigin (ModuleInput::iterator _formula, const FormulaT &_origin)`

*Adds the given set of formulas in the received formula to the origins of the given passed formula.*
  - const `FormulaT & getOrigins (ModuleInput::const_iterator _formula) const`

*Gets the origins of the passed formula at the given position.*
  - void `getOrigins (const FormulaT &_formula, FormulasT &_origins) const`
  - void `getOrigins (const FormulaT &_formula, FormulaSetT &_origins) const`
  - std::pair< `ModuleInput::iterator, bool` > `removeOrigin (ModuleInput::iterator _formula, const FormulaT &_origin)`
  - std::pair< `ModuleInput::iterator, bool` > `removeOrigins (ModuleInput::iterator _formula, const std::shared_ptr< std::vector< FormulaT >> &_origins)`
  - void `informBackends (const FormulaT &_constraint)`

*Informs all backends of this module about the given constraint.*
  - virtual void `addConstraintToInform (const FormulaT &_constraint)`

*Adds a constraint to the collection of constraints of this module, which are informed to a freshly generated backend.*
  - std::pair< `ModuleInput::iterator, bool` > `addReceivedSubformulaToPassedFormula (ModuleInput::const_iterator _subformula)`

*Copies the given sub-formula of the received formula to the passed formula.*
  - bool `originInReceivedFormula (const FormulaT &_origin) const`
  - std::pair< `ModuleInput::iterator, bool` > `addSubformulaToPassedFormula (const FormulaT &_formula)`

*Adds the given formula to the passed formula with no origin.*
  - std::pair< `ModuleInput::iterator, bool` > `addSubformulaToPassedFormula (const FormulaT &_formula, const std::shared_ptr< std::vector< FormulaT >> &_origins)`

*Adds the given formula to the passed formula.*
  - std::pair< `ModuleInput::iterator, bool` > `addSubformulaToPassedFormula (const FormulaT &_formula, const FormulaT &_origin)`

*Adds the given formula to the passed formula.*
  - void `generateTrivialInfeasibleSubset ()`

*Stores the trivial infeasible subset being the set of received formulas.*
  - void `receivedFormulasAsInfeasibleSubset (ModuleInput::const_iterator _subformula)`

*Stores an infeasible subset consisting only of the given received formula.*
  - std::vector< `FormulaT` >::const\_iterator `findBestOrigin (const std::vector< FormulaT > &_origins) const`
  - void `getInfeasibleSubsets ()`

*Copies the infeasible subsets of the passed formula.*
  - std::vector< `FormulaSetT` > `getInfeasibleSubsets (const Module &backend) const`

*Get the infeasible subsets the given backend provides.*
  - const `Model & backendsModel () const`

*Stores the model of a backend which determined satisfiability of the passed formula in the model of this module.*
  - void `getBackendsModel () const`
  - void `getBackendsAllModels () const`

*Stores all models of a backend in the list of all models of this module.*
  - virtual `Answer runBackends (bool _final, bool _full, carl::Variable _objective)`

*Runs the backend solvers on the passed formula.*

- virtual `Answer runBackends ()`
- virtual `ModuleInput::iterator eraseSubformulaFromPassedFormula (ModuleInput::iterator _subformula, bool _ignoreOrigins=false)`

*Removes everything related to the sub-formula to remove from the passed formula in the backends of this module.*
- void `clearPassedFormula ()`
- std::vector< `FormulaT` > `merge` (const std::vector< `FormulaT` > &, const std::vector< `FormulaT` > &) const

*Merges the two vectors of sets into the first one.*
- size\_t `determine_smallest_origin` (const std::vector< `FormulaT` > &origins) const
- bool `probablyLooping` (const typename Poly::PolyType &\_branchingPolynomial, const `Rational` &\_branchingValue) const

*Checks whether given the current branching value and branching variable/polynomial it is (highly) probable that this branching is part of an infinite loop of branchings.*
- bool `branchAt` (const `Poly` &\_polynomial, bool \_integral, const `Rational` &\_value, std::vector< `FormulaT` > &&\_premise, bool \_leftCaseWeak=true, bool \_preferLeftCase=true, bool \_useReceivedFormulaAsPremise=false)

*Adds a lemmas which provoke a branching for the given variable at the given value, if this module returns Unknown and there exists a preceding SATModule.*
- bool `branchAt` (const `Poly` &\_polynomial, bool \_integral, const `Rational` &\_value, bool \_leftCaseWeak=true, bool \_preferLeftCase=true, bool \_useReceivedFormulaAsPremise=false, const std::vector< `FormulaT` > &\_premise=std::vector< `FormulaT` >())
- bool `branchAt` (carl::Variable::Arg \_var, const `Rational` &\_value, std::vector< `FormulaT` > &&\_premise, bool \_leftCaseWeak=true, bool \_preferLeftCase=true, bool \_useReceivedFormulaAsPremise=false)
- bool `branchAt` (carl::Variable::Arg \_var, const `Rational` &\_value, bool \_leftCaseWeak=true, bool \_preferLeftCase=true, bool \_useReceivedFormulaAsPremise=false, const std::vector< `FormulaT` > &\_premise=std::vector< `FormulaT` >())
- void `splitUnequalConstraint` (const `FormulaT` &)

*Adds the following lemmas for the given constraint  $p \neq 0$ .*
- unsigned `checkModel ()` const
- void `addInformationRelevantFormula` (const `FormulaT` &formula)

*Adds a formula to the InformationRelevantFormula.*
- const std::set< `FormulaT` > & `getInformationRelevantFormulas ()`

*Gets all InformationRelevantFormulas.*
- bool `isLemmaLevel` (`LemmaLevel` level)

*Checks if current lemma level is greater or equal to given level.*

## Static Protected Member Functions

- static bool `modelsDisjoint` (const `Model` &\_modelA, const `Model` &\_modelB)

*Checks whether there is no variable assigned by both models.*

## Protected Attributes

- Settings::Groebner `mBasis`

*The current Groebner basis.*
- InequalitiesTable< `Settings` > `mInequalities`

*The inequalities table for handling inequalities.*
- std::vector< `ModuleInput::const_iterator` > `mBacktrackPoints`

*The vector of backtrack points, which has pointers to received constraints.*
- std::list< `GBModuleState< Settings >` > `mStateHistory`

*Saves the relevant history to support backtracking.*
- bool `mRecalculateGB`

*After popping in the history, it might be necessary to recalculate. This flag indicates this.*
- std::list< typename InequalitiesTable< `Settings` >::Rows::iterator > `mNewInequalities`

*A list of inequalities which were added after the last consistency check.*

- **groebner::RewriteRules mRewriteRules**  
*The rewrite rules for the variables.*
- **std::map< ConstraintT, carl::Variable > mAdditionalVarMap**
- **FormulasT mGbEqualities**  
*A workaround to associate equalities in the passed formula originating from the gb (in contrast to those which originate from simplified formulae)*
- **std::vector< FormulaSetT > mInfeasibleSubsets**  
*Stores the infeasible subsets.*
- **Manager \*const mpManager**  
*A reference to the manager.*
- **Model mModel**  
*Stores the assignment of the current satisfiable result, if existent.*
- **std::vector< Model > mAllModels**  
*Stores all satisfying assignments.*
- **bool mModelComputed**  
*True, if the model has already been computed.*
- **bool mFinalCheck**  
*true, if the check procedure should perform a final check which especially means not to postpone splitting decisions*
- **bool mFullCheck**  
*false, if this module should avoid too expensive procedures and rather return unknown instead.*
- **carl::Variable mObjectiveVariable**  
*Objective variable to be minimized. If set to NO\_VARIABLE, a normal sat check should be performed.*
- **std::vector< TheoryPropagation > mTheoryPropagations**
- **std::atomic< Answer > mSolverState**  
*States whether the received formula is known to be satisfiable or unsatisfiable otherwise it is set to unknown.*
- **std::atomic\_bool \* mBackendsFoundAnswer**  
*This flag is passed to any backend and if it determines an answer to a prior check call, this flag is fired.*
- **Conditionals mFoundAnswer**  
*Vector of Booleans: If any of them is true, we have to terminate a running check procedure.*
- **std::vector< Module \* > mUsedBackends**  
*The backends of this module which are currently used (conditions to use this module are fulfilled for the passed formula).*
- **std::vector< Module \* > mAllBackends**  
*The backends of this module which have been used.*
- **std::vector< Lemma > mLemmas**  
*Stores the lemmas being valid formulas this module or its backends made.*
- **ModuleInput::iterator mFirstSubformulaToPass**  
*Stores the position of the first sub-formula in the passed formula, which has not yet been considered for a consistency check of the backends.*
- **carl::FastSet< FormulaT > mConstraintsToInform**  
*Stores the constraints which the backends must be informed about.*
- **carl::FastSet< FormulaT > mInformedConstraints**  
*Stores the position of the first constraint of which no backend has been informed about.*
- **ModuleInput::const\_iterator mFirstUncheckedReceivedSubformula**  
*Stores the position of the first (by this module) unchecked sub-formula of the received formula.*
- **unsigned mSmallerMusesCheckCounter**  
*Counter used for the generation of the smt2 files to check for smaller muses.*
- **std::vector< std::size\_t > mVariableCounters**  
*Maps variables to the number of their occurrences.*

```

### 0.15.227.5 Member Function Documentation

**0.15.227.5.1 add()** `bool smtrat::Module::add ( ModuleInput::const_iterator _subformula ) [inherited]`

The module has to take the given sub-formula of the received formula into account.

#### Parameters

|                          |                                                    |
|--------------------------|----------------------------------------------------|
| <code>_subformula</code> | The sub-formula to take additionally into account. |
|--------------------------|----------------------------------------------------|

#### Returns

false, if it can be easily decided that this sub-formula causes a conflict with the already considered sub-formulas; true, otherwise.

**0.15.227.5.2 addConstraintToInform()** `void smtrat::Module::addConstraintToInform ( const FormulaT & _constraint ) [protected], [virtual], [inherited]`

Adds a constraint to the collection of constraints of this module, which are informed to a freshly generated backend.

#### Parameters

|                          |                        |
|--------------------------|------------------------|
| <code>_constraint</code> | The constraint to add. |
|--------------------------|------------------------|

Reimplemented in [smtrat::SATModule< Settings >](#).

**0.15.227.5.3 addCore()** `template<class Settings > bool smtrat::GBModule< Settings >::addCore ( ModuleInput::const_iterator formula ) [virtual]`

The module has to take the given sub-formula of the received formula into account.

#### Parameters

|                      |                                                    |
|----------------------|----------------------------------------------------|
| <code>formula</code> | The sub-formula to take additionally into account. |
|----------------------|----------------------------------------------------|

#### Returns

false, if it can be easily decided that this sub-formula causes a conflict with the already considered sub-formulas; true, otherwise.

Reimplemented from [smtrat::Module](#).

**0.15.227.5.4 addInformationRelevantFormula()** `void smtrat::Module::addInformationRelevantFormula ( const FormulaT & formula ) [protected], [inherited]`

Adds a formula to the InformationRelevantFormula.

#### Parameters

|                      |                |
|----------------------|----------------|
| <code>formula</code> | Formula to add |
|----------------------|----------------|

---

**0.15.227.5.5 addLemma()** void smtrat::Module::addLemma (

```
const FormulaT & _lemma,
const LemmaType & _lt = LemmaType::NORMAL,
const FormulaT & _preferredFormula = FormulaT(carl::FormulaType::TRUE)) [inline],
[inherited]
```

Stores a lemma being a valid formula.

#### Parameters

|                   |                                                                       |
|-------------------|-----------------------------------------------------------------------|
| _lemma            | The eduction/lemma to store.                                          |
| _lt               | The type of the lemma.                                                |
| _preferredFormula | Hint for the next decision, which formula should be assigned to true. |

**0.15.227.5.6 addOrigin()** void smtrat::Module::addOrigin (

```
ModuleInput::iterator _formula,
const FormulaT & _origin) [inline], [protected], [inherited]
```

Adds the given set of formulas in the received formula to the origins of the given passed formula.

#### Parameters

|          |                                                           |
|----------|-----------------------------------------------------------|
| _formula | The passed formula to set the origins for.                |
| _origin  | A set of formulas in the received formula of this module. |

**0.15.227.5.7 addReceivedSubformulaToPassedFormula()** std::pair<ModuleInput::iterator,bool>  
smtrat::Module::addReceivedSubformulaToPassedFormula (

```
ModuleInput::const_iterator _subformula) [inline], [protected], [inherited]
```

Copies the given sub-formula of the received formula to the passed formula.

Note, that there is always a link between sub-formulas of the passed formulas to sub-formulas of the received formulas, which are responsible for its occurrence.

#### Parameters

|             |                                                  |
|-------------|--------------------------------------------------|
| _subformula | The sub-formula of the received formula to copy. |
|-------------|--------------------------------------------------|

**0.15.227.5.8 addSubformulaToPassedFormula()** [1/3] std::pair<ModuleInput::iterator,bool> smtrat::Module::addSubformulaToPassedFormula (

```
const FormulaT & _formula) [inline], [protected], [inherited]
```

Adds the given formula to the passed formula with no origin.

Note that in the next call of this module's removeSubformula, all formulas in the passed formula without origins will be removed.

#### Parameters

|          |                                           |
|----------|-------------------------------------------|
| _formula | The formula to add to the passed formula. |
|----------|-------------------------------------------|

#### Returns

A pair to the position where the formula to add has been inserted (or its first sub-formula which has not yet been in the passed formula, in case the formula to add is a conjunction), and a Boolean stating whether anything has been added to the passed formula.

```
0.15.227.5.9 addSubformulaToPassedFormula() [2/3] std::pair<ModuleInput::iterator,bool> smtrat::Module::addSubformulaToPassedFormula (
 const FormulaT & _formula,
 const FormulaT & _origin) [inline], [protected], [inherited]
```

Adds the given formula to the passed formula.

#### Parameters

|                 |                                                                                                                           |
|-----------------|---------------------------------------------------------------------------------------------------------------------------|
| <i>_formula</i> | The formula to add to the passed formula.                                                                                 |
| <i>_origin</i>  | The sub-formula of the received formula being responsible for the occurrence of the formula to add to the passed formula. |

#### Returns

A pair to the position where the formula to add has been inserted (or its first sub-formula which has not yet been in the passed formula, in case the formula to add is a conjunction), and a Boolean stating whether anything has been added to the passed formula.

```
0.15.227.5.10 addSubformulaToPassedFormula() [3/3] std::pair<ModuleInput::iterator,bool> smtrat::Module::addSubformulaToPassedFormula (
 const FormulaT & _formula,
 const std::shared_ptr< std::vector<FormulaT> >& _origins) [inline], [protected], [inherited]
```

Adds the given formula to the passed formula.

#### Parameters

|                 |                                                                                                                                         |
|-----------------|-----------------------------------------------------------------------------------------------------------------------------------------|
| <i>_formula</i> | The formula to add to the passed formula.                                                                                               |
| <i>_origins</i> | The link of the formula to add to the passed formula to sub-formulas of the received formulas, which are responsible for its occurrence |

#### Returns

A pair to the position where the formula to add has been inserted (or its first sub-formula which has not yet been in the passed formula, in case the formula to add is a conjunction), and a Boolean stating whether anything has been added to the passed formula.

```
0.15.227.5.11 allModels() const std::vector<Model>& smtrat::Module::allModels () const [inline], [inherited]
```

#### Returns

All satisfying assignments, if existent.

```
0.15.227.5.12 anAnswerFound() bool smtrat::Module::anAnswerFound () const [inline], [protected], [inherited]
```

Checks for all antecedent modules and those which run in parallel with the same antecedent modules, whether one of them has determined a result.

#### Returns

True, if one of them has determined a result.

---

**0.15.227.5.13 answerFound()** const `smtrat::Conditionals`& `smtrat::Module::answerFound` ( ) const [inline], [inherited]

#### Returns

A vector of Booleans: If any of them is true, we have to terminate a running check procedure.

**0.15.227.5.14 backendsModel()** const `Model` & `smtrat::Module::backendsModel` ( ) const [protected], [inherited]

Stores the model of a backend which determined satisfiability of the passed formula in the model of this module.

**0.15.227.5.15 branchAt() [1/4]** bool `smtrat::Module::branchAt` ( carl::Variable::Arg `_var`, const `Rational` & `_value`, bool `_leftCaseWeak` = `true`, bool `_preferLeftCase` = `true`, bool `_useReceivedFormulaAsPremise` = `false`, const std::vector< `FormulaT` > & `_premise` = std::vector<`FormulaT`>() ) [inline], [protected], [inherited]

**0.15.227.5.16 branchAt() [2/4]** bool `smtrat::Module::branchAt` ( carl::Variable::Arg `_var`, const `Rational` & `_value`, std::vector< `FormulaT` > && `_premise`, bool `_leftCaseWeak` = `true`, bool `_preferLeftCase` = `true`, bool `_useReceivedFormulaAsPremise` = `false` ) [inline], [protected], [inherited]

**0.15.227.5.17 branchAt() [3/4]** bool `smtrat::Module::branchAt` ( const `Poly` & `_polynomial`, bool `_integral`, const `Rational` & `_value`, bool `_leftCaseWeak` = `true`, bool `_preferLeftCase` = `true`, bool `_useReceivedFormulaAsPremise` = `false`, const std::vector< `FormulaT` > & `_premise` = std::vector<`FormulaT`>() ) [inline], [protected], [inherited]

**0.15.227.5.18 branchAt() [4/4]** bool `smtrat::Module::branchAt` ( const `Poly` & `_polynomial`, bool `_integral`, const `Rational` & `_value`, std::vector< `FormulaT` > && `_premise`, bool `_leftCaseWeak` = `true`, bool `_preferLeftCase` = `true`, bool `_useReceivedFormulaAsPremise` = `false` ) [protected], [inherited]

Adds a lemmas which provoke a branching for the given variable at the given value, if this module returns Unknown and there exists a preceding `SATModule`.

Note that the given value is rounded down and up, if the given variable is integer-valued.

#### Parameters

|                          |                             |
|--------------------------|-----------------------------|
| <code>_polynomial</code> | The variable to branch for. |
|--------------------------|-----------------------------|

## Parameters

|                                           |                                                                                                                                                                                                                |
|-------------------------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>_integral</code>                    | A flag being true, if all variables in the polynomial to branch for are integral.                                                                                                                              |
| <code>_value</code>                       | The value to branch at.                                                                                                                                                                                        |
| <code>_premise</code>                     | The sub-formulas of the received formula from which the branch is followed. Note, that a premise is not necessary, as every branch is a valid formula. But a premise can prevent from branching unnecessarily. |
| <code>_leftCaseWeak</code>                | true, if a branching in the form of (or ( $\leq p b$ ) ( $> p b$ )) is desired. false, if a branching in the form of (or ( $< p b$ ) ( $\geq p b$ )) is desired.                                               |
| <code>_preferLeftCase</code>              | true, if the left case (polynomial less(or equal) 0 shall be chosen first. false, otherwise.                                                                                                                   |
| <code>_useReceivedFormulaAsPremise</code> | true, if the whole received formula should be used as premise                                                                                                                                                  |

**0.15.227.5.19 `callGroebnerToSDP()`** template<class Settings >  
`GBPolynomial smtrat::GBModule< Settings >::callGroebnerToSDP (`  
`const Ideal & gb ) [protected]`

**0.15.227.5.20 `check()`** `Answer smtrat::Module::check (`

```
bool _final = false,
bool _full = true,
carl::Variable _objective = carl::Variable::NO_VARIABLE) [virtual], [inherited]
```

Checks the received formula for consistency.

Note, that this is an implementation of the satisfiability check of the conjunction of the so far received formulas, which does actually nothing but passing the problem to its backends. This implementation is only used internally and must be overwritten by any derived module.

## Parameters

|                         |                                                                                                                                       |
|-------------------------|---------------------------------------------------------------------------------------------------------------------------------------|
| <code>_final</code>     | true, if this satisfiability check will be the last one (for a global sat-check), if its result is SAT                                |
| <code>_full</code>      | false, if this module should avoid too expensive procedures and rather return unknown instead.                                        |
| <code>_objective</code> | if not set to NO_VARIABLE, the module should find an assignment minimizing this objective variable; otherwise any assignment is good. |

## Returns

True, if the received formula is satisfiable; False, if the received formula is not satisfiable; Unknown, otherwise.

Reimplemented in [smtrat::PModule](#).

**0.15.227.5.21 `checkCore()`** template<class Settings >  
`virtual Answer smtrat::GBModule< Settings >::checkCore ( ) [virtual]`

Checks the received formula for consistency.

Note, that this is an implementation of the satisfiability check of the conjunction of the so far received formulas, which does actually nothing but passing the problem to its backends. This implementation is only used internally and must be overwritten by any derived module.

## Returns

True, if the received formula is satisfiable; False, if the received formula is not satisfiable; Unknown, otherwise.

Reimplemented from [smtrat::Module](#).

```
0.15.227.5.22 checkInfSubsetForMinimality() void smrat::Module::checkInfSubsetForMinimality (
 std::vector< FormulaSetT >::const_iterator _infssubset,
 const std::string & _filename = "smaller_muses",
 unsigned _maxSizeDifference = 1) const [inherited]
```

Checks the given infeasible subset for minimality by storing all subsets of it, which have a smaller size which differs from the size of the infeasible subset not more than the given threshold.

#### Parameters

|                                 |                                                                                                        |
|---------------------------------|--------------------------------------------------------------------------------------------------------|
| <code>_infssubset</code>        | The infeasible subset to check for minimality.                                                         |
| <code>_filename</code>          | The name of the file to store the infeasible subsets in order to be able to check their infeasibility. |
| <code>_maxSizeDifference</code> | The maximal difference between the sizes of the subsets compared to the size of the infeasible subset. |

```
0.15.227.5.23 checkModel() unsigned smrat::Module::checkModel () const [protected], [inherited]
```

#### Returns

false, if the current model of this module does not satisfy the current given formula; true, if it cannot be said whether the model satisfies the given formula.

```
0.15.227.5.24 cleanModel() void smrat::Module::cleanModel () const [inline], [protected], [inherited]
```

Substitutes variable occurrences by its model value in the model values of other variables.

```
0.15.227.5.25 clearLemmas() void smrat::Module::clearLemmas () [inline], [inherited]
```

Deletes all yet found lemmas.

```
0.15.227.5.26 clearModel() void smrat::Module::clearModel () const [inline], [protected], [inherited]
```

Clears the assignment, if any was found.

```
0.15.227.5.27 clearModels() void smrat::Module::clearModels () const [inline], [protected], [inherited]
```

Clears all assignments, if any was found.

```
0.15.227.5.28 clearPassedFormula() void smrat::Module::clearPassedFormula () [protected], [inherited]
```

```
0.15.227.5.29 collectOrigins() [1/2] void smrat::Module::collectOrigins (
 const FormulaT & _formula,
 FormulaSetT & _origins) const [inherited]
```

```
0.15.227.5.30 collectOrigins() [2/2] void smtrat::Module::collectOrigins (
 const FormulaT & _formula,
 FormulasT & _origins) const [inherited]
```

Collects the formulas in the given formula, which are part of the received formula.

If the given formula directly occurs in the received formula, it is inserted into the given set. Otherwise, the given formula must be of type AND and all its sub-formulas part of the received formula. Hence, they will be added to the given set.

#### Parameters

|                       |                                                                                                      |
|-----------------------|------------------------------------------------------------------------------------------------------|
| <code>_formula</code> | The formula from which to collect the formulas being sub-formulas of the received formula (origins). |
| <code>_origins</code> | The set in which to store the origins.                                                               |

```
0.15.227.5.31 collectTheoryPropagations() void smtrat::Module::collectTheoryPropagations () [inherited]
```

```
0.15.227.5.32 constraintByGB() template<class Settings >
bool smtrat::GBModule< Settings >::constraintByGB (
 carl::Relation cr) [protected]
```

```
0.15.227.5.33 constraintsToInform() const carl::FastSet<FormulaT>& smtrat::Module::constraintsToInform () const [inline], [inherited]
```

#### Returns

The constraints which the backends must be informed about.

```
0.15.227.5.34 currentlySatisfied() virtual unsigned smtrat::Module::currentlySatisfied (
 const FormulaT &) const [inline], [virtual], [inherited]
```

#### Returns

0, if the given formula is conflicted by the current model; 1, if the given formula is satisfied by the current model; 2, otherwise; 3, if we do not know anything (default)

Reimplemented in [smtrat::LRAbstractModule< Settings >](#), [smtrat::LRAbstractModule< LRASettingsICP >](#), and [smtrat::LRAbstractModule< LRASettingsCP >](#)

```
0.15.227.5.35 currentlySatisfiedByBackend() unsigned smtrat::Module::currentlySatisfiedByBackend (
 const FormulaT & _formula) const [inherited]
```

#### Returns

0, if the given formula is conflicted by the current model; 1, if the given formula is satisfied by the current model; 2, otherwise 3, if we do not know anything (default)

```
0.15.227.5.36 deinform() void smtrat::Module::deinform (
 const FormulaT & _constraint) [inherited]
```

The inverse of informing about a constraint.

All data structures which were kept regarding this constraint are going to be removed. Note, that this makes only sense if it is not likely enough that a formula with this constraint must be solved again.

**Parameters**

|                          |                                                         |
|--------------------------|---------------------------------------------------------|
| <code>_constraint</code> | The constraint to remove from internal data structures. |
|--------------------------|---------------------------------------------------------|

**0.15.227.5.37 `deinformCore()`** `virtual void smtrat::Module::deinformCore (`

```
 const FormulaT & _constraint) [inline], [protected], [virtual], [inherited]
```

The inverse of informing about a constraint.

All data structures which were kept regarding this constraint are going to be removed. Note, that this makes only sense if it is not likely enough that a formula with this constraint must be solved again.

**Parameters**

|                          |                                                         |
|--------------------------|---------------------------------------------------------|
| <code>_constraint</code> | The constraint to remove from internal data structures. |
|--------------------------|---------------------------------------------------------|

Reimplemented in [smtrat::LRAModule< Settings >](#), [smtrat::LRAModule< LRASettingsICP >](#), and [smtrat::LRAModule< LRASettings1 >](#).

**0.15.227.5.38 `determine_smallest_origin()`** `size_t smtrat::Module::determine_smallest_origin (`

```
 const std::vector< FormulaT > & origins) const [protected], [inherited]
```

**Parameters**

|                      |                              |
|----------------------|------------------------------|
| <code>origins</code> | A vector of sets of origins. |
|----------------------|------------------------------|

**Returns**

The index of the smallest (regarding the size of the sets) element of origins

**0.15.227.5.39 `eraseSubformulaFromPassedFormula()`** `ModuleInput::iterator smtrat::Module::eraseSubformulaFromPassedFormula (`

```
 ModuleInput::iterator _subformula,
```

```
 bool _ignoreOrigins = false) [protected], [virtual], [inherited]
```

Removes everything related to the sub-formula to remove from the passed formula in the backends of this module. Afterwards the sub-formula is removed from the passed formula.

**Parameters**

|                             |                                                                                                              |
|-----------------------------|--------------------------------------------------------------------------------------------------------------|
| <code>_subformula</code>    | The sub-formula to remove from the passed formula.                                                           |
| <code>_ignoreOrigins</code> | True, if the sub-formula shall be removed regardless of its origins (should only be applied with expertise). |

**Returns**

Reimplemented in [smtrat::ICPModule< Settings >](#), [smtrat::ICPModule< ICPSettings4 >](#), and [smtrat::ICPModule< ICPSettings1 >](#).

**0.15.227.5.40 `excludeNotReceivedVariablesFromModel()`** `void smtrat::Module::excludeNotReceivedVariablesFromModel ( ) const [inherited]`

Excludes all variables from the current model, which do not occur in the received formula.

```
0.15.227.5.41 factorisedConstraintDeduction() template<class Settings >
void smtrat::GBModule< Settings >::factorisedConstraintDeduction (
 const std::list< GBPolynomial > & factorisation,
 const carl::BitVector & reasons) [protected]
```

```
0.15.227.5.42 findBestOrigin() std::vector< FormulaT >::const_iterator smtrat::Module::findBestOrigin (
 const std::vector< FormulaT > & _origins) const [protected], [inherited]
```

#### Parameters

|                 |  |
|-----------------|--|
| <i>_origins</i> |  |
|-----------------|--|

#### Returns

```
0.15.227.5.43 findTrivialFactorisations() template<class Settings >
bool smtrat::GBModule< Settings >::findTrivialFactorisations () [protected]
```

```
0.15.227.5.44 firstSubformulaToPass() ModuleInput::const_iterator smtrat::Module::firstSubformulaToPass () const [inline], [inherited]
```

#### Returns

The position of the first sub-formula in the passed formula, which has not yet been considered for a consistency check of the backends.

```
0.15.227.5.45 firstUncheckedReceivedSubformula() ModuleInput::const_iterator smtrat::Module::firstUncheckedReceivedSubformula () const [inline], [inherited]
```

#### Returns

The position of the first (by this module) unchecked sub-formula of the received formula.

```
0.15.227.5.46 freeSplittingVariable() static void smtrat::Module::freeSplittingVariable (
 const FormulaT & _splittingVariable) [inline], [static], [inherited]
```

```
0.15.227.5.47 generateReasons() template<class Settings >
FormulasT smtrat::GBModule< Settings >::generateReasons (
 const carl::BitVector & reasons) [protected]
```

```
0.15.227.5.48 generateReasonSet() template<class Settings >
FormulaSetT smtrat::GBModule< Settings >::generateReasonSet (
 const carl::BitVector & reasons) [protected]
```

```
0.15.227.5.49 generateTrivialInfeasibleSubset() void smtrat::Module::generateTrivialInfeasibleSubset () [inline], [protected], [inherited]
```

Stores the trivial infeasible subset being the set of received formulas.

**0.15.227.5.50 getBackendsAllModels()** void smtrat::Module::getBackendsAllModels () const [protected], [inherited]  
Stores all models of a backend in the list of all models of this module.

**0.15.227.5.51 getBackendsModel()** void smtrat::Module::getBackendsModel () const [protected], [inherited]

**0.15.227.5.52 getInfeasibleSubsets() [1/2]** void smtrat::Module::getInfeasibleSubsets () [protected], [inherited]  
Copies the infeasible subsets of the passed formula.

**0.15.227.5.53 getInfeasibleSubsets() [2/2]** std::vector< [FormulaSetT](#) > smtrat::Module::getInfeasibleSubsets (

const [Module](#) & [\\_backend](#) ) const [protected], [inherited]

Get the infeasible subsets the given backend provides.

Note, that an infeasible subset in a backend contains sub formulas of the passed formula and an infeasible subset of this module contains sub formulas of the received formula. In this method the LATTER is returned.

#### Parameters

|                          |                                                          |
|--------------------------|----------------------------------------------------------|
| <a href="#">_backend</a> | The backend from which to obtain the infeasible subsets. |
|--------------------------|----------------------------------------------------------|

#### Returns

The infeasible subsets the given backend provides.

**0.15.227.5.54 getInformationRelevantFormulas()** const std::set< [FormulaT](#) > & smtrat::Module::getInformationRelevantFormulas () [protected], [inherited]  
Gets all InformationRelevantFormulas.

#### Returns

Set of all formulas

**0.15.227.5.55 getModelEqualities()** std::list< std::vector< [carl::Variable](#) > > smtrat::Module::getModelEqualities () const [virtual], [inherited]  
Partition the variables from the current model into equivalence classes according to their assigned value.  
The result is a set of equivalence classes of variables where all variables within one class are assigned the same value. Note that the number of classes may not be minimal, i.e. two classes may actually be equivalent.

#### Returns

Equivalence classes.

**0.15.227.5.56 getOrigins() [1/3]** void smtrat::Module::getOrigins (

const [FormulaT](#) & [\\_formula](#),

[FormulaSetT](#) & [\\_origins](#) ) const [inline], [protected], [inherited]

#### Parameters

|                          |  |
|--------------------------|--|
| <a href="#">_formula</a> |  |
| <a href="#">_origins</a> |  |

```
0.15.227.5.57 getOrigins() [2/3] void smtrat::Module::getOrigins (
 const FormulaT & _formula,
 FormulasT & _origins) const [inline], [protected], [inherited]
```

**Parameters**

|                 |  |
|-----------------|--|
| <u>_formula</u> |  |
| <u>_origins</u> |  |

```
0.15.227.5.58 getOrigins() [3/3] const FormulaT& smtrat::Module::getOrigins (
 ModuleInput::const_iterator _formula) const [inline], [protected], [inherited]
```

Gets the origins of the passed formula at the given position.

**Parameters**

|                 |                                                   |
|-----------------|---------------------------------------------------|
| <u>_formula</u> | The position of a formula in the passed formulas. |
|-----------------|---------------------------------------------------|

**Returns**

The origins of the passed formula at the given position.

```
0.15.227.5.59 getReceivedFormulaSimplified() std::pair< bool, FormulaT > smtrat::Module::get<-
ReceivedFormulaSimplified () [virtual], [inherited]
```

**Returns**

A pair of a Boolean and a formula, where the Boolean is true, if the received formula could be simplified to an equisatisfiable formula. The formula is equisatisfiable to this module's received formula, if the Boolean is true.

Reimplemented in [smtrat::PModule](#).

```
0.15.227.5.60 handleConstraintNotToGB() template<class Settings >
void smtrat::GBModule< Settings >::handleConstraintNotToGB (
 ModuleInput::const_iterator _formula) [protected]
```

```
0.15.227.5.61 handleConstraintToGBQueue() template<class Settings >
void smtrat::GBModule< Settings >::handleConstraintToGBQueue (
 ModuleInput::const_iterator _formula) [protected]
```

```
0.15.227.5.62 hasLemmas() bool smtrat::Module::hasLemmas () [inline], [inherited]
```

Checks whether this module or any of its backends provides any lemmas.

```
0.15.227.5.63 hasValidInfeasibleSubset() bool smtrat::Module::hasValidInfeasibleSubset () const
[inherited]
```

**Returns**

true, if the module has at least one valid infeasible subset, that is all its elements are sub-formulas of the received formula (pointer must be equal).

**0.15.227.5.64 `id()`** `std::size_t smtrat::Module::id () const [inline], [inherited]`

**Returns**

A unique ID to identify this module instance.

**0.15.227.5.65 `infeasibleSubsets()`** `const std::vector<FormulaSetT>& smtrat::Module::infeasibleSubsets () const [inline], [inherited]`

**Returns**

The infeasible subsets of the set of received formulas (empty, if this module has not detected unsatisfiability of the conjunction of received formulas).

**0.15.227.5.66 `inform()`** `bool smtrat::Module::inform (const FormulaT & _constraint) [inherited]`

Informs the module about the given constraint.

It should be tried to inform this module about any constraint it could receive eventually before assertSubformula is called (preferably for the first time, but at least before adding a formula containing that constraint).

**Parameters**

|                          |                                 |
|--------------------------|---------------------------------|
| <code>_constraint</code> | The constraint to inform about. |
|--------------------------|---------------------------------|

**Returns**

false, if it can be easily decided whether the given constraint is inconsistent; true, otherwise.

**0.15.227.5.67 `informBackends()`** `void smtrat::Module::informBackends (const FormulaT & _constraint) [inline], [protected], [inherited]`

Informs all backends of this module about the given constraint.

**Parameters**

|                          |                                 |
|--------------------------|---------------------------------|
| <code>_constraint</code> | The constraint to inform about. |
|--------------------------|---------------------------------|

**0.15.227.5.68 `informCore()`** `virtual bool smtrat::Module::informCore (const FormulaT & _constraint) [inline], [protected], [virtual], [inherited]`

Informs the module about the given constraint.

It should be tried to inform this module about any constraint it could receive eventually before assertSubformula is called (preferably for the first time, but at least before adding a formula containing that constraint).

**Parameters**

|                          |                                 |
|--------------------------|---------------------------------|
| <code>_constraint</code> | The constraint to inform about. |
|--------------------------|---------------------------------|

**Returns**

false, if it can be easily decided whether the given constraint is inconsistent; true, otherwise.

Reimplemented in [smtrat::UnionFindModule< Settings >](#), [smtrat::PBPPModule< Settings >](#), [smtrat::PBGaussModule< Settings >](#), [smtrat::NRAILModule< Settings >](#), [smtrat::NewCoveringModule< Settings >](#), [smtrat::NewCADModule< Settings >](#),

`smrat::LRAModule< Settings >, smrat::LRAModule< LRASettingsICP >, smrat::LRAModule< LRASettings1 >, smrat::IntBlastModule< Settings >, smrat::FPPModule< Settings >, smrat::EQModule< Settings >, smrat::CurryModule< Settings >, smrat::BVMModule< Settings >, smrat::ICPModule< Settings >, smrat::ICPModule< ICPSettings4 >, and smrat::ICPModule< ICPSettings1 >.`

**0.15.227.5.69 informedConstraints()** `const carl::FastSet<FormulaT>& smrat::Module::informedConstraints( ) const [inline], [inherited]`

**Returns**

The position of the first constraint of which no backend has been informed about.

**0.15.227.5.70 init()** `void smrat::Module::init( ) [virtual], [inherited]`

Informs all backends about the so far encountered constraints, which have not yet been communicated.

This method must not be called twice and only before the first runBackends call.

Reimplemented in `smrat::PBPPModule< Settings >, smrat::PBGaussModule< Settings >, smrat::NRAILModule< Settings >, smrat::NewCoveringModule< Settings >, smrat::NewCADModule< Settings >, smrat::LRAModule< Settings >, smrat::LRAModule< LRASettingsICP >, smrat::LRAModule< LRASettings1 >, smrat::IntBlastModule< Settings >, smrat::FPPModule< Settings >, smrat::EQModule< Settings >, smrat::CurryModule< Settings >, and smrat::BVMModule< Settings >.`

**0.15.227.5.71 is\_minimizing()** `bool smrat::Module::is_minimizing( ) const [inline], [inherited]`

**0.15.227.5.72 isLemmaLevel()** `bool smrat::Module::isLemmaLevel(`

`LemmaLevel level) [protected], [inherited]`

Checks if current lemma level is greater or equal to given level.

**Parameters**

|                    |                 |
|--------------------|-----------------|
| <code>level</code> | Level to check. |
|--------------------|-----------------|

**0.15.227.5.73 isPreprocessor()** `bool smrat::Module::isPreprocessor( ) const [inline], [inherited]`

**Returns**

true, if this module is a preprocessor that is a module, which simplifies its received formula to an equisatisfiable formula being passed to its backends. The simplified formula can be obtained with `getReceivedFormulaSimplified()`.

**0.15.227.5.74 iterativeVariableRewriting()** `template<class Settings >`

`bool smrat::GBModule< Settings >::iterativeVariableRewriting( ) [protected]`

**0.15.227.5.75 knownConstraintDeduction()** `template<class Settings >`

`void smrat::GBModule< Settings >::knownConstraintDeduction(`  
`const std::list< std::pair< carl::BitVector, carl::BitVector > > & deductions )`  
`[protected]`

**0.15.227.5.76 lemmas()** const std::vector<[Lemma](#)>& smtrat::Module::lemmas ( ) const [inline], [inherited]

**Returns**

A constant reference to the lemmas being valid formulas this module or its backends made.

**0.15.227.5.77 merge()** std::vector< [FormulaT](#) > smtrat::Module::merge ( const std::vector< [FormulaT](#) > & \_vecSetA, const std::vector< [FormulaT](#) > & \_vecSetB ) const [protected], [inherited]

Merges the two vectors of sets into the first one.

({a,b},{a,c}) and ({b,d},{b}) -> ({a,b,d},{a,b},{a,b,c,d},{a,b,c})

**Parameters**

|                       |                                  |
|-----------------------|----------------------------------|
| <code>_vecSetA</code> | A vector of sets of constraints. |
| <code>_vecSetB</code> | A vector of sets of constraints. |

**Returns**

The vector being the two given vectors merged.

**0.15.227.5.78 model()** const [Model](#)& smtrat::Module::model ( ) const [inline], [inherited]

**Returns**

The assignment of the current satisfiable result, if existent.

**0.15.227.5.79 modelsDisjoint()** bool smtrat::Module::modelsDisjoint ( const [Model](#) & `_modelA`, const [Model](#) & `_modelB` ) [static], [protected], [inherited]

Checks whether there is no variable assigned by both models.

**Parameters**

|                      |                                |
|----------------------|--------------------------------|
| <code>_modelA</code> | The first model to check for.  |
| <code>_modelB</code> | The second model to check for. |

**Returns**

true, if there is no variable assigned by both models; false, otherwise.

**0.15.227.5.80 moduleName()** template<class Settings > std::string smtrat::GBModule< [Settings](#) >::moduleName ( ) const [inline], [virtual]

**Returns**

The name of the given module type as name.

Reimplemented from [smtrat::Module](#).

```
0.15.227.5.81 newConstraintDeduction() template<class Settings >
void smtrat::GBModule< Settings >::newConstraintDeduction () [protected]
```

**0.15.227.5.82 objective()** carl::Variable smtrat::Module::objective ( ) const [inline], [inherited]

```
0.15.227.5.83 originInReceivedFormula() bool smtrat::Module::originInReceivedFormula (
 const FormulaT & _origin) const [protected], [inherited]
```

```
0.15.227.5.84 passedFormulaBegin() ModuleInput::iterator smtrat::Module::passedFormulaBegin (
) [inline], [protected], [inherited]
```

**Returns**

An iterator to the end of the passed formula. TODO: disable this method

```
0.15.227.5.85 passedFormulaEnd() ModuleInput::iterator smtrat::Module::passedFormulaEnd ()
[inline], [protected], [inherited]
```

**Returns**

An iterator to the end of the passed formula.

```
0.15.227.5.86 passGB() template<class Settings >
void smtrat::GBModule< Settings >::passGB () [protected]
```

```
0.15.227.5.87 popBacktrackPoint() template<class Settings >
void smtrat::GBModule< Settings >::popBacktrackPoint (
 ModuleInput::const_iterator btpoint) [protected]
```

```
0.15.227.5.88 pPassedFormula() const ModuleInput* smtrat::Module::pPassedFormula () const
[inline], [inherited]
```

**Returns**

A pointer to the formula passed to the backends of this module.

```
0.15.227.5.89 pReceivedFormula() const ModuleInput* smtrat::Module::pReceivedFormula () const
[inline], [inherited]
```

**Returns**

A pointer to the formula passed to this module.

```
0.15.227.5.90 print() void smtrat::Module::print (
 const std::string & _initiation = "***") const [inherited]
```

Prints everything relevant of the solver.

**Parameters**

|                    |                      |
|--------------------|----------------------|
| <i>_initiation</i> | The line initiation. |
|--------------------|----------------------|

**0.15.227.5.91 printAllModels()** void smtrat::Module::printAllModels ( std::ostream & *\_out* = std::cout ) const [inherited]

Prints all assignments of this module satisfying its received formula if it satisfiable and this module could find an assignment.

**Parameters**

|             |                                        |
|-------------|----------------------------------------|
| <i>_out</i> | The stream to print the assignment on. |
|-------------|----------------------------------------|

**0.15.227.5.92 printInfeasibleSubsets()** void smtrat::Module::printInfeasibleSubsets ( const std::string & *\_initiation* = "\*\*\*" ) const [inherited]

Prints the infeasible subsets.

**Parameters**

|                    |                      |
|--------------------|----------------------|
| <i>_initiation</i> | The line initiation. |
|--------------------|----------------------|

**0.15.227.5.93 printModel()** void smtrat::Module::printModel ( std::ostream & *\_out* = std::cout ) const [inherited]

Prints the assignment of this module satisfying its received formula if it satisfiable and this module could find an assignment.

**Parameters**

|             |                                        |
|-------------|----------------------------------------|
| <i>_out</i> | The stream to print the assignment on. |
|-------------|----------------------------------------|

**0.15.227.5.94 printPassedFormula()** void smtrat::Module::printPassedFormula ( const std::string & *\_initiation* = "\*\*\*" ) const [inherited]

Prints the vector of passed formula.

**Parameters**

|                    |                      |
|--------------------|----------------------|
| <i>_initiation</i> | The line initiation. |
|--------------------|----------------------|

**0.15.227.5.95 printReceivedFormula()** void smtrat::Module::printReceivedFormula ( const std::string & *\_initiation* = "\*\*\*" ) const [inherited]

Prints the vector of the received formula.

**Parameters**

|                    |                      |
|--------------------|----------------------|
| <i>_initiation</i> | The line initiation. |
|--------------------|----------------------|

**0.15.227.5.96 printRewriteRules()** template<class Settings >  
void smtrat::GBModule< Settings >::printRewriteRules ( )

**0.15.227.5.97 printStateHistory()** template<class Settings >  
void smtrat::GBModule< Settings >::printStateHistory ( )

**0.15.227.5.98 probablyLooping()** bool smtrat::Module::probablyLooping ( const typename Poly::PolyType & \_branchingPolynomial, const Rational & \_branchingValue ) const [protected], [inherited]

Checks whether given the current branching value and branching variable/polynomial it is (highly) probable that this branching is part of an infinite loop of branchings.

#### Parameters

|                             |                                                                                     |
|-----------------------------|-------------------------------------------------------------------------------------|
| <i>_branchingPolynomial</i> | The polynomial to branch at (in most branching strategies this is just a variable). |
| <i>_branchingValue</i>      | The value to branch at.                                                             |

#### Returns

true, if this branching is probably part of an infinite loop of branchings; false, otherwise.

**0.15.227.5.99 processNewConstraint()** template<class Settings >  
void smtrat::GBModule< Settings >::processNewConstraint ( ModuleInput::const\_iterator \_formula ) [protected]

**0.15.227.5.100 pushBacktrackPoint()** template<class Settings >  
void smtrat::GBModule< Settings >::pushBacktrackPoint ( ModuleInput::const\_iterator btpoint ) [protected]

**0.15.227.5.101 receivedFormulaChecked()** void smtrat::Module::receivedFormulaChecked ( ) [inline], [inherited]

Notifies that the received formulas has been checked.

**0.15.227.5.102 receivedFormulasAsInfeasibleSubset()** void smtrat::Module::receivedFormulasAsInfeasibleSubset ( ModuleInput::const\_iterator \_subformula ) [inline], [protected], [inherited]

Stores an infeasible subset consisting only of the given received formula.

**0.15.227.5.103 receivedVariable()** bool smtrat::Module::receivedVariable ( carl::Variable::Arg \_var ) const [inline], [inherited]

**0.15.227.5.104 remove()** void smtrat::Module::remove ( ModuleInput::const\_iterator \_subformula ) [virtual], [inherited]

Removes everything related to the given sub-formula of the received formula.

However, it is desired not to lose track of search spaces where no satisfying assignment can be found for the remaining sub-formulas.

**Parameters**

|                          |                                                    |
|--------------------------|----------------------------------------------------|
| <code>_subformula</code> | The sub formula of the received formula to remove. |
|--------------------------|----------------------------------------------------|

Reimplemented in [smtrat::PModule](#).

**0.15.227.5.105 `removeCore()`** template<class Settings >  
`void smtrat::GBModule< Settings >::removeCore (`  
`ModuleInput::const_iterator formula ) [virtual]`

Removes everything related to the given sub-formula of the received formula.

However, it is desired not to lose track of search spaces where no satisfying assignment can be found for the remaining sub-formulas.

**Parameters**

|                      |                                                    |
|----------------------|----------------------------------------------------|
| <code>formula</code> | The sub formula of the received formula to remove. |
|----------------------|----------------------------------------------------|

Reimplemented from [smtrat::Module](#).

**0.15.227.5.106 `removeOrigin()`** std::pair<`ModuleInput::iterator`,`bool`> `smtrat::Module::removeOrigin (`  
`ModuleInput::iterator _formula,`

`ModuleInput::iterator _formula ) [protected]`

**0.15.227.5.110 `rewriteVariable()`** template<class Settings >  
`GBPolynomial smtrat::GBModule< Settings >::rewriteVariable (`  
`const GBPolynomial & ,`  
`const carl::Variable & ,`  
`const TermT & ,`  
`const BitVector & ) [inline], [protected]`

**0.15.227.5.111 `rPassedFormula()`** const `ModuleInput&` `smtrat::Module::rPassedFormula ( ) const`  
`[inline], [inherited]`

**Returns**

A reference to the formula passed to the backends of this module.

**0.15.227.5.112 rReceivedFormula()** const [ModuleInput](#)& smtrat::Module::rReceivedFormula () const  
[inline], [inherited]

**Returns**

A reference to the formula passed to this module.

**0.15.227.5.113 runBackends() [1/2]** virtual [Answer](#) smtrat::Module::runBackends () [inline],  
[protected], [virtual], [inherited]  
Reimplemented in [smtrat::PModule](#).

**0.15.227.5.114 runBackends() [2/2]** [Answer](#) smtrat::Module::runBackends (  
    bool \_final,  
    bool \_full,  
    carl::Variable \_objective ) [protected], [virtual], [inherited]

Runs the backend solvers on the passed formula.

**Parameters**

|                   |                                                                                                                                       |
|-------------------|---------------------------------------------------------------------------------------------------------------------------------------|
| <i>_final</i>     | true, if this satisfiability check will be the last one (for a global sat-check), if its result is SAT                                |
| <i>_full</i>      | false, if this module should avoid too expensive procedures and rather return unknown instead.                                        |
| <i>_objective</i> | if not set to NO_VARIABLE, the module should find an assignment minimizing this objective variable; otherwise any assignment is good. |

**Returns**

True, if the passed formula is consistent; False, if the passed formula is inconsistent; Unknown, otherwise.

Reimplemented in [smtrat::PModule](#).

**0.15.227.5.115 saveState()** template<class Settings >  
bool smtrat::GBModule< Settings >::saveState () [protected]

**0.15.227.5.116 setId()** void smtrat::Module::setId (  
    std::size\_t \_id ) [inline], [inherited]

Sets this modules unique ID to identify itself.

**Parameters**

|                             |                                    |
|-----------------------------|------------------------------------|
| $\leftrightarrow$<br>$\_id$ | The id to set this module's id to. |
|-----------------------------|------------------------------------|

**0.15.227.5.117 setThreadPriority()** void smtrat::Module::setThreadPriority (  
    [thread\\_priority](#) \_threadPriority ) [inline], [inherited]

Sets the priority of this module to get a thread for running its check procedure.

#### Parameters

|                              |                                                       |
|------------------------------|-------------------------------------------------------|
| <code>_threadPriority</code> | The priority to set this module's thread priority to. |
|------------------------------|-------------------------------------------------------|

### 0.15.227.5.118 `solverState()` Answer smtrat::Module::solverState () const [inline], [inherited]

#### Returns

True, if this module is in a state, such that it has found a solution for its received formula; False, if this module is in a state, such that it has determined that there is no solution for its received formula; Unknown, otherwise.

### 0.15.227.5.119 `splitUnequalConstraint()` void smtrat::Module::splitUnequalConstraint (const FormulaT & `_unequalConstraint`) [protected], [inherited]

Adds the following lemmas for the given constraint  $p \neq 0$ .

$$(p \neq 0 \Leftrightarrow (p < 0 \text{ or } p > 0))$$

and  $\neg(p < 0 \text{ and } p > 0)$

#### Parameters

|                                 |                                                  |
|---------------------------------|--------------------------------------------------|
| <code>_unequalConstraint</code> | A constraint having the relation symbol $\neq$ . |
|---------------------------------|--------------------------------------------------|

### 0.15.227.5.120 `threadPriority()` thread\_priority smtrat::Module::threadPriority () const [inline], [inherited]

#### Returns

The priority of this module to get a thread for running its check procedure.

### 0.15.227.5.121 `transformIntoEquality()` template<class Settings > GBPolynomial smtrat::GBModule< Settings >::transformIntoEquality (ModuleInput::const\_iterator constraint) [protected]

### 0.15.227.5.122 `updateAllModels()` void smtrat::Module::updateAllModels () [virtual], [inherited]

Updates all satisfying models, if the solver has detected the consistency of the received formula, beforehand.  
Reimplemented in [smtrat::SATModule< Settings >](#).

### 0.15.227.5.123 `updateLemmas()` void smtrat::Module::updateLemmas () [inherited]

Stores all lemmas of any backend of this module in its own lemma vector.

### 0.15.227.5.124 `updateModel()` void smtrat::Module::updateModel () const [virtual], [inherited]

Updates the model, if the solver has detected the consistency of the received formula, beforehand.

Reimplemented in [smtrat::PModule](#), [smtrat::VSModule< Settings >](#), [smtrat::UnionFindModule< Settings >](#), [smtrat::UFCegarModule< Settings >](#), [smtrat::STropModule< Settings >](#), [smtrat::SATModule< Settings >](#), [smtrat::PBPPModule< Settings >](#), [smtrat::PBGaussModule< Settings >](#), [smtrat::NRAILModule< Settings >](#),

`smrat::NewCoveringModule< Settings >, smrat::NewCADModule< Settings >, smrat::MCBModule< Settings >, smrat::LVEModule< Settings >, smrat::LRAModule< Settings >, smrat::LRAModule< LRASettingsICP >, smrat::LRAModule< LRASettings1 >, smrat::IntEqModule< Settings >, smrat::IntBlastModule< Settings >, smrat::IncWidthModule< Settings >, smrat::ICPModule< Settings >, smrat::ICPModule< ICPSettings4 >, smrat::ICPModule< ICPSettings1 >, smrat::GBPPModule< Settings >, smrat::FPPModule< Settings >, smrat::FouMoModule< Settings >, smrat::ESModule< Settings >, smrat::EQPreprocessingModule< Settings >, smrat::EQModule< Settings >, smrat::CurryModule< Settings >, smrat::CubeLIAModule< Settings >, smrat::CSplitModule< Settings >, and smrat::BVMModule< Settings >.`

**0.15.227.5.125 `usedBackends()`** `const std::vector<Module*>& smrat::Module::usedBackends( )`  
const [inline], [inherited]

#### Returns

The backends of this module which are currently used (conditions to use this module are fulfilled for the passed formula).

**0.15.227.5.126 `validityCheck()`** `template<class Settings >`  
`bool smrat::GBModule< Settings >::validityCheck( ) [protected]`

## 0.15.227.6 Friends And Related Function Documentation

**0.15.227.6.1 `InequalitiesTable< Settings >`** `template<class Settings >`  
friend class `InequalitiesTable< Settings >` [friend]

## 0.15.227.7 Field Documentation

**0.15.227.7.1 `mAdditionalVarMap`** `template<class Settings >`  
`std::map<ConstraintT, carl::Variable> smrat::GBModule< Settings >::mAdditionalVarMap [protected]`

**0.15.227.7.2 `mAllBackends`** `std::vector<Module*> smrat::Module::mAllBackends [protected], [inherited]`

The backends of this module which have been used.

**0.15.227.7.3 `mAllModels`** `std::vector<Model> smrat::Module::mAllModels [mutable], [protected], [inherited]`  
Stores all satisfying assignments.

**0.15.227.7.4 `mBackendsFoundAnswer`** `std::atomic_bool* smrat::Module::mBackendsFoundAnswer [protected], [inherited]`  
This flag is passed to any backend and if it determines an answer to a prior check call, this flag is fired.

**0.15.227.7.5 `mBacktrackPoints`** `template<class Settings >`  
`std::vector<ModuleInput::const_iterator> smrat::GBModule< Settings >::mBacktrackPoints [protected]`  
The vector of backtrack points, which has pointers to received constraints.

**0.15.227.7.6 mBasis** template<class Settings >  
Settings::Groebner smtrat::GBModule< Settings >::mBasis [protected]  
The current Groebner basis.

**0.15.227.7.7 mConstraintsToInform** carl::FastSet<FormulaT> smtrat::Module::mConstraintsToInform  
[protected], [inherited]  
Stores the constraints which the backends must be informed about.

**0.15.227.7.8 mFinalCheck** bool smtrat::Module::mFinalCheck [protected], [inherited]  
true, if the check procedure should perform a final check which especially means not to postpone splitting decisions

**0.15.227.7.9 mFirstPosInLastBranches** std::size\_t smtrat::Module::mFirstPosInLastBranches = 0  
[static], [inherited]  
The beginning of the cyclic buffer storing the last branches.

**0.15.227.7.10 mFirstSubformulaToPass** ModuleInput::iterator smtrat::Module::mFirstSubformulaToPass [protected], [inherited]  
Stores the position of the first sub-formula in the passed formula, which has not yet been considered for a consistency check of the backends.

**0.15.227.7.11 mFirstUncheckedReceivedSubformula** ModuleInput::const\_iterator smtrat::Module::mFirstUncheckedReceivedSubformula [protected], [inherited]  
Stores the position of the first (by this module) unchecked sub-formula of the received formula.

**0.15.227.7.12 mFoundAnswer** Conditionals smtrat::Module::mFoundAnswer [protected], [inherited]  
Vector of Booleans: If any of them is true, we have to terminate a running check procedure.

**0.15.227.7.13 mFullCheck** bool smtrat::Module::mFullCheck [protected], [inherited]  
false, if this module should avoid too expensive procedures and rather return unknown instead.

**0.15.227.7.14 mGbEqualities** template<class Settings >  
FormulasT smtrat::GBModule< Settings >::mGbEqualities [protected]  
A workaround to associate equalities in the passed formula originating from the gb (in contrast to those which originate from simplified formulae)

**0.15.227.7.15 mInequalities** template<class Settings >  
InequalitiesTable<Settings> smtrat::GBModule< Settings >::mInequalities [protected]  
The inequalities table for handling inequalities.

**0.15.227.7.16 mInfeasibleSubsets** std::vector<FormulaSetT> smtrat::Module::mInfeasibleSubsets [protected], [inherited]  
Stores the infeasible subsets.

**0.15.227.7.17 mInformedConstraints** `carl::FastSet<FormulaT> smtrat::Module::mInformedConstraints` [protected], [inherited]  
Stores the position of the first constraint of which no backend has been informed about.

**0.15.227.7.18 mLastBranches** `std::vector< Branching > smtrat::Module::mLastBranches = std::vector<Branching> (mNumOfBranchVarsToStore, Branching(typename Poly::PolyType(), 0))` [static], [inherited]  
Stores the last branches in a cycle buffer.

**0.15.227.7.19 mLemmas** `std::vector<Lemma> smtrat::Module::mLemmas` [protected], [inherited]  
Stores the lemmas being valid formulas this module or its backends made.

**0.15.227.7.20 mModel Model** `smtrat::Module::mModel` [mutable], [protected], [inherited]  
Stores the assignment of the current satisfiable result, if existent.

**0.15.227.7.21 mModelComputed** `bool smtrat::Module::mModelComputed` [mutable], [protected], [inherited]  
True, if the model has already been computed.

**0.15.227.7.22 mNewInequalities** `template<class Settings > std::list<typename InequalitiesTable<Settings>::Rows::iterator> smtrat::GBModule< Settings >::mNewInequalities` [protected]  
A list of inequalities which were added after the last consistency check.

**0.15.227.7.23 mNumOfBranchVarsToStore** `std::size_t smtrat::Module::mNumOfBranchVarsToStore = 5` [static], [inherited]  
The number of different variables to consider for a probable infinite loop of branchings.

**0.15.227.7.24 mObjectiveVariable** `carl::Variable smtrat::Module::mObjectiveVariable` [protected], [inherited]  
Objective variable to be minimized. If set to NO\_VARIABLE, a normal sat check should be performed.

**0.15.227.7.25 mOldSplittingVariables** `std::vector< FormulaT > smtrat::Module::mOldSplittingVariables` [static], [inherited]  
Reusable splitting variables.

**0.15.227.7.26 mpManager Manager\*** `const smtrat::Module::mpManager` [protected], [inherited]  
A reference to the manager.

**0.15.227.7.27 mRecalculateGB** `template<class Settings > bool smtrat::GBModule< Settings >::mRecalculateGB` [protected]  
After popping in the history, it might be necessary to recalculate. This flag indicates this.

**0.15.227.7.28 mRewriteRules** template<class Settings >  
`groebner::RewriteRules smrat::GBModule< Settings >::mRewriteRules [protected]`  
The rewrite rules for the variables.

**0.15.227.7.29 mSmallerMusesCheckCounter** unsigned smrat::Module::mSmallerMusesCheckCounter  
[mutable], [protected], [inherited]  
Counter used for the generation of the smt2 files to check for smaller muses.

**0.15.227.7.30 mSolverState** std::atomic<[Answer](#)> smrat::Module::mSolverState [protected],  
[inherited]  
States whether the received formula is known to be satisfiable or unsatisfiable otherwise it is set to unknown.

**0.15.227.7.31 mStateHistory** template<class Settings >  
std::list<[GBModuleState<Settings>](#) > smrat::GBModule< Settings >::mStateHistory [protected]  
Saves the relevant history to support backtracking.

**0.15.227.7.32 mTheoryPropagations** std::vector<[TheoryPropagation](#)> smrat::Module::mTheory->  
Propagations [protected], [inherited]

**0.15.227.7.33 mUsedBackends** std::vector<[Module\\*](#)> smrat::Module::mUsedBackends [protected],  
[inherited]  
The backends of this module which are currently used (conditions to use this module are fulfilled for the passed formula).

**0.15.227.7.34 mVariableCounters** std::vector<std::size\_t> smrat::Module::mVariableCounters  
[protected], [inherited]  
Maps variables to the number of their occurrences.

## 0.15.228 smrat::GBModuleState< Settings > Class Template Reference

A class to save the current state of a [GBModule](#).

```
#include <GBModuleState.h>
```

### Public Member Functions

- [GBModuleState \(\)](#)
- [GBModuleState \(const typename Settings::Groebner &basisCalculation, const std::map< carl::Variable, std::pair< TermT, carl::BitVector > > &rewrites\)](#)
- const Settings::Groebner & [getBasis \(\) const](#)
- const std::map< carl::Variable, std::pair< TermT, carl::BitVector > > & [getRewriteRules \(\) const](#)

### Protected Attributes

- const Settings::Groebner [mBasis](#)  
*The state of the basis.*
- const std::map< carl::Variable, std::pair< TermT, carl::BitVector > > [mRewrites](#)

### 0.15.228.1 Detailed Description

```
template<typename Settings>
class smrat::GBModuleState< Settings >
```

A class to save the current state of a [GBModule](#).  
Used for backtracking-support

### 0.15.228.2 Constructor & Destructor Documentation

**0.15.228.2.1 GBModuleState() [1/2]** template<typename Settings >  
`smrat::GBModuleState< Settings >:::GBModuleState ( ) [inline]`

**0.15.228.2.2 GBModuleState() [2/2]** template<typename Settings >  
`smrat::GBModuleState< Settings >:::GBModuleState (`  
    `const typename Settings::Groebner & basisCalculation,`  
    `const std::map< carl::Variable, std::pair< TermT, carl::BitVector > > & rewrites`  
`) [inline]`

- void `addLemma` (const `FormulaT` &`_lemma`, const `LemmaType` &`_lt=LemmaType::NORMAL`, const `FormulaT` &`_preferredFormula=FormulaT(carl::FormulaType::TRUE)`)
 

*Stores a lemma being a valid formula.*

- `bool hasLemmas ()`  
*Checks whether this module or any of its backends provides any lemmas.*
- `void clearLemmas ()`  
*Deletes all yet found lemmas.*
- `const std::vector< Lemma > & lemmas () const`
- `ModuleInput::const_iterator firstUncheckedReceivedSubformula () const`
- `ModuleInput::const_iterator firstSubformulaToPass () const`
- `void receivedFormulaChecked ()`  
*Notifies that the received formulas has been checked.*
- `const smrat::Conditionals & answerFound () const`
- `virtual std::string moduleName () const`
- `carl::Variable objective () const`
- `bool is_minimizing () const`
- `void excludeNotReceivedVariablesFromModel () const`  
*Excludes all variables from the current model, which do not occur in the received formula.*
- `void updateLemmas ()`  
*Stores all lemmas of any backend of this module in its own lemma vector.*
- `void collectTheoryPropagations ()`
- `void collectOrigins (const FormulaT &_formula, FormulasT &_origins) const`  
*Collects the formulas in the given formula, which are part of the received formula.*
- `void collectOrigins (const FormulaT &_formula, FormulaSetT &_origins) const`
- `bool hasValidInfeasibleSubset () const`
- `void checkInfSubsetForMinimality (std::vector< FormulaSetT >::const_iterator _infsSubset, const std::string &_filename="smaller_muses", unsigned _maxSizeDifference=1) const`  
*Checks the given infeasible subset for minimality by storing all subsets of it, which have a smaller size which differs from the size of the infeasible subset not more than the given threshold.*
- `void print (const std::string &_initiation="***") const`  
*Prints everything relevant of the solver.*
- `void printReceivedFormula (const std::string &_initiation="***") const`  
*Prints the vector of the received formula.*
- `void printPassedFormula (const std::string &_initiation="***") const`  
*Prints the vector of passed formula.*
- `void printInfeasibleSubsets (const std::string &_initiation="***") const`  
*Prints the infeasible subsets.*
- `void printModel (std::ostream &_out=std::cout) const`  
*Prints the assignment of this module satisfying its received formula if it satisfiable and this module could find an assignment.*
- `void printAllModels (std::ostream &_out=std::cout)`  
*Prints all assignments of this module satisfying its received formula if it satisfiable and this module could find an assignment.*

## Static Public Member Functions

- `static void freeSplittingVariable (const FormulaT &_splittingVariable)`

## Static Public Attributes

- `static size_t mNumOfBranchVarsToStore = 5`  
*The number of different variables to consider for a probable infinite loop of branchings.*
- `static std::vector< Branching > mLastBranches = std::vector<Branching>(mNumOfBranchVarsToStore, Branching(typename Poly::PolyType(), 0))`  
*Stores the last branches in a cycle buffer.*
- `static size_t mFirstPosInLastBranches = 0`  
*The beginning of the cyclic buffer storing the last branches.*
- `static std::vector< FormulaT > mOldSplittingVariables`  
*Reusable splitting variables.*

## Protected Member Functions

- virtual bool `informCore` (const `FormulaT` &\_constraint)
 

*Informs the module about the given constraint.*
- virtual void `deinformCore` (const `FormulaT` &\_constraint)
 

*The inverse of informing about a constraint.*
- virtual bool `addCore` (`ModuleInput::const_iterator` formula)
 

*The module has to take the given sub-formula of the received formula into account.*
- virtual void `removeCore` (`ModuleInput::const_iterator` formula)
 

*Removes everything related to the given sub-formula of the received formula.*
- bool `anAnswerFound` () const
 

*Checks for all antecedent modules and those which run in parallel with the same antecedent modules, whether one of them has determined a result.*
- void `clearModel` () const
 

*Clears the assignment, if any was found.*
- void `clearModels` () const
 

*Clears all assignments, if any was found.*
- void `cleanModel` () const
 

*Substitutes variable occurrences by its model value in the model values of other variables.*
- `ModuleInput::iterator` `passedFormulaBegin` ()
- `ModuleInput::iterator` `passedFormulaEnd` ()
- void `addOrigin` (`ModuleInput::iterator` \_formula, const `FormulaT` &\_origin)
 

*Adds the given set of formulas in the received formula to the origins of the given passed formula.*
- const `FormulaT` & `getOrigins` (`ModuleInput::const_iterator` \_formula) const
 

*Gets the origins of the passed formula at the given position.*
- void `getOrigins` (const `FormulaT` &\_formula, `FormulasT` &\_origins) const
- void `getOrigins` (const `FormulaT` &\_formula, `FormulaSetT` &\_origins) const
- std::pair< `ModuleInput::iterator`, bool > `removeOrigin` (`ModuleInput::iterator` \_formula, const `FormulaT` &\_origin)
- std::pair< `ModuleInput::iterator`, bool > `removeOrigins` (`ModuleInput::iterator` \_formula, const std::shared\_ptr< std::vector< `FormulaT` >> &\_origins)
- void `informBackends` (const `FormulaT` &\_constraint)
 

*Informs all backends of this module about the given constraint.*
- virtual void `addConstraintToInform` (const `FormulaT` &\_constraint)
 

*Adds a constraint to the collection of constraints of this module, which are informed to a freshly generated backend.*
- std::pair< `ModuleInput::iterator`, bool > `addReceivedSubformulaToPassedFormula` (`ModuleInput::const_iterator` \_subformula)
 

*Copies the given sub-formula of the received formula to the passed formula.*
- bool `originInReceivedFormula` (const `FormulaT` &\_origin) const
- std::pair< `ModuleInput::iterator`, bool > `addSubformulaToPassedFormula` (const `FormulaT` &\_formula)
 

*Adds the given formula to the passed formula with no origin.*
- std::pair< `ModuleInput::iterator`, bool > `addSubformulaToPassedFormula` (const `FormulaT` &\_formula, const std::shared\_ptr< std::vector< `FormulaT` >> &\_origins)
 

*Adds the given formula to the passed formula.*
- std::pair< `ModuleInput::iterator`, bool > `addSubformulaToPassedFormula` (const `FormulaT` &\_formula, const `FormulaT` &\_origin)
 

*Adds the given formula to the passed formula.*
- void `generateTrivialInfeasibleSubset` ()
 

*Stores the trivial infeasible subset being the set of received formulas.*
- void `receivedFormulasAsInfeasibleSubset` (`ModuleInput::const_iterator` \_subformula)
 

*Stores an infeasible subset consisting only of the given received formula.*
- std::vector< `FormulaT` >::const\_iterator `findBestOrigin` (const std::vector< `FormulaT` > &\_origins) const
- void `getInfeasibleSubsets` ()

- Copies the infeasible subsets of the passed formula.
- std::vector< `FormulaSetT` > `getInfeasibleSubsets` (const `Module` &\_backend) const
  - Get the infeasible subsets the given backend provides.
- const `Model` & `backendsModel` () const
  - Stores the model of a backend which determined satisfiability of the passed formula in the model of this module.
- void `getBackendsModel` () const
- void `getBackendsAllModels` () const
  - Stores all models of a backend in the list of all models of this module.
- virtual `ModuleInput`::iterator `eraseSubformulaFromPassedFormula` (`ModuleInput`::iterator \_subformula, bool \_ignoreOrigins=false)
  - Removes everything related to the sub-formula to remove from the passed formula in the backends of this module.
- void `clearPassedFormula` ()
- std::vector< `FormulaT` > `merge` (const std::vector< `FormulaT` > &, const std::vector< `FormulaT` > &) const
  - Merges the two vectors of sets into the first one.
- size\_t `determine_smallest_origin` (const std::vector< `FormulaT` > &origins) const
- bool `probablyLooping` (const typename `Poly`::`PolyType` &\_branchingPolynomial, const `Rational` &\_branchingValue) const
  - Checks whether given the current branching value and branching variable/polynomial it is (highly) probable that this branching is part of an infinite loop of branchings.
- bool `branchAt` (const `Poly` &\_polynomial, bool \_integral, const `Rational` &\_value, std::vector< `FormulaT` > &&\_premise, bool \_leftCaseWeak=true, bool \_preferLeftCase=true, bool \_useReceivedFormulaAsPremise=false)
  - Adds a lemmas which provoke a branching for the given variable at the given value, if this module returns Unknown and there exists a preceding SATModule.
- bool `branchAt` (const `Poly` &\_polynomial, bool \_integral, const `Rational` &\_value, bool \_leftCaseWeak=true, bool \_preferLeftCase=true, bool \_useReceivedFormulaAsPremise=false, const std::vector< `FormulaT` > &&\_premise=std::vector< `FormulaT` >())
  - Adds a lemmas which provoke a branching for the given variable at the given value, if this module returns Unknown and there exists a preceding SATModule.
- bool `branchAt` (carl::Variable::Arg \_var, const `Rational` &\_value, std::vector< `FormulaT` > &&\_premise, bool \_leftCaseWeak=true, bool \_preferLeftCase=true, bool \_useReceivedFormulaAsPremise=false)
  - Adds a lemmas which provoke a branching for the given variable at the given value, if this module returns Unknown and there exists a preceding SATModule.
- bool `branchAt` (carl::Variable::Arg \_var, const `Rational` &\_value, bool \_leftCaseWeak=true, bool \_preferLeftCase=true, bool \_useReceivedFormulaAsPremise=false, const std::vector< `FormulaT` > &\_premise=std::vector< `FormulaT` >())
  - Adds a lemmas which provoke a branching for the given variable at the given value, if this module returns Unknown and there exists a preceding SATModule.
- void `splitUnequalConstraint` (const `FormulaT` &)
  - Adds the following lemmas for the given constraint  $p \neq 0$ .
- unsigned `checkModel` () const
- void `addInformationRelevantFormula` (const `FormulaT` &formula)
  - Adds a formula to the InformationRelevantFormula.
- const std::set< `FormulaT` > & `getInformationRelevantFormulas` ()
  - Gets all InformationRelevantFormulas.
- bool `isLemmaLevel` (`LemmaLevel` level)
  - Checks if current lemma level is greater or equal to given level.

## Static Protected Member Functions

- static bool `modelsDisjoint` (const `Model` &\_modelA, const `Model` &\_modelB)
  - Checks whether there is no variable assigned by both models.

## Protected Attributes

- std::vector< `FormulaSetT` > `mInfeasibleSubsets`
  - Stores the infeasible subsets.
- `Manager` \*const `mpManager`
  - A reference to the manager.
- `Model` `mModel`

- std::vector< Model > mAllModels
 

*Stores the assignment of the current satisfiable result, if existent.*
- bool mModelComputed
 

*Stores all satisfying assignments.*
- bool mFinalCheck
 

*True, if the model has already been computed.*
- bool mFullCheck
 

*true, if the check procedure should perform a final check which especially means not to postpone splitting decisions*
- bool mObjectiveVariable
 

*false, if this module should avoid too expensive procedures and rather return unknown instead.*
- carl::Variable mObjectiveVariable
 

*Objective variable to be minimized. If set to NO\_VARIABLE, a normal sat check should be performed.*
- std::vector< TheoryPropagation > mTheoryPropagations
- std::atomic< Answer > mSolverState
 

*States whether the received formula is known to be satisfiable or unsatisfiable otherwise it is set to unknown.*
- std::atomic\_bool \* mBackendsFoundAnswer
 

*This flag is passed to any backend and if it determines an answer to a prior check call, this flag is fired.*
- Conditionals mFoundAnswer
 

*Vector of Booleans: If any of them is true, we have to terminate a running check procedure.*
- std::vector< Module \* > mUsedBackends
 

*The backends of this module which are currently used (conditions to use this module are fulfilled for the passed formula).*
- std::vector< Module \* > mAllBackends
 

*The backends of this module which have been used.*
- std::vector< Lemma > mLemmas
 

*Stores the lemmas being valid formulas this module or its backends made.*
- ModuleInput::iterator mFirstSubformulaToPass
 

*Stores the position of the first sub-formula in the passed formula, which has not yet been considered for a consistency check of the backends.*
- carl::FastSet< FormulaT > mConstraintsToInform
 

*Stores the constraints which the backends must be informed about.*
- carl::FastSet< FormulaT > mInformedConstraints
 

*Stores the position of the first constraint of which no backend has been informed about.*
- ModuleInput::const\_iterator mFirstUncheckedReceivedSubformula
 

*Stores the position of the first (by this module) unchecked sub-formula of the received formula.*
- unsigned mSmallerMusesCheckCounter
 

*Counter used for the generation of the smt2 files to check for smaller muses.*
- std::vector< std::size\_t > mVariableCounters
 

*Maps variables to the number of their occurrences.*

### 0.15.229.1 Member Typedef Documentation

```
0.15.229.1.1 SettingsType template<typename Settings >
typedef Settings smtrat::GBPPModule< Settings >::SettingsType
```

### 0.15.229.2 Member Enumeration Documentation

```
0.15.229.2.1 LemmaType enum smtrat::Module::LemmaType : unsigned [strong], [inherited]
```

**Enumerator**

|           |  |
|-----------|--|
| NORMAL    |  |
| PERMANENT |  |

**0.15.229.3 Constructor & Destructor Documentation****0.15.229.3.1 GBPPModule()** `template<typename Settings >`

```
smrat::GBPPModule< Settings >::GBPPModule (
 const ModuleInput * _formula,
 Conditionals & _conditionals,
 Manager * _manager = nullptr)
```

**0.15.229.3.2 ~GBPPModule()** `template<typename Settings >`

```
smrat::GBPPModule< Settings >::~GBPPModule ()
```

**0.15.229.4 Member Function Documentation****0.15.229.4.1 add()** `bool smrat::PModule::add (`

```
 ModuleInput::const_iterator _subformula) [inherited]
```

The module has to take the given sub-formula of the received formula into account.

**Parameters**

|                          |                                                    |
|--------------------------|----------------------------------------------------|
| <code>_subformula</code> | The sub-formula to take additionally into account. |
|--------------------------|----------------------------------------------------|

**Returns**

false, if it can be easily decided that this sub-formula causes a conflict with the already considered sub-formulas; true, otherwise.

**0.15.229.4.2 addConstraintToInform()** `void smrat::Module::addConstraintToInform (`

```
 const FormulaT & _constraint) [protected], [virtual], [inherited]
```

Adds a constraint to the collection of constraints of this module, which are informed to a freshly generated backend.

**Parameters**

|                          |                        |
|--------------------------|------------------------|
| <code>_constraint</code> | The constraint to add. |
|--------------------------|------------------------|

Reimplemented in `smrat::SATModule< Settings >`.

**0.15.229.4.3 addCore()** `virtual bool smrat::Module::addCore (`

```
 ModuleInput::const_iterator formula) [inline], [protected], [virtual], [inherited]
```

The module has to take the given sub-formula of the received formula into account.

**Parameters**

|                      |                                                    |
|----------------------|----------------------------------------------------|
| <code>formula</code> | The sub-formula to take additionally into account. |
|----------------------|----------------------------------------------------|

**Returns**

false, if it can be easily decided that this sub-formula causes a conflict with the already considered sub-formulas; true, otherwise.

Reimplemented in [smrat::VSModule< Settings >](#), [smrat::SATModule< Settings >](#), [smrat::PFEModule< Settings >](#), [smrat::ICPModule< Settings >](#), [smrat::ICPModule< ICPSettings4 >](#), [smrat::ICPModule< ICPSettings1 >](#), [smrat::UnionFindModule< Settings >](#), [smrat::UFCegarModule< Settings >](#), [smrat::STropModule< Settings >](#), [smrat::PBPPModule< Settings >](#), [smrat::PBGaussModule< Settings >](#), [smrat::NRAILModule< Settings >](#), [smrat::NewCoveringModule< Settings >](#), [smrat::NewCADModule< Settings >](#), [smrat::LRAModule< Settings >](#), [smrat::LRAModule< LRASettingsICP >](#), [smrat::LRAModule< LRASettings1 >](#), [smrat::IntEqModule< Settings >](#), [smrat::IntBlastModule< Settings >](#), [smrat::IncWidthModule< Settings >](#), [smrat::ICEModule< Settings >](#), [smrat::FPPModule< Settings >](#), [smrat::FouMoModule< Settings >](#), [smrat::EQModule< Settings >](#), [smrat::CurryModule< Settings >](#), [smrat::CubeLIAModule< Settings >](#), [smrat::CSplitModule< Settings >](#), [smrat::BVMModule< Settings >](#), and [smrat::GBModule< Settings >](#).

**0.15.229.4.4 addInformationRelevantFormula()** void smrat::Module::addInformationRelevantFormula (

const [FormulaT](#) & formula ) [protected], [inherited]

Adds a formula to the InformationRelevantFormula.

**Parameters**

|                |                |
|----------------|----------------|
| <i>formula</i> | Formula to add |
|----------------|----------------|

**0.15.229.4.5 addLemma()** void smrat::Module::addLemma (

const [FormulaT](#) & \_lemma,

const [LemmaType](#) & \_lt = [LemmaType::NORMAL](#),

const [FormulaT](#) & \_preferredFormula = [FormulaT\( carl::FormulaType::TRUE \)](#) ) [inline],

[inherited]

Stores a lemma being a valid formula.

**Parameters**

|                          |                                                                       |
|--------------------------|-----------------------------------------------------------------------|
| <i>_lemma</i>            | The eduction/lemma to store.                                          |
| <i>_lt</i>               | The type of the lemma.                                                |
| <i>_preferredFormula</i> | Hint for the next decision, which formula should be assigned to true. |

**0.15.229.4.6 addOrigin()** void smrat::Module::addOrigin (

[ModuleInput::iterator](#) \_formula,

const [FormulaT](#) & \_origin ) [inline], [protected], [inherited]

Adds the given set of formulas in the received formula to the origins of the given passed formula.

**Parameters**

|                 |                                                           |
|-----------------|-----------------------------------------------------------|
| <i>_formula</i> | The passed formula to set the origins for.                |
| <i>_origin</i>  | A set of formulas in the received formula of this module. |

**0.15.229.4.7 addReceivedSubformulaToPassedFormula()** std::pair<[ModuleInput::iterator](#), bool> smrat::Module::addReceivedSubformulaToPassedFormula (

```
ModuleInput::const_iterator _subformula) [inline], [protected], [inherited]
```

Copies the given sub-formula of the received formula to the passed formula.

Note, that there is always a link between sub-formulas of the passed formulas to sub-formulas of the received formulas, which are responsible for its occurrence.

#### Parameters

|                          |                                                  |
|--------------------------|--------------------------------------------------|
| <code>_subformula</code> | The sub-formula of the received formula to copy. |
|--------------------------|--------------------------------------------------|

```
0.15.229.4.8 addSubformulaToPassedFormula() [1/3] std::pair<ModuleInput::iterator,bool> smtrat<→
::Module::addSubformulaToPassedFormula (
 const FormulaT & _formula) [inline], [protected], [inherited]
```

Adds the given formula to the passed formula with no origin.

Note that in the next call of this module's removeSubformula, all formulas in the passed formula without origins will be removed.

#### Parameters

|                       |                                           |
|-----------------------|-------------------------------------------|
| <code>_formula</code> | The formula to add to the passed formula. |
|-----------------------|-------------------------------------------|

#### Returns

A pair to the position where the formula to add has been inserted (or its first sub-formula which has not yet been in the passed formula, in case the formula to add is a conjunction), and a Boolean stating whether anything has been added to the passed formula.

```
0.15.229.4.9 addSubformulaToPassedFormula() [2/3] std::pair<ModuleInput::iterator,bool> smtrat<→
::Module::addSubformulaToPassedFormula (
 const FormulaT & _formula,
 const FormulaT & _origin) [inline], [protected], [inherited]
```

Adds the given formula to the passed formula.

#### Parameters

|                       |                                                                                                                           |
|-----------------------|---------------------------------------------------------------------------------------------------------------------------|
| <code>_formula</code> | The formula to add to the passed formula.                                                                                 |
| <code>_origin</code>  | The sub-formula of the received formula being responsible for the occurrence of the formula to add to the passed formula. |

#### Returns

A pair to the position where the formula to add has been inserted (or its first sub-formula which has not yet been in the passed formula, in case the formula to add is a conjunction), and a Boolean stating whether anything has been added to the passed formula.

```
0.15.229.4.10 addSubformulaToPassedFormula() [3/3] std::pair<ModuleInput::iterator,bool>
smtrat::Module::addSubformulaToPassedFormula (
 const FormulaT & _formula,
 const std::shared_ptr< std::vector< FormulaT >> & _origins) [inline], [protected],
[inherited]
```

Adds the given formula to the passed formula.

**Parameters**

|                       |                                                                                                                                         |
|-----------------------|-----------------------------------------------------------------------------------------------------------------------------------------|
| <code>_formula</code> | The formula to add to the passed formula.                                                                                               |
| <code>_origins</code> | The link of the formula to add to the passed formula to sub-formulas of the received formulas, which are responsible for its occurrence |

**Returns**

A pair to the position where the formula to add has been inserted (or its first sub-formula which has not yet been in the passed formula, in case the formula to add is a conjunction), and a Boolean stating whether anything has been added to the passed formula.

**0.15.229.4.11 `allModels()`** `const std::vector<Model>& smtrat::Module::allModels () const [inline], [inherited]`

**Returns**

All satisfying assignments, if existent.

**0.15.229.4.12 `anAnswerFound()`** `bool smtrat::Module::anAnswerFound () const [inline], [protected], [inherited]`

Checks for all antecedent modules and those which run in parallel with the same antecedent modules, whether one of them has determined a result.

**Returns**

True, if one of them has determined a result.

**0.15.229.4.13 `answerFound()`** `const smtrat::Conditionals& smtrat::Module::answerFound () const [inline], [inherited]`

**Returns**

A vector of Booleans: If any of them is true, we have to terminate a running check procedure.

**0.15.229.4.14 `appliedPreprocessing()`** `bool smtrat::PModule::appliedPreprocessing () const [inline], [inherited]`

**Returns**

true, if the current received formula has been simplified and the result of this simplification is stored in the passed formula.

**0.15.229.4.15 `backendsModel()`** `const Model & smtrat::Module::backendsModel () const [protected], [inherited]`

Stores the model of a backend which determined satisfiability of the passed formula in the model of this module.

---

**0.15.229.4.16 branchAt() [1/4]** bool smrat::Module::branchAt (

```
carl::Variable::Arg _var,
const Rational & _value,
bool _leftCaseWeak = true,
bool _preferLeftCase = true,
bool _useReceivedFormulaAsPremise = false,
const std::vector< FormulaT > & _premise = std::vector<FormulaT>()) [inline],
[protected], [inherited]
```

**0.15.229.4.17 branchAt() [2/4]** bool smrat::Module::branchAt (

```
carl::Variable::Arg _var,
const Rational & _value,
std::vector< FormulaT > && _premise,
bool _leftCaseWeak = true,
bool _preferLeftCase = true,
bool _useReceivedFormulaAsPremise = false) [inline], [protected], [inherited]
```

**0.15.229.4.18 branchAt() [3/4]** bool smrat::Module::branchAt (

```
const Poly & _polynomial,
bool _integral,
const Rational & _value,
bool _leftCaseWeak = true,
bool _preferLeftCase = true,
bool _useReceivedFormulaAsPremise = false,
const std::vector< FormulaT > & _premise = std::vector<FormulaT>()) [inline],
[protected], [inherited]
```

**0.15.229.4.19 branchAt() [4/4]** bool smrat::Module::branchAt (

```
const Poly & _polynomial,
bool _integral,
const Rational & _value,
std::vector< FormulaT > && _premise,
bool _leftCaseWeak = true,
bool _preferLeftCase = true,
bool _useReceivedFormulaAsPremise = false) [protected], [inherited]
```

Adds a lemmas which provoke a branching for the given variable at the given value, if this module returns Unknown and there exists a preceding [SATModule](#).

Note that the given value is rounded down and up, if the given variable is integer-valued.

#### Parameters

|                                           |                                                                                                                                                                                                                |
|-------------------------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>_polynomial</code>                  | The variable to branch for.                                                                                                                                                                                    |
| <code>_integral</code>                    | A flag being true, if all variables in the polynomial to branch for are integral.                                                                                                                              |
| <code>_value</code>                       | The value to branch at.                                                                                                                                                                                        |
| <code>_premise</code>                     | The sub-formulas of the received formula from which the branch is followed. Note, that a premise is not necessary, as every branch is a valid formula. But a premise can prevent from branching unnecessarily. |
| <code>_leftCaseWeak</code>                | true, if a branching in the form of (or ( $\leq p b$ ) ( $> p b$ )) is desired. false, if a branching in the form of (or ( $< p b$ ) ( $\geq p b$ )) is desired.                                               |
| <code>_preferLeftCase</code>              | true, if the left case (polynomial less(or equal) 0 shall be chosen first. false, otherwise.                                                                                                                   |
| <code>_useReceivedFormulaAsPremise</code> | true, if the whole received formula should be used as premise                                                                                                                                                  |

```
0.15.229.4.20 check() Answer smtrat::PModule::check (
 bool _final = false,
 bool _full = true,
 carl::Variable _objective = carl::Variable::NO_VARIABLE) [virtual], [inherited]
```

Checks the received formula for consistency.

Note, that this is an implementation of the satisfiability check of the conjunction of the so far received formulas, which does actually nothing but passing the problem to its backends. This implementation is only used internally and must be overwritten by any derived module.

#### Parameters

|                   |                                                                                                                                       |
|-------------------|---------------------------------------------------------------------------------------------------------------------------------------|
| <i>_final</i>     | true, if this satisfiability check will be the last one (for a global sat-check), if its result is SAT                                |
| <i>_full</i>      | false, if this module should avoid too expensive procedures and rather return unknown instead.                                        |
| <i>_objective</i> | if not set to NO_VARIABLE, the module should find an assignment minimizing this objective variable; otherwise any assignment is good. |

#### Returns

True, if the received formula is satisfiable; False, if the received formula is not satisfiable; Unknown, otherwise.

Reimplemented from [smtrat::Module](#).

```
0.15.229.4.21 checkCore() template<typename Settings >
Answer smtrat::GBPPModule< Settings >::checkCore () [virtual]
```

Checks the received formula for consistency.

#### Returns

True, if the received formula is satisfiable; False, if the received formula is not satisfiable; Unknown, otherwise.

Reimplemented from [smtrat::Module](#).

```
0.15.229.4.22 checkInfSubsetForMinimality() void smtrat::Module::checkInfSubsetForMinimality (
 std::vector< FormulaSetT >::const_iterator _infssubset,
 const std::string & _filename = "smaller_muses",
 unsigned _maxSizeDifference = 1) const [inherited]
```

Checks the given infeasible subset for minimality by storing all subsets of it, which have a smaller size which differs from the size of the infeasible subset not more than the given threshold.

#### Parameters

|                           |                                                                                                        |
|---------------------------|--------------------------------------------------------------------------------------------------------|
| <i>_infssubset</i>        | The infeasible subset to check for minimality.                                                         |
| <i>_filename</i>          | The name of the file to store the infeasible subsets in order to be able to check their infeasibility. |
| <i>_maxSizeDifference</i> | The maximal difference between the sizes of the subsets compared to the size of the infeasible subset. |

```
0.15.229.4.23 checkModel() unsigned smtrat::Module::checkModel () const [protected], [inherited]
```

**Returns**

false, if the current model of this module does not satisfy the current given formula; true, if it cannot be said whether the model satisfies the given formula.

**0.15.229.4.24 cleanModel()** void smtrat::Module::cleanModel ( ) const [inline], [protected], [inherited]

Substitutes variable occurrences by its model value in the model values of other variables.

**0.15.229.4.25 clearLemmas()** void smtrat::Module::clearLemmas ( ) [inline], [inherited]

Deletes all yet found lemmas.

**0.15.229.4.26 clearModel()** void smtrat::Module::clearModel ( ) const [inline], [protected], [inherited]

Clears the assignment, if any was found.

**0.15.229.4.27 clearModels()** void smtrat::Module::clearModels ( ) const [inline], [protected], [inherited]

Clears all assignments, if any was found.

**0.15.229.4.28 clearPassedFormula()** void smtrat::Module::clearPassedFormula ( ) [protected], [inherited]

**0.15.229.4.29 collectOrigins() [1/2]** void smtrat::Module::collectOrigins ( const `FormulaT` & `_formula`, `FormulaSetT` & `_origins` ) const [inherited]

**0.15.229.4.30 collectOrigins() [2/2]** void smtrat::Module::collectOrigins ( const `FormulaT` & `_formula`, `FormulasT` & `_origins` ) const [inherited]

Collects the formulas in the given formula, which are part of the received formula.

If the given formula directly occurs in the received formula, it is inserted into the given set. Otherwise, the given formula must be of type AND and all its sub-formulas part of the received formula. Hence, they will be added to the given set.

**Parameters**

|                       |                                                                                                      |
|-----------------------|------------------------------------------------------------------------------------------------------|
| <code>_formula</code> | The formula from which to collect the formulas being sub-formulas of the received formula (origins). |
| <code>_origins</code> | The set in which to store the origins.                                                               |

**0.15.229.4.31 collectTheoryPropagations()** void smtrat::Module::collectTheoryPropagations ( ) [inherited]

**0.15.229.4.32 constraintsToInform()** const carl::FastSet<`FormulaT`>& smtrat::Module::constraintsToInform ( ) const [inline], [inherited]

**Returns**

The constraints which the backends must be informed about.

**0.15.229.4.33 currentlySatisfied()** `virtual unsigned smtrat::Module::currentlySatisfied ( const FormulaT & ) const [inline], [virtual], [inherited]`

**Returns**

0, if the given formula is conflicted by the current model; 1, if the given formula is satisfied by the current model; 2, otherwise; 3, if we do not know anything (default)

Reimplemented in [smtrat::LRAModule< Settings >](#), [smtrat::LRAModule< LRASettingsICP >](#), and [smtrat::LRAModule< LRASettings >](#)

**0.15.229.4.34 currentlySatisfiedByBackend()** `unsigned smtrat::Module::currentlySatisfiedByBackend ( const FormulaT & _formula ) const [inherited]`

**Returns**

0, if the given formula is conflicted by the current model; 1, if the given formula is satisfied by the current model; 2, otherwise 3, if we do not know anything (default)

**0.15.229.4.35 deinform()** `void smtrat::Module::deinform ( const FormulaT & _constraint ) [inherited]`

The inverse of informing about a constraint.

All data structures which were kept regarding this constraint are going to be removed. Note, that this makes only sense if it is not likely enough that a formula with this constraint must be solved again.

**Parameters**

|                          |                                                         |
|--------------------------|---------------------------------------------------------|
| <code>_constraint</code> | The constraint to remove from internal data structures. |
|--------------------------|---------------------------------------------------------|

**0.15.229.4.36 deinformCore()** `virtual void smtrat::Module::deinformCore ( const FormulaT & _constraint ) [inline], [protected], [virtual], [inherited]`

The inverse of informing about a constraint.

All data structures which were kept regarding this constraint are going to be removed. Note, that this makes only sense if it is not likely enough that a formula with this constraint must be solved again.

**Parameters**

|                          |                                                         |
|--------------------------|---------------------------------------------------------|
| <code>_constraint</code> | The constraint to remove from internal data structures. |
|--------------------------|---------------------------------------------------------|

Reimplemented in [smtrat::LRAModule< Settings >](#), [smtrat::LRAModule< LRASettingsICP >](#), and [smtrat::LRAModule< LRASettings >](#)

**0.15.229.4.37 determine\_smallest\_origin()** `size_t smtrat::Module::determine_smallest_origin ( const std::vector< FormulaT > & origins ) const [protected], [inherited]`

**Parameters**

|                      |                              |
|----------------------|------------------------------|
| <code>origins</code> | A vector of sets of origins. |
|----------------------|------------------------------|

**Returns**

The index of the smallest (regarding the size of the sets) element of origins

**0.15.229.4.38 `eraseSubformulaFromPassedFormula()`** `ModuleInput::iterator smtrat::Module::eraseSubformulaFromPassedFormula ( ModuleInput::iterator _subformula, bool _ignoreOrigins = false )` [protected], [virtual], [inherited]

Removes everything related to the sub-formula to remove from the passed formula in the backends of this module. Afterwards the sub-formula is removed from the passed formula.

**Parameters**

|                             |                                                                                                              |
|-----------------------------|--------------------------------------------------------------------------------------------------------------|
| <code>_subformula</code>    | The sub-formula to remove from the passed formula.                                                           |
| <code>_ignoreOrigins</code> | True, if the sub-formula shall be removed regardless of its origins (should only be applied with expertise). |

**Returns**

Reimplemented in `smtrat::ICPModule< Settings >`, `smtrat::ICPModule< ICPSettings4 >`, and `smtrat::ICPModule< ICPSettings1 >`.

**0.15.229.4.39 `excludeNotReceivedVariablesFromModel()`** `void smtrat::Module::excludeNotReceivedVariablesFromModel ( ) const` [inherited]

Excludes all variables from the current model, which do not occur in the received formula.

**0.15.229.4.40 `findBestOrigin()`** `std::vector< FormulaT >::const_iterator smtrat::Module::findBestOrigin ( const std::vector< FormulaT > & _origins ) const` [protected], [inherited]

**Parameters**

|                       |  |
|-----------------------|--|
| <code>_origins</code> |  |
|-----------------------|--|

**Returns**

**0.15.229.4.41 `firstSubformulaToPass()`** `ModuleInput::const_iterator smtrat::Module::firstSubformulaToPass ( ) const` [inline], [inherited]

**Returns**

The position of the first sub-formula in the passed formula, which has not yet been considered for a consistency check of the backends.

**0.15.229.4.42 `firstUncheckedReceivedSubformula()`** `ModuleInput::const_iterator smtrat::Module::firstUncheckedReceivedSubformula ( ) const` [inline], [inherited]

**Returns**

The position of the first (by this module) unchecked sub-formula of the received formula.

**0.15.229.4.43 freeSplittingVariable()** static void smtrat::Module::freeSplittingVariable ( const `FormulaT` & `_splittingVariable` ) [inline], [static], [inherited]

**0.15.229.4.44 generateTrivialInfeasibleSubset()** void smtrat::Module::generateTrivialInfeasibleSubset ( ) [inline], [protected], [inherited]  
Stores the trivial infeasible subset being the set of received formulas.

**0.15.229.4.45 getBackendsAllModels()** void smtrat::Module::getBackendsAllModels ( ) const [protected], [inherited]  
Stores all models of a backend in the list of all models of this module.

**0.15.229.4.46 getBackendsModel()** void smtrat::Module::getBackendsModel ( ) const [protected], [inherited]

**0.15.229.4.47 getInfeasibleSubsets() [1/2]** void smtrat::Module::getInfeasibleSubsets ( ) [protected], [inherited]  
Copies the infeasible subsets of the passed formula.

**0.15.229.4.48 getInfeasibleSubsets() [2/2]** std::vector< `FormulaSetT` > smtrat::Module::getInfeasibleSubsets ( const `Module` & `_backend` ) const [protected], [inherited]

Get the infeasible subsets the given backend provides.

Note, that an infeasible subset in a backend contains sub formulas of the passed formula and an infeasible subset of this module contains sub formulas of the received formula. In this method the LATTER is returned.

#### Parameters

|                       |                                                          |
|-----------------------|----------------------------------------------------------|
| <code>_backend</code> | The backend from which to obtain the infeasible subsets. |
|-----------------------|----------------------------------------------------------|

#### Returns

The infeasible subsets the given backend provides.

**0.15.229.4.49 getInformationRelevantFormulas()** const std::set< `FormulaT` > & smtrat::Module::getInformationRelevantFormulas ( ) [protected], [inherited]

Gets all InformationRelevantFormulas.

#### Returns

Set of all formulas

**0.15.229.4.50 getModelEqualities()** std::list< std::vector< `carl::Variable` > > smtrat::Module::getModelEqualities ( ) const [virtual], [inherited]

Partition the variables from the current model into equivalence classes according to their assigned value.

The result is a set of equivalence classes of variables where all variables within one class are assigned the same value. Note that the number of classes may not be minimal, i.e. two classes may actually be equivalent.

#### Returns

Equivalence classes.

**0.15.229.4.51 getOrigins() [1/3]** void smtrat::Module::getOrigins ( const FormulaT & \_formula, FormulaSetT & \_origins ) const [inline], [protected], [inherited]

**Parameters**

|          |  |
|----------|--|
| _formula |  |
| _origins |  |

**0.15.229.4.52 getOrigins() [2/3]** void smtrat::Module::getOrigins ( const FormulaT & \_formula, FormulasT & \_origins ) const [inline], [protected], [inherited]

**Parameters**

|          |  |
|----------|--|
| _formula |  |
| _origins |  |

**0.15.229.4.53 getOrigins() [3/3]** const FormulaT& smtrat::Module::getOrigins ( ModuleInput::const\_iterator \_formula ) const [inline], [protected], [inherited]

Gets the origins of the passed formula at the given position.

**Parameters**

|          |                                                   |
|----------|---------------------------------------------------|
| _formula | The position of a formula in the passed formulas. |
|----------|---------------------------------------------------|

**Returns**

The origins of the passed formula at the given position.

**0.15.229.4.54 getReceivedFormulaSimplified()** std::pair< bool, FormulaT > smtrat::PModule::getReceivedFormulaSimplified ( ) [virtual], [inherited]

**Returns**

A pair of a Boolean and a formula, where the Boolean is true, if the received formula could be simplified to an equisatisfiable formula. The formula is equisatisfiable to this module's received formula, if the Boolean is true.

Reimplemented from [smtrat::Module](#).

**0.15.229.4.55 hasLemmas()** bool smtrat::Module::hasLemmas ( ) [inline], [inherited]

Checks whether this module or any of its backends provides any lemmas.

**0.15.229.4.56 hasValidInfeasibleSubset()** bool smtrat::Module::hasValidInfeasibleSubset ( ) const [inherited]

**Returns**

true, if the module has at least one valid infeasible subset, that is all its elements are sub-formulas of the received formula (pointer must be equal).

**0.15.229.4.57 `id()`** `std::size_t smtrat::Module::id () const [inline], [inherited]`

**Returns**

A unique ID to identify this module instance.

**0.15.229.4.58 `infeasibleSubsets()`** `const std::vector<FormulaSetT>& smtrat::Module::infeasibleSubsets () const [inline], [inherited]`

**Returns**

The infeasible subsets of the set of received formulas (empty, if this module has not detected unsatisfiability of the conjunction of received formulas).

**0.15.229.4.59 `inform()`** `bool smtrat::Module::inform (const FormulaT & _constraint) [inherited]`

Informs the module about the given constraint.

It should be tried to inform this module about any constraint it could receive eventually before assertSubformula is called (preferably for the first time, but at least before adding a formula containing that constraint).

**Parameters**

|                          |                                 |
|--------------------------|---------------------------------|
| <code>_constraint</code> | The constraint to inform about. |
|--------------------------|---------------------------------|

**Returns**

false, if it can be easily decided whether the given constraint is inconsistent; true, otherwise.

**0.15.229.4.60 `informBackends()`** `void smtrat::Module::informBackends (const FormulaT & _constraint) [inline], [protected], [inherited]`

Informs all backends of this module about the given constraint.

**Parameters**

|                          |                                 |
|--------------------------|---------------------------------|
| <code>_constraint</code> | The constraint to inform about. |
|--------------------------|---------------------------------|

**0.15.229.4.61 `informCore()`** `virtual bool smtrat::Module::informCore (const FormulaT & _constraint) [inline], [protected], [virtual], [inherited]`

Informs the module about the given constraint.

It should be tried to inform this module about any constraint it could receive eventually before assertSubformula is called (preferably for the first time, but at least before adding a formula containing that constraint).

**Parameters**

|                          |                                 |
|--------------------------|---------------------------------|
| <code>_constraint</code> | The constraint to inform about. |
|--------------------------|---------------------------------|

**Returns**

false, if it can be easily decided whether the given constraint is inconsistent; true, otherwise.

Reimplemented in [smtrat::UnionFindModule< Settings >](#), [smtrat::PBPPModule< Settings >](#), [smtrat::PBGaussModule< Settings >](#), [smtrat::NRAILModule< Settings >](#), [smtrat::NewCoveringModule< Settings >](#), [smtrat::NewCADModule< Settings >](#),

`smrat::LRAModule< Settings >, smrat::LRAModule< LRASettingsICP >, smrat::LRAModule< LRASettings1 >, smrat::IntBlastModule< Settings >, smrat::FPPModule< Settings >, smrat::EQModule< Settings >, smrat::CurryModule< Settings >, smrat::BVMModule< Settings >, smrat::ICPModule< Settings >, smrat::ICPModule< ICPSettings4 >, and smrat::ICPModule< ICPSettings1 >.`

**0.15.229.4.62 informedConstraints()** `const carl::FastSet<FormulaT>& smrat::Module::informedConstraints( ) const [inline], [inherited]`

**Returns**

The position of the first constraint of which no backend has been informed about.

**0.15.229.4.63 init()** `void smrat::Module::init( ) [virtual], [inherited]`

Informs all backends about the so far encountered constraints, which have not yet been communicated.

This method must not be called twice and only before the first runBackends call.

Reimplemented in `smrat::PBPPModule< Settings >, smrat::PBGaussModule< Settings >, smrat::NRAILModule< Settings >, smrat::NewCoveringModule< Settings >, smrat::NewCADModule< Settings >, smrat::LRAModule< Settings >, smrat::LRAModule< LRASettingsICP >, smrat::LRAModule< LRASettings1 >, smrat::IntBlastModule< Settings >, smrat::FPPModule< Settings >, smrat::EQModule< Settings >, smrat::CurryModule< Settings >, and smrat::BVMModule< Settings >.`

**0.15.229.4.64 is\_minimizing()** `bool smrat::Module::is_minimizing( ) const [inline], [inherited]`

**0.15.229.4.65 isLemmaLevel()** `bool smrat::Module::isLemmaLevel( LemmaLevel level ) [protected], [inherited]`

Checks if current lemma level is greater or equal to given level.

**Parameters**

|                    |                 |
|--------------------|-----------------|
| <code>level</code> | Level to check. |
|--------------------|-----------------|

**0.15.229.4.66 isPreprocessor()** `bool smrat::PModule::isPreprocessor( ) const [inline], [inherited]`

**Returns**

true, if this module is a preprocessor that is a module, which simplifies its received formula to an equisatisfiable formula being passed to its backends. The simplified formula can be obtained with `getReceivedFormulaSimplified()`.

**0.15.229.4.67 lemmas()** `const std::vector<Lemma>& smrat::Module::lemmas( ) const [inline], [inherited]`

**Returns**

A constant reference to the lemmas being valid formulas this module or its backends made.

**0.15.229.4.68 merge()** `std::vector< FormulaT > smrat::Module::merge( const std::vector< FormulaT > & _vecSetA, const std::vector< FormulaT > & _vecSetB ) const [protected], [inherited]`

Merges the two vectors of sets into the first one.

({a,b},{a,c}) and ({b,d},{b}) -> ({a,b,d},{a,b},{a,b,c,d},{a,b,c})

**Parameters**

|                       |                                  |
|-----------------------|----------------------------------|
| <code>_vecSetA</code> | A vector of sets of constraints. |
| <code>_vecSetB</code> | A vector of sets of constraints. |

**Returns**

The vector being the two given vectors merged.

**0.15.229.4.69 `model()`** `const Model& smtrat::Module::model () const [inline], [inherited]`**Returns**

The assignment of the current satisfiable result, if existent.

**0.15.229.4.70 `modelsDisjoint()`** `bool smtrat::Module::modelsDisjoint (`

```
 const Model & _modelA,
 const Model & _modelB) [static], [protected], [inherited]
```

Checks whether there is no variable assigned by both models.

**Parameters**

|                      |                                |
|----------------------|--------------------------------|
| <code>_modelA</code> | The first model to check for.  |
| <code>_modelB</code> | The second model to check for. |

**Returns**

true, if there is no variable assigned by both models; false, otherwise.

**0.15.229.4.71 `moduleName()`** `virtual std::string smtrat::Module::moduleName () const [inline], [virtual], [inherited]`**Returns**

The name of the given module type as name.

Reimplemented in [smtrat::VSModule< Settings >](#), [smtrat::UnionFindModule< Settings >](#), [smtrat::UFCegarModule< Settings >](#), [smtrat::STropModule< Settings >](#), [smtrat::SplitSOSModule< Settings >](#), [smtrat::PBPPModule< Settings >](#), [smtrat::PBGaussModule< Settings >](#), [smtrat::NRAILModule< Settings >](#), [smtrat::NewCADModule< Settings >](#), [smtrat::LVEModule< Settings >](#), [smtrat::LRAModule< Settings >](#), [smtrat::LRAModule< LRASettingsICP >](#), [smtrat::LRAModule< LRASettings1 >](#), [smtrat::IntEqModule< Settings >](#), [smtrat::IntBlastModule< Settings >](#), [smtrat::IncWidthModule< Settings >](#), [smtrat::ICPModule< Settings >](#), [smtrat::ICPModule< ICPSettings4 >](#), [smtrat::ICPModule< ICPSettings1 >](#), [smtrat::GBModule< Settings >](#), [smtrat::FouMoModule< Settings >](#), [smtrat::EQPreprocessingModule< Settings >](#), [smtrat::EQModule< Settings >](#), [smtrat::CurryModule< Settings >](#), [smtrat::CubeLIAModule< Settings >](#), [smtrat::CSplitModule< Settings >](#), [smtrat::BVMModule< Settings >](#), and [smtrat::BEModule< Settings >](#).

**0.15.229.4.72 `objective()`** `carl::Variable smtrat::Module::objective () const [inline], [inherited]`**0.15.229.4.73 `originInReceivedFormula()`** `bool smtrat::Module::originInReceivedFormula (`

```
 const FormulaT & _origin) const [protected], [inherited]
```

**0.15.229.4.74 passedFormulaBegin()** `ModuleInput::iterator smtrat::Module::passedFormulaBegin ( )` [inline], [protected], [inherited]

**Returns**

An iterator to the end of the passed formula. TODO: disable this method

**0.15.229.4.75 passedFormulaEnd()** `ModuleInput::iterator smtrat::Module::passedFormulaEnd ( )` [inline], [protected], [inherited]

**Returns**

An iterator to the end of the passed formula.

**0.15.229.4.76 pPassedFormula()** `const ModuleInput* smtrat::Module::pPassedFormula ( ) const` [inline], [inherited]

**Returns**

A pointer to the formula passed to the backends of this module.

**0.15.229.4.77 pReceivedFormula()** `const ModuleInput* smtrat::Module::pReceivedFormula ( ) const` [inline], [inherited]

**Returns**

A pointer to the formula passed to this module.

**0.15.229.4.78 print()** `void smtrat::Module::print ( const std::string & _initiation = "***" ) const` [inherited]

Prints everything relevant of the solver.

**Parameters**

|                          |                      |
|--------------------------|----------------------|
| <code>_initiation</code> | The line initiation. |
|--------------------------|----------------------|

**0.15.229.4.79 printAllModels()** `void smtrat::Module::printAllModels ( std::ostream & _out = std::cout )` [inherited]

Prints all assignments of this module satisfying its received formula if it satisfiable and this module could find an assignment.

**Parameters**

|                   |                                        |
|-------------------|----------------------------------------|
| <code>_out</code> | The stream to print the assignment on. |
|-------------------|----------------------------------------|

**0.15.229.4.80 printInfeasibleSubsets()** `void smtrat::Module::printInfeasibleSubsets ( const std::string & _initiation = "***" ) const` [inherited]

Prints the infeasible subsets.

**Parameters**

|                          |                      |
|--------------------------|----------------------|
| <code>_initiation</code> | The line initiation. |
|--------------------------|----------------------|

**0.15.229.4.81 `printModel()`** `void smtrat::Module::printModel ( std::ostream & _out = std::cout ) const [inherited]`

Prints the assignment of this module satisfying its received formula if it satisfiable and this module could find an assignment.

**Parameters**

|                   |                                        |
|-------------------|----------------------------------------|
| <code>_out</code> | The stream to print the assignment on. |
|-------------------|----------------------------------------|

**0.15.229.4.82 `printPassedFormula()`** `void smtrat::Module::printPassedFormula ( const std::string & _initiation = "***" ) const [inherited]`

Prints the vector of passed formula.

**Parameters**

|                          |                      |
|--------------------------|----------------------|
| <code>_initiation</code> | The line initiation. |
|--------------------------|----------------------|

**0.15.229.4.83 `printReceivedFormula()`** `void smtrat::Module::printReceivedFormula ( const std::string & _initiation = "***" ) const [inherited]`

Prints the vector of the received formula.

**Parameters**

|                          |                      |
|--------------------------|----------------------|
| <code>_initiation</code> | The line initiation. |
|--------------------------|----------------------|

**0.15.229.4.84 `probablyLooping()`** `bool smtrat::Module::probablyLooping ( const typename Poly::PolyType & _branchingPolynomial, const Rational & _branchingValue ) const [protected], [inherited]`

Checks whether given the current branching value and branching variable/polynomial it is (highly) probable that this branching is part of an infinite loop of branchings.

**Parameters**

|                                   |                                                                                     |
|-----------------------------------|-------------------------------------------------------------------------------------|
| <code>_branchingPolynomial</code> | The polynomial to branch at (in most branching strategies this is just a variable). |
| <code>_branchingValue</code>      | The value to branch at.                                                             |

**Returns**

true, if this branching is probably part of an infinite loop of branchings; false, otherwise.

**0.15.229.4.85 `receivedFormulaChecked()`** `void smtrat::Module::receivedFormulaChecked ( ) [inline], [inherited]`

Notifies that the received formulas has been checked.

**0.15.229.4.86 `receivedFormulasAsInfeasibleSubset()`** void smtrat::Module::receivedFormulasAsInfeasibleSubset (

```
 ModuleInput::const_iterator _subformula) [inline], [protected], [inherited]
```

Stores an infeasible subset consisting only of the given received formula.

**0.15.229.4.87 `receivedVariable()`** bool smtrat::Module::receivedVariable (

```
 carl::Variable::Arg _var) const [inline], [inherited]
```

**0.15.229.4.88 `remove()`** void smtrat::PModule::remove (

```
 ModuleInput::const_iterator _subformula) [virtual], [inherited]
```

Removes everything related to the given sub-formula of the received formula.

However, it is desired not to lose track of search spaces where no satisfying assignment can be found for the remaining sub-formulas.

#### Parameters

|                          |                                                    |
|--------------------------|----------------------------------------------------|
| <code>_subformula</code> | The sub formula of the received formula to remove. |
|--------------------------|----------------------------------------------------|

Reimplemented from [smtrat::Module](#).

**0.15.229.4.89 `removeCore()`** virtual void smtrat::Module::removeCore (

```
 ModuleInput::const_iterator formula) [inline], [protected], [virtual], [inherited]
```

Removes everything related to the given sub-formula of the received formula.

However, it is desired not to lose track of search spaces where no satisfying assignment can be found for the remaining sub-formulas.

#### Parameters

|                      |                                                    |
|----------------------|----------------------------------------------------|
| <code>formula</code> | The sub formula of the received formula to remove. |
|----------------------|----------------------------------------------------|

Reimplemented in [smtrat::VSModule< Settings >](#), [smtrat::SATModule< Settings >](#), [smtrat::PFEModule< Settings >](#), [smtrat::ICPModule< Settings >](#), [smtrat::ICPModule< ICPSettings4 >](#), [smtrat::ICPModule< ICPSettings1 >](#), [smtrat::UnionFindModule< Settings >](#), [smtrat::UFCegarModule< Settings >](#), [smtrat::STropModule< Settings >](#), [smtrat::PBPPModule< Settings >](#), [smtrat::PBGaussModule< Settings >](#), [smtrat::NRAILModule< Settings >](#), [smtrat::NewCoveringModule< Settings >](#), [smtrat::NewCADModule< Settings >](#), [smtrat::LRAModule< Settings >](#), [smtrat::LRAModule< LRASettingsICP >](#), [smtrat::LRAModule< LRASettings1 >](#), [smtrat::IntEqModule< Settings >](#), [smtrat::IntBlastModule< Settings >](#), [smtrat::IncWidthModule< Settings >](#), [smtrat::ICEModule< Settings >](#), [smtrat::FPPModule< Settings >](#), [smtrat::FouMoModule< Settings >](#), [smtrat::EQModule< Settings >](#), [smtrat::CurryModule< Settings >](#), [smtrat::CubeLIAModule< Settings >](#), [smtrat::CSplitModule< Settings >](#), [smtrat::BVMModule< Settings >](#), and [smtrat::GBModule< Settings >](#).

**0.15.229.4.90 `removeOrigin()`** std::pair<ModuleInput::iterator, bool> smtrat::Module::remove←

Origin (

```
 ModuleInput::iterator _formula,
 const FormulaT & _origin) [inline], [protected], [inherited]
```

**0.15.229.4.91 `removeOrigins()`** std::pair<ModuleInput::iterator, bool> smtrat::Module::remove←

Origins (

```
 ModuleInput::iterator _formula,
 const std::shared_ptr< std::vector< FormulaT >> & _origins) [inline], [protected],
[inherited]
```

#### 0.15.229.4.92 **rPassedFormula()** const [ModuleInput](#)& smtrat::Module::rPassedFormula () const [inline], [inherited]

##### Returns

A reference to the formula passed to the backends of this module.

#### 0.15.229.4.93 **rReceivedFormula()** const [ModuleInput](#)& smtrat::Module::rReceivedFormula () const [inline], [inherited]

##### Returns

A reference to the formula passed to this module.

#### 0.15.229.4.94 **runBackends()** [1/2] virtual [Answer](#) smtrat::PModule::runBackends () [inline], [virtual], [inherited]

Reimplemented from [smtrat::Module](#).

#### 0.15.229.4.95 **runBackends()** [2/2] [Answer](#) smtrat::PModule::runBackends ( bool \_final, bool \_full, carl::Variable \_objective ) [virtual], [inherited]

Runs the backend solvers on the passed formula.

##### Parameters

|                         |                                                                                                                                       |
|-------------------------|---------------------------------------------------------------------------------------------------------------------------------------|
| <code>_final</code>     | true, if this satisfiability check will be the last one (for a global sat-check), if its result is SAT.                               |
| <code>_full</code>      | false, if this module should avoid too expensive procedures and rather return unknown instead.                                        |
| <code>_objective</code> | if not set to NO_VARIABLE, the module should find an assignment minimizing this objective variable; otherwise any assignment is good. |

##### Returns

True, if the passed formula is consistent; False, if the passed formula is inconsistent; Unknown, otherwise.

Reimplemented from [smtrat::Module](#).

#### 0.15.229.4.96 **setId()** void smtrat::Module::setId ( std::size\_t \_id ) [inline], [inherited]

Sets this modules unique ID to identify itself.

##### Parameters

|                             |                                    |
|-----------------------------|------------------------------------|
| $\leftrightarrow$<br>$\_id$ | The id to set this module's id to. |
|-----------------------------|------------------------------------|

**0.15.229.4.97 `setThreadPriority()`** `void smtrat::Module::setThreadPriority (`  
`thread_priority _threadPriority )` [inline], [inherited]  
 Sets the priority of this module to get a thread for running its check procedure.

Parameters

|                              |                                                       |
|------------------------------|-------------------------------------------------------|
| <code>_threadPriority</code> | The priority to set this module's thread priority to. |
|------------------------------|-------------------------------------------------------|

**0.15.229.4.98 `solverState()`** `Answer smtrat::Module::solverState ( ) const` [inline], [inherited]

Returns

True, if this module is in a state, such that it has found a solution for its received formula; False, if this module is in a state, such that it has determined that there is no solution for its received formula; Unknown, otherwise.

**0.15.229.4.99 `splitUnequalConstraint()`** `void smtrat::Module::splitUnequalConstraint (`  
`const FormulaT & _unequalConstraint )` [protected], [inherited]

Adds the following lemmas for the given constraint  $p \neq 0$ .

$(p \neq 0 \Leftrightarrow (p < 0 \text{ or } p > 0))$

and  $\neg(p < 0 \text{ and } p > 0)$

Parameters

|                                 |                                                  |
|---------------------------------|--------------------------------------------------|
| <code>_unequalConstraint</code> | A constraint having the relation symbol $\neq$ . |
|---------------------------------|--------------------------------------------------|

**0.15.229.4.100 `threadPriority()`** `thread_priority smtrat::Module::threadPriority ( ) const` [inline], [inherited]

Returns

The priority of this module to get a thread for running its check procedure.

**0.15.229.4.101 `updateAllModels()`** `void smtrat::Module::updateAllModels ( )` [virtual], [inherited]

Updates all satisfying models, if the solver has detected the consistency of the received formula, beforehand.

Reimplemented in [smtrat::SATModule< Settings >](#).

**0.15.229.4.102 `updateLemmas()`** `void smtrat::Module::updateLemmas ( )` [inherited]

Stores all lemmas of any backend of this module in its own lemma vector.

**0.15.229.4.103 `updateModel()`** `template<typename Settings >`

`void smtrat::GBPPModule< Settings >::updateModel ( ) const` [virtual]

Updates the current assignment into the model.

Note, that this is a unique but possibly symbolic assignment maybe containing newly introduced variables.

Reimplemented from [smtrat::Module](#).

**0.15.229.4.104 usedBackends()** const std::vector<[Module](#)\*>& smrat::Module::usedBackends ( )  
const [inline], [inherited]

**Returns**

The backends of this module which are currently used (conditions to use this module are fulfilled for the passed formula).

## 0.15.229.5 Field Documentation

**0.15.229.5.1 mAllBackends** std::vector<[Module](#)\*> smrat::Module::mAllBackends [protected], [inherited]

The backends of this module which have been used.

**0.15.229.5.2 mAllModels** std::vector<[Model](#)> smrat::Module::mAllModels [mutable], [protected], [inherited]

Stores all satisfying assignments.

**0.15.229.5.3 mBackendsFoundAnswer** std::atomic\_bool\* smrat::Module::mBackendsFoundAnswer [protected], [inherited]

This flag is passed to any backend and if it determines an answer to a prior check call, this flag is fired.

**0.15.229.5.4 mConstraintsToInform** carl::FastSet<[FormulaT](#)> smrat::Module::mConstraintsToInform [protected], [inherited]

Stores the constraints which the backends must be informed about.

**0.15.229.5.5 mFinalCheck** bool smrat::Module::mFinalCheck [protected], [inherited]

true, if the check procedure should perform a final check which especially means not to postpone splitting decisions

**0.15.229.5.6 mFirstPosInLastBranches** std::size\_t smrat::Module::mFirstPosInLastBranches = 0 [static], [inherited]

The beginning of the cyclic buffer storing the last branches.

**0.15.229.5.7 mFirstSubformulaToPass** [ModuleInput](#)::iterator smrat::Module::mFirstSubformulaToPass [protected], [inherited]

Stores the position of the first sub-formula in the passed formula, which has not yet been considered for a consistency check of the backends.

**0.15.229.5.8 mFirstUncheckedReceivedSubformula** [ModuleInput](#)::const\_iterator smrat::Module::mFirstUncheckedReceivedSubformula [protected], [inherited]

Stores the position of the first (by this module) unchecked sub-formula of the received formula.

**0.15.229.5.9 mFoundAnswer** [Conditionals](#) smrat::Module::mFoundAnswer [protected], [inherited]

Vector of Booleans: If any of them is true, we have to terminate a running check procedure.

**0.15.229.5.10 mFullCheck** `bool smtrat::Module::mFullCheck` [protected], [inherited]  
false, if this module should avoid too expensive procedures and rather return unknown instead.

**0.15.229.5.11 mInfeasibleSubsets** `std::vector<FormulaSetT> smtrat::Module::mInfeasibleSubsets` [protected], [inherited]  
Stores the infeasible subsets.

**0.15.229.5.12 mInformedConstraints** `carl::FastSet<FormulaT> smtrat::Module::mInformedConstraints` [protected], [inherited]  
Stores the position of the first constraint of which no backend has been informed about.

**0.15.229.5.13 mLastBranches** `std::vector< Branching > smtrat::Module::mLastBranches = std::vector<Branching> (mNumOfBranchVarsToStore, Branching(typename Poly::PolyType(), 0))` [static], [inherited]  
Stores the last branches in a cycle buffer.

**0.15.229.5.14 mLemmas** `std::vector<Lemma> smtrat::Module::mLemmas` [protected], [inherited]  
Stores the lemmas being valid formulas this module or its backends made.

**0.15.229.5.15 mModel** `Model smtrat::Module::mModel` [mutable], [protected], [inherited]  
Stores the assignment of the current satisfiable result, if existent.

**0.15.229.5.16 mModelComputed** `bool smtrat::Module::mModelComputed` [mutable], [protected], [inherited]  
True, if the model has already been computed.

**0.15.229.5.17 mNumOfBranchVarsToStore** `std::size_t smtrat::Module::mNumOfBranchVarsToStore = 5` [static], [inherited]  
The number of different variables to consider for a probable infinite loop of branchings.

**0.15.229.5.18 mObjectiveVariable** `carl::Variable smtrat::Module::mObjectiveVariable` [protected], [inherited]  
Objective variable to be minimized. If set to NO\_VARIABLE, a normal sat check should be performed.

**0.15.229.5.19 mOldSplittingVariables** `std::vector< FormulaT > smtrat::Module::mOldSplittingVariables` [static], [inherited]  
Reusable splitting variables.

**0.15.229.5.20 mpManager** `Manager* const smtrat::Module::mpManager` [protected], [inherited]  
A reference to the manager.

**0.15.229.5.21 mSmallerMusesCheckCounter** `unsigned smtrat::Module::mSmallerMusesCheckCounter` [mutable], [protected], [inherited]  
Counter used for the generation of the smt2 files to check for smaller muses.

**0.15.229.5.22 mSolverState** std::atomic<[Answer](#)> smrat::Module::mSolverState [protected], [inherited]

States whether the received formula is known to be satisfiable or unsatisfiable otherwise it is set to unknown.

**0.15.229.5.23 mTheoryPropagations** std::vector<[TheoryPropagation](#)> smrat::Module::mTheory← Propagations [protected], [inherited]

**0.15.229.5.24 mUsedBackends** std::vector<[Module\\*](#)> smrat::Module::mUsedBackends [protected], [inherited]

The backends of this module which are currently used (conditions to use this module are fulfilled for the passed formula).

**0.15.229.5.25 mVariableCounters** std::vector<std::size\_t> smrat::Module::mVariableCounters [protected], [inherited]

Maps variables to the number of their occurrences.

## 0.15.244 smtrat::parser::HexadecimalParser Struct Reference

Parses hexadecimals: #x [0-9a-fA-F] +  
#include <Lexicon.h>

### Public Types

- `typedef boost::iterator_range< Iterator > ITRange`

### Public Member Functions

- `HexadecimalParser ()`
- `FixedWidthConstant< Integer > build (const ITRange &itr, const Integer &val)`

### Data Fields

- `qi::uint_parser< Integer, 16, 1,-1 > number`
- `qi::rule< Iterator, FixedWidthConstant< Integer >, Skipper, qi::locals< Integer > > main`
- `qi::rule< Iterator, FixedWidthConstant< Integer >, Skipper > main2`

### 0.15.244.1 Detailed Description

Parses hexadecimals: #x [0-9a-fA-F] +

### 0.15.244.2 Member Typedef Documentation

**0.15.244.2.1 ITRange** `typedef boost::iterator_range<Iterator> smtrat::parser::HexadecimalParser::ITRange`

### 0.15.244.3 Constructor & Destructor Documentation

**0.15.244.3.1 HexadecimalParser()** `smtrat::parser::HexadecimalParser::HexadecimalParser ( ) [inline]`

### 0.15.244.4 Member Function Documentation

**0.15.244.4.1 build()** `FixedWidthConstant<Integer> smtrat::parser::HexadecimalParser::build ( const ITRange & itr, const Integer & val ) [inline]`

### 0.15.244.5 Field Documentation

**0.15.244.5.1 main** `qi::rule<Iterator, FixedWidthConstant<Integer>), Skipper, qi::locals<Integer>> smrat::parser::HexadecimalParser::main`

**0.15.244.5.2 main2** `qi::rule<Iterator, FixedWidthConstant<Integer>), Skipper> smrat::parser<::HexadecimalParser::main2`

**0.15.244.5.3 number** `qi::uint_parser<Integer,16,1,-1> smrat::parser::HexadecimalParser<::number`

## 0.15.245 smrat::icp::HistoryNode Class Reference

## 0.15.246 smtrat::ICEModule< Settings > Class Template Reference

#include <ICEModule.h>

### Public Types

- typedef Settings SettingsType
- enum class LemmaType : unsigned { NORMAL = 0 , PERMANENT = 1 }

### Public Member Functions

- ICEModule (const ModuleInput \* \_formula, Conditionals & \_conditionals, Manager \* \_manager=nullptr)
- ~ICEModule ()
- bool addCore (ModuleInput::const\_iterator \_subformula)
 

*The module has to take the given sub-formula of the received formula into account.*
- void removeCore (ModuleInput::const\_iterator \_subformula)
 

*Removes the subformula of the received formula at the given position to the considered ones of this module.*
- Answer checkCore ()
 

*Checks the received formula for consistency.*
- bool isPreprocessor () const
- bool appliedPreprocessing () const
- bool add (ModuleInput::const\_iterator \_subformula)
 

*The module has to take the given sub-formula of the received formula into account.*
- void remove (ModuleInput::const\_iterator \_subformula)
 

*Removes everything related to the given sub-formula of the received formula.*
- Answer check (bool \_final=false, bool \_full=true, carl::Variable \_objective=carl::Variable::NO\_VARIABLE)
 

*Checks the received formula for consistency.*
- Answer runBackends (bool \_final, bool \_full, carl::Variable \_objective)
 

*Runs the backend solvers on the passed formula.*
- virtual Answer runBackends ()
- std::pair< bool, FormulaT > getReceivedFormulaSimplified ()
 

*Updates the current assignment into the model.*
- void updateModel () const
 

*Updates the current assignment into the model.*
- bool inform (const FormulaT & \_constraint)

- **Informs the module about the given constraint.**
  - void **deinform** (const **FormulaT** &\_constraint)  
*The inverse of informing about a constraint.*
  - virtual void **init** ()  
*Informs all backends about the so far encountered constraints, which have not yet been communicated.*
  - virtual void **updateAllModels** ()  
*Updates all satisfying models, if the solver has detected the consistency of the received formula, beforehand.*
  - virtual std::list< std::vector< carl::Variable > > **getModelEqualities** () const  
*Partition the variables from the current model into equivalence classes according to their assigned value.*
  - unsigned **currentlySatisfiedByBackend** (const **FormulaT** &\_formula) const
  - virtual unsigned **currentlySatisfied** (const **FormulaT** &) const
  - bool **receivedVariable** (carl::Variable::Arg \_var) const
  - **Answer solverState** () const
  - std::size\_t **id** () const
  - void **setId** (std::size\_t \_id)  
*Sets this modules unique ID to identify itself.*
  - **thread\_priority threadPriority** () const
  - void **setThreadPriority** (**thread\_priority** \_threadPriority)  
*Sets the priority of this module to get a thread for running its check procedure.*
  - const **ModuleInput** \* **pReceivedFormula** () const
  - const **ModuleInput** & **rReceivedFormula** () const
  - const **ModuleInput** \* **pPassedFormula** () const
  - const **ModuleInput** & **rPassedFormula** () const

  - void **addLemma** (const **FormulaT** &\_lemma, const **LemmaType** &\_lt= **LemmaType**::NORMAL, const **FormulaT** &\_preferredFormula= **FormulaT**(carl::FormulaType::TRUE))  
*Stores a lemma being a valid formula.*
  - bool **hasLemmas** ()  
*Checks whether this module or any of its backends provides any lemmas.*
  - void **clearLemmas** ()  
*Deletes all yet found lemmas.*
  - const std::vector< **Lemma** > & **lemmas** () const
  - **ModuleInput**::const\_iterator **firstUncheckedReceivedSubformula** () const
  - **ModuleInput**::const\_iterator **firstSubformulaToPass** () const
  - void **receivedFormulaChecked** ()  
*Notifies that the received formulas has been checked.*
  - const **smrat::Conditionals** & **answerFound** () const
  - virtual std::string **moduleName** () const
  - carl::Variable **objective** () const
  - bool **is\_minimizing** () const
  - void **excludeNotReceivedVariablesFromModel** () const  
*Excludes all variables from the current model, which do not occur in the received formula.*
  - void **updateLemmas** ()  
*Stores all lemmas of any backend of this module in its own lemma vector.*
  - void **collectTheoryPropagations** ()
  - void **collectOrigins** (const **FormulaT** &\_formula, **FormulasT** &\_origins) const  
*Collects the formulas in the given formula, which are part of the received formula.*
  - void **collectOrigins** (const **FormulaT** &\_formula, **FormulaSetT** &\_origins) const

- bool `isValidInfeasibleSubset () const`
- void `checkInfeasibleSubsetForMinimality (std::vector< FormulaSetT >::const_iterator _insubset, const std::string &_filename="smaller_muses", unsigned _maxSizeDifference=1) const`

*Checks the given infeasible subset for minimality by storing all subsets of it, which have a smaller size which differs from the size of the infeasible subset not more than the given threshold.*
- void `print (const std::string &_initiation="***") const`

*Prints everything relevant of the solver.*
- void `printReceivedFormula (const std::string &_initiation="***") const`

*Prints the vector of the received formula.*
- void `printPassedFormula (const std::string &_initiation="***") const`

*Prints the vector of passed formula.*
- void `printInfeasibleSubsets (const std::string &_initiation="***") const`

*Prints the infeasible subsets.*
- void `printModel (std::ostream &_out=std::cout) const`

*Prints the assignment of this module satisfying its received formula if it satisfiable and this module could find an assignment.*
- void `printAllModels (std::ostream &_out=std::cout)`

*Prints all assignments of this module satisfying its received formula if it satisfiable and this module could find an assignment.*

### Static Public Member Functions

- static void `freeSplittingVariable (const FormulaT &_splittingVariable)`

### Static Public Attributes

- static size\_t `mNumOfBranchVarsToStore = 5`

*The number of different variables to consider for a probable infinite loop of branchings.*
- static std::vector< Branching > `mLastBranches = std::vector<Branching>(mNumOfBranchVarsToStore, Branching(typename Poly::PolyType(), 0))`

*Stores the last branches in a cycle buffer.*
- static size\_t `mFirstPosInLastBranches = 0`

*The beginning of the cyclic buffer storing the last branches.*
- static std::vector< FormulaT > `mOldSplittingVariables`

*Reusable splitting variables.*

### Protected Member Functions

- virtual bool `informCore (const FormulaT &_constraint)`

*Informs the module about the given constraint.*
- virtual void `deinformCore (const FormulaT &_constraint)`

*The inverse of informing about a constraint.*
- bool `anAnswerFound () const`

*Checks for all antecedent modules and those which run in parallel with the same antecedent modules, whether one of them has determined a result.*
- void `clearModel () const`

*Clears the assignment, if any was found.*
- void `clearModels () const`

*Clears all assignments, if any was found.*
- void `cleanModel () const`

*Substitutes variable occurrences by its model value in the model values of other variables.*
- `ModuleInput::iterator passedFormulaBegin ()`
- `ModuleInput::iterator passedFormulaEnd ()`
- void `addOrigin (ModuleInput::iterator _formula, const FormulaT &_origin)`

- Adds the given set of formulas in the received formula to the origins of the given passed formula.*
- const `FormulaT & getOrigins (ModuleInput::const_iterator _formula) const`

*Gets the origins of the passed formula at the given position.*
  - void `getOrigins (const FormulaT &_formula, FormulasT &_origins) const`
  - void `getOrigins (const FormulaT &_formula, FormulaSetT &_origins) const`
  - std::pair< `ModuleInput::iterator, bool > removeOrigin (ModuleInput::iterator _formula, const FormulaT &_origin)`
  - std::pair< `ModuleInput::iterator, bool > removeOrigins (ModuleInput::iterator _formula, const std::shared_ptr< std::vector< FormulaT >> &_origins)`
  - void `informBackends (const FormulaT &_constraint)`

*Informs all backends of this module about the given constraint.*
  - virtual void `addConstraintToInform (const FormulaT &_constraint)`

*Adds a constraint to the collection of constraints of this module, which are informed to a freshly generated backend.*
  - std::pair< `ModuleInput::iterator, bool > addReceivedSubformulaToPassedFormula (ModuleInput::const_iterator _subformula)`

*Copies the given sub-formula of the received formula to the passed formula.*
  - bool `originInReceivedFormula (const FormulaT &_origin) const`
  - std::pair< `ModuleInput::iterator, bool > addSubformulaToPassedFormula (const FormulaT &_formula)`

*Adds the given formula to the passed formula with no origin.*
  - std::pair< `ModuleInput::iterator, bool > addSubformulaToPassedFormula (const FormulaT &_formula, const std::shared_ptr< std::vector< FormulaT >> &_origins)`

*Adds the given formula to the passed formula.*
  - std::pair< `ModuleInput::iterator, bool > addSubformulaToPassedFormula (const FormulaT &_formula, const FormulaT &_origin)`

*Adds the given formula to the passed formula.*
  - void `generateTrivialInfeasibleSubset ()`

*Stores the trivial infeasible subset being the set of received formulas.*
  - void `receivedFormulasAsInfeasibleSubset (ModuleInput::const_iterator _subformula)`

*Stores an infeasible subset consisting only of the given received formula.*
  - std::vector< `FormulaT >::const_iterator findBestOrigin (const std::vector< FormulaT > &_origins) const`
  - void `getInfeasibleSubsets ()`

*Copies the infeasible subsets of the passed formula.*
  - std::vector< `FormulaSetT > getInfeasibleSubsets (const Module &_backend) const`

*Get the infeasible subsets the given backend provides.*
  - const `Model & backendsModel () const`

*Stores the model of a backend which determined satisfiability of the passed formula in the model of this module.*
  - void `getBackendsModel () const`
  - void `getBackendsAllModels () const`

*Stores all models of a backend in the list of all models of this module.*
  - virtual `ModuleInput::iterator eraseSubformulaFromPassedFormula (ModuleInput::iterator _subformula, bool _ignoreOrigins=false)`

*Removes everything related to the sub-formula to remove from the passed formula in the backends of this module.*
  - void `clearPassedFormula ()`
  - std::vector< `FormulaT > merge (const std::vector< FormulaT > &, const std::vector< FormulaT > &) const`

*Merges the two vectors of sets into the first one.*
  - size\_t `determine_smallest_origin (const std::vector< FormulaT > &origins) const`
  - bool `probablyLooping (const typename Poly::PolyType &_branchingPolynomial, const Rational &_branchingValue) const`

*Checks whether given the current branching value and branching variable/polynomial it is (highly) probable that this branching is part of an infinite loop of branchings.*
  - bool `branchAt (const Poly &_polynomial, bool _integral, const Rational &_value, std::vector< FormulaT > &&_premise, bool _leftCaseWeak=true, bool _preferLeftCase=true, bool _useReceivedFormulaAsPremise=false)`

- Adds a lemmas which provoke a branching for the given variable at the given value, if this module returns Unknown and there exists a preceding SATModule.
- bool `branchAt` (const `Poly` &\_polynomial, bool \_integral, const `Rational` &\_value, bool \_leftCaseWeak=true, bool \_preferLeftCase=true, bool \_useReceivedFormulaAsPremise=false, const std::vector<`FormulaT`> &\_premise=std::vector<`FormulaT`>())
  - bool `branchAt` (carl::Variable::Arg \_var, const `Rational` &\_value, std::vector<`FormulaT`> &&\_premise, bool \_leftCaseWeak=true, bool \_preferLeftCase=true, bool \_useReceivedFormulaAsPremise=false)
  - bool `branchAt` (carl::Variable::Arg \_var, const `Rational` &\_value, bool \_leftCaseWeak=true, bool \_preferLeftCase=true, bool \_useReceivedFormulaAsPremise=false, const std::vector<`FormulaT`> &\_premise=std::vector<`FormulaT`>())
    - void `splitUnequalConstraint` (const `FormulaT` &
 

Adds the following lemmas for the given constraint  $p \neq 0$ .
- unsigned `checkModel` () const
- void `addInformationRelevantFormula` (const `FormulaT` &formula)
  - Adds a formula to the InformationRelevantFormula.
- const std::set<`FormulaT`> & `getInformationRelevantFormulas` ()
  - Gets all InformationRelevantFormulas.
- bool `isLemmaLevel` (`LemmaLevel` level)
  - Checks if current lemma level is greater or equal to given level.

## Static Protected Member Functions

- static bool `modelsDisjoint` (const `Model` &\_modelA, const `Model` &\_modelB)
  - Checks whether there is no variable assigned by both models.

## Protected Attributes

- std::vector<`FormulaSetT`> `mInfeasibleSubsets`
  - Stores the infeasible subsets.
- `Manager` \*const `mpManager`
  - A reference to the manager.
- `Model` `mModel`
  - Stores the assignment of the current satisfiable result, if existent.
- std::vector<`Model`> `mAllModels`
  - Stores all satisfying assignments.
- bool `mModelComputed`
  - True, if the model has already been computed.
- bool `mFinalCheck`
  - true, if the check procedure should perform a final check which especially means not to postpone splitting decisions
- bool `mFullCheck`
  - false, if this module should avoid too expensive procedures and rather return unknown instead.
- carl::Variable `mObjectiveVariable`
  - Objective variable to be minimized. If set to NO\_VARIABLE, a normal sat check should be performed.
- std::vector<`TheoryPropagation`> `mTheoryPropagations`
- std::atomic<`Answer`> `mSolverState`
  - States whether the received formula is known to be satisfiable or unsatisfiable otherwise it is set to unknown.
- std::atomic\_bool \* `mBackendsFoundAnswer`
  - This flag is passed to any backend and if it determines an answer to a prior check call, this flag is fired.
- `Conditionals` `mFoundAnswer`
  - Vector of Booleans: If any of them is true, we have to terminate a running check procedure.
- std::vector<`Module`\*> `mUsedBackends`
  - The backends of this module which are currently used (conditions to use this module are fulfilled for the passed formula).

- `std::vector< Module * > mAllBackends`  
*The backends of this module which have been used.*
- `std::vector< Lemma > mLemmas`  
*Stores the lemmas being valid formulas this module or its backends made.*
- `ModuleInput::iterator mFirstSubformulaToPass`  
*Stores the position of the first sub-formula in the passed formula, which has not yet been considered for a consistency check of the backends.*
- `carl::FastSet< FormulaT > mConstraintsToInform`  
*Stores the constraints which the backends must be informed about.*
- `carl::FastSet< FormulaT > mInformedConstraints`  
*Stores the position of the first constraint of which no backend has been informed about.*
- `ModuleInput::const_iterator mFirstUncheckedReceivedSubformula`  
*Stores the position of the first (by this module) unchecked sub-formula of the received formula.*
- `unsigned mSmallerMusesCheckCounter`  
*Counter used for the generation of the smt2 files to check for smaller muses.*
- `std::vector< std::size_t > mVariableCounters`  
*Maps variables to the number of their occurrences.*

`ModuleInput::const_iterator _subformula )` [inherited]

The module has to take the given sub-formula of the received formula into account.

Parameters

|                          |                                                    |
|--------------------------|----------------------------------------------------|
| <code>_subformula</code> | The sub-formula to take additionally into account. |
|--------------------------|----------------------------------------------------|

Returns

false, if it can be easily decided that this sub-formula causes a conflict with the already considered sub-formulas; true, otherwise.

**0.15.246.4.2 addConstraintToInform()** `void smtrat::Module::addConstraintToInform (`  
`const FormulaT & _constraint )` [protected], [virtual], [inherited]

Adds a constraint to the collection of constraints of this module, which are informed to a freshly generated backend.

Parameters

|                          |                        |
|--------------------------|------------------------|
| <code>_constraint</code> | The constraint to add. |
|--------------------------|------------------------|

Reimplemented in [smtrat::SATModule< Settings >](#).

**0.15.246.4.3 addCore()** `template<typename Settings >`  
`bool smtrat::ICEModule< Settings >::addCore (`  
`ModuleInput::const_iterator _subformula )` [virtual]

The module has to take the given sub-formula of the received formula into account.

Parameters

|                          |                                                    |
|--------------------------|----------------------------------------------------|
| <code>_subformula</code> | The sub-formula to take additionally into account. |
|--------------------------|----------------------------------------------------|

Returns

false, if it can be easily decided that this sub-formula causes a conflict with the already considered sub-formulas; true, otherwise.

Reimplemented from [smtrat::Module](#).

**0.15.246.4.4 addInformationRelevantFormula()** `void smtrat::Module::addInformationRelevantFormula (`  
`const FormulaT & formula )` [protected], [inherited]

Adds a formula to the InformationRelevantFormula.

Parameters

|                      |                |
|----------------------|----------------|
| <code>formula</code> | Formula to add |
|----------------------|----------------|

**0.15.246.4.5 addLemma()** `void smtrat::Module::addLemma (`  
`const FormulaT & _lemma,`  
`const LemmaType & _lt = LemmaType::NORMAL,`

```
const FormulaT & _preferredFormula = FormulaT(carl::FormulaType::TRUE)) [inline],
[inherited]
Stores a lemma being a valid formula.
```

**Parameters**

|                   |                                                                       |
|-------------------|-----------------------------------------------------------------------|
| _lemma            | The eduction/lemma to store.                                          |
| _lt               | The type of the lemma.                                                |
| _preferredFormula | Hint for the next decision, which formula should be assigned to true. |

**0.15.246.4.6 addOrigin()** void smtrat::Module::addOrigin (

```
ModuleInput::iterator _formula,
const FormulaT & _origin) [inline], [protected], [inherited]
```

Adds the given set of formulas in the received formula to the origins of the given passed formula.

**Parameters**

|          |                                                           |
|----------|-----------------------------------------------------------|
| _formula | The passed formula to set the origins for.                |
| _origin  | A set of formulas in the received formula of this module. |

**0.15.246.4.7 addReceivedSubformulaToPassedFormula()** std::pair<ModuleInput::iterator,bool>

```
smtrat::Module::addReceivedSubformulaToPassedFormula (
```

```
ModuleInput::const_iterator _subformula) [inline], [protected], [inherited]
```

Copies the given sub-formula of the received formula to the passed formula.

Note, that there is always a link between sub-formulas of the passed formulas to sub-formulas of the received formulas, which are responsible for its occurrence.

**Parameters**

|             |                                                  |
|-------------|--------------------------------------------------|
| _subformula | The sub-formula of the received formula to copy. |
|-------------|--------------------------------------------------|

**0.15.246.4.8 addSubformulaToPassedFormula() [1/3]** std::pair<ModuleInput::iterator,bool> smtrat<->

```
::Module::addSubformulaToPassedFormula (
```

```
const FormulaT & _formula) [inline], [protected], [inherited]
```

Adds the given formula to the passed formula with no origin.

Note that in the next call of this module's removeSubformula, all formulas in the passed formula without origins will be removed.

**Parameters**

|          |                                           |
|----------|-------------------------------------------|
| _formula | The formula to add to the passed formula. |
|----------|-------------------------------------------|

**Returns**

A pair to the position where the formula to add has been inserted (or its first sub-formula which has not yet been in the passed formula, in case the formula to add is a conjunction), and a Boolean stating whether anything has been added to the passed formula.

```
0.15.246.4.9 addSubformulaToPassedFormula() [2/3] std::pair<ModuleInput::iterator,bool> smtrat::Module::addSubformulaToPassedFormula (
 const FormulaT & _formula,
 const FormulaT & _origin) [inline], [protected], [inherited]
```

Adds the given formula to the passed formula.

**Parameters**

|                 |                                                                                                                           |
|-----------------|---------------------------------------------------------------------------------------------------------------------------|
| <i>_formula</i> | The formula to add to the passed formula.                                                                                 |
| <i>_origin</i>  | The sub-formula of the received formula being responsible for the occurrence of the formula to add to the passed formula. |

**Returns**

A pair to the position where the formula to add has been inserted (or its first sub-formula which has not yet been in the passed formula, in case the formula to add is a conjunction), and a Boolean stating whether anything has been added to the passed formula.

```
0.15.246.4.10 addSubformulaToPassedFormula() [3/3] std::pair<ModuleInput::iterator,bool> smtrat::Module::addSubformulaToPassedFormula (
 const FormulaT & _formula,
 const std::shared_ptr< std::vector<FormulaT>> & _origins) [inline], [protected], [inherited]
```

Adds the given formula to the passed formula.

**Parameters**

|                 |                                                                                                                                         |
|-----------------|-----------------------------------------------------------------------------------------------------------------------------------------|
| <i>_formula</i> | The formula to add to the passed formula.                                                                                               |
| <i>_origins</i> | The link of the formula to add to the passed formula to sub-formulas of the received formulas, which are responsible for its occurrence |

**Returns**

A pair to the position where the formula to add has been inserted (or its first sub-formula which has not yet been in the passed formula, in case the formula to add is a conjunction), and a Boolean stating whether anything has been added to the passed formula.

```
0.15.246.4.11 allModels() const std::vector<Model>& smtrat::Module::allModels () const [inline], [inherited]
```

**Returns**

All satisfying assignments, if existent.

```
0.15.246.4.12 anAnswerFound() bool smtrat::Module::anAnswerFound () const [inline], [protected], [inherited]
```

Checks for all antecedent modules and those which run in parallel with the same antecedent modules, whether one of them has determined a result.

**Returns**

True, if one of them has determined a result.

**0.15.246.4.13 answerFound()** const smtrat::Conditionals& smtrat::Module::answerFound ( ) const [inline], [inherited]

**Returns**

A vector of Booleans: If any of them is true, we have to terminate a running check procedure.

**0.15.246.4.14 appliedPreprocessing()** bool smtrat::PModule::appliedPreprocessing ( ) const [inline], [inherited]

**Returns**

true, if the current received formula has been simplified and the result of this simplification is stored in the passed formula.

**0.15.246.4.15 backendsModel()** const Model & smtrat::Module::backendsModel ( ) const [protected], [inherited]

Stores the model of a backend which determined satisfiability of the passed formula in the model of this module.

**0.15.246.4.16 branchAt() [1/4]** bool smtrat::Module::branchAt ( carl::Variable::Arg \_var, const Rational & \_value, bool \_leftCaseWeak = true, bool \_preferLeftCase = true, bool \_useReceivedFormulaAsPremise = false, const std::vector< FormulaT > & \_premise = std::vector<FormulaT>() ) [inline], [protected], [inherited]

**0.15.246.4.17 branchAt() [2/4]** bool smtrat::Module::branchAt ( carl::Variable::Arg \_var, const Rational & \_value, std::vector< FormulaT > && \_premise, bool \_leftCaseWeak = true, bool \_preferLeftCase = true, bool \_useReceivedFormulaAsPremise = false ) [inline], [protected], [inherited]

**0.15.246.4.18 branchAt() [3/4]** bool smtrat::Module::branchAt ( const Poly & \_polynomial, bool \_integral, const Rational & \_value, bool \_leftCaseWeak = true, bool \_preferLeftCase = true, bool \_useReceivedFormulaAsPremise = false, const std::vector< FormulaT > & \_premise = std::vector<FormulaT>() ) [inline], [protected], [inherited]

**0.15.246.4.19 branchAt() [4/4]** bool smtrat::Module::branchAt ( const Poly & \_polynomial, bool \_integral, const Rational & \_value, std::vector< FormulaT > && \_premise,

```

 bool _leftCaseWeak = true,
 bool _preferLeftCase = true,
 bool _useReceivedFormulaAsPremise = false) [protected], [inherited]

```

Adds a lemmas which provoke a branching for the given variable at the given value, if this module returns Unknown and there exists a preceding [SATModule](#).

Note that the given value is rounded down and up, if the given variable is integer-valued.

#### Parameters

|                                           |                                                                                                                                                                                                                |
|-------------------------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>_polynomial</code>                  | The variable to branch for.                                                                                                                                                                                    |
| <code>_integral</code>                    | A flag being true, if all variables in the polynomial to branch for are integral.                                                                                                                              |
| <code>_value</code>                       | The value to branch at.                                                                                                                                                                                        |
| <code>_premise</code>                     | The sub-formulas of the received formula from which the branch is followed. Note, that a premise is not necessary, as every branch is a valid formula. But a premise can prevent from branching unnecessarily. |
| <code>_leftCaseWeak</code>                | true, if a branching in the form of (or ( $\leq p b$ ) ( $> p b$ )) is desired. false, if a branching in the form of (or ( $< p b$ ) ( $\geq p b$ )) is desired.                                               |
| <code>_preferLeftCase</code>              | true, if the left case (polynomial less(or equal) 0 shall be chosen first. false, otherwise.                                                                                                                   |
| <code>_useReceivedFormulaAsPremise</code> | true, if the whole received formula should be used as premise                                                                                                                                                  |

#### 0.15.246.4.20 `check()` Answer `smtrat::PModule::check (`

```

 bool _final = false,
 bool _full = true,
 carl::Variable _objective = carl::Variable::NO_VARIABLE) [virtual], [inherited]

```

Checks the received formula for consistency.

Note, that this is an implementation of the satisfiability check of the conjunction of the so far received formulas, which does actually nothing but passing the problem to its backends. This implementation is only used internally and must be overwritten by any derived module.

#### Parameters

|                         |                                                                                                                                       |
|-------------------------|---------------------------------------------------------------------------------------------------------------------------------------|
| <code>_final</code>     | true, if this satisfiability check will be the last one (for a global sat-check), if its result is SAT                                |
| <code>_full</code>      | false, if this module should avoid too expensive procedures and rather return unknown instead.                                        |
| <code>_objective</code> | if not set to NO_VARIABLE, the module should find an assignment minimizing this objective variable; otherwise any assignment is good. |

#### Returns

True, if the received formula is satisfiable; False, if the received formula is not satisfiable; Unknown, otherwise.

Reimplemented from [smtrat::Module](#).

#### 0.15.246.4.21 `checkCore()` template<typename Settings >

```
Answer smtrat::ICEModule< Settings >::checkCore () [virtual]
```

Checks the received formula for consistency.

#### Returns

SAT, if the received formula is satisfiable; UNSAT, if the received formula is not satisfiable; Unknown, otherwise.

Reimplemented from [smtrat::Module](#).

```
0.15.246.4.22 checkInfSubsetForMinimality() void smrat::Module::checkInfSubsetForMinimality (
 std::vector< FormulaSetT >::const_iterator _infsSubset,
 const std::string & _filename = "smaller_muses",
 unsigned _maxSizeDifference = 1) const [inherited]
```

Checks the given infeasible subset for minimality by storing all subsets of it, which have a smaller size which differs from the size of the infeasible subset not more than the given threshold.

#### Parameters

|                                 |                                                                                                        |
|---------------------------------|--------------------------------------------------------------------------------------------------------|
| <code>_infsSubset</code>        | The infeasible subset to check for minimality.                                                         |
| <code>_filename</code>          | The name of the file to store the infeasible subsets in order to be able to check their infeasibility. |
| <code>_maxSizeDifference</code> | The maximal difference between the sizes of the subsets compared to the size of the infeasible subset. |

```
0.15.246.4.23 checkModel() unsigned smrat::Module::checkModel () const [protected], [inherited]
```

#### Returns

false, if the current model of this module does not satisfy the current given formula; true, if it cannot be said whether the model satisfies the given formula.

```
0.15.246.4.24 cleanModel() void smrat::Module::cleanModel () const [inline], [protected], [inherited]
```

Substitutes variable occurrences by its model value in the model values of other variables.

```
0.15.246.4.25 clearLemmas() void smrat::Module::clearLemmas () [inline], [inherited]
```

Deletes all yet found lemmas.

```
0.15.246.4.26 clearModel() void smrat::Module::clearModel () const [inline], [protected], [inherited]
```

Clears the assignment, if any was found.

```
0.15.246.4.27 clearModels() void smrat::Module::clearModels () const [inline], [protected], [inherited]
```

Clears all assignments, if any was found.

```
0.15.246.4.28 clearPassedFormula() void smrat::Module::clearPassedFormula () [protected], [inherited]
```

```
0.15.246.4.29 collectOrigins() [1/2] void smrat::Module::collectOrigins (
 const FormulaT & _formula,
 FormulaSetT & _origins) const [inherited]
```

```
0.15.246.4.30 collectOrigins() [2/2] void smtrat::Module::collectOrigins (
 const FormulaT & _formula,
 FormulasT & _origins) const [inherited]
```

Collects the formulas in the given formula, which are part of the received formula.

If the given formula directly occurs in the received formula, it is inserted into the given set. Otherwise, the given formula must be of type AND and all its sub-formulas part of the received formula. Hence, they will be added to the given set.

#### Parameters

|                 |                                                                                                      |
|-----------------|------------------------------------------------------------------------------------------------------|
| <i>_formula</i> | The formula from which to collect the formulas being sub-formulas of the received formula (origins). |
| <i>_origins</i> | The set in which to store the origins.                                                               |

```
0.15.246.4.31 collectTheoryPropagations() void smtrat::Module::collectTheoryPropagations () [inherited]
```

```
0.15.246.4.32 constraintsToInform() const carl::FastSet<FormulaT>& smtrat::Module::constraintsToInform () const [inline], [inherited]
```

#### Returns

The constraints which the backends must be informed about.

```
0.15.246.4.33 currentlySatisfied() virtual unsigned smtrat::Module::currentlySatisfied (
 const FormulaT &) const [inline], [virtual], [inherited]
```

#### Returns

0, if the given formula is conflicted by the current model; 1, if the given formula is satisfied by the current model; 2, otherwise; 3, if we do not know anything (default)

Reimplemented in [smtrat::LRAModule< Settings >](#), [smtrat::LRAModule< LRASettingsICP >](#), and [smtrat::LRAModule< LRASettings >](#)

```
0.15.246.4.34 currentlySatisfiedByBackend() unsigned smtrat::Module::currentlySatisfiedByBackend (
 const FormulaT & _formula) const [inherited]
```

#### Returns

0, if the given formula is conflicted by the current model; 1, if the given formula is satisfied by the current model; 2, otherwise 3, if we do not know anything (default)

```
0.15.246.4.35 deinform() void smtrat::Module::deinform (
 const FormulaT & _constraint) [inherited]
```

The inverse of informing about a constraint.

All data structures which were kept regarding this constraint are going to be removed. Note, that this makes only sense if it is not likely enough that a formula with this constraint must be solved again.

#### Parameters

|                    |                                                         |
|--------------------|---------------------------------------------------------|
| <i>_constraint</i> | The constraint to remove from internal data structures. |
|--------------------|---------------------------------------------------------|

**0.15.246.4.36 `deinformCore()`** `virtual void smtrat::Module::deinformCore (`  
    `const FormulaT & _constraint )` [inline], [protected], [virtual], [inherited]

The inverse of informing about a constraint.

All data structures which were kept regarding this constraint are going to be removed. Note, that this makes only sense if it is not likely enough that a formula with this constraint must be solved again.

#### Parameters

|                          |                                                         |
|--------------------------|---------------------------------------------------------|
| <code>_constraint</code> | The constraint to remove from internal data structures. |
|--------------------------|---------------------------------------------------------|

Reimplemented in [smtrat::LRAModule< Settings >](#), [smtrat::LRAModule< LRASettingsICP >](#), and [smtrat::LRAModule< LRASettings1 >](#).

**0.15.246.4.37 `determine_smallest_origin()`** `size_t smtrat::Module::determine_smallest_origin (`  
    `const std::vector< FormulaT > & origins ) const` [protected], [inherited]

#### Parameters

|                      |                              |
|----------------------|------------------------------|
| <code>origins</code> | A vector of sets of origins. |
|----------------------|------------------------------|

#### Returns

The index of the smallest (regarding the size of the sets) element of origins

**0.15.246.4.38 `eraseSubformulaFromPassedFormula()`** `ModuleInput::iterator smtrat::Module::eraseSubformulaFromPassedFormula (`  
    `ModuleInput::iterator _subformula,`  
    `bool _ignoreOrigins = false )` [protected], [virtual], [inherited]

Removes everything related to the sub-formula to remove from the passed formula in the backends of this module.  
Afterwards the sub-formula is removed from the passed formula.

#### Parameters

|                             |                                                                                                              |
|-----------------------------|--------------------------------------------------------------------------------------------------------------|
| <code>_subformula</code>    | The sub-formula to remove from the passed formula.                                                           |
| <code>_ignoreOrigins</code> | True, if the sub-formula shall be removed regardless of its origins (should only be applied with expertise). |

#### Returns

Reimplemented in [smtrat::ICPModule< Settings >](#), [smtrat::ICPModule< ICPSettings4 >](#), and [smtrat::ICPModule< ICPSettings1 >](#).

**0.15.246.4.39 `excludeNotReceivedVariablesFromModel()`** `void smtrat::Module::excludeNotReceivedVariablesFromModel ( ) const` [inherited]

Excludes all variables from the current model, which do not occur in the received formula.

**0.15.246.4.40 `findBestOrigin()`** `std::vector< FormulaT >::const_iterator smtrat::Module::findBestOrigin (`  
    `const std::vector< FormulaT > & _origins ) const` [protected], [inherited]

**Parameters**

|                 |  |
|-----------------|--|
| <i>_origins</i> |  |
|-----------------|--|

**Returns**

**0.15.246.4.41 `firstSubformulaToPass()`** `ModuleInput::const_iterator smtrat::Module::firstSubformulaToPass () const [inline], [inherited]`

**Returns**

The position of the first sub-formula in the passed formula, which has not yet been considered for a consistency check of the backends.

**0.15.246.4.42 `firstUncheckedReceivedSubformula()`** `ModuleInput::const_iterator smtrat::Module::firstUncheckedReceivedSubformula () const [inline], [inherited]`

**Returns**

The position of the first (by this module) unchecked sub-formula of the received formula.

**0.15.246.4.43 `freeSplittingVariable()`** `static void smtrat::Module::freeSplittingVariable (const FormulaT & _splittingVariable) [inline], [static], [inherited]`

**0.15.246.4.44 `generateTrivialInfeasibleSubset()`** `void smtrat::Module::generateTrivialInfeasibleSubset () [inline], [protected], [inherited]`

Stores the trivial infeasible subset being the set of received formulas.

**0.15.246.4.45 `getBackendsAllModels()`** `void smtrat::Module::getBackendsAllModels () const [protected], [inherited]`

Stores all models of a backend in the list of all models of this module.

**0.15.246.4.46 `getBackendsModel()`** `void smtrat::Module::getBackendsModel () const [protected], [inherited]`

**0.15.246.4.47 `getInfeasibleSubsets() [1/2]`** `void smtrat::Module::getInfeasibleSubsets () [protected], [inherited]`

Copies the infeasible subsets of the passed formula.

**0.15.246.4.48 `getInfeasibleSubsets() [2/2]`** `std::vector< FormulaSetT > smtrat::Module::getInfeasibleSubsets (const Module & _backend) const [protected], [inherited]`

Get the infeasible subsets the given backend provides.

Note, that an infeasible subset in a backend contains sub formulas of the passed formula and an infeasible subset of this module contains sub formulas of the received formula. In this method the LATTER is returned.

**Parameters**

|                       |                                                          |
|-----------------------|----------------------------------------------------------|
| <code>_backend</code> | The backend from which to obtain the infeasible subsets. |
|-----------------------|----------------------------------------------------------|

**Returns**

The infeasible subsets the given backend provides.

**0.15.246.4.49 `getInformationRelevantFormulas()`** `const std::set< FormulaT > & smtrat::Module::getInformationRelevantFormulas ( ) [protected], [inherited]`  
Gets all InformationRelevantFormulas.

**Returns**

Set of all formulas

**0.15.246.4.50 `getModelEqualities()`** `std::list< std::vector< carl::Variable > > smtrat::Module::getModelEqualities ( ) const [virtual], [inherited]`  
Partition the variables from the current model into equivalence classes according to their assigned value.  
The result is a set of equivalence classes of variables where all variables within one class are assigned the same value. Note that the number of classes may not be minimal, i.e. two classes may actually be equivalent.

**Returns**

Equivalence classes.

**0.15.246.4.51 `getOrigins() [1/3]`** `void smtrat::Module::getOrigins ( const FormulaT & _formula, FormulaSetT & _origins ) const [inline], [protected], [inherited]`

**Parameters**

|                       |  |
|-----------------------|--|
| <code>_formula</code> |  |
| <code>_origins</code> |  |

**0.15.246.4.52 `getOrigins() [2/3]`** `void smtrat::Module::getOrigins ( const FormulaT & _formula, FormulasT & _origins ) const [inline], [protected], [inherited]`

**Parameters**

|                       |  |
|-----------------------|--|
| <code>_formula</code> |  |
| <code>_origins</code> |  |

**0.15.246.4.53 `getOrigins() [3/3]`** `const FormulaT& smtrat::Module::getOrigins ( ModuleInput::const_iterator _formula ) const [inline], [protected], [inherited]`  
Gets the origins of the passed formula at the given position.

**Parameters**

|                 |                                                   |
|-----------------|---------------------------------------------------|
| <i>_formula</i> | The position of a formula in the passed formulas. |
|-----------------|---------------------------------------------------|

**Returns**

The origins of the passed formula at the given position.

**0.15.246.4.54 `getReceivedFormulaSimplified()`** `std::pair< bool, FormulaT > smtrat::PModule::getReceivedFormulaSimplified( ) [virtual], [inherited]`

**Returns**

A pair of a Boolean and a formula, where the Boolean is true, if the received formula could be simplified to an equisatisfiable formula. The formula is equisatisfiable to this module's received formula, if the Boolean is true.

Reimplemented from [smtrat::Module](#).

**0.15.246.4.55 `hasLemmas()`** `bool smtrat::Module::hasLemmas( ) [inline], [inherited]`

Checks whether this module or any of its backends provides any lemmas.

**0.15.246.4.56 `hasValidInfeasibleSubset()`** `bool smtrat::Module::hasValidInfeasibleSubset( ) const [inherited]`

**Returns**

true, if the module has at least one valid infeasible subset, that is all its elements are sub-formulas of the received formula (pointer must be equal).

**0.15.246.4.57 `id()`** `std::size_t smtrat::Module::id( ) const [inline], [inherited]`

**Returns**

A unique ID to identify this module instance.

**0.15.246.4.58 `infeasibleSubsets()`** `const std::vector<FormulaSetT>& smtrat::Module::infeasibleSubsets( ) const [inline], [inherited]`

**Returns**

The infeasible subsets of the set of received formulas (empty, if this module has not detected unsatisfiability of the conjunction of received formulas).

**0.15.246.4.59 `inform()`** `bool smtrat::Module::inform( const FormulaT & _constraint ) [inherited]`

Informs the module about the given constraint.

It should be tried to inform this module about any constraint it could receive eventually before assertSubformula is called (preferably for the first time, but at least before adding a formula containing that constraint).

**Parameters**

|                    |                                 |
|--------------------|---------------------------------|
| <i>_constraint</i> | The constraint to inform about. |
|--------------------|---------------------------------|

**Returns**

false, if it can be easily decided whether the given constraint is inconsistent; true, otherwise.

**0.15.246.4.60 informBackends()** void smrat::Module::informBackends ( const FormulaT & \_constraint ) [inline], [protected], [inherited]

Informs all backends of this module about the given constraint.

**Parameters**

|                          |                                 |
|--------------------------|---------------------------------|
| <code>_constraint</code> | The constraint to inform about. |
|--------------------------|---------------------------------|

**0.15.246.4.61 informCore()** virtual bool smrat::Module::informCore (

const FormulaT & \_constraint ) [inline], [protected], [virtual], [inherited]

Informs the module about the given constraint.

It should be tried to inform this module about any constraint it could receive eventually before assertSubformula is called (preferably for the first time, but at least before adding a formula containing that constraint).

**Parameters**

|                          |                                 |
|--------------------------|---------------------------------|
| <code>_constraint</code> | The constraint to inform about. |
|--------------------------|---------------------------------|

**Returns**

false, if it can be easily decided whether the given constraint is inconsistent; true, otherwise.

Reimplemented in [smrat::UnionFindModule< Settings >](#), [smrat::PBPPModule< Settings >](#), [smrat::PBGaussModule< Settings >](#), [smrat::NRAILModule< Settings >](#), [smrat::NewCoveringModule< Settings >](#), [smrat::NewCADModule< Settings >](#), [smrat::LRAModule< Settings >](#), [smrat::LRAModule< LRASettingsICP >](#), [smrat::LRAModule< LRASettings1 >](#), [smrat::IntBlastModule< Settings >](#), [smrat::FPPModule< Settings >](#), [smrat::EQModule< Settings >](#), [smrat::CurryModule< Settings >](#), [smrat::BVMModule< Settings >](#), [smrat::ICPModule< Settings >](#), [smrat::ICPModule< ICPSettings4 >](#), and [smrat::ICPModule< ICPSettings1 >](#).

**0.15.246.4.62 informedConstraints()** const carl::FastSet<FormulaT>& smrat::Module::informedConstraints ( ) const [inline], [inherited]

**Returns**

The position of the first constraint of which no backend has been informed about.

**0.15.246.4.63 init()** void smrat::Module::init ( ) [virtual], [inherited]

Informs all backends about the so far encountered constraints, which have not yet been communicated.

This method must not be called twice and only before the first runBackends call.

Reimplemented in [smrat::PBPPModule< Settings >](#), [smrat::PBGaussModule< Settings >](#), [smrat::NRAILModule< Settings >](#), [smrat::NewCoveringModule< Settings >](#), [smrat::NewCADModule< Settings >](#), [smrat::LRAModule< Settings >](#), [smrat::LRAModule< LRASettingsICP >](#), [smrat::LRAModule< LRASettings1 >](#), [smrat::IntBlastModule< Settings >](#), [smrat::FPPModule< Settings >](#), [smrat::EQModule< Settings >](#), [smrat::CurryModule< Settings >](#), and [smrat::BVMModule< Settings >](#).

**0.15.246.4.64 is\_minimizing()** bool smrat::Module::is\_minimizing ( ) const [inline], [inherited]

**0.15.246.4.65 `isLemmaLevel()`** `bool smtrat::Module::isLemmaLevel (``LemmaLevel level ) [protected], [inherited]`

Checks if current lemma level is greater or equal to given level.

**Parameters**

|                    |                 |
|--------------------|-----------------|
| <code>level</code> | Level to check. |
|--------------------|-----------------|

**0.15.246.4.66 `isPreprocessor()`** `bool smtrat::PModule::isPreprocessor ( ) const [inline], [inherited]`**Returns**

true, if this module is a preprocessor that is a module, which simplifies its received formula to an equisatisfiable formula being passed to its backends. The simplified formula can be obtained with [getReceivedFormulaSimplified\(\)](#).

**0.15.246.4.67 `lemmas()`** `const std::vector<Lemma>& smtrat::Module::lemmas ( ) const [inline], [inherited]`**Returns**

A constant reference to the lemmas being valid formulas this module or its backends made.

**0.15.246.4.68 `merge()`** `std::vector< FormulaT > smtrat::Module::merge (``const std::vector< FormulaT > & _vecSetA,``const std::vector< FormulaT > & _vecSetB ) const [protected], [inherited]`

Merges the two vectors of sets into the first one.

({a,b},{a,c}) and ({b,d},{b}) -> ({a,b,d},{a,b},{a,b,c,d},{a,b,c})

**Parameters**

|                       |                                  |
|-----------------------|----------------------------------|
| <code>_vecSetA</code> | A vector of sets of constraints. |
| <code>_vecSetB</code> | A vector of sets of constraints. |

**Returns**

The vector being the two given vectors merged.

**0.15.246.4.69 `model()`** `const Model& smtrat::Module::model ( ) const [inline], [inherited]`**Returns**

The assignment of the current satisfiable result, if existent.

**0.15.246.4.70 `modelsDisjoint()`** `bool smtrat::Module::modelsDisjoint (``const Model & _modelA,``const Model & _modelB ) [static], [protected], [inherited]`

Checks whether there is no variable assigned by both models.

**Parameters**

|                      |                                |
|----------------------|--------------------------------|
| <code>_modelA</code> | The first model to check for.  |
| <code>_modelB</code> | The second model to check for. |

**Returns**

true, if there is no variable assigned by both models; false, otherwise.

**0.15.246.4.71 `moduleName()`** `virtual std::string smtrat::Module::moduleName ( ) const [inline], [virtual], [inherited]`

**Returns**

The name of the given module type as name.

Reimplemented in `smtrat::VSModule< Settings >`, `smtrat::UnionFindModule< Settings >`, `smtrat::UFCegarModule< Settings >`, `smtrat::STropModule< Settings >`, `smtrat::SplitSOSModule< Settings >`, `smtrat::PBPPModule< Settings >`, `smtrat::PBGaussModule< Settings >`, `smtrat::NRAILModule< Settings >`, `smtrat::NewCADModule< Settings >`, `smtrat::LVEModule< Settings >`, `smtrat::LRAModule< Settings >`, `smtrat::LRAModule< LRASettingsICP >`, `smtrat::LRAModule< LRASettings1 >`, `smtrat::IntEqModule< Settings >`, `smtrat::IntBlastModule< Settings >`, `smtrat::IncWidthModule< Settings >`, `smtrat::ICPModule< Settings >`, `smtrat::ICPModule< ICPSettings4 >`, `smtrat::ICPModule< ICPSettings1 >`, `smtrat::GBModule< Settings >`, `smtrat::FouMoModule< Settings >`, `smtrat::EQPreprocessingModule< Settings >`, `smtrat::EQModule< Settings >`, `smtrat::CurryModule< Settings >`, `smtrat::CubeLIAModule< Settings >`, `smtrat::CSplitModule< Settings >`, `smtrat::BVMModule< Settings >`, and `smtrat::BEModule< Settings >`.

**0.15.246.4.72 `objective()`** `carl::Variable smtrat::Module::objective ( ) const [inline], [inherited]`

**0.15.246.4.73 `originInReceivedFormula()`** `bool smtrat::Module::originInReceivedFormula ( const FormulaT & _origin ) const [protected], [inherited]`

**0.15.246.4.74 `passedFormulaBegin()`** `ModuleInput::iterator smtrat::Module::passedFormulaBegin ( ) [inline], [protected], [inherited]`

**Returns**

An iterator to the end of the passed formula. TODO: disable this method

**0.15.246.4.75 `passedFormulaEnd()`** `ModuleInput::iterator smtrat::Module::passedFormulaEnd ( ) [inline], [protected], [inherited]`

**Returns**

An iterator to the end of the passed formula.

**0.15.246.4.76 `pPassedFormula()`** `const ModuleInput* smtrat::Module::pPassedFormula ( ) const [inline], [inherited]`

**Returns**

A pointer to the formula passed to the backends of this module.

**0.15.246.4.77 pReceivedFormula()** const `ModuleInput*` smtrat::Module::pReceivedFormula ( ) const [inline], [inherited]

**Returns**

A pointer to the formula passed to this module.

**0.15.246.4.78 print()** void smtrat::Module::print ( const std::string & `_initiation` = "\*\*\*" ) const [inherited]  
Prints everything relevant of the solver.

**Parameters**

|                          |                      |
|--------------------------|----------------------|
| <code>_initiation</code> | The line initiation. |
|--------------------------|----------------------|

**0.15.246.4.79 printAllModels()** void smtrat::Module::printAllModels ( std::ostream & `_out` = `std::cout` ) [inherited]

Prints all assignments of this module satisfying its received formula if it satisfiable and this module could find an assignment.

**Parameters**

|                   |                                        |
|-------------------|----------------------------------------|
| <code>_out</code> | The stream to print the assignment on. |
|-------------------|----------------------------------------|

**0.15.246.4.80 printInfeasibleSubsets()** void smtrat::Module::printInfeasibleSubsets ( const std::string & `_initiation` = "\*\*\*" ) const [inherited]

Prints the infeasible subsets.

**Parameters**

|                          |                      |
|--------------------------|----------------------|
| <code>_initiation</code> | The line initiation. |
|--------------------------|----------------------|

**0.15.246.4.81 printModel()** void smtrat::Module::printModel ( std::ostream & `_out` = `std::cout` ) const [inherited]

Prints the assignment of this module satisfying its received formula if it satisfiable and this module could find an assignment.

**Parameters**

|                   |                                        |
|-------------------|----------------------------------------|
| <code>_out</code> | The stream to print the assignment on. |
|-------------------|----------------------------------------|

**0.15.246.4.82 printPassedFormula()** void smtrat::Module::printPassedFormula ( const std::string & `_initiation` = "\*\*\*" ) const [inherited]

Prints the vector of passed formula.

**Parameters**

|                          |                      |
|--------------------------|----------------------|
| <code>_initiation</code> | The line initiation. |
|--------------------------|----------------------|

**0.15.246.4.83 printReceivedFormula()** void smtrat::Module::printReceivedFormula (const std::string & *\_initiation* = "\*\*\*" ) const [inherited]

Prints the vector of the received formula.

## Parameters

|                    |                      |
|--------------------|----------------------|
| <i>_initiation</i> | The line initiation. |
|--------------------|----------------------|

**0.15.246.4.84 probablyLooping()** bool smtrat::Module::probablyLooping (const typename Poly::PolyType & *\_branchingPolynomial*,const Rational & *\_branchingValue* ) const [protected], [inherited]

Checks whether given the current branching value and branching variable/polynomial it is (highly) probable that this branching is part of an infinite loop of branchings.

## Parameters

|                             |                                                                                     |
|-----------------------------|-------------------------------------------------------------------------------------|
| <i>_branchingPolynomial</i> | The polynomial to branch at (in most branching strategies this is just a variable). |
| <i>_branchingValue</i>      | The value to branch at.                                                             |

## Returns

true, if this branching is probably part of an infinite loop of branchings; false, otherwise.

**0.15.246.4.85 receivedFormulaChecked()** void smtrat::Module::receivedFormulaChecked ( ) [inline], [inherited]

Notifies that the received formulas has been checked.

**0.15.246.4.86 receivedFormulasAsInfeasibleSubset()** void smtrat::Module::receivedFormulasAsInfeasibleSubset (ModuleInput::const\_iterator *\_subformula* ) [inline], [protected], [inherited]

Stores an infeasible subset consisting only of the given received formula.

**0.15.246.4.87 receivedVariable()** bool smtrat::Module::receivedVariable (carl::Variable::Arg *\_var* ) const [inline], [inherited]**0.15.246.4.88 remove()** void smtrat::PModule::remove (ModuleInput::const\_iterator *\_subformula* ) [virtual], [inherited]

Removes everything related to the given sub-formula of the received formula.

However, it is desired not to lose track of search spaces where no satisfying assignment can be found for the remaining sub-formulas.

## Parameters

|                    |                                                    |
|--------------------|----------------------------------------------------|
| <i>_subformula</i> | The sub formula of the received formula to remove. |
|--------------------|----------------------------------------------------|

Reimplemented from [smtrat::Module](#).

```
0.15.246.4.89 removeCore() template<typename Settings >
void smtrat::ICEModule< Settings >::removeCore (
 ModuleInput::const_iterator _subformula) [virtual]
```

Removes the subformula of the received formula at the given position to the considered ones of this module.  
Note that this includes every stored calculation which depended on this subformula, but should keep the other stored calculation, if possible, untouched.

#### Parameters

|                          |                                           |
|--------------------------|-------------------------------------------|
| <code>_subformula</code> | The position of the subformula to remove. |
|--------------------------|-------------------------------------------|

Reimplemented from [smtrat::Module](#).

```
0.15.246.4.90 removeOrigin() std::pair<ModuleInput::iterator,bool> smtrat::Module::remove<-
Origin (
 ModuleInput::iterator _formula,
 const FormulaT & _origin) [inline], [protected], [inherited]
```

```
0.15.246.4.91 removeOrigins() std::pair<ModuleInput::iterator,bool> smtrat::Module::remove<-
Origins (
 ModuleInput::iterator _formula,
 const std::shared_ptr< std::vector< FormulaT >> & _origins) [inline], [protected],
[inherited]
```

```
0.15.246.4.92 rPassedFormula() const ModuleInput& smtrat::Module::rPassedFormula () const
[inline], [inherited]
```

#### Returns

A reference to the formula passed to the backends of this module.

```
0.15.246.4.93 rReceivedFormula() const ModuleInput& smtrat::Module::rReceivedFormula () const
[inline], [inherited]
```

#### Returns

A reference to the formula passed to this module.

```
0.15.246.4.94 runBackends() [1/2] virtual Answer smtrat::PModule::runBackends () [inline],
[virtual], [inherited]
```

Reimplemented from [smtrat::Module](#).

```
0.15.246.4.95 runBackends() [2/2] Answer smtrat::PModule::runBackends (
 bool _final,
 bool _full,
 carl::Variable _objective) [virtual], [inherited]
```

Runs the backend solvers on the passed formula.

#### Parameters

|                     |                                                                                                         |
|---------------------|---------------------------------------------------------------------------------------------------------|
| <code>_final</code> | true, if this satisfiability check will be the last one (for a global sat-check), if its result is SAT. |
|---------------------|---------------------------------------------------------------------------------------------------------|

**Parameters**

|                         |                                                                                                                                       |
|-------------------------|---------------------------------------------------------------------------------------------------------------------------------------|
| <code>_full</code>      | false, if this module should avoid too expensive procedures and rather return unknown instead.                                        |
| <code>_objective</code> | if not set to NO_VARIABLE, the module should find an assignment minimizing this objective variable; otherwise any assignment is good. |

**Returns**

True, if the passed formula is consistent; False, if the passed formula is inconsistent; Unknown, otherwise.

Reimplemented from [smtrat::Module](#).

**0.15.246.4.96 `setId()`** `void smtrat::Module::setId ( std::size_t _id ) [inline], [inherited]`

Sets this modules unique ID to identify itself.

**Parameters**

|                                                      |                                    |
|------------------------------------------------------|------------------------------------|
| <code>←</code><br><code>—←</code><br><code>id</code> | The id to set this module's id to. |
|------------------------------------------------------|------------------------------------|

**0.15.246.4.97 `setThreadPriority()`** `void smtrat::Module::setThreadPriority ( thread_priority _threadPriority ) [inline], [inherited]`

Sets the priority of this module to get a thread for running its check procedure.

**Parameters**

|                              |                                                       |
|------------------------------|-------------------------------------------------------|
| <code>_threadPriority</code> | The priority to set this module's thread priority to. |
|------------------------------|-------------------------------------------------------|

**0.15.246.4.98 `solverState()`** [Answer](#) `smtrat::Module::solverState ( ) const [inline], [inherited]`

**Returns**

True, if this module is in a state, such that it has found a solution for its received formula; False, if this module is in a state, such that it has determined that there is no solution for its received formula; Unknown, otherwise.

**0.15.246.4.99 `splitUnequalConstraint()`** `void smtrat::Module::splitUnequalConstraint ( const FormulaT & _unequalConstraint ) [protected], [inherited]`

Adds the following lemmas for the given constraint  $p \neq 0$ .

$(p \neq 0 \leftrightarrow (p < 0 \text{ or } p > 0))$

and  $\neg(p < 0 \text{ and } p > 0)$

**Parameters**

|                                 |                                                  |
|---------------------------------|--------------------------------------------------|
| <code>_unequalConstraint</code> | A constraint having the relation symbol $\neq$ . |
|---------------------------------|--------------------------------------------------|

**0.15.246.4.100 `threadPriority()`** `thread_priority` `smtrat::Module::threadPriority () const [inline], [inherited]`

**Returns**

The priority of this module to get a thread for running its check procedure.

**0.15.246.4.101 `updateAllModels()`** `void smtrat::Module::updateAllModels () [virtual], [inherited]`

Updates all satisfying models, if the solver has detected the consistency of the received formula, beforehand.

Reimplemented in `smtrat::SATModule< Settings >`.

**0.15.246.4.102 `updateLemmas()`** `void smtrat::Module::updateLemmas () [inherited]`

Stores all lemmas of any backend of this module in its own lemma vector.

**0.15.246.4.103 `updateModel()`** `void smtrat::PModule::updateModel () const [virtual], [inherited]`

Updates the current assignment into the model.

Note, that this is a unique but possibly symbolic assignment maybe containing newly introduced variables.

Reimplemented from `smtrat::Module`.

**0.15.246.4.104 `usedBackends()`** `const std::vector<Module*>& smtrat::Module::usedBackends () const [inline], [inherited]`

**Returns**

The backends of this module which are currently used (conditions to use this module are fulfilled for the passed formula).

## 0.15.246.5 Field Documentation

**0.15.246.5.1 `mAllBackends`** `std::vector<Module*> smtrat::Module::mAllBackends [protected], [inherited]`

The backends of this module which have been used.

**0.15.246.5.2 `mAllModels`** `std::vector<Model> smtrat::Module::mAllModels [mutable], [protected], [inherited]`

Stores all satisfying assignments.

**0.15.246.5.3 `mBackendsFoundAnswer`** `std::atomic_bool* smtrat::Module::mBackendsFoundAnswer [protected], [inherited]`

This flag is passed to any backend and if it determines an answer to a prior check call, this flag is fired.

**0.15.246.5.4 `mConstraintsToInform`** `carl::FastSet<FormulaT> smtrat::Module::mConstraintsToInform [protected], [inherited]`

Stores the constraints which the backends must be informed about.

**0.15.246.5.5 `mFinalCheck`** `bool smtrat::Module::mFinalCheck [protected], [inherited]`

true, if the check procedure should perform a final check which especially means not to postpone splitting decisions

**0.15.246.5.6 mFirstPosInLastBranches** `std::size_t smrat::Module::mFirstPosInLastBranches = 0`  
[static], [inherited]  
The beginning of the cyclic buffer storing the last branches.

**0.15.246.5.7 mFirstSubformulaToPass** `ModuleInput::iterator smrat::Module::mFirstSubformulaToPass` [protected], [inherited]  
Stores the position of the first sub-formula in the passed formula, which has not yet been considered for a consistency check of the backends.

**0.15.246.5.8 mFirstUncheckedReceivedSubformula** `ModuleInput::const_iterator smrat::Module::mFirstUncheckedReceivedSubformula` [protected], [inherited]  
Stores the position of the first (by this module) unchecked sub-formula of the received formula.

**0.15.246.5.9 mFoundAnswer** `Conditionals smrat::Module::mFoundAnswer` [protected], [inherited]  
Vector of Booleans: If any of them is true, we have to terminate a running check procedure.

**0.15.246.5.10 mFullCheck** `bool smrat::Module::mFullCheck` [protected], [inherited]  
false, if this module should avoid too expensive procedures and rather return unknown instead.

**0.15.246.5.11 mInfeasibleSubsets** `std::vector<FormulaSetT> smrat::Module::mInfeasibleSubsets`  
[protected], [inherited]  
Stores the infeasible subsets.

**0.15.246.5.12 mInformedConstraints** `carl::FastSet<FormulaT> smrat::Module::mInformedConstraints`  
[protected], [inherited]  
Stores the position of the first constraint of which no backend has been informed about.

**0.15.246.5.13 mLastBranches** `std::vector< Branching > smrat::Module::mLastBranches = std::vector<Branching>(mNumOfBranchVarsToStore, Branching(typename Poly::PolyType(), 0))` [static],  
[inherited]  
Stores the last branches in a cycle buffer.

**0.15.246.5.14 mLemmas** `std::vector<Lemma> smrat::Module::mLemmas` [protected], [inherited]  
Stores the lemmas being valid formulas this module or its backends made.

**0.15.246.5.15 mModel** `Model smrat::Module::mModel` [mutable], [protected], [inherited]  
Stores the assignment of the current satisfiable result, if existent.

**0.15.246.5.16 mModelComputed** `bool smrat::Module::mModelComputed` [mutable], [protected],  
[inherited]  
True, if the model has already been computed.

**0.15.246.5.17 mNumOfBranchVarsToStore** std::size\_t smtrat::Module::mNumOfBranchVarsToStore = 5 [static], [inherited]

The number of different variables to consider for a probable infinite loop of branchings.

**0.15.246.5.18 mObjectiveVariable** carl::Variable smtrat::Module::mObjectiveVariable [protected], [inherited]

Objective variable to be minimized. If set to NO\_VARIABLE, a normal sat check should be performed.

**0.15.246.5.19 mOldSplittingVariables** std::vector< FormulaT > smtrat::Module::mOldSplittingVariables [static], [inherited]

Reusable splitting variables.

**0.15.246.5.20 mpManager** Manager\* const smtrat::Module::mpManager [protected], [inherited]

A reference to the manager.

**0.15.246.5.21 mSmallerMusesCheckCounter** unsigned smtrat::Module::mSmallerMusesCheckCounter [mutable], [protected], [inherited]

Counter used for the generation of the smt2 files to check for smaller muses.

**0.15.246.5.22 mSolverState** std::atomic<Answer> smtrat::Module::mSolverState [protected], [inherited]

States whether the received formula is known to be satisfiable or unsatisfiable otherwise it is set to unknown.

**0.15.246.5.23 mTheoryPropagations** std::vector<TheoryPropagation> smtrat::Module::mTheoryPropagations [protected], [inherited]

**0.15.246.5.24 mUsedBackends** std::vector<Module\*> smtrat::Module::mUsedBackends [protected], [inherited]

The backends of this module which are currently used (conditions to use this module are fulfilled for the passed formula).

**0.15.246.5.25 mVariableCounters** std::vector<std::size\_t> smtrat::Module::mVariableCounters [protected], [inherited]

Maps variables to the number of their occurrences.

## 0.15.247 smtrat::ICPModule< Settings > Class Template Reference

#include <ICPModule.h>

*Prints the vector of passed formula.*
- void `printInfeasibleSubsets (const std::string &_initiation="***") const`

*Prints the infeasible subsets.*
- void `printModel (std::ostream &_out=std::cout) const`

*Prints the assignment of this module satisfying its received formula if it satisfiable and this module could find an assignment.*
- void `printAllModels (std::ostream &_out=std::cout)`

*Prints all assignments of this module satisfying its received formula if it satisfiable and this module could find an assignment.*

## Static Public Member Functions

- static void `freeSplittingVariable` (const `FormulaT` &\_splittingVariable)

## Static Public Attributes

- static size\_t `mNumOfBranchVarsToStore` = 5

*The number of different variables to consider for a probable infinite loop of branchings.*
- static std::vector< `Branching` > `mLastBranches` = std::vector<`Branching`>(mNumOfBranchVarsToStore, `Branching`(typename Poly::PolyType(), 0))

*Stores the last branches in a cycle buffer.*
- static size\_t `mFirstPosInLastBranches` = 0

*The beginning of the cyclic buffer storing the last branches.*
- static std::vector< `FormulaT` > `mOldSplittingVariables`

*Reusable splitting variables.*

## Protected Member Functions

- `ModuleInput::iterator eraseSubformulaFromPassedFormula` (`ModuleInput::iterator` \_subformula, bool \_← ignoreOrigins=false)

*Removes everything related to the sub-formula to remove from the passed formula in the backends of this module.*
- virtual void `deinformCore` (const `FormulaT` &\_constraint)

*The inverse of informing about a constraint.*
- bool `anAnswerFound` () const

*Checks for all antecedent modules and those which run in parallel with the same antecedent modules, whether one of them has determined a result.*
- void `clearModel` () const

*Clears the assignment, if any was found.*
- void `clearModels` () const

*Clears all assignments, if any was found.*
- void `cleanModel` () const

*Substitutes variable occurrences by its model value in the model values of other variables.*
- `ModuleInput::iterator passedFormulaBegin` ()
- `ModuleInput::iterator passedFormulaEnd` ()
- void `addOrigin` (`ModuleInput::iterator` \_formula, const `FormulaT` &\_origin)

*Adds the given set of formulas in the received formula to the origins of the given passed formula.*
- const `FormulaT` & `getOrigins` (`ModuleInput::const_iterator` \_formula) const

*Gets the origins of the passed formula at the given position.*
- void `getOrigins` (const `FormulaT` &\_formula, `FormulasT` &\_origins) const
- void `getOrigins` (const `FormulaT` &\_formula, `FormulaSetT` &\_origins) const
- std::pair< `ModuleInput::iterator`, bool > `removeOrigin` (`ModuleInput::iterator` \_formula, const `FormulaT` &\_← origin)

*Adds a lemmas which provoke a branching for the given variable at the given value, if this module returns Unknown and there exists a preceding SATModule.*
- void [splitUnequalConstraint](#) (const [FormulaT](#) &)
 

*Adds the following lemmas for the given constraint p!=0.*
- unsigned [checkModel](#) () const
- void [addInformationRelevantFormula](#) (const [FormulaT](#) &formula)
 

*Adds a formula to the InformationRelevantFormula.*
- const std::set< [FormulaT](#) > & [getInformationRelevantFormulas](#) ()
 

*Gets all InformationRelevantFormulas.*
- bool [isLemmaLevel](#) ([LemmaLevel](#) level)
 

*Checks if current lemma level is greater or equal to given level.*

## Static Protected Member Functions

- static bool `modelsDisjoint` (const `Model` &\_modelA, const `Model` &\_modelB)

*Checks whether there is no variable assigned by both models.*

## Protected Attributes

- `std::vector<FormulaSetT> mInfeasibleSubsets`

*Stores the infeasible subsets.*

- `Manager *const mpManager`

*A reference to the manager.*

- `Model mModel`

*Stores the assignment of the current satisfiable result, if existent.*

- `std::vector<Model> mAllModels`

*Stores all satisfying assignments.*

- `bool mModelComputed`

*True, if the model has already been computed.*

- `bool mFinalCheck`

*true, if the check procedure should perform a final check which especially means not to postpone splitting decisions*

- `bool mFullCheck`

*false, if this module should avoid too expensive procedures and rather return unknown instead.*

- `carl::Variable mObjectiveVariable`

*Objective variable to be minimized. If set to NO\_VARIABLE, a normal sat check should be performed.*

- `std::vector<TheoryPropagation> mTheoryPropagations`

- `std::atomic<Answer> mSolverState`

*States whether the received formula is known to be satisfiable or unsatisfiable otherwise it is set to unknown.*

- `std::atomic_bool * mBackendsFoundAnswer`

*This flag is passed to any backend and if it determines an answer to a prior check call, this flag is fired.*

- `Conditionals mFoundAnswer`

*Vector of Booleans: If any of them is true, we have to terminate a running check procedure.*

- `std::vector<Module *> mUsedBackends`

*The backends of this module which are currently used (conditions to use this module are fulfilled for the passed formula).*

- `std::vector<Module *> mAllBackends`

*The backends of this module which have been used.*

- `std::vector<Lemma> mLemmas`

*Stores the lemmas being valid formulas this module or its backends made.*

- `ModuleInput::iterator mFirstSubformulaToPass`

*Stores the position of the first sub-formula in the passed formula, which has not yet been considered for a consistency check of the backends.*

- `carl::FastSet<FormulaT> mConstraintsToInform`

*Stores the constraints which the backends must be informed about.*

- `carl::FastSet<FormulaT> mInformedConstraints`

*Stores the position of the first constraint of which no backend has been informed about.*

- `ModuleInput::const_iterator mFirstUncheckedReceivedSubformula`

*Stores the position of the first (by this module) unchecked sub-formula of the received formula.*

- `unsigned mSmallerMusesCheckCounter`

*Counter used for the generation of the smt2 files to check for smaller muses.*

- `std::vector<std::size_t> mVariableCounters`

*Maps variables to the number of their occurrences.*

```

Destructor:

### 0.15.247.4 Member Function Documentation

#### 0.15.247.4.1 add() bool smtrat::Module::add (

```
ModuleInput::const_iterator _subformula) [inherited]
```

The module has to take the given sub-formula of the received formula into account.

Parameters

|             |                                                    |
|-------------|----------------------------------------------------|
| _subformula | The sub-formula to take additionally into account. |
|-------------|----------------------------------------------------|

Returns

false, if it can be easily decided that this sub-formula causes a conflict with the already considered sub-formulas; true, otherwise.

**0.15.247.4.2 addConstraintToInform()** `void smtrat::Module::addConstraintToInform (``const FormulaT & _constraint ) [protected], [virtual], [inherited]`

Adds a constraint to the collection of constraints of this module, which are informed to a freshly generated backend.

**Parameters**

|                          |                        |
|--------------------------|------------------------|
| <code>_constraint</code> | The constraint to add. |
|--------------------------|------------------------|

Reimplemented in [smtrat::SATModule< Settings >](#).

**0.15.247.4.3 addCore()** `template<class Settings >``bool smtrat::ICPModule< Settings >::addCore (``ModuleInput::const_iterator formula ) [virtual]`

The module has to take the given sub-formula of the received formula into account.

**Parameters**

|                      |                                                    |
|----------------------|----------------------------------------------------|
| <code>formula</code> | The sub-formula to take additionally into account. |
|----------------------|----------------------------------------------------|

**Returns**

false, if it can be easily decided that this sub-formula causes a conflict with the already considered sub-formulas; true, otherwise.

Reimplemented from [smtrat::Module](#).

**0.15.247.4.4 addInformationRelevantFormula()** `void smtrat::Module::addInformationRelevantFormula (``const FormulaT & formula ) [protected], [inherited]`

Adds a formula to the InformationRelevantFormula.

**Parameters**

|                      |                |
|----------------------|----------------|
| <code>formula</code> | Formula to add |
|----------------------|----------------|

**0.15.247.4.5 addLemma()** `void smtrat::Module::addLemma (``const FormulaT & _lemma,``const LemmaType & _lt = LemmaType::NORMAL,``const FormulaT & _preferredFormula = FormulaT( carl::FormulaType::TRUE ) ) [inline],``[inherited]`

Stores a lemma being a valid formula.

**Parameters**

|                                |                                                                       |
|--------------------------------|-----------------------------------------------------------------------|
| <code>_lemma</code>            | The eduction/lemma to store.                                          |
| <code>_lt</code>               | The type of the lemma.                                                |
| <code>_preferredFormula</code> | Hint for the next decision, which formula should be assigned to true. |

**0.15.247.4.6 addOrigin()** `void smtrat::Module::addOrigin (``ModuleInput::iterator _formula,`

```
const FormulaT & _origin) [inline], [protected], [inherited]
Adds the given set of formulas in the received formula to the origins of the given passed formula.
```

#### Parameters

|                       |                                                           |
|-----------------------|-----------------------------------------------------------|
| <code>_formula</code> | The passed formula to set the origins for.                |
| <code>_origin</code>  | A set of formulas in the received formula of this module. |

**0.15.247.4.7 addReceivedSubformulaToPassedFormula()** std::pair<[ModuleInput::iterator](#),bool> smrat::Module::addReceivedSubformulaToPassedFormula (

```
ModuleInput::const_iterator _subformula) [inline], [protected], [inherited]
```

Copies the given sub-formula of the received formula to the passed formula.

Note, that there is always a link between sub-formulas of the passed formulas to sub-formulas of the received formulas, which are responsible for its occurrence.

#### Parameters

|                          |                                                  |
|--------------------------|--------------------------------------------------|
| <code>_subformula</code> | The sub-formula of the received formula to copy. |
|--------------------------|--------------------------------------------------|

**0.15.247.4.8 addSubformulaToPassedFormula() [1/3]** std::pair<[ModuleInput::iterator](#),bool> smrat::Module::addSubformulaToPassedFormula (

```
const FormulaT & _formula) [inline], [protected], [inherited]
```

Adds the given formula to the passed formula with no origin.

Note that in the next call of this module's removeSubformula, all formulas in the passed formula without origins will be removed.

#### Parameters

|                       |                                           |
|-----------------------|-------------------------------------------|
| <code>_formula</code> | The formula to add to the passed formula. |
|-----------------------|-------------------------------------------|

#### Returns

A pair to the position where the formula to add has been inserted (or its first sub-formula which has not yet been in the passed formula, in case the formula to add is a conjunction), and a Boolean stating whether anything has been added to the passed formula.

**0.15.247.4.9 addSubformulaToPassedFormula() [2/3]** std::pair<[ModuleInput::iterator](#),bool> smrat::Module::addSubformulaToPassedFormula (

```
const FormulaT & _formula,
```

```
const FormulaT & _origin) [inline], [protected], [inherited]
```

Adds the given formula to the passed formula.

#### Parameters

|                       |                                                                                                                           |
|-----------------------|---------------------------------------------------------------------------------------------------------------------------|
| <code>_formula</code> | The formula to add to the passed formula.                                                                                 |
| <code>_origin</code>  | The sub-formula of the received formula being responsible for the occurrence of the formula to add to the passed formula. |

**Returns**

A pair to the position where the formula to add has been inserted (or its first sub-formula which has not yet been in the passed formula, in case the formula to add is a conjunction), and a Boolean stating whether anything has been added to the passed formula.

**0.15.247.4.10 addSubformulaToPassedFormula() [3/3]** `std::pair<ModuleInput::iterator, bool>`

```
smrat::Module::addSubformulaToPassedFormula (
 const FormulaT & _formula,
 const std::shared_ptr< std::vector< FormulaT >> & _origins) [inline], [protected],
[inherited]
```

Adds the given formula to the passed formula.

**Parameters**

|                       |                                                                                                                                         |
|-----------------------|-----------------------------------------------------------------------------------------------------------------------------------------|
| <code>_formula</code> | The formula to add to the passed formula.                                                                                               |
| <code>_origins</code> | The link of the formula to add to the passed formula to sub-formulas of the received formulas, which are responsible for its occurrence |

**Returns**

A pair to the position where the formula to add has been inserted (or its first sub-formula which has not yet been in the passed formula, in case the formula to add is a conjunction), and a Boolean stating whether anything has been added to the passed formula.

**0.15.247.4.11 allModels()** `const std::vector<Model>& smrat::Module::allModels () const [inline], [inherited]`**Returns**

All satisfying assignments, if existent.

**0.15.247.4.12 anAnswerFound()** `bool smrat::Module::anAnswerFound () const [inline], [protected], [inherited]`

Checks for all antecedent modules and those which run in parallel with the same antecedent modules, whether one of them has determined a result.

**Returns**

True, if one of them has determined a result.

**0.15.247.4.13 answerFound()** `const smrat::Conditionals& smrat::Module::answerFound () const [inline], [inherited]`**Returns**

A vector of Booleans: If any of them is true, we have to terminate a running check procedure.

**0.15.247.4.14 backendsModel()** `const Model & smrat::Module::backendsModel () const [protected], [inherited]`

Stores the model of a backend which determined satisfiability of the passed formula in the model of this module.

**0.15.247.4.15 branchAt() [1/4]** bool smtrat::Module::branchAt (

```
carl::Variable::Arg _var,
const Rational & _value,
bool _leftCaseWeak = true,
bool _preferLeftCase = true,
bool _useReceivedFormulaAsPremise = false,
const std::vector< FormulaT > & _premise = std::vector<FormulaT>()) [inline],
[protected], [inherited]
```

**0.15.247.4.16 branchAt() [2/4]** bool smtrat::Module::branchAt (

```
carl::Variable::Arg _var,
const Rational & _value,
std::vector< FormulaT > && _premise,
bool _leftCaseWeak = true,
bool _preferLeftCase = true,
bool _useReceivedFormulaAsPremise = false) [inline], [protected], [inherited]
```

**0.15.247.4.17 branchAt() [3/4]** bool smtrat::Module::branchAt (

```
const Poly & _polynomial,
bool _integral,
const Rational & _value,
bool _leftCaseWeak = true,
bool _preferLeftCase = true,
bool _useReceivedFormulaAsPremise = false,
const std::vector< FormulaT > & _premise = std::vector<FormulaT>()) [inline],
[protected], [inherited]
```

**0.15.247.4.18 branchAt() [4/4]** bool smtrat::Module::branchAt (

```
const Poly & _polynomial,
bool _integral,
const Rational & _value,
std::vector< FormulaT > && _premise,
bool _leftCaseWeak = true,
bool _preferLeftCase = true,
bool _useReceivedFormulaAsPremise = false) [protected], [inherited]
```

Adds a lemmas which provoke a branching for the given variable at the given value, if this module returns Unknown and there exists a preceding [SATModule](#).

Note that the given value is rounded down and up, if the given variable is integer-valued.

#### Parameters

|                                           |                                                                                                                                                                                                                |
|-------------------------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>_polynomial</code>                  | The variable to branch for.                                                                                                                                                                                    |
| <code>_integral</code>                    | A flag being true, if all variables in the polynomial to branch for are integral.                                                                                                                              |
| <code>_value</code>                       | The value to branch at.                                                                                                                                                                                        |
| <code>_premise</code>                     | The sub-formulas of the received formula from which the branch is followed. Note, that a premise is not necessary, as every branch is a valid formula. But a premise can prevent from branching unnecessarily. |
| <code>_leftCaseWeak</code>                | true, if a branching in the form of (or ( $\leq p b$ ) ( $> p b$ )) is desired. false, if a branching in the form of (or ( $< p b$ ) ( $\geq p b$ )) is desired.                                               |
| <code>_preferLeftCase</code>              | true, if the left case (polynomial less(or equal) 0 shall be chosen first. false, otherwise.                                                                                                                   |
| <code>_useReceivedFormulaAsPremise</code> | true, if the whole received formula should be used as premise                                                                                                                                                  |

---

**0.15.247.4.19 check()** *Answer* smtrat::Module::check (

```
 bool _final = false,
 bool _full = true,
 carl::Variable _objective = carl::Variable::NO_VARIABLE) [virtual], [inherited]
```

Checks the received formula for consistency.

Note, that this is an implementation of the satisfiability check of the conjunction of the so far received formulas, which does actually nothing but passing the problem to its backends. This implementation is only used internally and must be overwritten by any derived module.

#### Parameters

|                   |                                                                                                                                       |
|-------------------|---------------------------------------------------------------------------------------------------------------------------------------|
| <i>_final</i>     | true, if this satisfiability check will be the last one (for a global sat-check), if its result is SAT                                |
| <i>_full</i>      | false, if this module should avoid too expensive procedures and rather return unknown instead.                                        |
| <i>_objective</i> | if not set to NO_VARIABLE, the module should find an assignment minimizing this objective variable; otherwise any assignment is good. |

#### Returns

True, if the received formula is satisfiable; False, if the received formula is not satisfiable; Unknown, otherwise.

Reimplemented in [smtrat::PModule](#).

**0.15.247.4.20 checkCore()** *template<class Settings >*  
*Answer* smtrat::ICPModule< Settings >::checkCore ( ) [virtual]

Checks the received formula for consistency.

#### Parameters

|                   |                                                                                                                                       |
|-------------------|---------------------------------------------------------------------------------------------------------------------------------------|
| <i>_final</i>     | true, if this satisfiability check will be the last one (for a global sat-check), if its result is SAT                                |
| <i>_full</i>      | false, if this module should avoid too expensive procedures and rather return unknown instead.                                        |
| <i>_objective</i> | if not set to NO_VARIABLE, the module should find an assignment minimizing this objective variable; otherwise any assignment is good. |

#### Returns

SAT, if the received formula is satisfiable; UNSAT, if the received formula is not satisfiable; Unknown, otherwise.

Reimplemented from [smtrat::Module](#).

**0.15.247.4.21 checkInfSubsetForMinimality()** *void* smtrat::Module::checkInfSubsetForMinimality (

```
 std::vector< FormulaSetT >::const_iterator _infssubset,
 const std::string & _filename = "smaller_muses",
 unsigned _maxSizeDifference = 1) const [inherited]
```

Checks the given infeasible subset for minimality by storing all subsets of it, which have a smaller size which differs from the size of the infeasible subset not more than the given threshold.

#### Parameters

|                           |                                                                                                        |
|---------------------------|--------------------------------------------------------------------------------------------------------|
| <i>_infssubset</i>        | The infeasible subset to check for minimality.                                                         |
| <i>_filename</i>          | The name of the file to store the infeasible subsets in order to be able to check their infeasibility. |
| <i>_maxSizeDifference</i> | The maximal difference between the sizes of the subsets compared to the size of the infeasible subset. |

**0.15.247.4.22 checkModel()** `unsigned smtrat::Module::checkModel ( ) const [protected], [inherited]`

**Returns**

false, if the current model of this module does not satisfy the current given formula; true, if it cannot be said whether the model satisfies the given formula.

**0.15.247.4.23 cleanModel()** `void smtrat::Module::cleanModel ( ) const [inline], [protected], [inherited]`

Substitutes variable occurrences by its model value in the model values of other variables.

**0.15.247.4.24 clearLemmas()** `void smtrat::Module::clearLemmas ( ) [inline], [inherited]`  
Deletes all yet found lemmas.**0.15.247.4.25 clearModel()** `void smtrat::Module::clearModel ( ) const [inline], [protected], [inherited]`

Clears the assignment, if any was found.

**0.15.247.4.26 clearModels()** `void smtrat::Module::clearModels ( ) const [inline], [protected], [inherited]`

Clears all assignments, if any was found.

**0.15.247.4.27 clearPassedFormula()** `void smtrat::Module::clearPassedFormula ( ) [protected], [inherited]`**0.15.247.4.28 collectOrigins() [1/2]** `void smtrat::Module::collectOrigins ( const FormulaT & _formula, FormulaSetT & _origins ) const [inherited]`**0.15.247.4.29 collectOrigins() [2/2]** `void smtrat::Module::collectOrigins ( const FormulaT & _formula, FormulasT & _origins ) const [inherited]`

Collects the formulas in the given formula, which are part of the received formula.

If the given formula directly occurs in the received formula, it is inserted into the given set. Otherwise, the given formula must be of type AND and all its sub-formulas part of the received formula. Hence, they will be added to the given set.

**Parameters**

|                       |                                                                                                      |
|-----------------------|------------------------------------------------------------------------------------------------------|
| <code>_formula</code> | The formula from which to collect the formulas being sub-formulas of the received formula (origins). |
| <code>_origins</code> | The set in which to store the origins.                                                               |

**0.15.247.4.30 collectTheoryPropagations()** `void smtrat::Module::collectTheoryPropagations ( ) [inherited]`

**0.15.247.4.31 constraintsToInform()** const carl::FastSet<[FormulaT](#)>& smrat::Module::constraintsToInform( ) const [inline], [inherited]

**Returns**

The constraints which the backends must be informed about.

**0.15.247.4.32 currentlySatisfied()** virtual unsigned smrat::Module::currentlySatisfied( const [FormulaT](#) & ) const [inline], [virtual], [inherited]

**Returns**

0, if the given formula is conflicted by the current model; 1, if the given formula is satisfied by the current model; 2, otherwise; 3, if we do not know anything (default)

Reimplemented in [smrat::LRAbstractModule< Settings >](#), [smrat::LRAbstractModule< LRASettingsICP >](#), and [smrat::LRAbstractModule< LRASettings >](#)

**0.15.247.4.33 currentlySatisfiedByBackend()** unsigned smrat::Module::currentlySatisfiedByBackend( const [FormulaT](#) & \_formula ) const [inherited]

**Returns**

0, if the given formula is conflicted by the current model; 1, if the given formula is satisfied by the current model; 2, otherwise 3, if we do not know anything (default)

**0.15.247.4.34 deinform()** void smrat::Module::deinform( const [FormulaT](#) & \_constraint ) [inherited]

The inverse of informing about a constraint.

All data structures which were kept regarding this constraint are going to be removed. Note, that this makes only sense if it is not likely enough that a formula with this constraint must be solved again.

**Parameters**

|                          |                                                         |
|--------------------------|---------------------------------------------------------|
| <code>_constraint</code> | The constraint to remove from internal data structures. |
|--------------------------|---------------------------------------------------------|

**0.15.247.4.35 deinformCore()** virtual void smrat::Module::deinformCore( const [FormulaT](#) & \_constraint ) [inline], [protected], [virtual], [inherited]

The inverse of informing about a constraint.

All data structures which were kept regarding this constraint are going to be removed. Note, that this makes only sense if it is not likely enough that a formula with this constraint must be solved again.

**Parameters**

|                          |                                                         |
|--------------------------|---------------------------------------------------------|
| <code>_constraint</code> | The constraint to remove from internal data structures. |
|--------------------------|---------------------------------------------------------|

Reimplemented in [smrat::LRAbstractModule< Settings >](#), [smrat::LRAbstractModule< LRASettingsICP >](#), and [smrat::LRAbstractModule< LRASettings >](#)

**0.15.247.4.36 determine\_smallest\_origin()** size\_t smrat::Module::determine\_smallest\_origin( const std::vector< [FormulaT](#) > & origins ) const [protected], [inherited]

## Parameters

|                |                              |
|----------------|------------------------------|
| <i>origins</i> | A vector of sets of origins. |
|----------------|------------------------------|

## Returns

The index of the smallest (regarding the size of the sets) element of origins

```
0.15.247.4.37 eraseSubformulaFromPassedFormula() template<class Settings >
ModuleInput::iterator smtrat::ICPModule< Settings >::eraseSubformulaFromPassedFormula (
 ModuleInput::iterator _subformula,
 bool _ignoreOrigins = false) [protected], [virtual]
```

Removes everything related to the sub-formula to remove from the passed formula in the backends of this module.  
Afterwards the sub-formula is removed from the passed formula.

## Parameters

|                       |                                                                                                             |
|-----------------------|-------------------------------------------------------------------------------------------------------------|
| <i>_subformula</i>    | The sub-formula to remove from the passed formula.                                                          |
| <i>_ignoreOrigins</i> | SAT, if the sub-formula shall be removed regardless of its origins (should only be applied with expertise). |

## Returns

Reimplemented from [smtrat::Module](#).

```
0.15.247.4.38 excludeNotReceivedVariablesFromModel() void smtrat::Module::excludeNotReceived←
VariablesFromModel () const [inherited]
Excludes all variables from the current model, which do not occur in the received formula.
```

```
0.15.247.4.39 findBestOrigin() std::vector< FormulaT >::const_iterator smtrat::Module::find←
BestOrigin (
 const std::vector< FormulaT > & _origins) const [protected], [inherited]
```

## Parameters

|                 |  |
|-----------------|--|
| <i>_origins</i> |  |
|-----------------|--|

## Returns

```
0.15.247.4.40 firstSubformulaToPass() ModuleInput::const_iterator smtrat::Module::firstSubformula←
ToPass () const [inline], [inherited]
```

## Returns

The position of the first sub-formula in the passed formula, which has not yet been considered for a consistency check of the backends.

**0.15.247.4.41 firstUncheckedReceivedSubformula()** `ModuleInput::const_iterator smtrat::Module::firstUncheckedReceivedSubformula ( ) const [inline], [inherited]`

**Returns**

The position of the first (by this module) unchecked sub-formula of the received formula.

**0.15.247.4.42 freeSplittingVariable()** `static void smtrat::Module::freeSplittingVariable ( const FormulaT & _splittingVariable ) [inline], [static], [inherited]`

**0.15.247.4.43 generateTrivialInfeasibleSubset()** `void smtrat::Module::generateTrivialInfeasibleSubset ( ) [inline], [protected], [inherited]`

Stores the trivial infeasible subset being the set of received formulas.

**0.15.247.4.44 getBackendsAllModels()** `void smtrat::Module::getBackendsAllModels ( ) const [protected], [inherited]`

Stores all models of a backend in the list of all models of this module.

**0.15.247.4.45 getBackendsModel()** `void smtrat::Module::getBackendsModel ( ) const [protected], [inherited]`

**0.15.247.4.46 getCurrentBoxAsFormulas()** `template<class Settings > FormulasT smtrat::ICPModule< Settings >::getCurrentBoxAsFormulas ( ) const`

**0.15.247.4.47 getCurrentBoxAsIntervals()** `template<class Settings > EvalRationalIntervalMap smtrat::ICPModule< Settings >::getCurrentBoxAsIntervals ( ) const`

**0.15.247.4.48 getInfeasibleSubsets() [1/2]** `void smtrat::Module::getInfeasibleSubsets ( ) [protected], [inherited]`

Copies the infeasible subsets of the passed formula.

**0.15.247.4.49 getInfeasibleSubsets() [2/2]** `std::vector< FormulaSetT > smtrat::Module::getInfeasibleSubsets ( const Module & _backend ) const [protected], [inherited]`

Get the infeasible subsets the given backend provides.

Note, that an infeasible subset in a backend contains sub formulas of the passed formula and an infeasible subset of this module contains sub formulas of the received formula. In this method the LATTER is returned.

**Parameters**

|                       |                                                          |
|-----------------------|----------------------------------------------------------|
| <code>_backend</code> | The backend from which to obtain the infeasible subsets. |
|-----------------------|----------------------------------------------------------|

**Returns**

The infeasible subsets the given backend provides.

**0.15.247.4.50 getInformationRelevantFormulas()** const std::set< [FormulaT](#) > & smtrat::Module::getInformationRelevantFormulas ( ) [protected], [inherited]  
Gets all InformationRelevantFormulas.

**Returns**

Set of all formulas

**0.15.247.4.51 getModelEqualities()** std::list< std::vector< carl::Variable > > smtrat::Module::getModelEqualities ( ) const [virtual], [inherited]  
Partition the variables from the current model into equivalence classes according to their assigned value.  
The result is a set of equivalence classes of variables where all variables within one class are assigned the same value. Note that the number of classes may not be minimal, i.e. two classes may actually be equivalent.

**Returns**

Equivalence classes.

**0.15.247.4.52 getOrigins() [1/3]** void smtrat::Module::getOrigins ( const [FormulaT](#) & *\_formula*, [FormulaSetT](#) & *\_origins* ) const [inline], [protected], [inherited]

**Parameters**

|                 |  |
|-----------------|--|
| <i>_formula</i> |  |
| <i>_origins</i> |  |

**0.15.247.4.53 getOrigins() [2/3]** void smtrat::Module::getOrigins ( const [FormulaT](#) & *\_formula*, [FormulasT](#) & *\_origins* ) const [inline], [protected], [inherited]

**Parameters**

|                 |  |
|-----------------|--|
| <i>_formula</i> |  |
| <i>_origins</i> |  |

**0.15.247.4.54 getOrigins() [3/3]** const [FormulaT](#)& smtrat::Module::getOrigins ( [ModuleInput::const\\_iterator](#) *\_formula* ) const [inline], [protected], [inherited]  
Gets the origins of the passed formula at the given position.

**Parameters**

|                 |                                                   |
|-----------------|---------------------------------------------------|
| <i>_formula</i> | The position of a formula in the passed formulas. |
|-----------------|---------------------------------------------------|

**Returns**

The origins of the passed formula at the given position.

**0.15.247.4.55 `getReceivedFormulaSimplified()`** `std::pair< bool, FormulaT > smtrat::Module::getReceivedFormulaSimplified( ) [virtual], [inherited]`

**Returns**

A pair of a Boolean and a formula, where the Boolean is true, if the received formula could be simplified to an equisatisfiable formula. The formula is equisatisfiable to this module's received formula, if the Boolean is true.

Reimplemented in [smtrat::PModule](#).

**0.15.247.4.56 `hasLemmas()`** `bool smtrat::Module::hasLemmas( ) [inline], [inherited]`

Checks whether this module or any of its backends provides any lemmas.

**0.15.247.4.57 `hasValidInfeasibleSubset()`** `bool smtrat::Module::hasValidInfeasibleSubset( ) const [inherited]`

**Returns**

true, if the module has at least one valid infeasible subset, that is all its elements are sub-formulas of the received formula (pointer must be equal).

**0.15.247.4.58 `id()`** `std::size_t smtrat::Module::id( ) const [inline], [inherited]`

**Returns**

A unique ID to identify this module instance.

**0.15.247.4.59 `infeasibleSubsets()`** `const std::vector<FormulaSetT>& smtrat::Module::infeasibleSubsets( ) const [inline], [inherited]`

**Returns**

The infeasible subsets of the set of received formulas (empty, if this module has not detected unsatisfiability of the conjunction of received formulas).

**0.15.247.4.60 `inform()`** `bool smtrat::Module::inform( const FormulaT & _constraint ) [inherited]`

Informs the module about the given constraint.

It should be tried to inform this module about any constraint it could receive eventually before assertSubformula is called (preferably for the first time, but at least before adding a formula containing that constraint).

**Parameters**

|                          |                                 |
|--------------------------|---------------------------------|
| <code>_constraint</code> | The constraint to inform about. |
|--------------------------|---------------------------------|

**Returns**

false, if it can be easily decided whether the given constraint is inconsistent; true, otherwise.

**0.15.247.4.61 informBackends()** void smtrat::Module::informBackends (

```
const FormulaT & _constraint) [inline], [protected], [inherited]
```

Informs all backends of this module about the given constraint.

**Parameters**

|                          |                                 |
|--------------------------|---------------------------------|
| <code>_constraint</code> | The constraint to inform about. |
|--------------------------|---------------------------------|

**0.15.247.4.62 informCore()** template<class Settings >

```
bool smtrat::ICPModule< Settings >::informCore (
 const FormulaT & _constraint) [virtual]
```

Informs the module about the given constraint.

It should be tried to inform this module about any constraint it could receive eventually before assertSubformula is called (preferably for the first time, but at least before adding a formula containing that constraint).

**Parameters**

|                          |                                 |
|--------------------------|---------------------------------|
| <code>_constraint</code> | The constraint to inform about. |
|--------------------------|---------------------------------|

**Returns**

false, if it can be easily decided whether the given constraint is inconsistent; true, otherwise.

Reimplemented from [smtrat::Module](#).

**0.15.247.4.63 informedConstraints()** const carl::FastSet<FormulaT>& smtrat::Module::informedConstraints ( ) const [inline], [inherited]**Returns**

The position of the first constraint of which no backend has been informed about.

**0.15.247.4.64 init()** void smtrat::Module::init ( ) [virtual], [inherited]

Informs all backends about the so far encountered constraints, which have not yet been communicated.

This method must not be called twice and only before the first runBackends call.

Reimplemented in [smtrat::PBPPModule](#)< Settings >, [smtrat::PBGaussModule](#)< Settings >, [smtrat::NRAILModule](#)< Settings >, [smtrat::NewCoveringModule](#)< Settings >, [smtrat::NewCADModule](#)< Settings >, [smtrat::LRAModule](#)< Settings >, [smtrat::LRAModule](#)< LRASettingsICP >, [smtrat::LRAModule](#)< LRASettings1 >, [smtrat::IntBlastModule](#)< Settings >, [smtrat::FPPModule](#)< Settings >, [smtrat::EQModule](#)< Settings >, [smtrat::CurryModule](#)< Settings >, and [smtrat::BVMModule](#)< Settings >.

**0.15.247.4.65 is\_minimizing()** bool smtrat::Module::is\_minimizing ( ) const [inline], [inherited]**0.15.247.4.66 isLemmaLevel()** bool smtrat::Module::isLemmaLevel (

```
LemmaLevel level) [protected], [inherited]
```

Checks if current lemma level is greater or equal to given level.

**Parameters**

|              |                 |
|--------------|-----------------|
| <i>level</i> | Level to check. |
|--------------|-----------------|

**0.15.247.4.67 `isPreprocessor()`** `bool smtrat::Module::isPreprocessor () const [inline], [inherited]`**Returns**

true, if this module is a preprocessor that is a module, which simplifies its received formula to an equisatisfiable formula being passed to its backends. The simplified formula can be obtained with [getReceivedFormulaSimplified\(\)](#).

**0.15.247.4.68 `lemmas()`** `const std::vector<Lemma>& smtrat::Module::lemmas () const [inline], [inherited]`**Returns**

A constant reference to the lemmas being valid formulas this module or its backends made.

**0.15.247.4.69 `merge()`** `std::vector< FormulaT > smtrat::Module::merge (const std::vector< FormulaT > & _vecSetA, const std::vector< FormulaT > & _vecSetB ) const [protected], [inherited]`

Merges the two vectors of sets into the first one.

({a,b},{a,c}) and ({b,d},{b}) -> ({a,b,d},{a,b},{a,b,c,d},{a,b,c})

**Parameters**

|                 |                                  |
|-----------------|----------------------------------|
| <i>_vecSetA</i> | A vector of sets of constraints. |
| <i>_vecSetB</i> | A vector of sets of constraints. |

**Returns**

The vector being the two given vectors merged.

**0.15.247.4.70 `model()`** `const Model& smtrat::Module::model () const [inline], [inherited]`**Returns**

The assignment of the current satisfiable result, if existent.

**0.15.247.4.71 `modelsDisjoint()`** `bool smtrat::Module::modelsDisjoint (const Model & _modelA, const Model & _modelB ) [static], [protected], [inherited]`

Checks whether there is no variable assigned by both models.

**Parameters**

|                |                                |
|----------------|--------------------------------|
| <i>_modelA</i> | The first model to check for.  |
| <i>_modelB</i> | The second model to check for. |

**Returns**

true, if there is no variable assigned by both models; false, otherwise.

**0.15.247.4.72 `moduleName()`** `template<class Settings >`  
`std::string smtrat::ICPModule< Settings >::moduleName ( ) const [inline], [virtual]`

**Returns**

The name of the given module type as name.

Reimplemented from [smtrat::Module](#).

**0.15.247.4.73 `objective()`** `carl::Variable smtrat::Module::objective ( ) const [inline], [inherited]`

**0.15.247.4.74 `originInReceivedFormula()`** `bool smtrat::Module::originInReceivedFormula (`  
`const FormulaT & _origin ) const [protected], [inherited]`

**0.15.247.4.75 `passedFormulaBegin()`** `ModuleInput::iterator smtrat::Module::passedFormulaBegin (`  
`) [inline], [protected], [inherited]`

**Returns**

An iterator to the end of the passed formula. TODO: disable this method

**0.15.247.4.76 `passedFormulaEnd()`** `ModuleInput::iterator smtrat::Module::passedFormulaEnd ( )`  
`[inline], [protected], [inherited]`

**Returns**

An iterator to the end of the passed formula.

**0.15.247.4.77 `pPassedFormula()`** `const ModuleInput* smtrat::Module::pPassedFormula ( ) const`  
`[inline], [inherited]`

**Returns**

A pointer to the formula passed to the backends of this module.

**0.15.247.4.78 `pReceivedFormula()`** `const ModuleInput* smtrat::Module::pReceivedFormula ( ) const`  
`[inline], [inherited]`

**Returns**

A pointer to the formula passed to this module.

**0.15.247.4.79 `print()`** `void smtrat::Module::print (`  
`const std::string & _initiation = "***" ) const [inherited]`

Prints everything relevant of the solver.

**Parameters**

|                    |                      |
|--------------------|----------------------|
| <i>_initiation</i> | The line initiation. |
|--------------------|----------------------|

**0.15.247.4.80 printAllModels()** void smtrat::Module::printAllModels ( std::ostream & *\_out* = std::cout ) const [inherited]

Prints all assignments of this module satisfying its received formula if it satisfiable and this module could find an assignment.

**Parameters**

|             |                                        |
|-------------|----------------------------------------|
| <i>_out</i> | The stream to print the assignment on. |
|-------------|----------------------------------------|

**0.15.247.4.81 printInfeasibleSubsets()** void smtrat::Module::printInfeasibleSubsets ( const std::string & *\_initiation* = "\*\*\*" ) const [inherited]

Prints the infeasible subsets.

**Parameters**

|                    |                      |
|--------------------|----------------------|
| <i>_initiation</i> | The line initiation. |
|--------------------|----------------------|

**0.15.247.4.82 printModel()** void smtrat::Module::printModel ( std::ostream & *\_out* = std::cout ) const [inherited]

Prints the assignment of this module satisfying its received formula if it satisfiable and this module could find an assignment.

**Parameters**

|             |                                        |
|-------------|----------------------------------------|
| <i>_out</i> | The stream to print the assignment on. |
|-------------|----------------------------------------|

**0.15.247.4.83 printPassedFormula()** void smtrat::Module::printPassedFormula ( const std::string & *\_initiation* = "\*\*\*" ) const [inherited]

Prints the vector of passed formula.

**Parameters**

|                    |                      |
|--------------------|----------------------|
| <i>_initiation</i> | The line initiation. |
|--------------------|----------------------|

**0.15.247.4.84 printReceivedFormula()** void smtrat::Module::printReceivedFormula ( const std::string & *\_initiation* = "\*\*\*" ) const [inherited]

Prints the vector of the received formula.

**Parameters**

|                    |                      |
|--------------------|----------------------|
| <i>_initiation</i> | The line initiation. |
|--------------------|----------------------|

```
0.15.247.4.85 probablyLooping() bool smtrat::Module::probablyLooping (
 const typename Poly::PolyType & _branchingPolynomial,
 const Rational & _branchingValue) const [protected], [inherited]
```

Checks whether given the current branching value and branching variable/polynomial it is (highly) probable that this branching is part of an infinite loop of branchings.

#### Parameters

|                             |                                                                                     |
|-----------------------------|-------------------------------------------------------------------------------------|
| <i>_branchingPolynomial</i> | The polynomial to branch at (in most branching strategies this is just a variable). |
| <i>_branchingValue</i>      | The value to branch at.                                                             |

#### Returns

true, if this branching is probably part of an infinite loop of branchings; false, otherwise.

```
0.15.247.4.86 receivedFormulaChecked() void smtrat::Module::receivedFormulaChecked () [inline], [inherited]
```

Notifies that the received formulas has been checked.

```
0.15.247.4.87 receivedFormulasAsInfeasibleSubset() void smtrat::Module::receivedFormulasAs<= InfeasibleSubset (
```

```
 ModuleInput::const_iterator _subformula) [inline], [protected], [inherited]
```

Stores an infeasible subset consisting only of the given received formula.

```
0.15.247.4.88 receivedVariable() bool smtrat::Module::receivedVariable (
 carl::Variable::Arg _var) const [inline], [inherited]
```

```
0.15.247.4.89 remove() void smtrat::Module::remove (
```

```
 ModuleInput::const_iterator _subformula) [virtual], [inherited]
```

Removes everything related to the given sub-formula of the received formula.

However, it is desired not to lose track of search spaces where no satisfying assignment can be found for the remaining sub-formulas.

#### Parameters

|                    |                                                    |
|--------------------|----------------------------------------------------|
| <i>_subformula</i> | The sub formula of the received formula to remove. |
|--------------------|----------------------------------------------------|

Reimplemented in [smtrat::PModule](#).

```
0.15.247.4.90 removeCore() template<class Settings >
void smtrat::ICPModule< Settings >::removeCore (
```

```
 ModuleInput::const_iterator formula) [virtual]
```

Removes everything related to the given sub-formula of the received formula.

However, it is desired not to lose track of search spaces where no satisfying assignment can be found for the remaining sub-formulas.

#### Parameters

|                |                                                    |
|----------------|----------------------------------------------------|
| <i>formula</i> | The sub formula of the received formula to remove. |
|----------------|----------------------------------------------------|

Reimplemented from [smtrat::Module](#).

**0.15.247.4.91 removeOrigin()** std::pair<ModuleInput::iterator, bool> smtrat::Module::removeOrigin (

```
 ModuleInput::iterator _formula,
 const FormulaT & _origin) [inline], [protected], [inherited]
```

**0.15.247.4.92 removeOrigins()** std::pair<ModuleInput::iterator, bool> smtrat::Module::removeOrigins (

```
 ModuleInput::iterator _formula,
 const std::shared_ptr< std::vector< FormulaT >> & _origins) [inline], [protected],
[inherited]
```

**0.15.247.4.93 rPassedFormula()** const ModuleInput& smtrat::Module::rPassedFormula ( ) const [inline], [inherited]

**Returns**

A reference to the formula passed to the backends of this module.

**0.15.247.4.94 rReceivedFormula()** const ModuleInput& smtrat::Module::rReceivedFormula ( ) const [inline], [inherited]

**Returns**

A reference to the formula passed to this module.

**0.15.247.4.95 runBackends() [1/2]** virtual Answer smtrat::Module::runBackends ( ) [inline], [protected], [virtual], [inherited]

Reimplemented in [smtrat::PModule](#).

**0.15.247.4.96 runBackends() [2/2]** Answer smtrat::Module::runBackends (

```
 bool _final,
 bool _full,
 carl::Variable _objective) [protected], [virtual], [inherited]
```

Runs the backend solvers on the passed formula.

**Parameters**

|                         |                                                                                                                                       |
|-------------------------|---------------------------------------------------------------------------------------------------------------------------------------|
| <code>_final</code>     | true, if this satisfiability check will be the last one (for a global sat-check), if its result is SAT                                |
| <code>_full</code>      | false, if this module should avoid too expensive procedures and rather return unknown instead.                                        |
| <code>_objective</code> | if not set to NO_VARIABLE, the module should find an assignment minimizing this objective variable; otherwise any assignment is good. |

**Returns**

True, if the passed formula is consistent; False, if the passed formula is inconsistent; Unknown, otherwise.

Reimplemented in [smtrat::PModule](#).

**0.15.247.4.97 setId()** void smtrat::Module::setId ( std::size\_t \_id ) [inline], [inherited]  
 Sets this modules unique ID to identify itself.

#### Parameters

|                                                                                            |                                    |
|--------------------------------------------------------------------------------------------|------------------------------------|
| <br>$_id$ | The id to set this module's id to. |
|--------------------------------------------------------------------------------------------|------------------------------------|

**0.15.247.4.98 setThreadPriority()** void smtrat::Module::setThreadPriority ( thread\_priority \_threadPriority ) [inline], [inherited]  
 Sets the priority of this module to get a thread for running its check procedure.

#### Parameters

|                   |                                                       |
|-------------------|-------------------------------------------------------|
| $_threadPriority$ | The priority to set this module's thread priority to. |
|-------------------|-------------------------------------------------------|

**0.15.247.4.99 solverState()** Answer smtrat::Module::solverState ( ) const [inline], [inherited]

#### Returns

True, if this module is in a state, such that it has found a solution for its received formula; False, if this module is in a state, such that it has determined that there is no solution for its received formula; Unknown, otherwise.

**0.15.247.4.100 splitUnequalConstraint()** void smtrat::Module::splitUnequalConstraint ( const FormulaT & \_unequalConstraint ) [protected], [inherited]  
 Adds the following lemmas for the given constraint  $p \neq 0$ .

$(p \neq 0 \leftrightarrow (p < 0 \text{ or } p > 0))$

and  $\neg(p < 0 \text{ and } p > 0)$

#### Parameters

|                      |                                                  |
|----------------------|--------------------------------------------------|
| $_unequalConstraint$ | A constraint having the relation symbol $\neq$ . |
|----------------------|--------------------------------------------------|

**0.15.247.4.101 threadPriority()** thread\_priority smtrat::Module::threadPriority ( ) const [inline], [inherited]

#### Returns

The priority of this module to get a thread for running its check procedure.

**0.15.247.4.102 updateAllModels()** void smtrat::Module::updateAllModels ( ) [virtual], [inherited]  
 Updates all satisfying models, if the solver has detected the consistency of the received formula, beforehand.  
 Reimplemented in [smtrat::SATModule< Settings >](#).

**0.15.247.4.103 updateLemmas()** void smrat::Module::updateLemmas ( ) [inherited]  
Stores all lemmas of any backend of this module in its own lemma vector.

**0.15.247.4.104 updateModel()** template<class Settings >  
void smrat::ICPModule< Settings >::updateModel ( ) const [virtual]  
Updates the model, if the solver has detected the consistency of the received formula, beforehand.  
Reimplemented from [smrat::Module](#).

**0.15.247.4.105 usedBackends()** const std::vector<[Module](#)\*>& smrat::Module::usedBackends ( )  
const [inline], [inherited]

**Returns**

The backends of this module which are currently used (conditions to use this module are fulfilled for the passed formula).

## 0.15.247.5 Field Documentation

**0.15.247.5.1 mAllBackends** std::vector<[Module](#)\*> smrat::Module::mAllBackends [protected],  
[inherited]  
The backends of this module which have been used.

**0.15.247.5.2 mAllModels** std::vector<[Model](#)> smrat::Module::mAllModels [mutable], [protected],  
[inherited]  
Stores all satisfying assignments.

**0.15.247.5.3 mBackendsFoundAnswer** std::atomic\_bool\* smrat::Module::mBackendsFoundAnswer  
[protected], [inherited]  
This flag is passed to any backend and if it determines an answer to a prior check call, this flag is fired.

**0.15.247.5.4 mConstraintsToInform** carl::FastSet<[FormulaT](#)> smrat::Module::mConstraintsToInform  
[protected], [inherited]  
Stores the constraints which the backends must be informed about.

**0.15.247.5.5 mFinalCheck** bool smrat::Module::mFinalCheck [protected], [inherited]  
true, if the check procedure should perform a final check which especially means not to postpone splitting decisions

**0.15.247.5.6 mFirstPosInLastBranches** std::size\_t smrat::Module::mFirstPosInLastBranches = 0  
[static], [inherited]  
The beginning of the cyclic buffer storing the last branches.

**0.15.247.5.7 mFirstSubformulaToPass** [ModuleInput](#)::iterator smrat::Module::mFirstSubformulaToPass [protected], [inherited]  
Stores the position of the first sub-formula in the passed formula, which has not yet been considered for a consistency check of the backends.

**0.15.247.5.8 mFirstUncheckedReceivedSubformula** `ModuleInput::const_iterator smtrat::Module::mFirstUncheckedReceivedSubformula [protected], [inherited]`  
Stores the position of the first (by this module) unchecked sub-formula of the received formula.

**0.15.247.5.9 mFoundAnswer** `Conditionals smtrat::Module::mFoundAnswer [protected], [inherited]`  
Vector of Booleans: If any of them is true, we have to terminate a running check procedure.

**0.15.247.5.10 mFullCheck** `bool smtrat::Module::mFullCheck [protected], [inherited]`  
false, if this module should avoid too expensive procedures and rather return unknown instead.

**0.15.247.5.11 mInfeasibleSubsets** `std::vector<FormulaSetT> smtrat::Module::mInfeasibleSubsets [protected], [inherited]`  
Stores the infeasible subsets.

**0.15.247.5.12 mInformedConstraints** `carl::FastSet<FormulaT> smtrat::Module::mInformedConstraints [protected], [inherited]`  
Stores the position of the first constraint of which no backend has been informed about.

**0.15.247.5.13 mLastBranches** `std::vector<Branching> smtrat::Module::mLastBranches = std::vector<Branching>(mNumOfBranchVarsToStore, Branching(typename Poly::PolyType(), 0)) [static], [inherited]`  
Stores the last branches in a cycle buffer.

**0.15.247.5.14 mLemmas** `std::vector<Lemma> smtrat::Module::mLemmas [protected], [inherited]`  
Stores the lemmas being valid formulas this module or its backends made.

**0.15.247.5.15 mModel** `Model smtrat::Module::mModel [mutable], [protected], [inherited]`  
Stores the assignment of the current satisfiable result, if existent.

**0.15.247.5.16 mModelComputed** `bool smtrat::Module::mModelComputed [mutable], [protected], [inherited]`  
True, if the model has already been computed.

**0.15.247.5.17 mNumOfBranchVarsToStore** `std::size_t smtrat::Module::mNumOfBranchVarsToStore = 5 [static], [inherited]`  
The number of different variables to consider for a probable infinite loop of branchings.

**0.15.247.5.18 mObjectiveVariable** `carl::Variable smtrat::Module::mObjectiveVariable [protected], [inherited]`  
Objective variable to be minimized. If set to NO\_VARIABLE, a normal sat check should be performed.

**0.15.247.5.19 mOldSplittingVariables** `std::vector<FormulaT> smtrat::Module::mOldSplittingVariables [static], [inherited]`  
Reusable splitting variables.

**0.15.247.5.20 mpManager** `Manager* const smtrat::Module::mpManager [protected], [inherited]`  
A reference to the manager.

**0.15.247.5.21 mSmallerMusesCheckCounter** `unsigned smtrat::Module::mSmallerMusesCheckCounter [mutable], [protected], [inherited]`  
Counter used for the generation of the smt2 files to check for smaller muses.

**0.15.247.5.22 mSolverState** `std::atomic<Answer> smtrat::Module::mSolverState [protected], [inherited]`  
States whether the received formula is known to be satisfiable or unsatisfiable otherwise it is set to unknown.

**0.15.247.5.23 mTheoryPropagations** `std::vector<TheoryPropagation> smtrat::Module::mTheoryPropagations [protected], [inherited]`

**0.15.247.5.24 mUsedBackends** `std::vector<Module*> smtrat::Module::mUsedBackends [protected], [inherited]`  
The backends of this module which are currently used (conditions to use this module are fulfilled for the passed formula).

**0.15.247.5.25 mVariableCounters** `std::vector<std::size_t> smtrat::Module::mVariableCounters [protected], [inherited]`  
Maps variables to the number of their occurrences.

## 0.15.248 smtrat::icp::IcpVariable Class Reference

- std::vector< `FormulaT` > `merge` (const std::vector< `FormulaT` > &, const std::vector< `FormulaT` > &) const
 

*Checks whether given the current branching value and branching variable/polynomial it is (highly) probable that this branching is part of an infinite loop of branchings.*
- bool `branchAt` (const `Poly` &`_polynomial`, bool `_integral`, const `Rational` &`_value`, std::vector< `FormulaT` > &&`_premise`, bool `_leftCaseWeak=true`, bool `_preferLeftCase=true`, bool `_useReceivedFormulaAsPremise=false`)
 

*Adds a lemmas which provoke a branching for the given variable at the given value, if this module returns Unknown and there exists a preceding SATModule.*
- bool `branchAt` (const `Poly` &`_polynomial`, bool `_integral`, const `Rational` &`_value`, bool `_leftCaseWeak=true`, bool `_preferLeftCase=true`, bool `_useReceivedFormulaAsPremise=false`, const std::vector< `FormulaT` > &`_premise=std::vector< FormulaT >()`)
 

*Adds a formula to the InformationRelevantFormula.*
- bool `branchAt` (carl::Variable::Arg `_var`, const `Rational` &`_value`, std::vector< `FormulaT` > &&`_premise`, bool `_leftCaseWeak=true`, bool `_preferLeftCase=true`, bool `_useReceivedFormulaAsPremise=false`)
 

*Adds a formula to the InformationRelevantFormula.*
- bool `branchAt` (carl::Variable::Arg `_var`, const `Rational` &`_value`, bool `_leftCaseWeak=true`, bool `_preferLeftCase=true`, bool `_useReceivedFormulaAsPremise=false`, const std::vector< `FormulaT` > &`_premise=std::vector< FormulaT >()`)
 

*Adds the following lemmas for the given constraint  $p!=0$ .*
- unsigned `checkModel` () const
 

*Gets all InformationRelevantFormulas.*
- void `addInformationRelevantFormula` (const `FormulaT` &`formula`)
 

*Checks if current lemma level is greater or equal to given level.*
- const std::set< `FormulaT` > & `getInformationRelevantFormulas` ()
 

*Checks if current lemma level is greater or equal to given level.*

## Static Protected Member Functions

- static bool `modelsDisjoint` (const `Model` &\_modelA, const `Model` &\_modelB)

*Checks whether there is no variable assigned by both models.*

## Protected Attributes

- `std::vector<FormulaSetT> mInfeasibleSubsets`

*Stores the infeasible subsets.*

- `Manager *const mpManager`

*A reference to the manager.*

- `Model mModel`

*Stores the assignment of the current satisfiable result, if existent.*

- `std::vector<Model> mAllModels`

*Stores all satisfying assignments.*

- `bool mModelComputed`

*True, if the model has already been computed.*

- `bool mFinalCheck`

*true, if the check procedure should perform a final check which especially means not to postpone splitting decisions*

- `bool mFullCheck`

*false, if this module should avoid too expensive procedures and rather return unknown instead.*

- `carl::Variable mObjectiveVariable`

*Objective variable to be minimized. If set to NO\_VARIABLE, a normal sat check should be performed.*

- `std::vector<TheoryPropagation> mTheoryPropagations`

- `std::atomic<Answer> mSolverState`

*States whether the received formula is known to be satisfiable or unsatisfiable otherwise it is set to unknown.*

- `std::atomic_bool * mBackendsFoundAnswer`

*This flag is passed to any backend and if it determines an answer to a prior check call, this flag is fired.*

- `Conditionals mFoundAnswer`

*Vector of Booleans: If any of them is true, we have to terminate a running check procedure.*

- `std::vector<Module *> mUsedBackends`

*The backends of this module which are currently used (conditions to use this module are fulfilled for the passed formula).*

- `std::vector<Module *> mAllBackends`

*The backends of this module which have been used.*

- `std::vector<Lemma> mLemmas`

*Stores the lemmas being valid formulas this module or its backends made.*

- `ModuleInput::iterator mFirstSubformulaToPass`

*Stores the position of the first sub-formula in the passed formula, which has not yet been considered for a consistency check of the backends.*

- `carl::FastSet<FormulaT> mConstraintsToInform`

*Stores the constraints which the backends must be informed about.*

- `carl::FastSet<FormulaT> mInformedConstraints`

*Stores the position of the first constraint of which no backend has been informed about.*

- `ModuleInput::const_iterator mFirstUncheckedReceivedSubformula`

*Stores the position of the first (by this module) unchecked sub-formula of the received formula.*

- `unsigned mSmallerMusesCheckCounter`

*Counter used for the generation of the smt2 files to check for smaller muses.*

- `std::vector<std::size_t> mVariableCounters`

*Maps variables to the number of their occurrences.*

### 0.15.254.1 Member Typedef Documentation

|-----------|--|
| NORMAL    |  |
| PERMANENT |  |

### 0.15.254.3 Constructor & Destructor Documentation

**0.15.254.3.1 IncWidthModule()** template<typename Settings >  
`smtrat::IncWidthModule< Settings >::IncWidthModule` (  
    const `ModuleInput` \* `_formula`,  
    `Conditionals` & `_conditionals`,  
    `Manager` \* `_manager` = `NULL` )

**0.15.254.3.2 ~IncWidthModule()** template<typename Settings >  
`smtrat::IncWidthModule< Settings >::~IncWidthModule` ( )

### 0.15.254.4 Member Function Documentation

**0.15.254.4.1 add()** bool `smtrat::Module::add` (  
    `ModuleInput::const_iterator` `_subformula` ) [inherited]

The module has to take the given sub-formula of the received formula into account.

Parameters

|                          |                                                    |
|--------------------------|----------------------------------------------------|
| <code>_subformula</code> | The sub-formula to take additionally into account. |
|--------------------------|----------------------------------------------------|

Returns

false, if it can be easily decided that this sub-formula causes a conflict with the already considered sub-formulas; true, otherwise.

**0.15.254.4.2 addConstraintToInform()** void `smtrat::Module::addConstraintToInform` (  
    const `FormulaT` & `_constraint` ) [protected], [virtual], [inherited]

Adds a constraint to the collection of constraints of this module, which are informed to a freshly generated backend.

**Parameters**

|                    |                        |
|--------------------|------------------------|
| <i>_constraint</i> | The constraint to add. |
|--------------------|------------------------|

Reimplemented in [smtrat::SATModule< Settings >](#).

**0.15.254.4.3 addCore()** `template<typename Settings >`

```
bool smtrat::IncWidthModule< Settings >::addCore (
 ModuleInput::const_iterator _subformula) [virtual]
```

The module has to take the given sub-formula of the received formula into account.

**Parameters**

|                    |                                                    |
|--------------------|----------------------------------------------------|
| <i>_subformula</i> | The sub-formula to take additionally into account. |
|--------------------|----------------------------------------------------|

**Returns**

false, if it can be easily decided that this sub-formula causes a conflict with the already considered sub-formulas; true, otherwise.

Reimplemented from [smtrat::Module](#).

**0.15.254.4.4 addInformationRelevantFormula()** `void smtrat::Module::addInformationRelevantFormula (`

```
 const FormulaT & formula) [protected], [inherited]
```

Adds a formula to the InformationRelevantFormula.

**Parameters**

|                |                |
|----------------|----------------|
| <i>formula</i> | Formula to add |
|----------------|----------------|

**0.15.254.4.5 addLemma()** `void smtrat::Module::addLemma (`

```
 const FormulaT & _lemma,
```

```
 const LemmaType & _lt = LemmaType::NORMAL,
```

```
 const FormulaT & _preferredFormula = FormulaT(carl::FormulaType::TRUE)) [inline],
```

[inherited]

Stores a lemma being a valid formula.

**Parameters**

|                          |                                                                       |
|--------------------------|-----------------------------------------------------------------------|
| <i>_lemma</i>            | The eduction/lemma to store.                                          |
| <i>_lt</i>               | The type of the lemma.                                                |
| <i>_preferredFormula</i> | Hint for the next decision, which formula should be assigned to true. |

**0.15.254.4.6 addOrigin()** `void smtrat::Module::addOrigin (`

```
 ModuleInput::iterator _formula,
```

```
 const FormulaT & _origin) [inline], [protected], [inherited]
```

Adds the given set of formulas in the received formula to the origins of the given passed formula.

**Parameters**

|                       |                                                           |
|-----------------------|-----------------------------------------------------------|
| <code>_formula</code> | The passed formula to set the origins for.                |
| <code>_origin</code>  | A set of formulas in the received formula of this module. |

**0.15.254.4.7 addReceivedSubformulaToPassedFormula()** `std::pair<ModuleInput::iterator,bool>`

```
smrat::Module::addReceivedSubformulaToPassedFormula (
 ModuleInput::const_iterator _subformula) [inline], [protected], [inherited]
```

Copies the given sub-formula of the received formula to the passed formula.

Note, that there is always a link between sub-formulas of the passed formulas to sub-formulas of the received formulas, which are responsible for its occurrence.

**Parameters**

|                          |                                                  |
|--------------------------|--------------------------------------------------|
| <code>_subformula</code> | The sub-formula of the received formula to copy. |
|--------------------------|--------------------------------------------------|

**0.15.254.4.8 addSubformulaToPassedFormula() [1/3]** `std::pair<ModuleInput::iterator,bool>`

```
smrat::Module::addSubformulaToPassedFormula (
 const FormulaT & _formula) [inline], [protected], [inherited]
```

Adds the given formula to the passed formula with no origin.

Note that in the next call of this module's removeSubformula, all formulas in the passed formula without origins will be removed.

**Parameters**

|                       |                                           |
|-----------------------|-------------------------------------------|
| <code>_formula</code> | The formula to add to the passed formula. |
|-----------------------|-------------------------------------------|

**Returns**

A pair to the position where the formula to add has been inserted (or its first sub-formula which has not yet been in the passed formula, in case the formula to add is a conjunction), and a Boolean stating whether anything has been added to the passed formula.

**0.15.254.4.9 addSubformulaToPassedFormula() [2/3]** `std::pair<ModuleInput::iterator,bool>`

```
smrat::Module::addSubformulaToPassedFormula (
 const FormulaT & _formula,
 const FormulaT & _origin) [inline], [protected], [inherited]
```

Adds the given formula to the passed formula.

**Parameters**

|                       |                                                                                                                           |
|-----------------------|---------------------------------------------------------------------------------------------------------------------------|
| <code>_formula</code> | The formula to add to the passed formula.                                                                                 |
| <code>_origin</code>  | The sub-formula of the received formula being responsible for the occurrence of the formula to add to the passed formula. |

**Returns**

A pair to the position where the formula to add has been inserted (or its first sub-formula which has not yet been in the passed formula, in case the formula to add is a conjunction), and a Boolean stating whether anything has been added to the passed formula.

```
0.15.254.4.10 addSubformulaToPassedFormula() [3/3] std::pair<ModuleInput::iterator,bool>
smrat::Module::addSubformulaToPassedFormula (
 const FormulaT & _formula,
 const std::shared_ptr< std::vector< FormulaT >> & _origins) [inline], [protected],
[inherited]
```

Adds the given formula to the passed formula.

#### Parameters

|                 |                                                                                                                                         |
|-----------------|-----------------------------------------------------------------------------------------------------------------------------------------|
| <i>_formula</i> | The formula to add to the passed formula.                                                                                               |
| <i>_origins</i> | The link of the formula to add to the passed formula to sub-formulas of the received formulas, which are responsible for its occurrence |

#### Returns

A pair to the position where the formula to add has been inserted (or its first sub-formula which has not yet been in the passed formula, in case the formula to add is a conjunction), and a Boolean stating whether anything has been added to the passed formula.

```
0.15.254.4.11 allModels() const std::vector<Model>& smrat::Module::allModels () const [inline],
[inherited]
```

#### Returns

All satisfying assignments, if existent.

```
0.15.254.4.12 anAnswerFound() bool smrat::Module::anAnswerFound () const [inline], [protected],
[inherited]
```

Checks for all antecedent modules and those which run in parallel with the same antecedent modules, whether one of them has determined a result.

#### Returns

True, if one of them has determined a result.

```
0.15.254.4.13 answerFound() const smrat::Conditionals& smrat::Module::answerFound () const
[inline], [inherited]
```

#### Returns

A vector of Booleans: If any of them is true, we have to terminate a running check procedure.

```
0.15.254.4.14 backendsModel() const Model & smrat::Module::backendsModel () const [protected],
[inherited]
```

Stores the model of a backend which determined satisfiability of the passed formula in the model of this module.

---

**0.15.254.4.15** **branchAt()** [1/4] `bool smrat::Module::branchAt (`

```
carl::Variable::Arg _var,
const Rational & _value,
bool _leftCaseWeak = true,
bool _preferLeftCase = true,
bool _useReceivedFormulaAsPremise = false,
const std::vector< FormulaT > & _premise = std::vector<FormulaT>()) [inline],
[protected], [inherited]
```

**0.15.254.4.16** **branchAt()** [2/4] `bool smrat::Module::branchAt (`

```
carl::Variable::Arg _var,
const Rational & _value,
std::vector< FormulaT > && _premise,
bool _leftCaseWeak = true,
bool _preferLeftCase = true,
bool _useReceivedFormulaAsPremise = false) [inline], [protected], [inherited]
```

**0.15.254.4.17** **branchAt()** [3/4] `bool smrat::Module::branchAt (`

```
const Poly & _polynomial,
bool _integral,
const Rational & _value,
bool _leftCaseWeak = true,
bool _preferLeftCase = true,
bool _useReceivedFormulaAsPremise = false,
const std::vector< FormulaT > & _premise = std::vector<FormulaT>()) [inline],
[protected], [inherited]
```

**0.15.254.4.18** **branchAt()** [4/4] `bool smrat::Module::branchAt (`

```
const Poly & _polynomial,
bool _integral,
const Rational & _value,
std::vector< FormulaT > && _premise,
bool _leftCaseWeak = true,
bool _preferLeftCase = true,
bool _useReceivedFormulaAsPremise = false) [protected], [inherited]
```

Adds a lemmas which provoke a branching for the given variable at the given value, if this module returns Unknown and there exists a preceding [SATModule](#).

Note that the given value is rounded down and up, if the given variable is integer-valued.

#### Parameters

|                                           |                                                                                                                                                                                                                |
|-------------------------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>_polynomial</code>                  | The variable to branch for.                                                                                                                                                                                    |
| <code>_integral</code>                    | A flag being true, if all variables in the polynomial to branch for are integral.                                                                                                                              |
| <code>_value</code>                       | The value to branch at.                                                                                                                                                                                        |
| <code>_premise</code>                     | The sub-formulas of the received formula from which the branch is followed. Note, that a premise is not necessary, as every branch is a valid formula. But a premise can prevent from branching unnecessarily. |
| <code>_leftCaseWeak</code>                | true, if a branching in the form of (or ( $\leq p b$ ) ( $> p b$ )) is desired. false, if a branching in the form of (or ( $< p b$ ) ( $\geq p b$ )) is desired.                                               |
| <code>_preferLeftCase</code>              | true, if the left case (polynomial less(or equal) 0 shall be chosen first. false, otherwise.                                                                                                                   |
| <code>_useReceivedFormulaAsPremise</code> | true, if the whole received formula should be used as premise                                                                                                                                                  |

```
0.15.254.4.19 check() Answer smrat::Module::check (
 bool _final = false,
 bool _full = true,
 carl::Variable _objective = carl::Variable::NO_VARIABLE) [virtual], [inherited]
```

Checks the received formula for consistency.

Note, that this is an implementation of the satisfiability check of the conjunction of the so far received formulas, which does actually nothing but passing the problem to its backends. This implementation is only used internally and must be overwritten by any derived module.

#### Parameters

|                   |                                                                                                                                       |
|-------------------|---------------------------------------------------------------------------------------------------------------------------------------|
| <i>_final</i>     | true, if this satisfiability check will be the last one (for a global sat-check), if its result is SAT                                |
| <i>_full</i>      | false, if this module should avoid too expensive procedures and rather return unknown instead.                                        |
| <i>_objective</i> | if not set to NO_VARIABLE, the module should find an assignment minimizing this objective variable; otherwise any assignment is good. |

#### Returns

True, if the received formula is satisfiable; False, if the received formula is not satisfiable; Unknown, otherwise.

Reimplemented in [smrat::PModule](#).

```
0.15.254.4.20 checkCore() template<typename Settings >
Answer smrat::IncWidthModule< Settings >::checkCore () [virtual]
```

Checks the received formula for consistency.

#### Returns

SAT, if the received formula is satisfiable; UNSAT, if the received formula is not satisfiable; Unknown, otherwise.

Reimplemented from [smrat::Module](#).

```
0.15.254.4.21 checkInfeasibleSubsetForMinimality() void smrat::Module::checkInfeasibleSubsetForMinimality (
 std::vector< FormulaSetT >::const_iterator _infssubset,
 const std::string & _filename = "smaller_muses",
 unsigned _maxSizeDifference = 1) const [inherited]
```

Checks the given infeasible subset for minimality by storing all subsets of it, which have a smaller size which differs from the size of the infeasible subset not more than the given threshold.

#### Parameters

|                           |                                                                                                        |
|---------------------------|--------------------------------------------------------------------------------------------------------|
| <i>_infssubset</i>        | The infeasible subset to check for minimality.                                                         |
| <i>_filename</i>          | The name of the file to store the infeasible subsets in order to be able to check their infeasibility. |
| <i>_maxSizeDifference</i> | The maximal difference between the sizes of the subsets compared to the size of the infeasible subset. |

```
0.15.254.4.22 checkModel() unsigned smrat::Module::checkModel () const [protected], [inherited]
```

**Returns**

false, if the current model of this module does not satisfy the current given formula; true, if it cannot be said whether the model satisfies the given formula.

**0.15.254.4.23 cleanModel()** void smtrat::Module::cleanModel ( ) const [inline], [protected], [inherited]

Substitutes variable occurrences by its model value in the model values of other variables.

**0.15.254.4.24 clearLemmas()** void smtrat::Module::clearLemmas ( ) [inline], [inherited]

Deletes all yet found lemmas.

**0.15.254.4.25 clearModel()** void smtrat::Module::clearModel ( ) const [inline], [protected], [inherited]

Clears the assignment, if any was found.

**0.15.254.4.26 clearModels()** void smtrat::Module::clearModels ( ) const [inline], [protected], [inherited]

Clears all assignments, if any was found.

**0.15.254.4.27 clearPassedFormula()** void smtrat::Module::clearPassedFormula ( ) [protected], [inherited]

**0.15.254.4.28 collectOrigins() [1/2]** void smtrat::Module::collectOrigins ( const `FormulaT` & `_formula`, `FormulaSetT` & `_origins` ) const [inherited]

**0.15.254.4.29 collectOrigins() [2/2]** void smtrat::Module::collectOrigins ( const `FormulaT` & `_formula`, `FormulasT` & `_origins` ) const [inherited]

Collects the formulas in the given formula, which are part of the received formula.

If the given formula directly occurs in the received formula, it is inserted into the given set. Otherwise, the given formula must be of type AND and all its sub-formulas part of the received formula. Hence, they will be added to the given set.

**Parameters**

|                       |                                                                                                      |
|-----------------------|------------------------------------------------------------------------------------------------------|
| <code>_formula</code> | The formula from which to collect the formulas being sub-formulas of the received formula (origins). |
| <code>_origins</code> | The set in which to store the origins.                                                               |

**0.15.254.4.30 collectTheoryPropagations()** void smtrat::Module::collectTheoryPropagations ( ) [inherited]

**0.15.254.4.31 constraintsToInform()** const carl::FastSet<`FormulaT`>& smtrat::Module::constraintsToInform ( ) const [inline], [inherited]

**Returns**

The constraints which the backends must be informed about.

**0.15.254.4.32 currentlySatisfied()** `virtual unsigned smtrat::Module::currentlySatisfied ( const FormulaT & ) const [inline], [virtual], [inherited]`

**Returns**

0, if the given formula is conflicted by the current model; 1, if the given formula is satisfied by the current model; 2, otherwise; 3, if we do not know anything (default)

Reimplemented in [smtrat::LRAModule< Settings >](#), [smtrat::LRAModule< LRASettingsICP >](#), and [smtrat::LRAModule< LRASettings >](#)

**0.15.254.4.33 currentlySatisfiedByBackend()** `unsigned smtrat::Module::currentlySatisfiedByBackend ( const FormulaT & _formula ) const [inherited]`

**Returns**

0, if the given formula is conflicted by the current model; 1, if the given formula is satisfied by the current model; 2, otherwise 3, if we do not know anything (default)

**0.15.254.4.34 deinform()** `void smtrat::Module::deinform ( const FormulaT & _constraint ) [inherited]`

The inverse of informing about a constraint.

All data structures which were kept regarding this constraint are going to be removed. Note, that this makes only sense if it is not likely enough that a formula with this constraint must be solved again.

**Parameters**

|                          |                                                         |
|--------------------------|---------------------------------------------------------|
| <code>_constraint</code> | The constraint to remove from internal data structures. |
|--------------------------|---------------------------------------------------------|

**0.15.254.4.35 deinformCore()** `virtual void smtrat::Module::deinformCore ( const FormulaT & _constraint ) [inline], [protected], [virtual], [inherited]`

The inverse of informing about a constraint.

All data structures which were kept regarding this constraint are going to be removed. Note, that this makes only sense if it is not likely enough that a formula with this constraint must be solved again.

**Parameters**

|                          |                                                         |
|--------------------------|---------------------------------------------------------|
| <code>_constraint</code> | The constraint to remove from internal data structures. |
|--------------------------|---------------------------------------------------------|

Reimplemented in [smtrat::LRAModule< Settings >](#), [smtrat::LRAModule< LRASettingsICP >](#), and [smtrat::LRAModule< LRASettings >](#)

**0.15.254.4.36 determine\_smallest\_origin()** `size_t smtrat::Module::determine_smallest_origin ( const std::vector< FormulaT > & origins ) const [protected], [inherited]`

**Parameters**

|                      |                              |
|----------------------|------------------------------|
| <code>origins</code> | A vector of sets of origins. |
|----------------------|------------------------------|

**Returns**

The index of the smallest (regarding the size of the sets) element of origins

**0.15.254.4.37 eraseSubformulaFromPassedFormula()** `ModuleInput::iterator smtrat::Module::eraseSubformulaFromPassedFormula (`

```
 ModuleInput::iterator _subformula,
 bool _ignoreOrigins = false) [protected], [virtual], [inherited]
```

Removes everything related to the sub-formula to remove from the passed formula in the backends of this module. Afterwards the sub-formula is removed from the passed formula.

**Parameters**

|                             |                                                                                                              |
|-----------------------------|--------------------------------------------------------------------------------------------------------------|
| <code>_subformula</code>    | The sub-formula to remove from the passed formula.                                                           |
| <code>_ignoreOrigins</code> | True, if the sub-formula shall be removed regardless of its origins (should only be applied with expertise). |

**Returns**

Reimplemented in `smtrat::ICPModule< Settings >`, `smtrat::ICPModule< ICPSettings4 >`, and `smtrat::ICPModule< ICPSettings1 >`.

**0.15.254.4.38 excludeNotReceivedVariablesFromModel()** `void smtrat::Module::excludeNotReceivedVariablesFromModel ( ) const [inherited]`

Excludes all variables from the current model, which do not occur in the received formula.

**0.15.254.4.39 findBestOrigin()** `std::vector< FormulaT >::const_iterator smtrat::Module::findBestOrigin (`

```
 const std::vector< FormulaT > & _origins) const [protected], [inherited]
```

**Parameters**

|                       |  |
|-----------------------|--|
| <code>_origins</code> |  |
|-----------------------|--|

**Returns****0.15.254.4.40 firstSubformulaToPass()** `ModuleInput::const_iterator smtrat::Module::firstSubformulaToPass ( ) const [inline], [inherited]`**Returns**

The position of the first sub-formula in the passed formula, which has not yet been considered for a consistency check of the backends.

**0.15.254.4.41 firstUncheckedReceivedSubformula()** `ModuleInput::const_iterator smtrat::Module::firstUncheckedReceivedSubformula ( ) const [inline], [inherited]`**Returns**

The position of the first (by this module) unchecked sub-formula of the received formula.

**0.15.254.4.42 freeSplittingVariable()** static void smtrat::Module::freeSplittingVariable ( const `FormulaT` & `_splittingVariable` ) [inline], [static], [inherited]

**0.15.254.4.43 generateTrivialInfeasibleSubset()** void smtrat::Module::generateTrivialInfeasibleSubset ( ) [inline], [protected], [inherited]  
Stores the trivial infeasible subset being the set of received formulas.

**0.15.254.4.44 getBackendsAllModels()** void smtrat::Module::getBackendsAllModels ( ) const [protected], [inherited]  
Stores all models of a backend in the list of all models of this module.

**0.15.254.4.45 getBackendsModel()** void smtrat::Module::getBackendsModel ( ) const [protected], [inherited]

**0.15.254.4.46 getInfeasibleSubsets() [1/2]** void smtrat::Module::getInfeasibleSubsets ( ) [protected], [inherited]  
Copies the infeasible subsets of the passed formula.

**0.15.254.4.47 getInfeasibleSubsets() [2/2]** std::vector< `FormulaSetT` > smtrat::Module::getInfeasibleSubsets ( const `Module` & `_backend` ) const [protected], [inherited]

Get the infeasible subsets the given backend provides.  
Note, that an infeasible subset in a backend contains sub formulas of the passed formula and an infeasible subset of this module contains sub formulas of the received formula. In this method the LATTER is returned.

#### Parameters

|                       |                                                          |
|-----------------------|----------------------------------------------------------|
| <code>_backend</code> | The backend from which to obtain the infeasible subsets. |
|-----------------------|----------------------------------------------------------|

#### Returns

The infeasible subsets the given backend provides.

**0.15.254.4.48 getInformationRelevantFormulas()** const std::set< `FormulaT` > & smtrat::Module::getInformationRelevantFormulas ( ) [protected], [inherited]  
Gets all InformationRelevantFormulas.

#### Returns

Set of all formulas

**0.15.254.4.49 getModelEqualities()** std::list< std::vector< `carl::Variable` > > smtrat::Module::getModelEqualities ( ) const [virtual], [inherited]

Partition the variables from the current model into equivalence classes according to their assigned value.  
The result is a set of equivalence classes of variables where all variables within one class are assigned the same value. Note that the number of classes may not be minimal, i.e. two classes may actually be equivalent.

#### Returns

Equivalence classes.

**0.15.254.4.50 getOrigins() [1/3]** void smtrat::Module::getOrigins ( const FormulaT & \_formula, FormulaSetT & \_origins ) const [inline], [protected], [inherited]

**Parameters**

|          |  |
|----------|--|
| _formula |  |
| _origins |  |

**0.15.254.4.51 getOrigins() [2/3]** void smtrat::Module::getOrigins ( const FormulaT & \_formula, FormulasT & \_origins ) const [inline], [protected], [inherited]

**Parameters**

|          |  |
|----------|--|
| _formula |  |
| _origins |  |

**0.15.254.4.52 getOrigins() [3/3]** const FormulaT& smtrat::Module::getOrigins ( ModuleInput::const\_iterator \_formula ) const [inline], [protected], [inherited]

Gets the origins of the passed formula at the given position.

**Parameters**

|          |                                                   |
|----------|---------------------------------------------------|
| _formula | The position of a formula in the passed formulas. |
|----------|---------------------------------------------------|

**Returns**

The origins of the passed formula at the given position.

**0.15.254.4.53 getReceivedFormulaSimplified()** std::pair< bool, FormulaT > smtrat::Module::getReceivedFormulaSimplified ( ) [virtual], [inherited]

**Returns**

A pair of a Boolean and a formula, where the Boolean is true, if the received formula could be simplified to an equisatisfiable formula. The formula is equisatisfiable to this module's received formula, if the Boolean is true.

Reimplemented in [smtrat::PModule](#).

**0.15.254.4.54 hasLemmas()** bool smtrat::Module::hasLemmas ( ) [inline], [inherited]

Checks whether this module or any of its backends provides any lemmas.

**0.15.254.4.55 hasValidInfeasibleSubset()** bool smtrat::Module::hasValidInfeasibleSubset ( ) const [inherited]

**Returns**

true, if the module has at least one valid infeasible subset, that is all its elements are sub-formulas of the received formula (pointer must be equal).

**0.15.254.4.56 `id()`** `std::size_t smtrat::Module::id () const [inline], [inherited]`

**Returns**

A unique ID to identify this module instance.

**0.15.254.4.57 `infeasibleSubsets()`** `const std::vector<FormulaSetT>& smtrat::Module::infeasibleSubsets () const [inline], [inherited]`

**Returns**

The infeasible subsets of the set of received formulas (empty, if this module has not detected unsatisfiability of the conjunction of received formulas).

**0.15.254.4.58 `inform()`** `bool smtrat::Module::inform (const FormulaT & _constraint) [inherited]`

Informs the module about the given constraint.

It should be tried to inform this module about any constraint it could receive eventually before assertSubformula is called (preferably for the first time, but at least before adding a formula containing that constraint).

**Parameters**

|                          |                                 |
|--------------------------|---------------------------------|
| <code>_constraint</code> | The constraint to inform about. |
|--------------------------|---------------------------------|

**Returns**

false, if it can be easily decided whether the given constraint is inconsistent; true, otherwise.

**0.15.254.4.59 `informBackends()`** `void smtrat::Module::informBackends (const FormulaT & _constraint) [inline], [protected], [inherited]`

Informs all backends of this module about the given constraint.

**Parameters**

|                          |                                 |
|--------------------------|---------------------------------|
| <code>_constraint</code> | The constraint to inform about. |
|--------------------------|---------------------------------|

**0.15.254.4.60 `informCore()`** `virtual bool smtrat::Module::informCore (const FormulaT & _constraint) [inline], [protected], [virtual], [inherited]`

Informs the module about the given constraint.

It should be tried to inform this module about any constraint it could receive eventually before assertSubformula is called (preferably for the first time, but at least before adding a formula containing that constraint).

**Parameters**

|                          |                                 |
|--------------------------|---------------------------------|
| <code>_constraint</code> | The constraint to inform about. |
|--------------------------|---------------------------------|

**Returns**

false, if it can be easily decided whether the given constraint is inconsistent; true, otherwise.

Reimplemented in [smtrat::UnionFindModule< Settings >](#), [smtrat::PBPPModule< Settings >](#), [smtrat::PBGaussModule< Settings >](#), [smtrat::NRAILModule< Settings >](#), [smtrat::NewCoveringModule< Settings >](#), [smtrat::NewCADModule< Settings >](#),

`smrat::LRAModule< Settings >, smrat::LRAModule< LRASettingsICP >, smrat::LRAModule< LRASettings1 >, smrat::IntBlastModule< Settings >, smrat::FPPModule< Settings >, smrat::EQModule< Settings >, smrat::CurryModule< Settings >, smrat::BVMModule< Settings >, smrat::ICPModule< Settings >, smrat::ICPModule< ICPSettings4 >, and smrat::ICPModule< ICPSettings1 >.`

**0.15.254.4.61 informedConstraints()** `const carl::FastSet<FormulaT>& smrat::Module::informedConstraints( ) const [inline], [inherited]`

**Returns**

The position of the first constraint of which no backend has been informed about.

**0.15.254.4.62 init()** `void smrat::Module::init( ) [virtual], [inherited]`

Informs all backends about the so far encountered constraints, which have not yet been communicated.

This method must not be called twice and only before the first runBackends call.

Reimplemented in `smrat::PBPPModule< Settings >, smrat::PBGaussModule< Settings >, smrat::NRAILModule< Settings >, smrat::NewCoveringModule< Settings >, smrat::NewCADModule< Settings >, smrat::LRAModule< Settings >, smrat::LRAModule< LRASettingsICP >, smrat::LRAModule< LRASettings1 >, smrat::IntBlastModule< Settings >, smrat::FPPModule< Settings >, smrat::EQModule< Settings >, smrat::CurryModule< Settings >, and smrat::BVMModule< Settings >.`

**0.15.254.4.63 is\_minimizing()** `bool smrat::Module::is_minimizing( ) const [inline], [inherited]`

**0.15.254.4.64 isLemmaLevel()** `bool smrat::Module::isLemmaLevel( LemmaLevel level ) [protected], [inherited]`

Checks if current lemma level is greater or equal to given level.

**Parameters**

|                    |                 |
|--------------------|-----------------|
| <code>level</code> | Level to check. |
|--------------------|-----------------|

**0.15.254.4.65 isPreprocessor()** `bool smrat::Module::isPreprocessor( ) const [inline], [inherited]`

**Returns**

true, if this module is a preprocessor that is a module, which simplifies its received formula to an equisatisfiable formula being passed to its backends. The simplified formula can be obtained with `getReceivedFormulaSimplified()`.

**0.15.254.4.66 lemmas()** `const std::vector<Lemma>& smrat::Module::lemmas( ) const [inline], [inherited]`

**Returns**

A constant reference to the lemmas being valid formulas this module or its backends made.

**0.15.254.4.67 merge()** `std::vector< FormulaT > smrat::Module::merge( const std::vector< FormulaT > & _vecSetA, const std::vector< FormulaT > & _vecSetB ) const [protected], [inherited]`

Merges the two vectors of sets into the first one.

({a,b},{a,c}) and ({b,d},{b}) -> ({a,b,d},{a,b},{a,b,c,d},{a,b,c})

**Parameters**

|                       |                                  |
|-----------------------|----------------------------------|
| <code>_vecSetA</code> | A vector of sets of constraints. |
| <code>_vecSetB</code> | A vector of sets of constraints. |

**Returns**

The vector being the two given vectors merged.

**0.15.254.4.68 `model()`** `const Model& smtrat::Module::model( ) const [inline], [inherited]`**Returns**

The assignment of the current satisfiable result, if existent.

**0.15.254.4.69 `modelsDisjoint()`** `bool smtrat::Module::modelsDisjoint( const Model & _modelA, const Model & _modelB ) [static], [protected], [inherited]`

Checks whether there is no variable assigned by both models.

**Parameters**

|                      |                                |
|----------------------|--------------------------------|
| <code>_modelA</code> | The first model to check for.  |
| <code>_modelB</code> | The second model to check for. |

**Returns**

true, if there is no variable assigned by both models; false, otherwise.

**0.15.254.4.70 `moduleName()`** `template<typename Settings> std::string smtrat::IncWidthModule< Settings >::moduleName( ) const [inline], [virtual]`**Returns**

The name of the given module type as name.

Reimplemented from [smtrat::Module](#).

**0.15.254.4.71 `objective()`** `carl::Variable smtrat::Module::objective( ) const [inline], [inherited]`**0.15.254.4.72 `originInReceivedFormula()`** `bool smtrat::Module::originInReceivedFormula( const FormulaT & _origin ) const [protected], [inherited]`**0.15.254.4.73 `passedFormulaBegin()`** `ModuleInput::iterator smtrat::Module::passedFormulaBegin( ) [inline], [protected], [inherited]`**Returns**

An iterator to the end of the passed formula. TODO: disable this method

**0.15.254.4.74 passedFormulaEnd()** `ModuleInput::iterator smtrat::Module::passedFormulaEnd ()`  
[inline], [protected], [inherited]

**Returns**

An iterator to the end of the passed formula.

**0.15.254.4.75 pPassedFormula()** `const ModuleInput* smtrat::Module::pPassedFormula () const`  
[inline], [inherited]

**Returns**

A pointer to the formula passed to the backends of this module.

**0.15.254.4.76 pReceivedFormula()** `const ModuleInput* smtrat::Module::pReceivedFormula () const`  
[inline], [inherited]

**Returns**

A pointer to the formula passed to this module.

**0.15.254.4.77 print()** `void smtrat::Module::print (`  
`const std::string & _initiation = "***" ) const` [inherited]  
Prints everything relevant of the solver.

**Parameters**

|                          |                      |
|--------------------------|----------------------|
| <code>_initiation</code> | The line initiation. |
|--------------------------|----------------------|

**0.15.254.4.78 printAllModels()** `void smtrat::Module::printAllModels (`  
`std::ostream & _out = std::cout )` [inherited]

Prints all assignments of this module satisfying its received formula if it satisfiable and this module could find an assignment.

**Parameters**

|                   |                                        |
|-------------------|----------------------------------------|
| <code>_out</code> | The stream to print the assignment on. |
|-------------------|----------------------------------------|

**0.15.254.4.79 printInfeasibleSubsets()** `void smtrat::Module::printInfeasibleSubsets (`  
`const std::string & _initiation = "***" ) const` [inherited]

Prints the infeasible subsets.

**Parameters**

|                          |                      |
|--------------------------|----------------------|
| <code>_initiation</code> | The line initiation. |
|--------------------------|----------------------|

**0.15.254.4.80 printModel()** `void smtrat::Module::printModel (`  
`std::ostream & _out = std::cout ) const` [inherited]

Prints the assignment of this module satisfying its received formula if it satisfiable and this module could find an assignment.

Parameters

|                   |                                        |
|-------------------|----------------------------------------|
| <code>_out</code> | The stream to print the assignment on. |
|-------------------|----------------------------------------|

**0.15.254.4.81 `printPassedFormula()`** `void smtrat::Module::printPassedFormula ( const std::string & _initiation = "***" ) const [inherited]`

Prints the vector of passed formula.

Parameters

|                          |                      |
|--------------------------|----------------------|
| <code>_initiation</code> | The line initiation. |
|--------------------------|----------------------|

**0.15.254.4.82 `printReceivedFormula()`** `void smtrat::Module::printReceivedFormula ( const std::string & _initiation = "***" ) const [inherited]`

Prints the vector of the received formula.

Parameters

|                          |                      |
|--------------------------|----------------------|
| <code>_initiation</code> | The line initiation. |
|--------------------------|----------------------|

**0.15.254.4.83 `probablyLooping()`** `bool smtrat::Module::probablyLooping ( const typename Poly::PolyType & _branchingPolynomial, const Rational & _branchingValue ) const [protected], [inherited]`

Checks whether given the current branching value and branching variable/polynomial it is (highly) probable that this branching is part of an infinite loop of branchings.

Parameters

|                                   |                                                                                     |
|-----------------------------------|-------------------------------------------------------------------------------------|
| <code>_branchingPolynomial</code> | The polynomial to branch at (in most branching strategies this is just a variable). |
| <code>_branchingValue</code>      | The value to branch at.                                                             |

Returns

true, if this branching is probably part of an infinite loop of branchings; false, otherwise.

**0.15.254.4.84 `receivedFormulaChecked()`** `void smtrat::Module::receivedFormulaChecked ( ) [inline], [inherited]`

Notifies that the received formulas has been checked.

**0.15.254.4.85 `receivedFormulasAsInfeasibleSubset()`** `void smtrat::Module::receivedFormulasAs<-InfeasibleSubset ( ModuleInput::const_iterator _subformula ) [inline], [protected], [inherited]`

Stores an infeasible subset consisting only of the given received formula.

**0.15.254.4.86 receivedVariable()** `bool smrat::Module::receivedVariable ( carl::Variable::Arg _var ) const [inline], [inherited]`

**0.15.254.4.87 remove()** `void smrat::Module::remove ( ModuleInput::const_iterator _subformula ) [virtual], [inherited]`

Removes everything related to the given sub-formula of the received formula.

However, it is desired not to lose track of search spaces where no satisfying assignment can be found for the remaining sub-formulas.

#### Parameters

|                          |                                                    |
|--------------------------|----------------------------------------------------|
| <code>_subformula</code> | The sub formula of the received formula to remove. |
|--------------------------|----------------------------------------------------|

Reimplemented in [smrat::PModule](#).

**0.15.254.4.88 removeCore()** `template<typename Settings > void smrat::IncWidthModule< Settings >::removeCore ( ModuleInput::const_iterator _subformula ) [virtual]`

Removes the subformula of the received formula at the given position to the considered ones of this module.

Note that this includes every stored calculation which depended on this subformula, but should keep the other stored calculation, if possible, untouched.

#### Parameters

|                          |                                           |
|--------------------------|-------------------------------------------|
| <code>_subformula</code> | The position of the subformula to remove. |
|--------------------------|-------------------------------------------|

Reimplemented from [smrat::Module](#).

**0.15.254.4.89 removeOrigin()** `std::pair<ModuleInput::iterator,bool> smrat::Module::removeOrigin ( ModuleInput::iterator _formula, const FormulaT & _origin ) [inline], [protected], [inherited]`

**0.15.254.4.90 removeOrigins()** `std::pair<ModuleInput::iterator,bool> smrat::Module::removeOrigins ( ModuleInput::iterator _formula, const std::shared_ptr< std::vector< FormulaT >> & _origins ) [inline], [protected], [inherited]`

**0.15.254.4.91 rPassedFormula()** `const ModuleInput& smrat::Module::rPassedFormula ( ) const [inline], [inherited]`

#### Returns

A reference to the formula passed to the backends of this module.

**0.15.254.4.92 rReceivedFormula()** `const ModuleInput& smrat::Module::rReceivedFormula ( ) const [inline], [inherited]`

**Returns**

A reference to the formula passed to this module.

**0.15.254.4.93 runBackends() [1/2]** `virtual Answer smtrat::Module::runBackends () [inline], [protected], [virtual], [inherited]`

Reimplemented in [smtrat::PModule](#).

**0.15.254.4.94 runBackends() [2/2]** `Answer smtrat::Module::runBackends (`

```
 bool _final,
 bool _full,
 carl::Variable _objective) [protected], [virtual], [inherited]
```

Runs the backend solvers on the passed formula.

**Parameters**

|                         |                                                                                                                                       |
|-------------------------|---------------------------------------------------------------------------------------------------------------------------------------|
| <code>_final</code>     | true, if this satisfiability check will be the last one (for a global sat-check), if its result is SAT                                |
| <code>_full</code>      | false, if this module should avoid too expensive procedures and rather return unknown instead.                                        |
| <code>_objective</code> | if not set to NO_VARIABLE, the module should find an assignment minimizing this objective variable; otherwise any assignment is good. |

**Returns**

True, if the passed formula is consistent; False, if the passed formula is inconsistent; Unknown, otherwise.

Reimplemented in [smtrat::PModule](#).

**0.15.254.4.95 setId()** `void smtrat::Module::setId (`

```
 std::size_t _id) [inline], [inherited]
```

Sets this modules unique ID to identify itself.

**Parameters**

|                   |                                    |
|-------------------|------------------------------------|
| <code>↔ id</code> | The id to set this module's id to. |
|-------------------|------------------------------------|

**0.15.254.4.96 setThreadPriority()** `void smtrat::Module::setThreadPriority (`

```
 thread_priority _threadPriority) [inline], [inherited]
```

Sets the priority of this module to get a thread for running its check procedure.

**Parameters**

|                              |                                                       |
|------------------------------|-------------------------------------------------------|
| <code>_threadPriority</code> | The priority to set this module's thread priority to. |
|------------------------------|-------------------------------------------------------|

**0.15.254.4.97 solverState()** `Answer smtrat::Module::solverState () const [inline], [inherited]`

**Returns**

True, if this module is in a state, such that it has found a solution for its received formula; False, if this module is in a state, such that it has determined that there is no solution for its received formula; Unknown, otherwise.

**0.15.254.4.98 splitUnequalConstraint()** `void smtrat::Module::splitUnequalConstraint (`

`const FormulaT & _unequalConstraint ) [protected], [inherited]`

Adds the following lemmas for the given constraint  $p \neq 0$ .

$(p \neq 0 \leftrightarrow (p < 0 \text{ or } p > 0))$

and  $\neg(p < 0 \text{ and } p > 0)$

**Parameters**

|                                 |                                                  |
|---------------------------------|--------------------------------------------------|
| <code>_unequalConstraint</code> | A constraint having the relation symbol $\neq$ . |
|---------------------------------|--------------------------------------------------|

**0.15.254.4.99 threadPriority()** `thread_priority smtrat::Module::threadPriority ( ) const [inline], [inherited]`**Returns**

The priority of this module to get a thread for running its check procedure.

**0.15.254.4.100 updateAllModels()** `void smtrat::Module::updateAllModels ( ) [virtual], [inherited]`

Updates all satisfying models, if the solver has detected the consistency of the received formula, beforehand.

Reimplemented in [smtrat::SATModule< Settings >](#).

**0.15.254.4.101 updateLemmas()** `void smtrat::Module::updateLemmas ( ) [inherited]`

Stores all lemmas of any backend of this module in its own lemma vector.

**0.15.254.4.102 updateModel()** `template<typename Settings >`

`void smtrat::IncWidthModule< Settings >::updateModel ( ) const [virtual]`

Updates the current assignment into the model.

Note, that this is a unique but possibly symbolic assignment maybe containing newly introduced variables.

Reimplemented from [smtrat::Module](#).

**0.15.254.4.103 usedBackends()** `const std::vector<Module*>& smtrat::Module::usedBackends ( )`

`const [inline], [inherited]`

**Returns**

The backends of this module which are currently used (conditions to use this module are fulfilled for the passed formula).

**0.15.254.5 Field Documentation****0.15.254.5.1 mAllBackends** `std::vector<Module*> smtrat::Module::mAllBackends [protected], [inherited]`

The backends of this module which have been used.

**0.15.254.5.2 mAllModels** `std::vector<Model>` `smtrat::Module::mAllModels` [mutable], [protected], [inherited]  
Stores all satisfying assignments.

**0.15.254.5.3 mBackendsFoundAnswer** `std::atomic_bool*` `smtrat::Module::mBackendsFoundAnswer` [protected], [inherited]  
This flag is passed to any backend and if it determines an answer to a prior check call, this flag is fired.

**0.15.254.5.4 mConstraintsToInform** `carl::FastSet<FormulaT>` `smtrat::Module::mConstraintsToInform` [protected], [inherited]  
Stores the constraints which the backends must be informed about.

**0.15.254.5.5 mFinalCheck** `bool` `smtrat::Module::mFinalCheck` [protected], [inherited]  
true, if the check procedure should perform a final check which especially means not to postpone splitting decisions

**0.15.254.5.6 mFirstPosInLastBranches** `std::size_t` `smtrat::Module::mFirstPosInLastBranches` = 0 [static], [inherited]  
The beginning of the cyclic buffer storing the last branches.

**0.15.254.5.7 mFirstSubformulaToPass** `ModuleInput::iterator` `smtrat::Module::mFirstSubformulaToPass` [protected], [inherited]  
Stores the position of the first sub-formula in the passed formula, which has not yet been considered for a consistency check of the backends.

**0.15.254.5.8 mFirstUncheckedReceivedSubformula** `ModuleInput::const_iterator` `smtrat::Module::mFirstUncheckedReceivedSubformula` [protected], [inherited]  
Stores the position of the first (by this module) unchecked sub-formula of the received formula.

**0.15.254.5.9 mFoundAnswer** `Conditionals` `smtrat::Module::mFoundAnswer` [protected], [inherited]  
Vector of Booleans: If any of them is true, we have to terminate a running check procedure.

**0.15.254.5.10 mFullCheck** `bool` `smtrat::Module::mFullCheck` [protected], [inherited]  
false, if this module should avoid too expensive procedures and rather return unknown instead.

**0.15.254.5.11 mInfeasibleSubsets** `std::vector<FormulaSetT>` `smtrat::Module::mInfeasibleSubsets` [protected], [inherited]  
Stores the infeasible subsets.

**0.15.254.5.12 mInformedConstraints** `carl::FastSet<FormulaT>` `smtrat::Module::mInformedConstraints` [protected], [inherited]  
Stores the position of the first constraint of which no backend has been informed about.

**0.15.254.5.13 mLastBranches** std::vector< Branching > smtrat::Module::mLastBranches = std::vector<Branching> (mNumOfBranchVarsToStore, Branching(typename Poly::PolyType(), 0)) [static], [inherited]

Stores the last branches in a cycle buffer.

**0.15.254.5.14 mLemmas** std::vector<Lemma> smtrat::Module::mLemmas [protected], [inherited]

Stores the lemmas being valid formulas this module or its backends made.

**0.15.254.5.15 mModel** Model smtrat::Module::mModel [mutable], [protected], [inherited]

Stores the assignment of the current satisfiable result, if existent.

**0.15.254.5.16 mModelComputed** bool smtrat::Module::mModelComputed [mutable], [protected], [inherited]

True, if the model has already been computed.

**0.15.254.5.17 mNumOfBranchVarsToStore** std::size\_t smtrat::Module::mNumOfBranchVarsToStore =

5 [static], [inherited]

The number of different variables to consider for a probable infinite loop of branchings.

**0.15.254.5.18 mObjectiveVariable** carl::Variable smtrat::Module::mObjectiveVariable [protected], [inherited]

Objective variable to be minimized. If set to NO\_VARIABLE, a normal sat check should be performed.

**0.15.254.5.19 mOldSplittingVariables** std::vector< FormulaT > smtrat::Module::mOldSplittingVariables [static], [inherited]

Reusable splitting variables.

**0.15.254.5.20 mpManager** Manager\* const smtrat::Module::mpManager [protected], [inherited]

A reference to the manager.

**0.15.254.5.21 mSmallerMusesCheckCounter** unsigned smtrat::Module::mSmallerMusesCheckCounter [mutable], [protected], [inherited]

Counter used for the generation of the smt2 files to check for smaller muses.

**0.15.254.5.22 mSolverState** std::atomic<Answer> smtrat::Module::mSolverState [protected], [inherited]

States whether the received formula is known to be satisfiable or unsatisfiable otherwise it is set to unknown.

**0.15.254.5.23 mTheoryPropagations** std::vector<TheoryPropagation> smtrat::Module::mTheoryPropagations [protected], [inherited]

**0.15.254.5.24 mUsedBackends** std::vector<Module\*> smrat::Module::mUsedBackends [protected], [inherited]

The backends of this module which are currently used (conditions to use this module are fulfilled for the passed formula).

**0.15.254.5.25 mVariableCounters** std::vector<std::size\_t> smrat::Module::mVariableCounters [protected], [inherited]

Maps variables to the number of their occurrences.

**0.15.255 smrat::parser::IndexedFunctionInstantiator Struct Reference**

```
0.15.260.3.4 position template<typename T1 , typename T2 >
ModuleInput::iterator smrat::lra::Bound< T1, T2 >::Info::position
The position of this bounds constraint in a formula, if it has been processed already.
Otherwise it points to the end of a formula.
```

```
0.15.260.3.5 updated template<typename T1 , typename T2 >
int smrat::lra::Bound< T1, T2 >::Info::updated
A value to store the information whether this bounds constraint has already been processed (=0), must be processed
(>0) or must be removed from consideration (<0).
```

### Static Public Attributes

- static size\_t `mNumOfBranchVarsToStore` = 5
  - The number of different variables to consider for a probable infinite loop of branchings.*
- static std::vector< Branching > `mLastBranches` = std::vector<Branching>(mNumOfBranchVarsToStore, Branching(typename Poly::PolyType(), 0))
  - Stores the last branches in a cycle buffer.*
- static size\_t `mFirstPosInLastBranches` = 0
  - The beginning of the cyclic buffer storing the last branches.*
- static std::vector< FormulaT > `mOldSplittingVariables`
  - Reusable splitting variables.*

### Protected Member Functions

- virtual void `deinformCore (const FormulaT &_constraint)`
  - The inverse of informing about a constraint.*
- bool `anAnswerFound () const`
  - Checks for all antecedent modules and those which run in parallel with the same antecedent modules, whether one of them has determined a result.*
- void `clearModel () const`
  - Clears the assignment, if any was found.*
- void `clearModels () const`
  - Clears all assignments, if any was found.*
- void `cleanModel () const`

- Substitutes variable occurrences by its model value in the model values of other variables.*
- `ModuleInput::iterator passedFormulaBegin ()`
  - `ModuleInput::iterator passedFormulaEnd ()`
  - `void addOrigin (ModuleInput::iterator _formula, const FormulaT &_origin)`

*Adds the given set of formulas in the received formula to the origins of the given passed formula.*
  - `const FormulaT & getOrigins (ModuleInput::const_iterator _formula) const`

*Gets the origins of the passed formula at the given position.*
  - `void getOrigins (const FormulaT &_formula, FormulasT &_origins) const`
  - `void getOrigins (const FormulaT &_formula, FormulaSetT &_origins) const`
  - `std::pair< ModuleInput::iterator, bool > removeOrigin (ModuleInput::iterator _formula, const FormulaT &_origin)`
  - `std::pair< ModuleInput::iterator, bool > removeOrigins (ModuleInput::iterator _formula, const std::shared_ptr< std::vector< FormulaT >> &_origins)`
  - `void informBackends (const FormulaT &_constraint)`

*Informs all backends of this module about the given constraint.*
  - `virtual void addConstraintToInform (const FormulaT &_constraint)`

*Adds a constraint to the collection of constraints of this module, which are informed to a freshly generated backend.*
  - `std::pair< ModuleInput::iterator, bool > addReceivedSubformulaToPassedFormula (ModuleInput::const_iterator _subformula)`

*Copies the given sub-formula of the received formula to the passed formula.*
  - `bool originInReceivedFormula (const FormulaT &_origin) const`
  - `std::pair< ModuleInput::iterator, bool > addSubformulaToPassedFormula (const FormulaT &_formula)`

*Adds the given formula to the passed formula with no origin.*
  - `std::pair< ModuleInput::iterator, bool > addSubformulaToPassedFormula (const FormulaT &_formula, const std::shared_ptr< std::vector< FormulaT >> &_origins)`

*Adds the given formula to the passed formula.*
  - `std::pair< ModuleInput::iterator, bool > addSubformulaToPassedFormula (const FormulaT &_formula, const FormulaT &_origin)`

*Adds the given formula to the passed formula.*
  - `void generateTrivialInfeasibleSubset ()`

*Stores the trivial infeasible subset being the set of received formulas.*
  - `void receivedFormulasAsInfeasibleSubset (ModuleInput::const_iterator _subformula)`

*Stores an infeasible subset consisting only of the given received formula.*
  - `std::vector< FormulaT >::const_iterator findBestOrigin (const std::vector< FormulaT > &_origins) const`
  - `void getInfeasibleSubsets ()`

*Copies the infeasible subsets of the passed formula.*
  - `std::vector< FormulaSetT > getInfeasibleSubsets (const Model & backend) const`

*Get the infeasible subsets the given backend provides.*
  - `const Model & backendsModel () const`

*Stores the model of a backend which determined satisfiability of the passed formula in the model of this module.*
  - `void getBackendsModel () const`
  - `void getBackendsAllModels () const`

*Stores all models of a backend in the list of all models of this module.*
  - `virtual Answer runBackends (bool _final, bool _full, carl::Variable _objective)`

*Runs the backend solvers on the passed formula.*
  - `virtual Answer runBackends ()`
  - `virtual ModuleInput::iterator eraseSubformulaFromPassedFormula (ModuleInput::iterator _subformula, bool _ignoreOrigins=false)`

*Removes everything related to the sub-formula to remove from the passed formula in the backends of this module.*
  - `void clearPassedFormula ()`
  - `std::vector< FormulaT > merge (const std::vector< FormulaT > &, const std::vector< FormulaT > &) const`

*Merges the two vectors of sets into the first one.*

- size\_t `determine_smallest_origin` (const std::vector< `FormulaT` > &origins) const
- bool `probablyLooping` (const typename `Poly::PolyType` &`_branchingPolynomial`, const `Rational` &`_branchingValue`) const
 

*Checks whether given the current branching value and branching variable/polynomial it is (highly) probable that this branching is part of an infinite loop of branchings.*
- bool `branchAt` (const `Poly` &`_polynomial`, bool `_integral`, const `Rational` &`_value`, std::vector< `FormulaT` > &&`_premise`, bool `_leftCaseWeak=true`, bool `_preferLeftCase=true`, bool `_useReceivedFormulaAsPremise=false`)
 

*Adds a lemmas which provoke a branching for the given variable at the given value, if this module returns Unknown and there exists a preceding `SATModule`.*
- bool `branchAt` (const `Poly` &`_polynomial`, bool `_integral`, const `Rational` &`_value`, bool `_leftCaseWeak=true`, bool `_preferLeftCase=true`, bool `_useReceivedFormulaAsPremise=false`, const std::vector< `FormulaT` > &`_premise=std::vector< FormulaT >()`)
 

*Adds a lemmas which provoke a branching for the given variable at the given value, if this module returns Unknown and there exists a preceding `SATModule`.*
- bool `branchAt` (carl::Variable::Arg `_var`, const `Rational` &`_value`, std::vector< `FormulaT` > &&`_premise`, bool `_leftCaseWeak=true`, bool `_preferLeftCase=true`, bool `_useReceivedFormulaAsPremise=false`)
 

*Adds a lemmas which provoke a branching for the given variable at the given value, if this module returns Unknown and there exists a preceding `SATModule`.*
- bool `branchAt` (carl::Variable::Arg `_var`, const `Rational` &`_value`, bool `_leftCaseWeak=true`, bool `_preferLeftCase=true`, bool `_useReceivedFormulaAsPremise=false`, const std::vector< `FormulaT` > &`_premise=std::vector< FormulaT >()`)
 

*Adds a lemmas which provoke a branching for the given variable at the given value, if this module returns Unknown and there exists a preceding `SATModule`.*
- void `splitUnequalConstraint` (const `FormulaT` &)
 

*Adds the following lemmas for the given constraint `p!=0`.*
- unsigned `checkModel` () const
- void `addInformationRelevantFormula` (const `FormulaT` &`formula`)
 

*Adds a formula to the `InformationRelevantFormula`.*
- const std::set< `FormulaT` > & `getInformationRelevantFormulas` ()
 

*Gets all `InformationRelevantFormulas`.*
- bool `isLemmaLevel` (`LemmaLevel` `level`)
 

*Checks if current lemma level is greater or equal to given level.*

## Static Protected Member Functions

- static bool `modelsDisjoint` (const `Model` &`_modelA`, const `Model` &`_modelB`)
 

*Checks whether there is no variable assigned by both models.*

## Protected Attributes

- std::vector< `FormulaSetT` > `mInfeasibleSubsets`

*Stores the infeasible subsets.*
- `Manager` \*const `mpManager`

*A reference to the manager.*
- `Model` `mModel`

*Stores the assignment of the current satisfiable result, if existent.*
- std::vector< `Model` > `mAllModels`

*Stores all satisfying assignments.*
- bool `mModelComputed`

*True, if the model has already been computed.*
- bool `mFinalCheck`

*true, if the check procedure should perform a final check which especially means not to postpone splitting decisions*
- bool `mFullCheck`

*false, if this module should avoid too expensive procedures and rather return unknown instead.*
- carl::Variable `mObjectiveVariable`

*Objective variable to be minimized. If set to NO\_VARIABLE, a normal sat check should be performed.*
- std::vector< `TheoryPropagation` > `mTheoryPropagations`
- std::atomic< `Answer` > `mSolverState`

*States whether the received formula is known to be satisfiable or unsatisfiable otherwise it is set to unknown.*

- `std::atomic_bool * mBackendsFoundAnswer`  
*This flag is passed to any backend and if it determines an answer to a prior check call, this flag is fired.*
- `Conditionals mFoundAnswer`  
*Vector of Booleans: If any of them is true, we have to terminate a running check procedure.*
- `std::vector< Module * > mUsedBackends`  
*The backends of this module which are currently used (conditions to use this module are fulfilled for the passed formula).*
- `std::vector< Module * > mAllBackends`  
*The backends of this module which have been used.*
- `std::vector< Lemma > mLemmas`  
*Stores the lemmas being valid formulas this module or its backends made.*
- `ModuleInput::iterator mFirstSubformulaToPass`  
*Stores the position of the first sub-formula in the passed formula, which has not yet been considered for a consistency check of the backends.*
- `carl::FastSet< FormulaT > mConstraintsToInform`  
*Stores the constraints which the backends must be informed about.*
- `carl::FastSet< FormulaT > mInformedConstraints`  
*Stores the position of the first constraint of which no backend has been informed about.*
- `ModuleInput::const_iterator mFirstUncheckedReceivedSubformula`  
*Stores the position of the first (by this module) unchecked sub-formula of the received formula.*
- `unsigned mSmallerMusesCheckCounter`  
*Counter used for the generation of the smt2 files to check for smaller muses.*
- `std::vector< std::size_t > mVariableCounters`  
*Maps variables to the number of their occurrences.*

#### 0.15.265.4 Member Function Documentation

**0.15.265.4.1 add()** bool smrat::Module::add (   
`ModuleInput::const_iterator _subformula` ) [inherited]

The module has to take the given sub-formula of the received formula into account.

##### Parameters

|                          |                                                    |
|--------------------------|----------------------------------------------------|
| <code>_subformula</code> | The sub-formula to take additionally into account. |
|--------------------------|----------------------------------------------------|

##### Returns

false, if it can be easily decided that this sub-formula causes a conflict with the already considered sub-formulas; true, otherwise.

**0.15.265.4.2 addConstraintToInform()** void smrat::Module::addConstraintToInform (   
`const FormulaT & _constraint` ) [protected], [virtual], [inherited]

Adds a constraint to the collection of constraints of this module, which are informed to a freshly generated backend.

##### Parameters

|                          |                        |
|--------------------------|------------------------|
| <code>_constraint</code> | The constraint to add. |
|--------------------------|------------------------|

Reimplemented in [smrat::SATModule< Settings >](#).

**0.15.265.4.3 addCore()** template<class Settings >
bool smrat::IntBlastModule< Settings >::addCore (   
`ModuleInput::const_iterator _subformula` ) [virtual]

The module has to take the given sub-formula of the received formula into account.

##### Parameters

|                          |                                                    |
|--------------------------|----------------------------------------------------|
| <code>_subformula</code> | The sub-formula to take additionally into account. |
|--------------------------|----------------------------------------------------|

##### Returns

false, if it can be easily decided that this sub-formula causes a conflict with the already considered sub-formulas; true, otherwise.

Reimplemented from [smrat::Module](#).

**0.15.265.4.4 addInformationRelevantFormula()** void smrat::Module::addInformationRelevantFormula (   
`const FormulaT & formula` ) [protected], [inherited]

Adds a formula to the InformationRelevantFormula.

##### Parameters

|                      |                |
|----------------------|----------------|
| <code>formula</code> | Formula to add |
|----------------------|----------------|

---

**0.15.265.4.5 addLemma()** void smtrat::Module::addLemma (

```
const FormulaT & _lemma,
const LemmaType & _lt = LemmaType::NORMAL,
const FormulaT & _preferredFormula = FormulaT(carl::FormulaType::TRUE)) [inline],
[inherited]
```

Stores a lemma being a valid formula.

#### Parameters

|                          |                                                                       |
|--------------------------|-----------------------------------------------------------------------|
| <i>_lemma</i>            | The eduction/lemma to store.                                          |
| <i>_lt</i>               | The type of the lemma.                                                |
| <i>_preferredFormula</i> | Hint for the next decision, which formula should be assigned to true. |

**0.15.265.4.6 addOrigin()** void smtrat::Module::addOrigin (

```
ModuleInput::iterator _formula,
const FormulaT & _origin) [inline], [protected], [inherited]
```

Adds the given set of formulas in the received formula to the origins of the given passed formula.

#### Parameters

|                 |                                                           |
|-----------------|-----------------------------------------------------------|
| <i>_formula</i> | The passed formula to set the origins for.                |
| <i>_origin</i>  | A set of formulas in the received formula of this module. |

**0.15.265.4.7 addReceivedSubformulaToPassedFormula()** std::pair<ModuleInput::iterator,bool>  
smtrat::Module::addReceivedSubformulaToPassedFormula (

```
ModuleInput::const_iterator _subformula) [inline], [protected], [inherited]
```

Copies the given sub-formula of the received formula to the passed formula.

Note, that there is always a link between sub-formulas of the passed formulas to sub-formulas of the received formulas, which are responsible for its occurrence.

#### Parameters

|                    |                                                  |
|--------------------|--------------------------------------------------|
| <i>_subformula</i> | The sub-formula of the received formula to copy. |
|--------------------|--------------------------------------------------|

**0.15.265.4.8 addSubformulaToPassedFormula()** [1/3] std::pair<ModuleInput::iterator,bool> smtrat->  
::Module::addSubformulaToPassedFormula (

```
const FormulaT & _formula) [inline], [protected], [inherited]
```

Adds the given formula to the passed formula with no origin.

Note that in the next call of this module's removeSubformula, all formulas in the passed formula without origins will be removed.

#### Parameters

|                 |                                           |
|-----------------|-------------------------------------------|
| <i>_formula</i> | The formula to add to the passed formula. |
|-----------------|-------------------------------------------|

**Returns**

A pair to the position where the formula to add has been inserted (or its first sub-formula which has not yet been in the passed formula, in case the formula to add is a conjunction), and a Boolean stating whether anything has been added to the passed formula.

```
0.15.265.4.9 addSubformulaToPassedFormula() [2/3] std::pair<ModuleInput::iterator,bool> smrat->
::Module::addSubformulaToPassedFormula (
 const FormulaT & _formula,
 const FormulaT & _origin) [inline], [protected], [inherited]
```

Adds the given formula to the passed formula.

**Parameters**

|                 |                                                                                                                           |
|-----------------|---------------------------------------------------------------------------------------------------------------------------|
| <i>_formula</i> | The formula to add to the passed formula.                                                                                 |
| <i>_origin</i>  | The sub-formula of the received formula being responsible for the occurrence of the formula to add to the passed formula. |

**Returns**

A pair to the position where the formula to add has been inserted (or its first sub-formula which has not yet been in the passed formula, in case the formula to add is a conjunction), and a Boolean stating whether anything has been added to the passed formula.

```
0.15.265.4.10 addSubformulaToPassedFormula() [3/3] std::pair<ModuleInput::iterator,bool>
smrat::Module::addSubformulaToPassedFormula (
 const FormulaT & _formula,
 const std::shared_ptr< std::vector< FormulaT >> & _origins) [inline], [protected],
[inherited]
```

Adds the given formula to the passed formula.

**Parameters**

|                 |                                                                                                                                         |
|-----------------|-----------------------------------------------------------------------------------------------------------------------------------------|
| <i>_formula</i> | The formula to add to the passed formula.                                                                                               |
| <i>_origins</i> | The link of the formula to add to the passed formula to sub-formulas of the received formulas, which are responsible for its occurrence |

**Returns**

A pair to the position where the formula to add has been inserted (or its first sub-formula which has not yet been in the passed formula, in case the formula to add is a conjunction), and a Boolean stating whether anything has been added to the passed formula.

```
0.15.265.4.11 allModels() const std::vector<Model>& smrat::Module::allModels () const [inline],
[inherited]
```

**Returns**

All satisfying assignments, if existent.

**0.15.265.4.12 `anAnswerFound()`** `bool smrat::Module::anAnswerFound ( ) const [inline], [protected], [inherited]`

Checks for all antecedent modules and those which run in parallel with the same antecedent modules, whether one of them has determined a result.

**Returns**

True, if one of them has determined a result.

**0.15.265.4.13 `answerFound()`** `const smrat::Conditionals& smrat::Module::answerFound ( ) const [inline], [inherited]`

**Returns**

A vector of Booleans: If any of them is true, we have to terminate a running check procedure.

**0.15.265.4.14 `backendsModel()`** `const Model & smrat::Module::backendsModel ( ) const [protected], [inherited]`

Stores the model of a backend which determined satisfiability of the passed formula in the model of this module.

**0.15.265.4.15 `branchAt() [1/4]`** `bool smrat::Module::branchAt ( carl::Variable::Arg _var, const Rational & _value, bool _leftCaseWeak = true, bool _preferLeftCase = true, bool _useReceivedFormulaAsPremise = false, const std::vector< FormulaT > & _premise = std::vector<FormulaT>() ) [inline], [protected], [inherited]`

**0.15.265.4.16 `branchAt() [2/4]`** `bool smrat::Module::branchAt ( carl::Variable::Arg _var, const Rational & _value, std::vector< FormulaT > && _premise, bool _leftCaseWeak = true, bool _preferLeftCase = true, bool _useReceivedFormulaAsPremise = false ) [inline], [protected], [inherited]`

**0.15.265.4.17 `branchAt() [3/4]`** `bool smrat::Module::branchAt ( const Poly & _polynomial, bool _integral, const Rational & _value, bool _leftCaseWeak = true, bool _preferLeftCase = true, bool _useReceivedFormulaAsPremise = false, const std::vector< FormulaT > & _premise = std::vector<FormulaT>() ) [inline], [protected], [inherited]`

**0.15.265.4.18 `branchAt() [4/4]`** `bool smrat::Module::branchAt ( const Poly & _polynomial, bool _integral, const Rational & _value,`

```
std::vector< FormulaT > && _premise,
bool _leftCaseWeak = true,
bool _preferLeftCase = true,
bool _useReceivedFormulaAsPremise = false) [protected], [inherited]
```

Adds a lemmas which provoke a branching for the given variable at the given value, if this module returns Unknown and there exists a preceding [SATModule](#).

Note that the given value is rounded down and up, if the given variable is integer-valued.

#### Parameters

|                                           |                                                                                                                                                                                                                |
|-------------------------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>_polynomial</code>                  | The variable to branch for.                                                                                                                                                                                    |
| <code>_integral</code>                    | A flag being true, if all variables in the polynomial to branch for are integral.                                                                                                                              |
| <code>_value</code>                       | The value to branch at.                                                                                                                                                                                        |
| <code>_premise</code>                     | The sub-formulas of the received formula from which the branch is followed. Note, that a premise is not necessary, as every branch is a valid formula. But a premise can prevent from branching unnecessarily. |
| <code>_leftCaseWeak</code>                | true, if a branching in the form of (or ( $\leq p b$ ) ( $> p b$ )) is desired. false, if a branching in the form of (or ( $< p b$ ) ( $\geq p b$ )) is desired.                                               |
| <code>_preferLeftCase</code>              | true, if the left case (polynomial less(or equal) 0 shall be chosen first. false, otherwise.                                                                                                                   |
| <code>_useReceivedFormulaAsPremise</code> | true, if the whole received formula should be used as premise                                                                                                                                                  |

#### 0.15.265.4.19 `check()`

```
Answer smtrat::Module::check (
 bool _final = false,
 bool _full = true,
 carl::Variable _objective = carl::Variable::NO_VARIABLE) [virtual], [inherited]
```

Checks the received formula for consistency.

Note, that this is an implementation of the satisfiability check of the conjunction of the so far received formulas, which does actually nothing but passing the problem to its backends. This implementation is only used internally and must be overwritten by any derived module.

#### Parameters

|                         |                                                                                                                                       |
|-------------------------|---------------------------------------------------------------------------------------------------------------------------------------|
| <code>_final</code>     | true, if this satisfiability check will be the last one (for a global sat-check), if its result is SAT                                |
| <code>_full</code>      | false, if this module should avoid too expensive procedures and rather return unknown instead.                                        |
| <code>_objective</code> | if not set to NO_VARIABLE, the module should find an assignment minimizing this objective variable; otherwise any assignment is good. |

#### Returns

True, if the received formula is satisfiable; False, if the received formula is not satisfiable; Unknown, otherwise.

Reimplemented in [smtrat::PModule](#).

#### 0.15.265.4.20 `checkCore()`

```
template<class Settings >
Answer smtrat::IntBlastModule< Settings >::checkCore () [virtual]
```

Checks the received formula for consistency.

#### Returns

SAT, if the received formula is satisfiable; UNSAT, if the received formula is not satisfiable; Unknown, otherwise.

Reimplemented from [smtrat::Module](#).

```
0.15.265.4.21 checkInfSubsetForMinimality() void smrat::Module::checkInfSubsetForMinimality (
 std::vector< FormulaSetT >::const_iterator _infsSubset,
 const std::string & _filename = "smaller_muses",
 unsigned _maxSizeDifference = 1) const [inherited]
```

Checks the given infeasible subset for minimality by storing all subsets of it, which have a smaller size which differs from the size of the infeasible subset not more than the given threshold.

#### Parameters

|                                 |                                                                                                        |
|---------------------------------|--------------------------------------------------------------------------------------------------------|
| <code>_infsSubset</code>        | The infeasible subset to check for minimality.                                                         |
| <code>_filename</code>          | The name of the file to store the infeasible subsets in order to be able to check their infeasibility. |
| <code>_maxSizeDifference</code> | The maximal difference between the sizes of the subsets compared to the size of the infeasible subset. |

```
0.15.265.4.22 checkModel() unsigned smrat::Module::checkModel () const [protected], [inherited]
```

#### Returns

false, if the current model of this module does not satisfy the current given formula; true, if it cannot be said whether the model satisfies the given formula.

```
0.15.265.4.23 cleanModel() void smrat::Module::cleanModel () const [inline], [protected], [inherited]
```

Substitutes variable occurrences by its model value in the model values of other variables.

```
0.15.265.4.24 clearLemmas() void smrat::Module::clearLemmas () [inline], [inherited]
```

Deletes all yet found lemmas.

```
0.15.265.4.25 clearModel() void smrat::Module::clearModel () const [inline], [protected], [inherited]
```

Clears the assignment, if any was found.

```
0.15.265.4.26 clearModels() void smrat::Module::clearModels () const [inline], [protected], [inherited]
```

Clears all assignments, if any was found.

```
0.15.265.4.27 clearPassedFormula() void smrat::Module::clearPassedFormula () [protected], [inherited]
```

```
0.15.265.4.28 collectOrigins() [1/2] void smrat::Module::collectOrigins (
 const FormulaT & _formula,
 FormulaSetT & _origins) const [inherited]
```

```
0.15.265.4.29 collectOrigins() [2/2] void smtrat::Module::collectOrigins (
 const FormulaT & _formula,
 FormulasT & _origins) const [inherited]
```

Collects the formulas in the given formula, which are part of the received formula.

If the given formula directly occurs in the received formula, it is inserted into the given set. Otherwise, the given formula must be of type AND and all its sub-formulas part of the received formula. Hence, they will be added to the given set.

#### Parameters

|                 |                                                                                                      |
|-----------------|------------------------------------------------------------------------------------------------------|
| <i>_formula</i> | The formula from which to collect the formulas being sub-formulas of the received formula (origins). |
| <i>_origins</i> | The set in which to store the origins.                                                               |

```
0.15.265.4.30 collectTheoryPropagations() void smtrat::Module::collectTheoryPropagations () [inherited]
```

```
0.15.265.4.31 constraintsToInform() const carl::FastSet<FormulaT>& smtrat::Module::constraints←ToInform () const [inline], [inherited]
```

#### Returns

The constraints which the backends must be informed about.

```
0.15.265.4.32 currentlySatisfied() virtual unsigned smtrat::Module::currentlySatisfied (
 const FormulaT &) const [inline], [virtual], [inherited]
```

#### Returns

0, if the given formula is conflicted by the current model; 1, if the given formula is satisfied by the current model; 2, otherwise; 3, if we do not know anything (default)

Reimplemented in [smtrat::LRAModule< Settings >](#), [smtrat::LRAModule< LRASettingsICP >](#), and [smtrat::LRAModule< LRASettings >](#)

```
0.15.265.4.33 currentlySatisfiedByBackend() unsigned smtrat::Module::currentlySatisfiedByBackend (
 const FormulaT & _formula) const [inherited]
```

#### Returns

0, if the given formula is conflicted by the current model; 1, if the given formula is satisfied by the current model; 2, otherwise 3, if we do not know anything (default)

```
0.15.265.4.34 deinform() void smtrat::Module::deinform (
 const FormulaT & _constraint) [inherited]
```

The inverse of informing about a constraint.

All data structures which were kept regarding this constraint are going to be removed. Note, that this makes only sense if it is not likely enough that a formula with this constraint must be solved again.

#### Parameters

|                    |                                                         |
|--------------------|---------------------------------------------------------|
| <i>_constraint</i> | The constraint to remove from internal data structures. |
|--------------------|---------------------------------------------------------|

---

**0.15.265.4.35 `deinformCore()`** `virtual void smtrat::Module::deinformCore (`  
`const FormulaT & _constraint )` [inline], [protected], [virtual], [inherited]

The inverse of informing about a constraint.

All data structures which were kept regarding this constraint are going to be removed. Note, that this makes only sense if it is not likely enough that a formula with this constraint must be solved again.

#### Parameters

|                          |                                                         |
|--------------------------|---------------------------------------------------------|
| <code>_constraint</code> | The constraint to remove from internal data structures. |
|--------------------------|---------------------------------------------------------|

Reimplemented in [smtrat::LRAModule< Settings >](#), [smtrat::LRAModule< LRASettingsICP >](#), and [smtrat::LRAModule< LRASettings1 >](#).

**0.15.265.4.36 `determine_smallest_origin()`** `size_t smtrat::Module::determine_smallest_origin (`  
`const std::vector< FormulaT > & origins ) const` [protected], [inherited]

#### Parameters

|                      |                              |
|----------------------|------------------------------|
| <code>origins</code> | A vector of sets of origins. |
|----------------------|------------------------------|

#### Returns

The index of the smallest (regarding the size of the sets) element of origins

**0.15.265.4.37 `eraseSubformulaFromPassedFormula()`** `ModuleInput::iterator smtrat::Module::eraseSubformulaFromPassedFormula (`  
`ModuleInput::iterator _subformula,`  
`bool _ignoreOrigins = false )` [protected], [virtual], [inherited]

Removes everything related to the sub-formula to remove from the passed formula in the backends of this module.  
 Afterwards the sub-formula is removed from the passed formula.

#### Parameters

|                             |                                                                                                              |
|-----------------------------|--------------------------------------------------------------------------------------------------------------|
| <code>_subformula</code>    | The sub-formula to remove from the passed formula.                                                           |
| <code>_ignoreOrigins</code> | True, if the sub-formula shall be removed regardless of its origins (should only be applied with expertise). |

#### Returns

Reimplemented in [smtrat::ICPModule< Settings >](#), [smtrat::ICPModule< ICPSettings4 >](#), and [smtrat::ICPModule< ICPSettings1 >](#).

**0.15.265.4.38 `excludeNotReceivedVariablesFromModel()`** `void smtrat::Module::excludeNotReceivedVariablesFromModel ( ) const` [inherited]

Excludes all variables from the current model, which do not occur in the received formula.

**0.15.265.4.39 `findBestOrigin()`** `std::vector< FormulaT >::const_iterator smtrat::Module::findBestOrigin (`  
`const std::vector< FormulaT > & _origins ) const` [protected], [inherited]

## Parameters

|                       |  |
|-----------------------|--|
| <code>_origins</code> |  |
|-----------------------|--|

## Returns

**0.15.265.4.40 `firstSubformulaToPass()`** `ModuleInput::const_iterator smtrat::Module::firstSubformulaToPass () const [inline], [inherited]`

## Returns

The position of the first sub-formula in the passed formula, which has not yet been considered for a consistency check of the backends.

**0.15.265.4.41 `firstUncheckedReceivedSubformula()`** `ModuleInput::const_iterator smtrat::Module::firstUncheckedReceivedSubformula () const [inline], [inherited]`

## Returns

The position of the first (by this module) unchecked sub-formula of the received formula.

**0.15.265.4.42 `freeSplittingVariable()`** `static void smtrat::Module::freeSplittingVariable (const FormulaT & _splittingVariable ) [inline], [static], [inherited]`

**0.15.265.4.43 `generateTrivialInfeasibleSubset()`** `void smtrat::Module::generateTrivialInfeasibleSubset () [inline], [protected], [inherited]`

Stores the trivial infeasible subset being the set of received formulas.

**0.15.265.4.44 `getBackendsAllModels()`** `void smtrat::Module::getBackendsAllModels () const [protected], [inherited]`

Stores all models of a backend in the list of all models of this module.

**0.15.265.4.45 `getBackendsModel()`** `void smtrat::Module::getBackendsModel () const [protected], [inherited]`

**0.15.265.4.46 `getInfeasibleSubsets() [1/2]`** `void smtrat::Module::getInfeasibleSubsets () [protected], [inherited]`

Copies the infeasible subsets of the passed formula.

**0.15.265.4.47 `getInfeasibleSubsets() [2/2]`** `std::vector< FormulaSetT > smtrat::Module::getInfeasibleSubsets (const Module & _backend ) const [protected], [inherited]`

Get the infeasible subsets the given backend provides.

Note, that an infeasible subset in a backend contains sub formulas of the passed formula and an infeasible subset of this module contains sub formulas of the received formula. In this method the LATTER is returned.

**Parameters**

|                       |                                                          |
|-----------------------|----------------------------------------------------------|
| <code>_backend</code> | The backend from which to obtain the infeasible subsets. |
|-----------------------|----------------------------------------------------------|

**Returns**

The infeasible subsets the given backend provides.

**0.15.265.4.48 `getInformationRelevantFormulas()`** `const std::set< FormulaT > & smtrat::Module::getInformationRelevantFormulas ( ) [protected], [inherited]`  
Gets all InformationRelevantFormulas.

**Returns**

Set of all formulas

**0.15.265.4.49 `getModelEqualities()`** `std::list< std::vector< carl::Variable > > smtrat::Module::getModelEqualities ( ) const [virtual], [inherited]`  
Partition the variables from the current model into equivalence classes according to their assigned value.  
The result is a set of equivalence classes of variables where all variables within one class are assigned the same value. Note that the number of classes may not be minimal, i.e. two classes may actually be equivalent.

**Returns**

Equivalence classes.

**0.15.265.4.50 `getOrigins()` [1/3]** `void smtrat::Module::getOrigins ( const FormulaT & _formula, FormulaSetT & _origins ) const [inline], [protected], [inherited]`

**Parameters**

|                       |  |
|-----------------------|--|
| <code>_formula</code> |  |
| <code>_origins</code> |  |

**0.15.265.4.51 `getOrigins()` [2/3]** `void smtrat::Module::getOrigins ( const FormulaT & _formula, FormulasT & _origins ) const [inline], [protected], [inherited]`

**Parameters**

|                       |  |
|-----------------------|--|
| <code>_formula</code> |  |
| <code>_origins</code> |  |

**0.15.265.4.52 `getOrigins()` [3/3]** `const FormulaT& smtrat::Module::getOrigins ( ModuleInput::const_iterator _formula ) const [inline], [protected], [inherited]`  
Gets the origins of the passed formula at the given position.

**Parameters**

|                 |                                                   |
|-----------------|---------------------------------------------------|
| <i>_formula</i> | The position of a formula in the passed formulas. |
|-----------------|---------------------------------------------------|

**Returns**

The origins of the passed formula at the given position.

**0.15.265.4.53 `getReceivedFormulaSimplified()`** `std::pair< bool, FormulaT > smtrat::Module::getReceivedFormulaSimplified( ) [virtual], [inherited]`

**Returns**

A pair of a Boolean and a formula, where the Boolean is true, if the received formula could be simplified to an equisatisfiable formula. The formula is equisatisfiable to this module's received formula, if the Boolean is true.

Reimplemented in [smtrat::PModule](#).

**0.15.265.4.54 `hasLemmas()`** `bool smtrat::Module::hasLemmas( ) [inline], [inherited]`

Checks whether this module or any of its backends provides any lemmas.

**0.15.265.4.55 `hasValidInfeasibleSubset()`** `bool smtrat::Module::hasValidInfeasibleSubset( ) const [inherited]`

**Returns**

true, if the module has at least one valid infeasible subset, that is all its elements are sub-formulas of the received formula (pointer must be equal).

**0.15.265.4.56 `id()`** `std::size_t smtrat::Module::id( ) const [inline], [inherited]`

**Returns**

A unique ID to identify this module instance.

**0.15.265.4.57 `infeasibleSubsets()`** `const std::vector<FormulaSetT>& smtrat::Module::infeasibleSubsets( ) const [inline], [inherited]`

**Returns**

The infeasible subsets of the set of received formulas (empty, if this module has not detected unsatisfiability of the conjunction of received formulas).

**0.15.265.4.58 `inform()`** `bool smtrat::Module::inform( const FormulaT & _constraint ) [inherited]`

Informs the module about the given constraint.

It should be tried to inform this module about any constraint it could receive eventually before assertSubformula is called (preferably for the first time, but at least before adding a formula containing that constraint).

**Parameters**

|                    |                                 |
|--------------------|---------------------------------|
| <i>_constraint</i> | The constraint to inform about. |
|--------------------|---------------------------------|

**Returns**

false, if it can be easily decided whether the given constraint is inconsistent; true, otherwise.

**0.15.265.4.59 informBackends()** `void smrat::Module::informBackends (`

`const FormulaT & _constraint ) [inline], [protected], [inherited]`

Informs all backends of this module about the given constraint.

**Parameters**

|                          |                                 |
|--------------------------|---------------------------------|
| <code>_constraint</code> | The constraint to inform about. |
|--------------------------|---------------------------------|

**0.15.265.4.60 informCore()** `template<class Settings >`

`bool smrat::IntBlastModule< Settings >::informCore (`

`const FormulaT & _constraint ) [virtual]`

Informs the module about the given constraint.

It should be tried to inform this module about any constraint it could receive eventually before assertSubformula is called (preferably for the first time, but at least before adding a formula containing that constraint).

**Parameters**

|                          |                                 |
|--------------------------|---------------------------------|
| <code>_constraint</code> | The constraint to inform about. |
|--------------------------|---------------------------------|

**Returns**

false, if it can be easily decided whether the given constraint is inconsistent; true, otherwise.

Reimplemented from [smrat::Module](#).

**0.15.265.4.61 informedConstraints()** `const carl::FastSet<FormulaT>& smrat::Module::informed→`

`Constraints ( ) const [inline], [inherited]`

**Returns**

The position of the first constraint of which no backend has been informed about.

**0.15.265.4.62 init()** `template<class Settings >`

`void smrat::IntBlastModule< Settings >::init ( ) [virtual]`

Informs all backends about the so far encountered constraints, which have not yet been communicated.

This method must not and will not be called more than once and only before the first runBackends call.

Reimplemented from [smrat::Module](#).

**0.15.265.4.63 is\_minimizing()** `bool smrat::Module::is_minimizing ( ) const [inline], [inherited]`**0.15.265.4.64 isLemmaLevel()** `bool smrat::Module::isLemmaLevel (`

`LemmaLevel level ) [protected], [inherited]`

Checks if current lemma level is greater or equal to given level.

**Parameters**

|              |                 |
|--------------|-----------------|
| <i>level</i> | Level to check. |
|--------------|-----------------|

**0.15.265.4.65 `isPreprocessor()`** `bool smtrat::Module::isPreprocessor () const [inline], [inherited]`**Returns**

true, if this module is a preprocessor that is a module, which simplifies its received formula to an equisatisfiable formula being passed to its backends. The simplified formula can be obtained with [getReceivedFormulaSimplified\(\)](#).

**0.15.265.4.66 `lemmas()`** `const std::vector<Lemma>& smtrat::Module::lemmas () const [inline], [inherited]`**Returns**

A constant reference to the lemmas being valid formulas this module or its backends made.

**0.15.265.4.67 `merge()`** `std::vector< FormulaT > smtrat::Module::merge (const std::vector< FormulaT > & _vecSetA, const std::vector< FormulaT > & _vecSetB) const [protected], [inherited]`

Merges the two vectors of sets into the first one.

({a,b},{a,c}) and ({b,d},{b}) -> ({a,b,d},{a,b},{a,b,c,d},{a,b,c})

**Parameters**

|                 |                                  |
|-----------------|----------------------------------|
| <i>_vecSetA</i> | A vector of sets of constraints. |
| <i>_vecSetB</i> | A vector of sets of constraints. |

**Returns**

The vector being the two given vectors merged.

**0.15.265.4.68 `model()`** `const Model& smtrat::Module::model () const [inline], [inherited]`**Returns**

The assignment of the current satisfiable result, if existent.

**0.15.265.4.69 `modelsDisjoint()`** `bool smtrat::Module::modelsDisjoint (const Model & _modelA, const Model & _modelB) [static], [protected], [inherited]`

Checks whether there is no variable assigned by both models.

**Parameters**

|                |                                |
|----------------|--------------------------------|
| <i>_modelA</i> | The first model to check for.  |
| <i>_modelB</i> | The second model to check for. |

**Returns**

true, if there is no variable assigned by both models; false, otherwise.

**0.15.265.4.70 `moduleName()`** `template<class Settings >`  
`std::string smtrat::IntBlastModule< Settings >::moduleName ( ) const [inline], [virtual]`

**Returns**

The name of the given module type as name.

Reimplemented from [smtrat::Module](#).

**0.15.265.4.71 `objective()`** `carl::Variable smtrat::Module::objective ( ) const [inline], [inherited]`

**0.15.265.4.72 `originInReceivedFormula()`** `bool smtrat::Module::originInReceivedFormula (`  
`const FormulaT & _origin ) const [protected], [inherited]`

**0.15.265.4.73 `passedFormulaBegin()`** `ModuleInput::iterator smtrat::Module::passedFormulaBegin (`  
`) [inline], [protected], [inherited]`

**Returns**

An iterator to the end of the passed formula. TODO: disable this method

**0.15.265.4.74 `passedFormulaEnd()`** `ModuleInput::iterator smtrat::Module::passedFormulaEnd ( )`  
[inline], [protected], [inherited]

**Returns**

An iterator to the end of the passed formula.

**0.15.265.4.75 `pPassedFormula()`** `const ModuleInput* smtrat::Module::pPassedFormula ( ) const`  
[inline], [inherited]

**Returns**

A pointer to the formula passed to the backends of this module.

**0.15.265.4.76 `pReceivedFormula()`** `const ModuleInput* smtrat::Module::pReceivedFormula ( ) const`  
[inline], [inherited]

**Returns**

A pointer to the formula passed to this module.

**0.15.265.4.77 `print()`** `void smtrat::Module::print (`  
`const std::string & _initiation = "***" ) const [inherited]`

Prints everything relevant of the solver.

**Parameters**

|                    |                      |
|--------------------|----------------------|
| <i>_initiation</i> | The line initiation. |
|--------------------|----------------------|

**0.15.265.4.78 printAllModels()** void smtrat::Module::printAllModels ( std::ostream & *\_out* = std::cout ) [inherited]

Prints all assignments of this module satisfying its received formula if it satisfiable and this module could find an assignment.

**Parameters**

|             |                                        |
|-------------|----------------------------------------|
| <i>_out</i> | The stream to print the assignment on. |
|-------------|----------------------------------------|

**0.15.265.4.79 printInfeasibleSubsets()** void smtrat::Module::printInfeasibleSubsets ( const std::string & *\_initiation* = "\*\*\*" ) const [inherited]

Prints the infeasible subsets.

**Parameters**

|                    |                      |
|--------------------|----------------------|
| <i>_initiation</i> | The line initiation. |
|--------------------|----------------------|

**0.15.265.4.80 printModel()** void smtrat::Module::printModel ( std::ostream & *\_out* = std::cout ) const [inherited]

Prints the assignment of this module satisfying its received formula if it satisfiable and this module could find an assignment.

**Parameters**

|             |                                        |
|-------------|----------------------------------------|
| <i>_out</i> | The stream to print the assignment on. |
|-------------|----------------------------------------|

**0.15.265.4.81 printPassedFormula()** void smtrat::Module::printPassedFormula ( const std::string & *\_initiation* = "\*\*\*" ) const [inherited]

Prints the vector of passed formula.

**Parameters**

|                    |                      |
|--------------------|----------------------|
| <i>_initiation</i> | The line initiation. |
|--------------------|----------------------|

**0.15.265.4.82 printReceivedFormula()** void smtrat::Module::printReceivedFormula ( const std::string & *\_initiation* = "\*\*\*" ) const [inherited]

Prints the vector of the received formula.

**Parameters**

|                    |                      |
|--------------------|----------------------|
| <i>_initiation</i> | The line initiation. |
|--------------------|----------------------|

---

**0.15.265.4.83 `probablyLooping()`** `bool smtrat::Module::probablyLooping (`  
 `const typename Poly::PolyType & _branchingPolynomial,`  
 `const Rational & _branchingValue ) const [protected], [inherited]`

Checks whether given the current branching value and branching variable/polynomial it is (highly) probable that this branching is part of an infinite loop of branchings.

#### Parameters

|                                   |                                                                                     |
|-----------------------------------|-------------------------------------------------------------------------------------|
| <code>_branchingPolynomial</code> | The polynomial to branch at (in most branching strategies this is just a variable). |
| <code>_branchingValue</code>      | The value to branch at.                                                             |

#### Returns

true, if this branching is probably part of an infinite loop of branchings; false, otherwise.

**0.15.265.4.84 `receivedFormulaChecked()`** `void smtrat::Module::receivedFormulaChecked ( ) [inline], [inherited]`

Notifies that the received formulas has been checked.

**0.15.265.4.85 `receivedFormulasAsInfeasibleSubset()`** `void smtrat::Module::receivedFormulasAsInfeasibleSubset (`

`ModuleInput::const_iterator _subformula ) [inline], [protected], [inherited]`

Stores an infeasible subset consisting only of the given received formula.

**0.15.265.4.86 `receivedVariable()`** `bool smtrat::Module::receivedVariable (`  
 `carl::Variable::Arg _var ) const [inline], [inherited]`

**0.15.265.4.87 `remove()`** `void smtrat::Module::remove (`  
 `ModuleInput::const_iterator _subformula ) [virtual], [inherited]`

Removes everything related to the given sub-formula of the received formula.

However, it is desired not to lose track of search spaces where no satisfying assignment can be found for the remaining sub-formulas.

#### Parameters

|                          |                                                    |
|--------------------------|----------------------------------------------------|
| <code>_subformula</code> | The sub formula of the received formula to remove. |
|--------------------------|----------------------------------------------------|

Reimplemented in [smtrat::PModule](#).

**0.15.265.4.88 `removeCore()`** `template<class Settings >`  
`void smtrat::IntBlastModule< Settings >::removeCore (`  
 `ModuleInput::const_iterator _subformula ) [virtual]`

Removes the subformula of the received formula at the given position to the considered ones of this module.

Note that this includes every stored calculation which depended on this subformula, but should keep the other stored calculation, if possible, untouched.

#### Parameters

|                          |                                           |
|--------------------------|-------------------------------------------|
| <code>_subformula</code> | The position of the subformula to remove. |
|--------------------------|-------------------------------------------|

Reimplemented from [smtrat::Module](#).

**0.15.265.4.89 `removeOrigin()`** `std::pair<ModuleInput::iterator, bool> smtrat::Module::removeOrigin (`

```
 ModuleInput::iterator _formula,
 const FormulaT & _origin) [inline], [protected], [inherited]
```

**0.15.265.4.90 `removeOrigins()`** `std::pair<ModuleInput::iterator, bool> smtrat::Module::removeOrigins (`

```
 ModuleInput::iterator _formula,
 const std::shared_ptr< std::vector< FormulaT >> & _origins) [inline], [protected],
 [inherited]
```

**0.15.265.4.91 `rPassedFormula()`** `const ModuleInput& smtrat::Module::rPassedFormula ( ) const`

`[inline], [inherited]`

#### Returns

A reference to the formula passed to the backends of this module.

**0.15.265.4.92 `rReceivedFormula()`** `const ModuleInput& smtrat::Module::rReceivedFormula ( ) const`

`[inline], [inherited]`

#### Returns

A reference to the formula passed to this module.

**0.15.265.4.93 `runBackends() [1/2]`** `virtual Answer smtrat::Module::runBackends ( ) [inline],`

`[protected], [virtual], [inherited]`

Reimplemented in [smtrat::PModule](#).

**0.15.265.4.94 `runBackends() [2/2]`** `Answer smtrat::Module::runBackends (`

```
 bool _final,
 bool _full,
 carl::Variable _objective) [protected], [virtual], [inherited]
```

Runs the backend solvers on the passed formula.

#### Parameters

|                         |                                                                                                                                       |
|-------------------------|---------------------------------------------------------------------------------------------------------------------------------------|
| <code>_final</code>     | true, if this satisfiability check will be the last one (for a global sat-check), if its result is SAT                                |
| <code>_full</code>      | false, if this module should avoid too expensive procedures and rather return unknown instead.                                        |
| <code>_objective</code> | if not set to NO_VARIABLE, the module should find an assignment minimizing this objective variable; otherwise any assignment is good. |

#### Returns

True, if the passed formula is consistent; False, if the passed formula is inconsistent; Unknown, otherwise.

Reimplemented in [smtrat::PModule](#).

**0.15.265.4.95 setId()** void smtrat::Module::setId ( std::size\_t \_id ) [inline], [inherited]  
Sets this modules unique ID to identify itself.

Parameters

|                             |                                    |
|-----------------------------|------------------------------------|
| $\leftrightarrow$<br>$\_id$ | The id to set this module's id to. |
|-----------------------------|------------------------------------|

**0.15.265.4.96 setThreadPriority()** void smtrat::Module::setThreadPriority ( thread\_priority \_threadPriority ) [inline], [inherited]  
Sets the priority of this module to get a thread for running its check procedure.

Parameters

|                    |                                                       |
|--------------------|-------------------------------------------------------|
| $\_threadPriority$ | The priority to set this module's thread priority to. |
|--------------------|-------------------------------------------------------|

**0.15.265.4.97 solverState()** Answer smtrat::Module::solverState ( ) const [inline], [inherited]

Returns

True, if this module is in a state, such that it has found a solution for its received formula; False, if this module is in a state, such that it has determined that there is no solution for its received formula; Unknown, otherwise.

**0.15.265.4.98 splitUnequalConstraint()** void smtrat::Module::splitUnequalConstraint ( const FormulaT & \_unequalConstraint ) [protected], [inherited]  
Adds the following lemmas for the given constraint  $p \neq 0$ .

$(p \neq 0 \leftrightarrow (p < 0 \text{ or } p > 0))$

and  $\neg(p < 0 \text{ and } p > 0)$

Parameters

|                       |                                                  |
|-----------------------|--------------------------------------------------|
| $\_unequalConstraint$ | A constraint having the relation symbol $\neq$ . |
|-----------------------|--------------------------------------------------|

**0.15.265.4.99 threadPriority()** thread\_priority smtrat::Module::threadPriority ( ) const [inline], [inherited]

Returns

The priority of this module to get a thread for running its check procedure.

**0.15.265.4.100 updateAllModels()** void smtrat::Module::updateAllModels ( ) [virtual], [inherited]  
Updates all satisfying models, if the solver has detected the consistency of the received formula, beforehand.  
Reimplemented in [smtrat::SATModule< Settings >](#).

**0.15.265.4.101 updateLemmas()** void smtrat::Module::updateLemmas () [inherited]  
Stores all lemmas of any backend of this module in its own lemma vector.

**0.15.265.4.102 updateModel()** template<class Settings >  
void smtrat::IntBlastModule< Settings >::updateModel () const [virtual]  
Updates the current assignment into the model.  
Note, that this is a unique but possibly symbolic assignment maybe containing newly introduced variables.  
Reimplemented from [smtrat::Module](#).

**0.15.265.4.103 usedBackends()** const std::vector<[Module](#)\*>& smtrat::Module::usedBackends ()  
const [inline], [inherited]

#### Returns

The backends of this module which are currently used (conditions to use this module are fulfilled for the passed formula).

### 0.15.265.5 Field Documentation

**0.15.265.5.1 mAllBackends** std::vector<[Module](#)\*> smtrat::Module::mAllBackends [protected],  
[inherited]

The backends of this module which have been used.

**0.15.265.5.2 mAllModels** std::vector<[Model](#)> smtrat::Module::mAllModels [mutable], [protected],  
[inherited]

Stores all satisfying assignments.

**0.15.265.5.3 mBackendsFoundAnswer** std::atomic\_bool\* smtrat::Module::mBackendsFoundAnswer  
[protected], [inherited]

This flag is passed to any backend and if it determines an answer to a prior check call, this flag is fired.

**0.15.265.5.4 mConstraintsToInform** carl::FastSet<[FormulaT](#)> smtrat::Module::mConstraintsToInform  
[protected], [inherited]

Stores the constraints which the backends must be informed about.

**0.15.265.5.5 mFinalCheck** bool smtrat::Module::mFinalCheck [protected], [inherited]  
true, if the check procedure should perform a final check which especially means not to postpone splitting decisions

**0.15.265.5.6 mFirstPosInLastBranches** std::size\_t smtrat::Module::mFirstPosInLastBranches = 0  
[static], [inherited]

The beginning of the cyclic buffer storing the last branches.

**0.15.265.5.7 mFirstSubformulaToPass** [ModuleInput](#)::iterator smtrat::Module::mFirstSubformulaToPass  
[protected], [inherited]

Stores the position of the first sub-formula in the passed formula, which has not yet been considered for a consistency check of the backends.

**0.15.265.5.8 mFirstUncheckedReceivedSubformula** `ModuleInput::const_iterator smrat::Module::mFirstUncheckedReceivedSubformula [protected], [inherited]`  
Stores the position of the first (by this module) unchecked sub-formula of the received formula.

**0.15.265.5.9 mFoundAnswer** `Conditionals smrat::Module::mFoundAnswer [protected], [inherited]`  
Vector of Booleans: If any of them is true, we have to terminate a running check procedure.

**0.15.265.5.10 mFullCheck** `bool smrat::Module::mFullCheck [protected], [inherited]`  
false, if this module should avoid too expensive procedures and rather return unknown instead.

**0.15.265.5.11 mInfeasibleSubsets** `std::vector<FormulaSetT> smrat::Module::mInfeasibleSubsets [protected], [inherited]`  
Stores the infeasible subsets.

**0.15.265.5.12 mInformedConstraints** `carl::FastSet<FormulaT> smrat::Module::mInformedConstraints [protected], [inherited]`  
Stores the position of the first constraint of which no backend has been informed about.

**0.15.265.5.13 mLastBranches** `std::vector<Branching> smrat::Module::mLastBranches = std::vector<Branching>(mNumOfBranchVarsToStore, Branching(typename Poly::PolyType(), 0)) [static], [inherited]`  
Stores the last branches in a cycle buffer.

**0.15.265.5.14 mLemmas** `std::vector<Lemma> smrat::Module::mLemmas [protected], [inherited]`  
Stores the lemmas being valid formulas this module or its backends made.

**0.15.265.5.15 mModel** `Model smrat::Module::mModel [mutable], [protected], [inherited]`  
Stores the assignment of the current satisfiable result, if existent.

**0.15.265.5.16 mModelComputed** `bool smrat::Module::mModelComputed [mutable], [protected], [inherited]`  
True, if the model has already been computed.

**0.15.265.5.17 mNumOfBranchVarsToStore** `std::size_t smrat::Module::mNumOfBranchVarsToStore = 5 [static], [inherited]`  
The number of different variables to consider for a probable infinite loop of branchings.

**0.15.265.5.18 mObjectiveVariable** `carl::Variable smrat::Module::mObjectiveVariable [protected], [inherited]`  
Objective variable to be minimized. If set to NO\_VARIABLE, a normal sat check should be performed.

**0.15.265.5.19 mOldSplittingVariables** `std::vector<FormulaT> smrat::Module::mOldSplittingVariables [static], [inherited]`  
Reusable splitting variables.

**0.15.265.5.20 mpManager** `Manager* const smtrat::Module::mpManager` [protected], [inherited]  
A reference to the manager.

**0.15.265.5.21 mSmallerMusesCheckCounter** `unsigned smtrat::Module::mSmallerMusesCheckCounter`  
[mutable], [protected], [inherited]  
Counter used for the generation of the smt2 files to check for smaller muses.

**0.15.265.5.22 mSolverState** `std::atomic<Answer> smtrat::Module::mSolverState` [protected],  
[inherited]  
States whether the received formula is known to be satisfiable or unsatisfiable otherwise it is set to unknown.

**0.15.265.5.23 mTheoryPropagations** `std::vector<TheoryPropagation> smtrat::Module::mTheory←→Propagations` [protected], [inherited]

**0.15.265.5.24 mUsedBackends** `std::vector<Module*> smtrat::Module::mUsedBackends` [protected],  
[inherited]  
The backends of this module which are currently used (conditions to use this module are fulfilled for the passed formula).

**0.15.265.5.25 mVariableCounters** `std::vector<std::size_t> smtrat::Module::mVariableCounters`  
[protected], [inherited]  
Maps variables to the number of their occurrences.

## 0.15.266 smtrat::IntEqModule< Settings > Class Template Reference

A module which checks whether the equations contained in the received (linear integer) formula have a solution.  
`#include <IntEqModule.h>`

### Public Types

- `typedef Settings SettingsType`
- `enum class LemmaType : unsigned { NORMAL = 0 , PERMANENT = 1 }`

### Public Member Functions

- `std::string moduleName () const`
- `IntEqModule (const ModuleInput *_formula, Conditionals &_conditionals, Manager *_manager=NULL)`
- `~IntEqModule ()`
- `bool addCore (ModuleInput::const_iterator _subformula)`

*The module has to take the given sub-formula of the received formula into account.*
- `void removeCore (ModuleInput::const_iterator _subformula)`

*Removes the subformula of the received formula at the given position to the considered ones of this module.*
- `void updateModel () const`

*Updates the current assignment into the model.*
- `Answer checkCore ()`

*Checks the received formula for consistency.*
- `bool inform (const FormulaT &_constraint)`

*Informs the module about the given constraint.*
- `void deinform (const FormulaT &_constraint)`

*The inverse of informing about a constraint.*

- virtual void `init ()`

*Informs all backends about the so far encountered constraints, which have not yet been communicated.*
- bool `add (ModuleInput::const_iterator _subformula)`

*The module has to take the given sub-formula of the received formula into account.*
- virtual `Answer check (bool _final=false, bool _full=true, carl::Variable _objective=carl::Variable::NO_← VARIABLE)`

*Checks the received formula for consistency.*
- virtual void `remove (ModuleInput::const_iterator _subformula)`

*Removes everything related to the given sub-formula of the received formula.*
- virtual void `updateAllModels ()`

*Updates all satisfying models, if the solver has detected the consistency of the received formula, beforehand.*
- virtual std::list< std::vector< carl::Variable > > `getModelEqualities () const`

*Partition the variables from the current model into equivalence classes according to their assigned value.*
- unsigned `currentlySatisfiedByBackend (const FormulaT &_formula) const`
- virtual unsigned `currentlySatisfied (const FormulaT &) const`
- bool `receivedVariable (carl::Variable::Arg _var) const`
- `Answer solverState () const`
- std::size\_t `id () const`
- void `setId (std::size_t _id)`

*Sets this modules unique ID to identify itself.*
- `thread_priority threadPriority () const`
- void `setThreadPriority (thread_priority _threadPriority)`

*Sets the priority of this module to get a thread for running its check procedure.*
- const `ModuleInput * pReceivedFormula () const`
- const `ModuleInput & rReceivedFormula () const`
- const `ModuleInput * pPassedFormula () const`
- const `ModuleInput & rPassedFormula () const`
- const `Model & model () const`
- const std::vector< `Model` > & `allModels () const`
- const std::vector< `FormulaSetT` > & `infeasibleSubsets () const`
- const std::vector< `Module` \* > & `usedBackends () const`
- const carl::FastSet< `FormulaT` > & `constraintsToInform () const`
- const carl::FastSet< `FormulaT` > & `informedConstraints () const`
- void `addLemma (const FormulaT &_lemma, const LemmaType &_lt=LemmaType::NORMAL, const FormulaT &_preferredFormula=FormulaT(carl::FormulaType::TRUE))`

*Stores a lemma being a valid formula.*
- bool `hasLemmas ()`

*Checks whether this module or any of its backends provides any lemmas.*
- void `clearLemmas ()`

*Deletes all yet found lemmas.*
- const std::vector< `Lemma` > & `lemmas () const`
- `ModuleInput::const_iterator firstUncheckedReceivedSubformula () const`
- `ModuleInput::const_iterator firstSubformulaToPass () const`
- void `receivedFormulaChecked ()`

*Notifies that the received formulas has been checked.*
- const `smrat::Conditionals & answerFound () const`
- bool `isPreprocessor () const`
- carl::Variable `objective () const`
- bool `is_minimizing () const`
- void `excludeNotReceivedVariablesFromModel () const`

*Excludes all variables from the current model, which do not occur in the received formula.*
- void `updateLemmas ()`

- Stores all lemmas of any backend of this module in its own lemma vector.
- void `collectTheoryPropagations ()`

*Collects the formulas in the given formula, which are part of the received formula.*
- void `collectOrigins (const FormulaT &_formula, FormulasT &_origins) const`

*Checks the given infeasible subset for minimality by storing all subsets of it, which have a smaller size which differs from the size of the infeasible subset not more than the given threshold.*
- void `checkInfSubsetForMinimality (std::vector< FormulaSetT >::const_iterator _infsSubset, const std::string &_filename="smaller_muses", unsigned _maxSizeDifference=1) const`

*Prints everything relevant of the solver.*
- virtual std::pair< bool, FormulaT > `getReceivedFormulaSimplified ()`

*Prints the vector of the received formula.*
- void `print (const std::string &_initiation="***") const`

*Prints the vector of passed formula.*
- void `printReceivedFormula (const std::string &_initiation="***") const`

*Prints the infeasible subsets.*
- void `printModel (std::ostream &_out=std::cout) const`

*Prints the assignment of this module satisfying its received formula if it satisfiable and this module could find an assignment.*
- void `printAllModels (std::ostream &_out=std::cout)`

*Prints all assignments of this module satisfying its received formula if it satisfiable and this module could find an assignment.*

### Static Public Member Functions

- static void `freeSplittingVariable (const FormulaT &_splittingVariable)`

### Static Public Attributes

- static size\_t `mNumOfBranchVarsToStore = 5`

*The number of different variables to consider for a probable infinite loop of branchings.*
- static std::vector< Branching > `mLastBranches = std::vector<Branching>(mNumOfBranchVarsToStore, Branching(typename Poly::PolyType(), 0))`

*Stores the last branches in a cycle buffer.*
- static size\_t `mFirstPosInLastBranches = 0`

*The beginning of the cyclic buffer storing the last branches.*
- static std::vector< FormulaT > `mOldSplittingVariables`

*Reusable splitting variables.*

### Protected Member Functions

- virtual bool `informCore (const FormulaT &_constraint)`

*Informs the module about the given constraint.*
- virtual void `deinformCore (const FormulaT &_constraint)`

*The inverse of informing about a constraint.*
- bool `anAnswerFound () const`

*Checks for all antecedent modules and those which run in parallel with the same antecedent modules, whether one of them has determined a result.*
- void `clearModel () const`

*Clears the assignment, if any was found.*
- void `clearModels () const`

- Clears all assignments, if any was found.
- void `cleanModel () const`

*Substitutes variable occurrences by its model value in the model values of other variables.*
- `ModuleInput::iterator passedFormulaBegin ()`
- `ModuleInput::iterator passedFormulaEnd ()`
- void `addOrigin (ModuleInput::iterator _formula, const FormulaT &_origin)`

*Adds the given set of formulas in the received formula to the origins of the given passed formula.*
- const `FormulaT & getOrigins (ModuleInput::const_iterator _formula) const`

*Gets the origins of the passed formula at the given position.*
- void `getOrigins (const FormulaT &_formula, FormulasT &_origins) const`
- void `getOrigins (const FormulaT &_formula, FormulaSetT &_origins) const`
- std::pair< `ModuleInput::iterator, bool > removeOrigin (ModuleInput::iterator _formula, const FormulaT &_origin)`
- std::pair< `ModuleInput::iterator, bool > removeOrigins (ModuleInput::iterator _formula, const std::shared_ptr< std::vector< FormulaT >> &_origins)`
- void `informBackends (const FormulaT &_constraint)`

*Informs all backends of this module about the given constraint.*
- virtual void `addConstraintToInform (const FormulaT &_constraint)`

*Adds a constraint to the collection of constraints of this module, which are informed to a freshly generated backend.*
- std::pair< `ModuleInput::iterator, bool > addReceivedSubformulaToPassedFormula (ModuleInput::const_iterator _subformula)`

*Copies the given sub-formula of the received formula to the passed formula.*
- bool `originInReceivedFormula (const FormulaT &_origin) const`
- std::pair< `ModuleInput::iterator, bool > addSubformulaToPassedFormula (const FormulaT &_formula)`

*Adds the given formula to the passed formula with no origin.*
- std::pair< `ModuleInput::iterator, bool > addSubformulaToPassedFormula (const FormulaT &_formula, const std::shared_ptr< std::vector< FormulaT >> &_origins)`

*Adds the given formula to the passed formula.*
- std::pair< `ModuleInput::iterator, bool > addSubformulaToPassedFormula (const FormulaT &_formula, const FormulaT &_origin)`

*Adds the given formula to the passed formula.*
- void `generateTrivialInfeasibleSubset ()`

*Stores the trivial infeasible subset being the set of received formulas.*
- void `receivedFormulasAsInfeasibleSubset (ModuleInput::const_iterator _subformula)`

*Stores an infeasible subset consisting only of the given received formula.*
- std::vector< `FormulaT >::const_iterator findBestOrigin (const std::vector< FormulaT > &_origins) const`
- void `getInfeasibleSubsets ()`

*Copies the infeasible subsets of the passed formula.*
- std::vector< `FormulaSetT > getInfeasibleSubsets (const Module &_backend) const`

*Get the infeasible subsets the given backend provides.*
- const `Model & backendsModel () const`

*Stores the model of a backend which determined satisfiability of the passed formula in the model of this module.*
- void `getBackendsModel () const`
- void `getBackendsAllModels () const`

*Stores all models of a backend in the list of all models of this module.*
- virtual `Answer runBackends (bool _final, bool _full, carl::Variable _objective)`

*Runs the backend solvers on the passed formula.*
- virtual `Answer runBackends ()`
- virtual `ModuleInput::iterator eraseSubformulaFromPassedFormula (ModuleInput::iterator _subformula, bool _ignoreOrigins=false)`

*Removes everything related to the sub-formula to remove from the passed formula in the backends of this module.*
- void `clearPassedFormula ()`

- std::vector< [FormulaT](#) > [merge](#) (const std::vector< [FormulaT](#) > &, const std::vector< [FormulaT](#) > &) const  
*Merges the two vectors of sets into the first one.*
- size\_t [determine\\_smallest\\_origin](#) (const std::vector< [FormulaT](#) > &origins) const
- bool [probablyLooping](#) (const typename Poly::PolyType &\_branchingPolynomial, const Rational &\_branchingValue) const  
*Checks whether given the current branching value and branching variable/polynomial it is (highly) probable that this branching is part of an infinite loop of branchings.*
- bool [branchAt](#) (const Poly &\_polynomial, bool \_integral, const Rational &\_value, std::vector< [FormulaT](#) > &&\_premise, bool \_leftCaseWeak=true, bool \_preferLeftCase=true, bool \_useReceivedFormulaAsPremise=false)  
*Adds a lemmas which provoke a branching for the given variable at the given value, if this module returns Unknown and there exists a preceding SATModule.*
- bool [branchAt](#) (const Poly &\_polynomial, bool \_integral, const Rational &\_value, bool \_leftCaseWeak=true, bool \_preferLeftCase=true, bool \_useReceivedFormulaAsPremise=false, const std::vector< [FormulaT](#) > &&\_premise=std::vector< [FormulaT](#) >())
- bool [branchAt](#) (carl::Variable::Arg \_var, const Rational &\_value, std::vector< [FormulaT](#) > &&\_premise, bool \_leftCaseWeak=true, bool \_preferLeftCase=true, bool \_useReceivedFormulaAsPremise=false)
- bool [branchAt](#) (carl::Variable::Arg \_var, const Rational &\_value, bool \_leftCaseWeak=true, bool \_preferLeftCase=true, bool \_useReceivedFormulaAsPremise=false, const std::vector< [FormulaT](#) > &\_premise=std::vector< [FormulaT](#) >())
- void [splitUnequalConstraint](#) (const [FormulaT](#) &)  
*Adds the following lemmas for the given constraint p!=0.*
- unsigned [checkModel](#) () const
- void [addInformationRelevantFormula](#) (const [FormulaT](#) &formula)  
*Adds a formula to the InformationRelevantFormula.*
- const std::set< [FormulaT](#) > & [getInformationRelevantFormulas](#) ()  
*Gets all InformationRelevantFormulas.*
- bool [isLemmaLevel](#) ([LemmaLevel](#) level)  
*Checks if current lemma level is greater or equal to given level.*

## Static Protected Member Functions

- static bool [modelsDisjoint](#) (const Model &\_modelA, const Model &\_modelB)  
*Checks whether there is no variable assigned by both models.*

## Protected Attributes

- std::vector< [FormulaSetT](#) > [mInfeasibleSubsets](#)  
*Stores the infeasible subsets.*
- Manager \*const [mpManager](#)  
*A reference to the manager.*
- Model [mModel](#)  
*Stores the assignment of the current satisfiable result, if existent.*
- std::vector< Model > [mAllModels](#)  
*Stores all satisfying assignments.*
- bool [mModelComputed](#)  
*True, if the model has already been computed.*
- bool [mFinalCheck](#)  
*true, if the check procedure should perform a final check which especially means not to postpone splitting decisions*
- bool [mFullCheck](#)  
*false, if this module should avoid too expensive procedures and rather return unknown instead.*
- carl::Variable [mObjectiveVariable](#)  
*Objective variable to be minimized. If set to NO\_VARIABLE, a normal sat check should be performed.*
- std::vector< TheoryPropagation > [mTheoryPropagations](#)

- std::atomic< [Answer](#) > mSolverState  
*States whether the received formula is known to be satisfiable or unsatisfiable otherwise it is set to unknown.*
- std::atomic\_bool \* mBackendsFoundAnswer  
*This flag is passed to any backend and if it determines an answer to a prior check call, this flag is fired.*
- [Conditionals](#) mFoundAnswer  
*Vector of Booleans: If any of them is true, we have to terminate a running check procedure.*
- std::vector< [Module](#) \* > mUsedBackends  
*The backends of this module which are currently used (conditions to use this module are fulfilled for the passed formula).*
- std::vector< [Module](#) \* > mAllBackends  
*The backends of this module which have been used.*
- std::vector< [Lemma](#) > mLemmas  
*Stores the lemmas being valid formulas this module or its backends made.*
- [ModuleInput](#)::iterator mFirstSubformulaToPass  
*Stores the position of the first sub-formula in the passed formula, which has not yet been considered for a consistency check of the backends.*
- carl::FastSet< [FormulaT](#) > mConstraintsToInform  
*Stores the constraints which the backends must be informed about.*
- carl::FastSet< [FormulaT](#) > mInformedConstraints  
*Stores the position of the first constraint of which no backend has been informed about.*
- [ModuleInput](#)::const\_iterator mFirstUncheckedReceivedSubformula  
*Stores the position of the first (by this module) unchecked sub-formula of the received formula.*
- unsigned mSmallerMusesCheckCounter  
*Counter used for the generation of the smt2 files to check for smaller muses.*
- std::vector< std::size\_t > mVariableCounters  
*Maps variables to the number of their occurrences.*

### 0.15.266.1 Detailed Description

```
template<typename Settings>
class smrat::IntEqModule< Settings >
```

A module which checks whether the equations contained in the received (linear integer) formula have a solution.

### 0.15.266.2 Member Typedef Documentation

```
0.15.266.2.1 SettingsType template<typename Settings >
typedef Settings smrat::IntEqModule< Settings >::SettingsType
```

### 0.15.266.3 Member Enumeration Documentation

```
0.15.266.3.1 LemmaType enum smrat::Module::LemmaType : unsigned [strong], [inherited]
```

Enumerator

|           |  |

| NORMAL    |  |
| PERMANENT |  |

#### 0.15.266.4 Constructor & Destructor Documentation

**0.15.266.4.1 `IntEqModule()`** template<typename Settings>  
`smtrat::IntEqModule< Settings >::IntEqModule (`  
 `const ModuleInput * _formula,`  
 `Conditionals & _conditionals,`  
 `Manager * _manager = NULL )`

**0.15.266.4.2 `~IntEqModule()`** template<typename Settings>  
`smtrat::IntEqModule< Settings >::~IntEqModule ( ) [inline]`

#### 0.15.266.5 Member Function Documentation

**0.15.266.5.1 `add()`** bool smtrat::Module::add (  
 `ModuleInput::const_iterator _subformula ) [inherited]`

The module has to take the given sub-formula of the received formula into account.

##### Parameters

|                          |                                                    |
|--------------------------|----------------------------------------------------|
| <code>_subformula</code> | The sub-formula to take additionally into account. |
|--------------------------|----------------------------------------------------|

##### Returns

false, if it can be easily decided that this sub-formula causes a conflict with the already considered sub-formulas; true, otherwise.

**0.15.266.5.2 `addConstraintToInform()`** void smtrat::Module::addConstraintToInform (  
 `const FormulaT & _constraint ) [protected], [virtual], [inherited]`

Adds a constraint to the collection of constraints of this module, which are informed to a freshly generated backend.

##### Parameters

|                          |                        |
|--------------------------|------------------------|
| <code>_constraint</code> | The constraint to add. |
|--------------------------|------------------------|

Reimplemented in [smtrat::SATModule< Settings >](#).

**0.15.266.5.3 `addCore()`** template<typename Settings>  
`bool smtrat::IntEqModule< Settings >::addCore (`  
 `ModuleInput::const_iterator _subformula ) [virtual]`

The module has to take the given sub-formula of the received formula into account.

##### Parameters

|                          |                                                    |
|--------------------------|----------------------------------------------------|
| <code>_subformula</code> | The sub-formula to take additionally into account. |
|--------------------------|----------------------------------------------------|

##### Returns

false, if it can be easily decided that this sub-formula causes a conflict with the already considered sub-formulas; true, otherwise.

Reimplemented from [smtrat::Module](#).

**0.15.266.5.4 addInformationRelevantFormula()** void smtrat::Module::addInformationRelevantFormula (  
    const [FormulaT](#) & formula ) [protected], [inherited]

Adds a formula to the InformationRelevantFormula.

#### Parameters

|                |                |
|----------------|----------------|
| <i>formula</i> | Formula to add |
|----------------|----------------|

**0.15.266.5.5 addLemma()** void smtrat::Module::addLemma (  
    const [FormulaT](#) & \_lemma,  
    const [LemmaType](#) & \_lt = [LemmaType::NORMAL](#),  
    const [FormulaT](#) & \_preferredFormula = [FormulaT](#)( [carl::FormulaType::TRUE](#) ) ) [inline],  
[inherited]

Stores a lemma being a valid formula.

#### Parameters

|                          |                                                                       |
|--------------------------|-----------------------------------------------------------------------|
| <i>_lemma</i>            | The eduction/lemma to store.                                          |
| <i>_lt</i>               | The type of the lemma.                                                |
| <i>_preferredFormula</i> | Hint for the next decision, which formula should be assigned to true. |

**0.15.266.5.6 addOrigin()** void smtrat::Module::addOrigin (  
    [ModuleInput::iterator](#) \_formula,  
    const [FormulaT](#) & \_origin ) [inline], [protected], [inherited]

Adds the given set of formulas in the received formula to the origins of the given passed formula.

#### Parameters

|                 |                                                           |
|-----------------|-----------------------------------------------------------|
| <i>_formula</i> | The passed formula to set the origins for.                |
| <i>_origin</i>  | A set of formulas in the received formula of this module. |

**0.15.266.5.7 addReceivedSubformulaToPassedFormula()** std::pair<[ModuleInput::iterator](#),bool>  
smtrat::Module::addReceivedSubformulaToPassedFormula (  
    [ModuleInput::const\\_iterator](#) \_subformula ) [inline], [protected], [inherited]

Copies the given sub-formula of the received formula to the passed formula.

Note, that there is always a link between sub-formulas of the passed formulas to sub-formulas of the received formulas, which are responsible for its occurrence.

#### Parameters

|                    |                                                  |
|--------------------|--------------------------------------------------|
| <i>_subformula</i> | The sub-formula of the received formula to copy. |
|--------------------|--------------------------------------------------|

**0.15.266.5.8 addSubformulaToPassedFormula()** [1/3] std::pair<[ModuleInput::iterator](#),bool> smtrat↔

```
::Module::addSubformulaToPassedFormula (
 const FormulaT & _formula) [inline], [protected], [inherited]
```

Adds the given formula to the passed formula with no origin.

Note that in the next call of this module's removeSubformula, all formulas in the passed formula without origins will be removed.

#### Parameters

|                       |                                           |
|-----------------------|-------------------------------------------|
| <code>_formula</code> | The formula to add to the passed formula. |
|-----------------------|-------------------------------------------|

#### Returns

A pair to the position where the formula to add has been inserted (or its first sub-formula which has not yet been in the passed formula, in case the formula to add is a conjunction), and a Boolean stating whether anything has been added to the passed formula.

**0.15.266.5.9 `addSubformulaToPassedFormula()` [2/3] std::pair<[ModuleInput::iterator](#),bool> smrat->**

```
::Module::addSubformulaToPassedFormula (
 const FormulaT & _formula,
 const FormulaT & _origin) [inline], [protected], [inherited]
```

Adds the given formula to the passed formula.

#### Parameters

|                       |                                                                                                                           |
|-----------------------|---------------------------------------------------------------------------------------------------------------------------|
| <code>_formula</code> | The formula to add to the passed formula.                                                                                 |
| <code>_origin</code>  | The sub-formula of the received formula being responsible for the occurrence of the formula to add to the passed formula. |

#### Returns

A pair to the position where the formula to add has been inserted (or its first sub-formula which has not yet been in the passed formula, in case the formula to add is a conjunction), and a Boolean stating whether anything has been added to the passed formula.

**0.15.266.5.10 `addSubformulaToPassedFormula()` [3/3] std::pair<[ModuleInput::iterator](#),bool>**

```
smrat::Module::addSubformulaToPassedFormula (
 const FormulaT & _formula,
 const std::shared_ptr< std::vector< FormulaT >> & _origins) [inline], [protected],
[inherited]
```

Adds the given formula to the passed formula.

#### Parameters

|                       |                                                                                                                                         |
|-----------------------|-----------------------------------------------------------------------------------------------------------------------------------------|
| <code>_formula</code> | The formula to add to the passed formula.                                                                                               |
| <code>_origins</code> | The link of the formula to add to the passed formula to sub-formulas of the received formulas, which are responsible for its occurrence |

#### Returns

A pair to the position where the formula to add has been inserted (or its first sub-formula which has not yet been in the passed formula, in case the formula to add is a conjunction), and a Boolean stating whether anything has been added to the passed formula.

**0.15.266.5.11 allModels()** const std::vector<[Model](#)>& smtrat::Module::allModels () const [inline], [inherited]

**Returns**

All satisfying assignments, if existent.

**0.15.266.5.12 anAnswerFound()** bool smtrat::Module::anAnswerFound () const [inline], [protected], [inherited]

Checks for all antecedent modules and those which run in parallel with the same antecedent modules, whether one of them has determined a result.

**Returns**

True, if one of them has determined a result.

**0.15.266.5.13 answerFound()** const [smtrat::Conditionals](#)& smtrat::Module::answerFound () const [inline], [inherited]

**Returns**

A vector of Booleans: If any of them is true, we have to terminate a running check procedure.

**0.15.266.5.14 backendsModel()** const [Model](#) & smtrat::Module::backendsModel () const [protected], [inherited]

Stores the model of a backend which determined satisfiability of the passed formula in the model of this module.

**0.15.266.5.15 branchAt() [1/4]** bool smtrat::Module::branchAt ( carl::Variable::Arg \_var, const [Rational](#) & \_value, bool \_leftCaseWeak = true, bool \_preferLeftCase = true, bool \_useReceivedFormulaAsPremise = false, const std::vector< [FormulaT](#) > & \_premise = std::vector<[FormulaT](#)>() ) [inline], [protected], [inherited]

**0.15.266.5.16 branchAt() [2/4]** bool smtrat::Module::branchAt ( carl::Variable::Arg \_var, const [Rational](#) & \_value, std::vector< [FormulaT](#) > && \_premise, bool \_leftCaseWeak = true, bool \_preferLeftCase = true, bool \_useReceivedFormulaAsPremise = false ) [inline], [protected], [inherited]

**0.15.266.5.17 branchAt() [3/4]** bool smtrat::Module::branchAt ( const [Poly](#) & \_polynomial, bool \_integral, const [Rational](#) & \_value, bool \_leftCaseWeak = true, bool \_preferLeftCase = true, bool \_useReceivedFormulaAsPremise = false, const std::vector< [FormulaT](#) > & \_premise = std::vector<[FormulaT](#)>() ) [inline], [protected], [inherited]

**0.15.266.5.18 branchAt() [4/4]** `bool smtrat::Module::branchAt (`

```
const Poly & _polynomial,
bool _integral,
const Rational & _value,
std::vector< FormulaT > && _premise,
bool _leftCaseWeak = true,
bool _preferLeftCase = true,
bool _useReceivedFormulaAsPremise = false) [protected], [inherited]
```

Adds a lemmas which provoke a branching for the given variable at the given value, if this module returns Unknown and there exists a preceding [SATModule](#).

Note that the given value is rounded down and up, if the given variable is integer-valued.

**Parameters**

|                                           |                                                                                                                                                                                                                |
|-------------------------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>_polynomial</code>                  | The variable to branch for.                                                                                                                                                                                    |
| <code>_integral</code>                    | A flag being true, if all variables in the polynomial to branch for are integral.                                                                                                                              |
| <code>_value</code>                       | The value to branch at.                                                                                                                                                                                        |
| <code>_premise</code>                     | The sub-formulas of the received formula from which the branch is followed. Note, that a premise is not necessary, as every branch is a valid formula. But a premise can prevent from branching unnecessarily. |
| <code>_leftCaseWeak</code>                | true, if a branching in the form of (or ( $\leq p b$ ) ( $> p b$ )) is desired. false, if a branching in the form of (or ( $< p b$ ) ( $\geq p b$ )) is desired.                                               |
| <code>_preferLeftCase</code>              | true, if the left case (polynomial less(or equal) 0 shall be chosen first. false, otherwise.                                                                                                                   |
| <code>_useReceivedFormulaAsPremise</code> | true, if the whole received formula should be used as premise                                                                                                                                                  |

**0.15.266.5.19 check() [Answer](#)** `smtrat::Module::check (`

```
bool _final = false,
bool _full = true,
carl::Variable _objective = carl::Variable::NO_VARIABLE) [virtual], [inherited]
```

Checks the received formula for consistency.

Note, that this is an implementation of the satisfiability check of the conjunction of the so far received formulas, which does actually nothing but passing the problem to its backends. This implementation is only used internally and must be overwritten by any derived module.

**Parameters**

|                         |                                                                                                                                       |
|-------------------------|---------------------------------------------------------------------------------------------------------------------------------------|
| <code>_final</code>     | true, if this satisfiability check will be the last one (for a global sat-check), if its result is SAT                                |
| <code>_full</code>      | false, if this module should avoid too expensive procedures and rather return unknown instead.                                        |
| <code>_objective</code> | if not set to NO_VARIABLE, the module should find an assignment minimizing this objective variable; otherwise any assignment is good. |

**Returns**

True, if the received formula is satisfiable; False, if the received formula is not satisfiable; Unknown, otherwise.

Reimplemented in [smtrat::PModule](#).

**0.15.266.5.20 checkCore()** `template<typename Settings >`

```
Answer smtrat::IntEqModule< Settings >::checkCore () [virtual]
```

Checks the received formula for consistency.

**Returns**

SAT, if the received formula is satisfiable; UNSAT, if the received formula is not satisfiable; Unknown, otherwise.

Reimplemented from [smrat::Module](#).

**0.15.266.5.21 `checkInfSubsetForMinimality()`** `void smrat::Module::checkInfSubsetForMinimality ( std::vector< FormulaSetT >::const_iterator _infssubset,`  
`const std::string & _filename = "smaller_muses",`  
`unsigned _maxSizeDifference = 1 ) const [inherited]`

Checks the given infeasible subset for minimality by storing all subsets of it, which have a smaller size which differs from the size of the infeasible subset not more than the given threshold.

**Parameters**

|                                 |                                                                                                        |
|---------------------------------|--------------------------------------------------------------------------------------------------------|
| <code>_infssubset</code>        | The infeasible subset to check for minimality.                                                         |
| <code>_filename</code>          | The name of the file to store the infeasible subsets in order to be able to check their infeasibility. |
| <code>_maxSizeDifference</code> | The maximal difference between the sizes of the subsets compared to the size of the infeasible subset. |

**0.15.266.5.22 `checkModel()`** `unsigned smrat::Module::checkModel ( ) const [protected], [inherited]`

**Returns**

false, if the current model of this module does not satisfy the current given formula; true, if it cannot be said whether the model satisfies the given formula.

**0.15.266.5.23 `cleanModel()`** `void smrat::Module::cleanModel ( ) const [inline], [protected], [inherited]`

Substitutes variable occurrences by its model value in the model values of other variables.

**0.15.266.5.24 `clearLemmas()`** `void smrat::Module::clearLemmas ( ) [inline], [inherited]`  
Deletes all yet found lemmas.

**0.15.266.5.25 `clearModel()`** `void smrat::Module::clearModel ( ) const [inline], [protected], [inherited]`

Clears the assignment, if any was found.

**0.15.266.5.26 `clearModels()`** `void smrat::Module::clearModels ( ) const [inline], [protected], [inherited]`

Clears all assignments, if any was found.

**0.15.266.5.27 `clearPassedFormula()`** `void smrat::Module::clearPassedFormula ( ) [protected], [inherited]`

```
0.15.266.5.28 collectOrigins() [1/2] void smtrat::Module::collectOrigins (
 const FormulaT & _formula,
 FormulaSetT & _origins) const [inherited]
```

```
0.15.266.5.29 collectOrigins() [2/2] void smtrat::Module::collectOrigins (
 const FormulaT & _formula,
 FormulasT & _origins) const [inherited]
```

Collects the formulas in the given formula, which are part of the received formula.

If the given formula directly occurs in the received formula, it is inserted into the given set. Otherwise, the given formula must be of type AND and all its sub-formulas part of the received formula. Hence, they will be added to the given set.

#### Parameters

|                       |                                                                                                      |
|-----------------------|------------------------------------------------------------------------------------------------------|
| <code>_formula</code> | The formula from which to collect the formulas being sub-formulas of the received formula (origins). |
| <code>_origins</code> | The set in which to store the origins.                                                               |

```
0.15.266.5.30 collectTheoryPropagations() void smtrat::Module::collectTheoryPropagations ()
[inherited]
```

```
0.15.266.5.31 constraintsToInform() const carl::FastSet<FormulaT>& smtrat::Module::constraintsToInform () const [inline], [inherited]
```

#### Returns

The constraints which the backends must be informed about.

```
0.15.266.5.32 currentlySatisfied() virtual unsigned smtrat::Module::currentlySatisfied (
 const FormulaT &) const [inline], [virtual], [inherited]
```

#### Returns

0, if the given formula is conflicted by the current model; 1, if the given formula is satisfied by the current model; 2, otherwise; 3, if we do not know anything (default)

Reimplemented in [smtrat::LRAbstractModule< Settings >](#), [smtrat::LRAbstractModule< LRASettingsICP >](#), and [smtrat::LRAbstractModule< LRASettings >](#)

```
0.15.266.5.33 currentlySatisfiedByBackend() unsigned smtrat::Module::currentlySatisfiedByBackend (
 const FormulaT & _formula) const [inherited]
```

#### Returns

0, if the given formula is conflicted by the current model; 1, if the given formula is satisfied by the current model; 2, otherwise 3, if we do not know anything (default)

```
0.15.266.5.34 deinform() void smtrat::Module::deinform (
 const FormulaT & _constraint) [inherited]
```

The inverse of informing about a constraint.

All data structures which were kept regarding this constraint are going to be removed. Note, that this makes only sense if it is not likely enough that a formula with this constraint must be solved again.

**Parameters**

|                          |                                                         |
|--------------------------|---------------------------------------------------------|
| <code>_constraint</code> | The constraint to remove from internal data structures. |
|--------------------------|---------------------------------------------------------|

**0.15.266.5.35 `deinformCore()`** `virtual void smtrat::Module::deinformCore (``const FormulaT & _constraint ) [inline], [protected], [virtual], [inherited]`

The inverse of informing about a constraint.

All data structures which were kept regarding this constraint are going to be removed. Note, that this makes only sense if it is not likely enough that a formula with this constraint must be solved again.

**Parameters**

|                          |                                                         |
|--------------------------|---------------------------------------------------------|
| <code>_constraint</code> | The constraint to remove from internal data structures. |
|--------------------------|---------------------------------------------------------|

Reimplemented in [smtrat::LRAModule< Settings >](#), [smtrat::LRAModule< LRASettingsICP >](#), and [smtrat::LRAModule< LRASettings1 >](#).

**0.15.266.5.36 `determine_smallest_origin()`** `size_t smtrat::Module::determine_smallest_origin (``const std::vector< FormulaT > & origins ) const [protected], [inherited]`**Parameters**

|                      |                              |
|----------------------|------------------------------|
| <code>origins</code> | A vector of sets of origins. |
|----------------------|------------------------------|

**Returns**

The index of the smallest (regarding the size of the sets) element of origins

**0.15.266.5.37 `eraseSubformulaFromPassedFormula()`** `ModuleInput::iterator smtrat::Module::eraseSubformulaFromPassedFormula (``ModuleInput::iterator _subformula,``bool _ignoreOrigins = false ) [protected], [virtual], [inherited]`

Removes everything related to the sub-formula to remove from the passed formula in the backends of this module. Afterwards the sub-formula is removed from the passed formula.

**Parameters**

|                             |                                                                                                              |
|-----------------------------|--------------------------------------------------------------------------------------------------------------|
| <code>_subformula</code>    | The sub-formula to remove from the passed formula.                                                           |
| <code>_ignoreOrigins</code> | True, if the sub-formula shall be removed regardless of its origins (should only be applied with expertise). |

**Returns**

Reimplemented in [smtrat::ICPModule< Settings >](#), [smtrat::ICPModule< ICPSettings4 >](#), and [smtrat::ICPModule< ICPSettings1 >](#).

**0.15.266.5.38 `excludeNotReceivedVariablesFromModel()`** `void smtrat::Module::excludeNotReceivedVariablesFromModel ( ) const [inherited]`

Excludes all variables from the current model, which do not occur in the received formula.

```
0.15.266.5.39 findBestOrigin() std::vector< FormulaT >::const_iterator smtrat::Module::findBestOrigin (const std::vector< FormulaT > & _origins) const [protected], [inherited]
```

**Parameters**

|                 |  |
|-----------------|--|
| <i>_origins</i> |  |
|-----------------|--|

**Returns**

```
0.15.266.5.40 firstSubformulaToPass() ModuleInput::const_iterator smtrat::Module::firstSubformulaToPass () const [inline], [inherited]
```

**Returns**

The position of the first sub-formula in the passed formula, which has not yet been considered for a consistency check of the backends.

```
0.15.266.5.41 firstUncheckedReceivedSubformula() ModuleInput::const_iterator smtrat::Module::firstUncheckedReceivedSubformula () const [inline], [inherited]
```

**Returns**

The position of the first (by this module) unchecked sub-formula of the received formula.

```
0.15.266.5.42 freeSplittingVariable() static void smtrat::Module::freeSplittingVariable (const FormulaT & _splittingVariable) [inline], [static], [inherited]
```

```
0.15.266.5.43 generateTrivialInfeasibleSubset() void smtrat::Module::generateTrivialInfeasibleSubset () [inline], [protected], [inherited]
```

Stores the trivial infeasible subset being the set of received formulas.

```
0.15.266.5.44 getBackendsAllModels() void smtrat::Module::getBackendsAllModels () const [protected], [inherited]
```

Stores all models of a backend in the list of all models of this module.

```
0.15.266.5.45 getBackendsModel() void smtrat::Module::getBackendsModel () const [protected], [inherited]
```

```
0.15.266.5.46 getInfeasibleSubsets() [1/2] void smtrat::Module::getInfeasibleSubsets () [protected], [inherited]
```

Copies the infeasible subsets of the passed formula.

**0.15.266.5.47 getInfeasibleSubsets()** [2/2] std::vector< `FormulaSetT` > smtrat::Module::getInfeasibleSubsets (

    const `Module` & `_backend` ) const [protected], [inherited]

Get the infeasible subsets the given backend provides.

Note, that an infeasible subset in a backend contains sub formulas of the passed formula and an infeasible subset of this module contains sub formulas of the received formula. In this method the LATTER is returned.

**Parameters**

|                       |                                                          |
|-----------------------|----------------------------------------------------------|
| <code>_backend</code> | The backend from which to obtain the infeasible subsets. |
|-----------------------|----------------------------------------------------------|

**Returns**

The infeasible subsets the given backend provides.

**0.15.266.5.48 `getInformationRelevantFormulas()`** `const std::set< FormulaT > & smtrat::Module::getInformationRelevantFormulas ( ) [protected], [inherited]`  
Gets all InformationRelevantFormulas.

**Returns**

Set of all formulas

**0.15.266.5.49 `getModelEqualities()`** `std::list< std::vector< carl::Variable > > smtrat::Module::getModelEqualities ( ) const [virtual], [inherited]`  
Partition the variables from the current model into equivalence classes according to their assigned value.  
The result is a set of equivalence classes of variables where all variables within one class are assigned the same value. Note that the number of classes may not be minimal, i.e. two classes may actually be equivalent.

**Returns**

Equivalence classes.

**0.15.266.5.50 `getOrigins()` [1/3]** `void smtrat::Module::getOrigins ( const FormulaT & _formula, FormulaSetT & _origins ) const [inline], [protected], [inherited]`

**Parameters**

|                       |  |
|-----------------------|--|
| <code>_formula</code> |  |
| <code>_origins</code> |  |

**0.15.266.5.51 `getOrigins()` [2/3]** `void smtrat::Module::getOrigins ( const FormulaT & _formula, FormulasT & _origins ) const [inline], [protected], [inherited]`

**Parameters**

|                       |  |
|-----------------------|--|
| <code>_formula</code> |  |
| <code>_origins</code> |  |

**0.15.266.5.52 `getOrigins()` [3/3]** `const FormulaT& smtrat::Module::getOrigins ( ModuleInput::const_iterator _formula ) const [inline], [protected], [inherited]`  
Gets the origins of the passed formula at the given position.

**Parameters**

|                       |                                                   |
|-----------------------|---------------------------------------------------|
| <code>_formula</code> | The position of a formula in the passed formulas. |
|-----------------------|---------------------------------------------------|

**Returns**

The origins of the passed formula at the given position.

**0.15.266.5.53 `getReceivedFormulaSimplified()`** `std::pair< bool, FormulaT >` `smtrat::Module::getReceivedFormulaSimplified( )` [virtual], [inherited]

**Returns**

A pair of a Boolean and a formula, where the Boolean is true, if the received formula could be simplified to an equisatisfiable formula. The formula is equisatisfiable to this module's received formula, if the Boolean is true.

Reimplemented in [smtrat::PModule](#).

**0.15.266.5.54 `hasLemmas()`** `bool smtrat::Module::hasLemmas( )` [inline], [inherited]

Checks whether this module or any of its backends provides any lemmas.

**0.15.266.5.55 `hasValidInfeasibleSubset()`** `bool smtrat::Module::hasValidInfeasibleSubset( ) const` [inherited]

**Returns**

true, if the module has at least one valid infeasible subset, that is all its elements are sub-formulas of the received formula (pointer must be equal).

**0.15.266.5.56 `id()`** `std::size_t smtrat::Module::id( ) const` [inline], [inherited]

**Returns**

A unique ID to identify this module instance.

**0.15.266.5.57 `infeasibleSubsets()`** `const std::vector<FormulaSetT>& smtrat::Module::infeasibleSubsets( ) const` [inline], [inherited]

**Returns**

The infeasible subsets of the set of received formulas (empty, if this module has not detected unsatisfiability of the conjunction of received formulas).

**0.15.266.5.58 `inform()`** `bool smtrat::Module::inform( const FormulaT & _constraint )` [inherited]

Informs the module about the given constraint.

It should be tried to inform this module about any constraint it could receive eventually before `assertSubformula` is called (preferably for the first time, but at least before adding a formula containing that constraint).

**Parameters**

|                          |                                 |
|--------------------------|---------------------------------|
| <code>_constraint</code> | The constraint to inform about. |
|--------------------------|---------------------------------|

**Returns**

false, if it can be easily decided whether the given constraint is inconsistent; true, otherwise.

**0.15.266.5.59 informBackends()** void smrat::Module::informBackends ( const FormulaT & \_constraint ) [inline], [protected], [inherited]

Informs all backends of this module about the given constraint.

**Parameters**

|                    |                                 |
|--------------------|---------------------------------|
| <i>_constraint</i> | The constraint to inform about. |
|--------------------|---------------------------------|

**0.15.266.5.60 informCore()** virtual bool smrat::Module::informCore (

const FormulaT & \_constraint ) [inline], [protected], [virtual], [inherited]

Informs the module about the given constraint.

It should be tried to inform this module about any constraint it could receive eventually before assertSubformula is called (preferably for the first time, but at least before adding a formula containing that constraint).

**Parameters**

|                    |                                 |
|--------------------|---------------------------------|
| <i>_constraint</i> | The constraint to inform about. |
|--------------------|---------------------------------|

**Returns**

false, if it can be easily decided whether the given constraint is inconsistent; true, otherwise.

Reimplemented in [smrat::UnionFindModule< Settings >](#), [smrat::PBPPModule< Settings >](#), [smrat::PBGaussModule< Settings >](#), [smrat::NRAILModule< Settings >](#), [smrat::NewCoveringModule< Settings >](#), [smrat::NewCADModule< Settings >](#), [smrat::LRAModule< Settings >](#), [smrat::LRAModule< LRASettingsICP >](#), [smrat::LRAModule< LRASettings1 >](#), [smrat::IntBlastModule< Settings >](#), [smrat::FPPModule< Settings >](#), [smrat::EQModule< Settings >](#), [smrat::CurryModule< Settings >](#), [smrat::BVMModule< Settings >](#), [smrat::ICPModule< Settings >](#), [smrat::ICPModule< ICPSettings4 >](#), and [smrat::ICPModule< ICPSettings1 >](#).

**0.15.266.5.61 informedConstraints()** const carl::FastSet<FormulaT>& smrat::Module::informedConstraints ( ) const [inline], [inherited]

**Returns**

The position of the first constraint of which no backend has been informed about.

**0.15.266.5.62 init()** void smrat::Module::init ( ) [virtual], [inherited]

Informs all backends about the so far encountered constraints, which have not yet been communicated.

This method must not be called twice and only before the first runBackends call.

Reimplemented in [smrat::PBPPModule< Settings >](#), [smrat::PBGaussModule< Settings >](#), [smrat::NRAILModule< Settings >](#), [smrat::NewCoveringModule< Settings >](#), [smrat::NewCADModule< Settings >](#), [smrat::LRAModule< Settings >](#), [smrat::LRAModule< LRASettingsICP >](#), [smrat::LRAModule< LRASettings1 >](#), [smrat::IntBlastModule< Settings >](#), [smrat::FPPModule< Settings >](#), [smrat::EQModule< Settings >](#), [smrat::CurryModule< Settings >](#), and [smrat::BVMModule< Settings >](#).

**0.15.266.5.63 is\_minimizing()** bool smrat::Module::is\_minimizing ( ) const [inline], [inherited]

**0.15.266.5.64 isLemmaLevel()** `bool smtrat::Module::isLemmaLevel (``LemmaLevel level ) [protected], [inherited]`

Checks if current lemma level is greater or equal to given level.

**Parameters**

|                    |                 |
|--------------------|-----------------|
| <code>level</code> | Level to check. |
|--------------------|-----------------|

**0.15.266.5.65 isPreprocessor()** `bool smtrat::Module::isPreprocessor ( ) const [inline], [inherited]`**Returns**

true, if this module is a preprocessor that is a module, which simplifies its received formula to an equisatisfiable formula being passed to its backends. The simplified formula can be obtained with [getReceivedFormulaSimplified\(\)](#).

**0.15.266.5.66 lemmas()** `const std::vector<Lemma>& smtrat::Module::lemmas ( ) const [inline], [inherited]`**Returns**

A constant reference to the lemmas being valid formulas this module or its backends made.

**0.15.266.5.67 merge()** `std::vector< FormulaT > smtrat::Module::merge (``const std::vector< FormulaT > & _vecSetA,``const std::vector< FormulaT > & _vecSetB ) const [protected], [inherited]`

Merges the two vectors of sets into the first one.

({a,b},{a,c}) and ({b,d},{b}) -> ({a,b,d},{a,b},{a,b,c,d},{a,b,c})

**Parameters**

|                       |                                  |
|-----------------------|----------------------------------|
| <code>_vecSetA</code> | A vector of sets of constraints. |
| <code>_vecSetB</code> | A vector of sets of constraints. |

**Returns**

The vector being the two given vectors merged.

**0.15.266.5.68 model()** `const Model& smtrat::Module::model ( ) const [inline], [inherited]`**Returns**

The assignment of the current satisfiable result, if existent.

**0.15.266.5.69 modelsDisjoint()** `bool smtrat::Module::modelsDisjoint (``const Model & _modelA,``const Model & _modelB ) [static], [protected], [inherited]`

Checks whether there is no variable assigned by both models.

**Parameters**

|                      |                                |
|----------------------|--------------------------------|
| <code>_modelA</code> | The first model to check for.  |
| <code>_modelB</code> | The second model to check for. |

**Returns**

true, if there is no variable assigned by both models; false, otherwise.

**0.15.266.5.70 `moduleName()`** `template<typename Settings >`  
`std::string smtrat::IntEqModule< Settings >::moduleName ( ) const [inline], [virtual]`

**Returns**

The name of the given module type as name.

Reimplemented from [smtrat::Module](#).

**0.15.266.5.71 `objective()`** `carl::Variable smtrat::Module::objective ( ) const [inline], [inherited]`

**0.15.266.5.72 `originInReceivedFormula()`** `bool smtrat::Module::originInReceivedFormula (`  
`const FormulaT & _origin ) const [protected], [inherited]`

**0.15.266.5.73 `passedFormulaBegin()`** `ModuleInput::iterator smtrat::Module::passedFormulaBegin (`  
`) [inline], [protected], [inherited]`

**Returns**

An iterator to the end of the passed formula. TODO: disable this method

**0.15.266.5.74 `passedFormulaEnd()`** `ModuleInput::iterator smtrat::Module::passedFormulaEnd ( )`  
`[inline], [protected], [inherited]`

**Returns**

An iterator to the end of the passed formula.

**0.15.266.5.75 `pPassedFormula()`** `const ModuleInput* smtrat::Module::pPassedFormula ( ) const`  
`[inline], [inherited]`

**Returns**

A pointer to the formula passed to the backends of this module.

**0.15.266.5.76 `pReceivedFormula()`** `const ModuleInput* smtrat::Module::pReceivedFormula ( ) const`  
`[inline], [inherited]`

**Returns**

A pointer to the formula passed to this module.

**0.15.266.5.77 `print()`** `void smtrat::Module::print (`  
`const std::string & _initiation = "***" ) const [inherited]`

Prints everything relevant of the solver.

**Parameters**

|                    |                      |
|--------------------|----------------------|
| <i>_initiation</i> | The line initiation. |
|--------------------|----------------------|

**0.15.266.5.78 printAllModels()** void smtrat::Module::printAllModels ( std::ostream & *\_out* = std::cout ) const [inherited]

Prints all assignments of this module satisfying its received formula if it satisfiable and this module could find an assignment.

**Parameters**

|             |                                        |
|-------------|----------------------------------------|
| <i>_out</i> | The stream to print the assignment on. |
|-------------|----------------------------------------|

**0.15.266.5.79 printInfeasibleSubsets()** void smtrat::Module::printInfeasibleSubsets ( const std::string & *\_initiation* = "\*\*\*" ) const [inherited]

Prints the infeasible subsets.

**Parameters**

|                    |                      |
|--------------------|----------------------|
| <i>_initiation</i> | The line initiation. |
|--------------------|----------------------|

**0.15.266.5.80 printModel()** void smtrat::Module::printModel ( std::ostream & *\_out* = std::cout ) const [inherited]

Prints the assignment of this module satisfying its received formula if it satisfiable and this module could find an assignment.

**Parameters**

|             |                                        |
|-------------|----------------------------------------|
| <i>_out</i> | The stream to print the assignment on. |
|-------------|----------------------------------------|

**0.15.266.5.81 printPassedFormula()** void smtrat::Module::printPassedFormula ( const std::string & *\_initiation* = "\*\*\*" ) const [inherited]

Prints the vector of passed formula.

**Parameters**

|                    |                      |
|--------------------|----------------------|
| <i>_initiation</i> | The line initiation. |
|--------------------|----------------------|

**0.15.266.5.82 printReceivedFormula()** void smtrat::Module::printReceivedFormula ( const std::string & *\_initiation* = "\*\*\*" ) const [inherited]

Prints the vector of the received formula.

**Parameters**

|                    |                      |
|--------------------|----------------------|
| <i>_initiation</i> | The line initiation. |
|--------------------|----------------------|

```
0.15.266.5.83 probablyLooping() bool smtrat::Module::probablyLooping (
 const typename Poly::PolyType & _branchingPolynomial,
 const Rational & _branchingValue) const [protected], [inherited]
```

Checks whether given the current branching value and branching variable/polynomial it is (highly) probable that this branching is part of an infinite loop of branchings.

#### Parameters

|                                   |                                                                                     |
|-----------------------------------|-------------------------------------------------------------------------------------|
| <code>_branchingPolynomial</code> | The polynomial to branch at (in most branching strategies this is just a variable). |
| <code>_branchingValue</code>      | The value to branch at.                                                             |

#### Returns

true, if this branching is probably part of an infinite loop of branchings; false, otherwise.

```
0.15.266.5.84 receivedFormulaChecked() void smtrat::Module::receivedFormulaChecked () [inline], [inherited]
```

Notifies that the received formulas has been checked.

```
0.15.266.5.85 receivedFormulasAsInfeasibleSubset() void smtrat::Module::receivedFormulasAs< InfeasibleSubset (
```

```
 ModuleInput::const_iterator _subformula) [inline], [protected], [inherited]
```

Stores an infeasible subset consisting only of the given received formula.

```
0.15.266.5.86 receivedVariable() bool smtrat::Module::receivedVariable (
 carl::Variable::Arg _var) const [inline], [inherited]
```

```
0.15.266.5.87 remove() void smtrat::Module::remove (
```

```
 ModuleInput::const_iterator _subformula) [virtual], [inherited]
```

Removes everything related to the given sub-formula of the received formula.

However, it is desired not to lose track of search spaces where no satisfying assignment can be found for the remaining sub-formulas.

#### Parameters

|                          |                                                    |
|--------------------------|----------------------------------------------------|
| <code>_subformula</code> | The sub formula of the received formula to remove. |
|--------------------------|----------------------------------------------------|

Reimplemented in [smtrat::PModule](#).

```
0.15.266.5.88 removeCore() template<typename Settings >
void smtrat::IntEqModule< Settings >::removeCore (
 ModuleInput::const_iterator _subformula) [virtual]
```

Removes the subformula of the received formula at the given position to the considered ones of this module.

Note that this includes every stored calculation which depended on this subformula, but should keep the other stored calculation, if possible, untouched.

#### Parameters

|                          |                                           |
|--------------------------|-------------------------------------------|
| <code>_subformula</code> | The position of the subformula to remove. |
|--------------------------|-------------------------------------------|

Reimplemented from [smtrat::Module](#).

**0.15.266.5.89 `removeOrigin()`** `std::pair<ModuleInput::iterator, bool> smtrat::Module::removeOrigin (`

`ModuleInput::iterator _formula,`  
`const FormulaT & _origin ) [inline], [protected], [inherited]`

**0.15.266.5.90 `removeOrigins()`** `std::pair<ModuleInput::iterator, bool> smtrat::Module::removeOrigins (`

`ModuleInput::iterator _formula,`  
`const std::shared_ptr< std::vector< FormulaT >> & _origins ) [inline], [protected],`  
`[inherited]`

**0.15.266.5.91 `rPassedFormula()`** `const ModuleInput& smtrat::Module::rPassedFormula ( ) const`  
[inline], [inherited]

**Returns**

A reference to the formula passed to the backends of this module.

**0.15.266.5.92 `rReceivedFormula()`** `const ModuleInput& smtrat::Module::rReceivedFormula ( ) const`  
[inline], [inherited]

**Returns**

A reference to the formula passed to this module.

**0.15.266.5.93 `runBackends() [1/2]`** `virtual Answer smtrat::Module::runBackends ( ) [inline],`

`bool _final,`  
`bool _full,`  
`carl::Variable _objective ) [protected], [virtual], [inherited]`

Runs the backend solvers on the passed formula.

**Parameters**

|                         |                                                                                                                                       |
|-------------------------|---------------------------------------------------------------------------------------------------------------------------------------|
| <code>_final</code>     | true, if this satisfiability check will be the last one (for a global sat-check), if its result is SAT                                |
| <code>_full</code>      | false, if this module should avoid too expensive procedures and rather return unknown instead.                                        |
| <code>_objective</code> | if not set to NO_VARIABLE, the module should find an assignment minimizing this objective variable; otherwise any assignment is good. |

**Returns**

True, if the passed formula is consistent; False, if the passed formula is inconsistent; Unknown, otherwise.

Reimplemented in [smtrat::PModule](#).

**0.15.266.5.95 setId()** void smtrat::Module::setId ( std::size\_t \_id ) [inline], [inherited]  
 Sets this modules unique ID to identify itself.

#### Parameters

|                                                 |                                    |
|-------------------------------------------------|------------------------------------|
| $\leftarrow$<br>$\overline{\leftarrow}$<br>$id$ | The id to set this module's id to. |
|-------------------------------------------------|------------------------------------|

**0.15.266.5.96 setThreadPriority()** void smtrat::Module::setThreadPriority ( thread\_priority \_threadPriority ) [inline], [inherited]  
 Sets the priority of this module to get a thread for running its check procedure.

#### Parameters

|                   |                                                       |
|-------------------|-------------------------------------------------------|
| $_threadPriority$ | The priority to set this module's thread priority to. |
|-------------------|-------------------------------------------------------|

**0.15.266.5.97 solverState()** Answer smtrat::Module::solverState ( ) const [inline], [inherited]

#### Returns

True, if this module is in a state, such that it has found a solution for its received formula; False, if this module is in a state, such that it has determined that there is no solution for its received formula; Unknown, otherwise.

**0.15.266.5.98 splitUnequalConstraint()** void smtrat::Module::splitUnequalConstraint ( const FormulaT & \_unequalConstraint ) [protected], [inherited]  
 Adds the following lemmas for the given constraint  $p \neq 0$ .

$(p \neq 0 \leftrightarrow (p < 0 \text{ or } p > 0))$

and  $\neg(p < 0 \text{ and } p > 0)$

#### Parameters

|                      |                                                  |
|----------------------|--------------------------------------------------|
| $_unequalConstraint$ | A constraint having the relation symbol $\neq$ . |
|----------------------|--------------------------------------------------|

**0.15.266.5.99 threadPriority()** thread\_priority smtrat::Module::threadPriority ( ) const [inline], [inherited]

#### Returns

The priority of this module to get a thread for running its check procedure.

**0.15.266.5.100 updateAllModels()** void smtrat::Module::updateAllModels ( ) [virtual], [inherited]  
 Updates all satisfying models, if the solver has detected the consistency of the received formula, beforehand.  
 Reimplemented in [smtrat::SATModule< Settings >](#).

**0.15.266.5.101 updateLemmas()** void smtrat::Module::updateLemmas () [inherited]  
Stores all lemmas of any backend of this module in its own lemma vector.

**0.15.266.5.102 updateModel()** template<typename Settings >  
void smtrat::IntEqModule< Settings >::updateModel () const [virtual]

Updates the current assignment into the model.

Note, that this is a unique but possibly symbolic assignment maybe containing newly introduced variables.  
Reimplemented from [smtrat::Module](#).

**0.15.266.5.103 usedBackends()** const std::vector<[Module](#)\*>& smtrat::Module::usedBackends ()  
const [inline], [inherited]

#### Returns

The backends of this module which are currently used (conditions to use this module are fulfilled for the passed formula).

## 0.15.266.6 Field Documentation

**0.15.266.6.1 mAllBackends** std::vector<[Module](#)\*> smtrat::Module::mAllBackends [protected],  
[inherited]

The backends of this module which have been used.

**0.15.266.6.2 mAllModels** std::vector<[Model](#)> smtrat::Module::mAllModels [mutable], [protected],  
[inherited]

Stores all satisfying assignments.

**0.15.266.6.3 mBackendsFoundAnswer** std::atomic\_bool\* smtrat::Module::mBackendsFoundAnswer  
[protected], [inherited]

This flag is passed to any backend and if it determines an answer to a prior check call, this flag is fired.

**0.15.266.6.4 mConstraintsToInform** carl::FastSet<[FormulaT](#)> smtrat::Module::mConstraintsToInform  
[protected], [inherited]

Stores the constraints which the backends must be informed about.

**0.15.266.6.5 mFinalCheck** bool smtrat::Module::mFinalCheck [protected], [inherited]  
true, if the check procedure should perform a final check which especially means not to postpone splitting decisions

**0.15.266.6.6 mFirstPosInLastBranches** std::size\_t smtrat::Module::mFirstPosInLastBranches = 0  
[static], [inherited]

The beginning of the cyclic buffer storing the last branches.

**0.15.266.6.7 mFirstSubformulaToPass** [ModuleInput](#)::iterator smtrat::Module::mFirstSubformulaToPass  
[protected], [inherited]

Stores the position of the first sub-formula in the passed formula, which has not yet been considered for a consistency check of the backends.

**0.15.266.6.8 mFirstUncheckedReceivedSubformula** `ModuleInput::const_iterator smtrat::Module::mFirstUncheckedReceivedSubformula [protected], [inherited]`  
Stores the position of the first (by this module) unchecked sub-formula of the received formula.

**0.15.266.6.9 mFoundAnswer** `Conditionals smtrat::Module::mFoundAnswer [protected], [inherited]`  
Vector of Booleans: If any of them is true, we have to terminate a running check procedure.

**0.15.266.6.10 mFullCheck** `bool smtrat::Module::mFullCheck [protected], [inherited]`  
false, if this module should avoid too expensive procedures and rather return unknown instead.

**0.15.266.6.11 mInfeasibleSubsets** `std::vector<FormulaSetT> smtrat::Module::mInfeasibleSubsets [protected], [inherited]`  
Stores the infeasible subsets.

**0.15.266.6.12 mInformedConstraints** `carl::FastSet<FormulaT> smtrat::Module::mInformedConstraints [protected], [inherited]`  
Stores the position of the first constraint of which no backend has been informed about.

**0.15.266.6.13 mLastBranches** `std::vector<Branching> smtrat::Module::mLastBranches = std::vector<Branching>(mNumOfBranchVarsToStore, Branching(typename Poly::PolyType(), 0)) [static], [inherited]`  
Stores the last branches in a cycle buffer.

**0.15.266.6.14 mLemmas** `std::vector<Lemma> smtrat::Module::mLemmas [protected], [inherited]`  
Stores the lemmas being valid formulas this module or its backends made.

**0.15.266.6.15 mModel** `Model smtrat::Module::mModel [mutable], [protected], [inherited]`  
Stores the assignment of the current satisfiable result, if existent.

**0.15.266.6.16 mModelComputed** `bool smtrat::Module::mModelComputed [mutable], [protected], [inherited]`  
True, if the model has already been computed.

**0.15.266.6.17 mNumOfBranchVarsToStore** `std::size_t smtrat::Module::mNumOfBranchVarsToStore = 5 [static], [inherited]`  
The number of different variables to consider for a probable infinite loop of branchings.

**0.15.266.6.18 mObjectiveVariable** `carl::Variable smtrat::Module::mObjectiveVariable [protected], [inherited]`  
Objective variable to be minimized. If set to NO\_VARIABLE, a normal sat check should be performed.

**0.15.266.6.19 mOldSplittingVariables** `std::vector<FormulaT> smtrat::Module::mOldSplittingVariables [static], [inherited]`  
Reusable splitting variables.

**0.15.266.6.20 mpManager** `Manager* const smtrat::Module::mpManager [protected], [inherited]`  
A reference to the manager.

**0.15.266.6.21 mSmallerMusesCheckCounter** `unsigned smtrat::Module::mSmallerMusesCheckCounter [mutable], [protected], [inherited]`  
Counter used for the generation of the smt2 files to check for smaller muses.

**0.15.266.6.22 mSolverState** `std::atomic<Answer> smtrat::Module::mSolverState [protected], [inherited]`  
States whether the received formula is known to be satisfiable or unsatisfiable otherwise it is set to unknown.

**0.15.266.6.23 mTheoryPropagations** `std::vector<TheoryPropagation> smtrat::Module::mTheoryPropagations [protected], [inherited]`

**0.15.266.6.24 mUsedBackends** `std::vector<Module*> smtrat::Module::mUsedBackends [protected], [inherited]`  
The backends of this module which are currently used (conditions to use this module are fulfilled for the passed formula).

**0.15.266.6.25 mVariableCounters** `std::vector<std::size_t> smtrat::Module::mVariableCounters [protected], [inherited]`  
Maps variables to the number of their occurrences.

## 0.15.267 smtrat::mcsat::icp::IntervalPropagation Class Reference

```

## 0.15.272 **smtrat::is\_variant< T > Struct Template Reference**

States whether a given type is a boost::variant.

#include <VariantMap.h>

### 0.15.272.1 Detailed Description

```
template<class T>
struct smtrat::is_variant< T >
```

States whether a given type is a boost::variant.

By default, a type is not.

## 0.15.273 **smtrat::expression::ITEExpression Struct Reference**

#include <ExpressionContent.h>

## Public Member Functions

- **ITEExpression** (ITEType, Expression &&\_condition, Expression &&\_then, Expression &&\_else)

**Data Fields**

- `ITEType type`
- `Expression condition`
- `Expression thencase`
- `Expression elsecase`

**0.15.273.1 Constructor & Destructor Documentation**

```
0.15.273.1.1 ITEExpression() smtrat::expression::ITEExpression::ITEExpression (
 ITEType ,
 Expression && _condition,
 Expression && _then,
 Expression && _else) [inline]
```

**0.15.273.2 Field Documentation**

**0.15.273.2.1 condition** `Expression` smtrat::expression::ITEExpression::condition

**0.15.273.2.2 elsecase** `Expression` smtrat::expression::ITEExpression::elsecase

**0.15.273.2.3 thencase** `Expression` smtrat::expression::ITEExpression::thencase

**0.15.273.2.4 type** `ITEType` smtrat::expression::ITEExpression::type

**0.15.274 benchmax::RandomizationAdaptor< T >::iterator Struct Reference**

```
#include <Jobs.h>
```

**Public Member Functions**

- `iterator (std::size_t k, std::size_t factor, const std::vector< T > &data)`  
*Create a randomized iterator.*
- `const T & operator* ()`  
*Dereference iterator.*
- `iterator & operator++ ()`  
*Increment iterator.*
- `bool operator!= (const iterator &rhs) const`  
*Compare two iterators.*

**0.15.274.1 Constructor & Destructor Documentation**

```
0.15.274.1.1 iterator() template<typename T >
benchmax::RandomizationAdaptor< T >::iterator::iterator (
 std::size_t k,
 std::size_t factor,
 const std::vector< T > & data) [inline]
```

Create a randomized iterator.

### 0.15.274.2 Member Function Documentation

**0.15.274.2.1 operator"!=()** template<typename T >  
 bool **benchmax::RandomizationAdaptor**< T >::iterator::operator!= ( const iterator & rhs ) const [inline]

Compare two iterators.

**0.15.274.2.2 operator\*()** template<typename T >  
 const T& **benchmax::RandomizationAdaptor**< T >::iterator::operator\* ( ) [inline]

Dereference iterator.

**0.15.274.2.3 operator++()** template<typename T >  
 iterator& **benchmax::RandomizationAdaptor**< T >::iterator::operator++ ( ) [inline]

Increment iterator.

## 0.15.275 smtrat::ModuleInput::IteratorCompare Struct Reference

#include <ModuleInput.h>

### Public Member Functions

- bool **operator()** (const iterator i1, const iterator i2) const

### 0.15.275.1 Member Function Documentation

**0.15.275.1.1 operator()** bool smtrat::ModuleInput::IteratorCompare::operator() ( const\_iterator i1, const\_iterator i2 ) const [inline]

## 0.15.276 benchmax::Jobs Class Reference

Represents a set of jobs, constructed as the cartesian product of a set of tools and a set of benchmarks.

#include <Jobs.h>

### Public Member Functions

- **Jobs** (const Tools &tools, const BenchmarkSet &benchmarks)  
*Construct jobs from a set of tools and a set of benchmark files.*
- const auto & **tools** () const  
*Returns the set of tools.*
- const auto & **files** () const  
*Returns the set of files.*
- auto **size** () const  
*Returns the overall number of jobs.*
- auto **begin** () const  
*Begin iterator.*
- auto **end** () const  
*End iterator.*
- auto **randomized** () const  
*Returns all jobs in a pseudo-randomized order.*

### 0.15.276.1 Detailed Description

Represents a set of jobs, constructed as the cartesian product of a set of tools and a set of benchmarks.

### 0.15.276.2 Constructor & Destructor Documentation

```
0.15.276.2.1 Jobs() benchmax::Jobs::Jobs (
 const Tools & tools,
 const BenchmarkSet & benchmarks) [inline]
```

Construct jobs from a set of tools and a set of benchmark files.

### 0.15.276.3 Member Function Documentation

```
0.15.276.3.1 begin() auto benchmax::Jobs::begin () const [inline]
```

Begin iterator.

```
0.15.276.3.2 end() auto benchmax::Jobs::end () const [inline]
```

End iterator.

```
0.15.276.3.3 files() const auto& benchmax::Jobs::files () const [inline]
```

Returns the set of files.

```
0.15.276.3.4 randomized() auto benchmax::Jobs::randomized () const [inline]
```

Returns all jobs in a pseudo-randomized order.

```
0.15.276.3.5 size() auto benchmax::Jobs::size () const [inline]
```

Returns the overall number of jobs.

```
0.15.276.3.6 tools() const auto& benchmax::Jobs::tools () const [inline]
```

Returns the set of tools.

## 0.15.277 smtrat::JunctorMerger Struct Reference

```

### Data Fields

- const std::vector< carl::Variable > & **variableOrder**

*Variables can also be indexed by level.*
- const RealAlgebraicPoint< Rational > & **point**

#### 0.15.288.1 Member Function Documentation

**0.15.288.1.1 coeffNonNull()** std::optional<Poly> smtrat::mcsat::onecellcad::OneCellCAD::coeffNonNull (const TagPoly & boundCandidate ) [inline], [inherited]

**0.15.288.1.2 constructCADCellEnclosingPoint()** std::optional<CADCell> smtrat::mcsat::onecellcad::levelwise::LevelwiseCAD::constructCADCellEnclosingPoint ( std::vector< std::vector< TagPoly >> & polys, int sectionHeuristic, int sectorHeuristic ) [inline]

Construct a single CADCell that contains the given 'point' and is sign-invariant for the given polynomials in 'polys'. The construction fails if a polynomial vanishes ( $p(a_1, \dots, a_{i-1}, x_i)$ ). Note that this cell is cylindrical only with respect to the given 'variableOrder'.

#### Parameters

|                      |                                                                                                                            |
|----------------------|----------------------------------------------------------------------------------------------------------------------------|
| <i>variableOrder</i> | must contain unique variables and at least one, because constant polynomials (without a variable) are prohibited.          |
| <i>point</i>         | <i>point.size() &gt;= variables.size()</i> .                                                                               |
| <i>polys</i>         | must contain only non-constant, irreducible tagged polynomials that mention only variables that appear in 'variableOrder'. |

*Hook to allow for asynchronous backends to wait for jobs to terminate.*
- `void madeProgress (std::size_t files=1)`

*Can be called to give information about the current progress, if available.*

- virtual bool `collect_results` (const `Jobs` &, bool)
- void `sanitize_results` (const `Jobs` &`jobs`) const
- void `write_results` (const `Jobs` &`jobs`) const

## Protected Attributes

- std::size\_t `mExpectedJobs`  
*Number of jobs that should be run.*
- std::atomic< std::size\_t > `mFinishedJobs`  
*Number of jobs that are finished.*
- std::atomic< std::size\_t > `mLastPercent`  
*Percentage of finished jobs when `madeProgress()` was last called.*

### 0.15.295.1 Detailed Description

This backend simply runs files sequentially on the local machine.

### 0.15.295.2 Member Function Documentation

**0.15.295.2.1 `addResult()`** void `benchmax::Backend::addResult` (  
    const `Tool` \* `tool`,  
    const `fs::path` & `file`,  
    `BenchmarkResult` && `result` ) [inline], [inherited]

Add a result.

**0.15.295.2.2 `collect_results()`** virtual bool `benchmax::Backend::collect_results` (  
    const `Jobs` & ,  
    bool ) [inline], [protected], [virtual], [inherited]

**0.15.295.2.3 `execute()`** virtual void `benchmax::LocalBackend::execute` (  
    const `Tool` \* `tool`,  
    const `fs::path` & `file` ) [inline], [protected], [virtual]  
Execute the tool on the file manually.  
Reimplemented from `benchmax::Backend`.

**0.15.295.2.4 `finalize()`** virtual void `benchmax::Backend::finalize` () [inline], [protected], [virtual], [inherited]  
Hook to allow for asynchronous backends to wait for jobs to terminate.

**0.15.295.2.5 `madeProgress()`** void `benchmax::Backend::madeProgress` (  
    std::size\_t `files` = 1 ) [inline], [protected], [inherited]  
Can be called to give information about the current progress, if available.

**0.15.295.2.6 `process_results()`** void `benchmax::Backend::process_results` (  
    const `Jobs` & `jobs`,  
    bool `check_finished` ) [inline], [inherited]

**0.15.295.2.7 run()** void benchmax::Backend::run ( const [Jobs](#) & jobs, bool [wait\\_for\\_termination](#) ) [inline], [inherited]

Run the list of tools against the list of benchmarks.

**0.15.295.2.8 sanitize\_results()** void benchmax::Backend::sanitize\_results ( const [Jobs](#) & jobs ) const [inline], [protected], [inherited]

**0.15.295.2.9 startTool()** virtual void benchmax::Backend::startTool ( const [Tool](#) \* ) [inline], [protected], [virtual], [inherited]

Hook for every tool at the beginning.

Can be used to upload the tool to some remote system.

**0.15.295.2.10 suspendable()** bool benchmax::Backend::suspendable () const [inline], [inherited]

**0.15.295.2.11 write\_results()** void benchmax::Backend::write\_results ( const [Jobs](#) & jobs ) const [inline], [protected], [inherited]

### 0.15.295.3 Field Documentation

**0.15.295.3.1 mExpectedJobs** std::size\_t benchmax::Backend::mExpectedJobs [protected], [inherited]  
Number of jobs that should be run.

**0.15.295.3.2 mFinishedJobs** std::atomic<std::size\_t> benchmax::Backend::mFinishedJobs [protected], [inherited]  
Number of jobs that are finished.

**0.15.295.3.3 mLastPercent** std::atomic<std::size\_t> benchmax::Backend::mLastPercent [protected], [inherited]  
Percentage of finished jobs when [madeProgress\(\)](#) was last called.

## 0.15.296 smrat::LOG Class Reference

    `const std::set< carl::Variable > & vars,`  
    `carl::FormulaType type ) [protected], [inherited]`

**0.15.298.2.6 name()** `std::string smtrat::LongFormulaEncoder::name ( ) [inline], [virtual]`  
Reimplemented from [smtrat::PseudoBoolEncoder](#).

### 0.15.298.3 Field Documentation

**0.15.298.3.1 problem\_size** `std::size_t smtrat::PseudoBoolEncoder::problem_size [inherited]`

## 0.15.299 smtrat::LRAmodule< Settings > Class Template Reference

A module which performs the Simplex method on the linear part of it's received formula.

```
#include <LRAmodule.h>
```

### Data Structures

- struct [Context](#)

*Stores a formula, being part of the received formula of this module, and the position of this formula in the passed formula.*

## Public Types

- **typedef Settings::BoundType LRABoundType**  
*Number type of the underlying value of a bound of a variable within the `LRAModule`.*
- **typedef Settings::EntryType LRAEntryType**  
*Type of an entry within the tableau.*
- **typedef Ira::Bound< LRABoundType, LRAEntryType > LRABound**  
*Type of a bound of a variable within the `LRAModule`.*
- **typedef Ira::Variable< LRABoundType, LRAEntryType > LRAVariable**  
*A variable of the `LRAModule`, being either a original variable or a slack variable representing a linear polynomial.*
- **typedef Ira::Value< LRABoundType > LRAValue**  
*The type of the assignment of a variable maintained by the `LRAModule`. It consists of a tuple of two value of the bound type.*
- **typedef Settings SettingsType**
- **typedef carl::FastMap< carl::Variable, LRAVariable \* > VarVariableMap**  
*Maps an original variable to it's corresponding `LRAModule` variable.*
- **typedef carl::FastPointerMap< typename Poly::PolyType, LRAVariable \* > ExVariableMap**  
*Maps a linear polynomial to it's corresponding `LRAModule` variable.*
- **typedef carl::FastMap< FormulaT, std::vector< const LRABound \* > \* > ConstraintBoundsMap**  
*Maps constraint to the bounds it represents (e.g., equations represent two bounds)*
- **typedef carl::FastMap< FormulaT, Context > ConstraintContextMap**  
*Stores the position of a received formula in the passed formula.*
- **typedef Ira::Tableau< typename Settings::Tableau\_settings, LRABoundType, LRAEntryType > LRATableau**  
*The tableau which is the main data structure maintained by the `LRAModule` responsible for the pivoting steps.*
- **enum class LemmaType : unsigned { NORMAL = 0 , PERMANENT = 1 }**

## Public Member Functions

- **std::string moduleName () const**
- **LRAModule (const ModuleInput \* \_formula, Conditionals & \_conditionals, Manager \* \_manager=NULL)**  
*Constructs a `LRAModule`.*
- **virtual ~LRAModule ()**  
*Destructs this `LRAModule`.*
- **bool informCore (const FormulaT & \_constraint)**  
*Informs this module about the existence of the given constraint, which means that it could be added in future.*
- **void deinformCore (const FormulaT & \_constraint)**  
*The inverse of informing about a constraint.*
- **void init ()**  
*Initializes the tableau according to all linear constraints, of which this module has been informed.*
- **bool addCore (ModuleInput::const\_iterator \_subformula)**  
*The module has to take the given sub-formula of the received formula into account.*
- **void removeCore (ModuleInput::const\_iterator \_subformula)**  
*Removes everything related to the given sub-formula of the received formula.*
- **Answer checkCore ()**  
*Checks the received formula for consistency.*
- **Answer checkCore\_old ()**
- **Answer processResult (Answer \_result)**
- **void updateModel () const**  
*Updates the model, if the solver has detected the consistency of the received formula, beforehand.*
- **unsigned currentlySatisfied (const FormulaT &) const**
- **const RationalAssignment & getRationalModel () const**  
*Gives a rational model if the received formula is satisfiable.*

- `Answer optimize (Answer _result)`
- `Answer checkNotEqualConstraints (Answer _result)`
- `void processLearnedBounds ()`
- `void createInfeasibleSubsets (Ira::EntryID _tableauEntry)`
- `EvalRationalIntervalMap getVariableBounds () const`

*Returns the bounds of the variables as intervals.*
- `void printLinearConstraints (std::ostream &_out=std::cout, const std::string _init="") const`

*Prints all linear constraints.*
- `void printNonlinearConstraints (std::ostream &_out=std::cout, const std::string _init="") const`

*Prints all non-linear constraints.*
- `void printConstraintToBound (std::ostream &_out=std::cout, const std::string _init="") const`

*Prints the mapping of constraints to their corresponding bounds.*
- `void printBoundCandidatesToPass (std::ostream &_out=std::cout, const std::string _init="") const`

*Prints the strictest bounds, which have to be passed the backend in case.*
- `void printRationalModel (std::ostream &_out=std::cout, const std::string _init="") const`

*Prints the current rational assignment.*
- `void printTableau (std::ostream &_out=std::cout, const std::string _init="") const`

*Prints the current tableau.*
- `void printVariables (std::ostream &_out=std::cout, const std::string _init="") const`

*Prints all Ira variables and their assignments.*
- `const VarVariableMap & originalVariables () const`
- `const ExVariableMap & slackVariables () const`
- `const LRAVariable * getSlackVariable (const FormulaT &_constraint) const`
- `bool inform (const FormulaT &_constraint)`

*Informs the module about the given constraint.*
- `void deinform (const FormulaT &_constraint)`

*The inverse of informing about a constraint.*
- `bool add (ModuleInput::const_iterator _subformula)`

*The module has to take the given sub-formula of the received formula into account.*
- `virtual Answer check (bool _final=false, bool _full=true, carl::Variable _objective=carl::Variable::NO_VARIABLE)`

*Checks the received formula for consistency.*
- `virtual void remove (ModuleInput::const_iterator _subformula)`

*Removes everything related to the given sub-formula of the received formula.*
- `virtual void updateAllModels ()`

*Updates all satisfying models, if the solver has detected the consistency of the received formula, beforehand.*
- `virtual std::list< std::vector< carl::Variable > > getModelEqualities () const`

*Partition the variables from the current model into equivalence classes according to their assigned value.*
- `unsigned currentlySatisfiedByBackend (const FormulaT &_formula) const`
- `bool receivedVariable (carl::Variable::Arg _var) const`
- `Answer solverState () const`
- `std::size_t id () const`
- `void setId (std::size_t _id)`

*Sets this modules unique ID to identify itself.*
- `thread_priority threadPriority () const`
- `void setThreadPriority (thread_priority _threadPriority)`

*Sets the priority of this module to get a thread for running its check procedure.*
- `const ModuleInput * pReceivedFormula () const`
- `const ModuleInput & rReceivedFormula () const`
- `const ModuleInput * pPassedFormula () const`
- `const ModuleInput & rPassedFormula () const`

- void **addLemma** (const FormulaT &\_lemma, const LemmaType &\_lt=LemmaType::NORMAL, const FormulaT &\_preferredFormula=FormulaT(carl::FormulaType::TRUE))
 

*Stores a lemma being a valid formula.*
- bool **hasLemmas** ()
 

*Checks whether this module or any of its backends provides any lemmas.*
- void **clearLemmas** ()
 

*Deletes all yet found lemmas.*
- const std::vector< Lemma > & **lemmas** () const
- ModuleInput::const\_iterator **firstUncheckedReceivedSubformula** () const
- ModuleInput::const\_iterator **firstSubformulaToPass** () const
- void **receivedFormulaChecked** ()
 

*Notifies that the received formulas has been checked.*
- const smrat::Conditionals & **answerFound** () const
- bool **isPreprocessor** () const
- carl::Variable **objective** () const
- bool **is\_minimizing** () const
- void **excludeNotReceivedVariablesFromModel** () const
 

*Excludes all variables from the current model, which do not occur in the received formula.*
- void **updateLemmas** ()
 

*Stores all lemmas of any backend of this module in its own lemma vector.*
- void **collectTheoryPropagations** ()
- void **collectOrigins** (const FormulaT &\_formula, FormulasT &\_origins) const
 

*Collects the formulas in the given formula, which are part of the received formula.*
- void **collectOrigins** (const FormulaT &\_formula, FormulaSetT &\_origins) const
- bool **hasValidInfeasibleSubset** () const
- void **checkInfSubsetForMinimality** (std::vector< FormulaSetT >::const\_iterator \_insubset, const std::string &filename="smaller\_muses", unsigned \_maxSizeDifference=1) const
 

*Checks the given infeasible subset for minimality by storing all subsets of it, which have a smaller size which differs from the size of the infeasible subset not more than the given threshold.*
- virtual std::pair< bool, FormulaT > **getReceivedFormulaSimplified** ()
- void **print** (const std::string &\_initiation="\*\*\*") const
 

*Prints everything relevant of the solver.*
- void **printReceivedFormula** (const std::string &\_initiation="\*\*\*") const
 

*Prints the vector of the received formula.*
- void **printPassedFormula** (const std::string &\_initiation="\*\*\*") const
 

*Prints the vector of passed formula.*
- void **printInfeasibleSubsets** (const std::string &\_initiation="\*\*\*") const
 

*Prints the infeasible subsets.*
- void **printModel** (std::ostream &\_out=std::cout) const
 

*Prints the assignment of this module satisfying its received formula if it satisfiable and this module could find an assignment.*
- void **printAllModels** (std::ostream &\_out=std::cout)
 

*Prints all assignments of this module satisfying its received formula if it satisfiable and this module could find an assignment.*

## Static Public Member Functions

- static void **freeSplittingVariable** (const FormulaT &\_splittingVariable)

## Static Public Attributes

- static size\_t `mNumOfBranchVarsToStore` = 5  
*The number of different variables to consider for a probable infinite loop of branchings.*
- static std::vector< Branching > `mLastBranches` = std::vector<Branching>(mNumOfBranchVarsToStore, Branching(typename Poly::PolyType(), 0))  
*Stores the last branches in a cycle buffer.*
- static size\_t `mFirstPosInLastBranches` = 0  
*The beginning of the cyclic buffer storing the last branches.*
- static std::vector< FormulaT > `mOldSplittingVariables`  
*Reusable splitting variables.*

## Protected Member Functions

- bool `anAnswerFound` () const  
*Checks for all antecedent modules and those which run in parallel with the same antecedent modules, whether one of them has determined a result.*
- void `clearModel` () const  
*Clears the assignment, if any was found.*
- void `clearModels` () const  
*Clears all assignments, if any was found.*

- `ModuleInput::iterator passedFormulaBegin` ()
- `ModuleInput::iterator passedFormulaEnd` ()
- void `addOrigin` (`ModuleInput::iterator` `_formula`, const `FormulaT` & `_origin`)  
*Adds the given set of formulas in the received formula to the origins of the given passed formula.*
- const `FormulaT` & `getOrigins` (`ModuleInput::const_iterator` `_formula`) const  
*Gets the origins of the passed formula at the given position.*
- void `getOrigins` (const `FormulaT` & `_formula`, `FormulasT` & `_origins`) const
- void `getOrigins` (const `FormulaT` & `_formula`, `FormulaSetT` & `_origins`) const
- std::pair< `ModuleInput::iterator`, bool > `removeOrigin` (`ModuleInput::iterator` `_formula`, const `FormulaT` & `_origin`)  
*Removes the origin of the given formula from the passed formula.*
- std::pair< `ModuleInput::iterator`, bool > `removeOrigins` (`ModuleInput::iterator` `_formula`, const std::shared\_ptr< std::vector< `FormulaT` >> & `_origins`)  
*Removes all origins of the given formula from the passed formula.*
- void `informBackends` (const `FormulaT` & `_constraint`)  
*Informs all backends of this module about the given constraint.*
- virtual void `addConstraintToInform` (const `FormulaT` & `_constraint`)  
*Adds a constraint to the collection of constraints of this module, which are informed to a freshly generated backend.*
- std::pair< `ModuleInput::iterator`, bool > `addReceivedSubformulaToPassedFormula` (`ModuleInput::const_iterator` `_subformula`)  
*Copies the given sub-formula of the received formula to the passed formula.*
- bool `originInReceivedFormula` (const `FormulaT` & `_origin`) const  
*Checks if the given formula is an origin of the received formula.*
- std::pair< `ModuleInput::iterator`, bool > `addSubformulaToPassedFormula` (const `FormulaT` & `_formula`)  
*Adds the given formula to the passed formula with no origin.*
- std::pair< `ModuleInput::iterator`, bool > `addSubformulaToPassedFormula` (const `FormulaT` & `_formula`, const std::shared\_ptr< std::vector< `FormulaT` >> & `_origins`)  
*Adds the given formula to the passed formula.*
- std::pair< `ModuleInput::iterator`, bool > `addSubformulaToPassedFormula` (const `FormulaT` & `_formula`, const `FormulaT` & `_origin`)  
*Adds the given formula to the passed formula.*
- void `generateTrivialInfeasibleSubset` ()  
*Stores the trivial infeasible subset being the set of received formulas.*

- void `receivedFormulasAsInfeasibleSubset (ModuleInput::const_iterator _subformula)`

*Stores an infeasible subset consisting only of the given received formula.*
- std::vector< `FormulaT` >::const\_iterator `findBestOrigin (const std::vector< FormulaT > &_origins) const`
- void `getInfeasibleSubsets ()`

*Copies the infeasible subsets of the passed formula.*
- std::vector< `FormulaSetT` > `getInfeasibleSubsets (const Module &_backend) const`

*Get the infeasible subsets the given backend provides.*
- const `Model & backendsModel () const`

*Stores the model of a backend which determined satisfiability of the passed formula in the model of this module.*
- void `getBackendsModel () const`
- void `getBackendsAllModels () const`

*Stores all models of a backend in the list of all models of this module.*
- virtual `Answer runBackends (bool _final, bool _full, carl::Variable _objective)`

*Runs the backend solvers on the passed formula.*
- virtual `Answer runBackends ()`
- virtual `ModuleInput::iterator eraseSubformulaFromPassedFormula (ModuleInput::iterator _subformula, bool _ignoreOrigins=false)`

*Removes everything related to the sub-formula to remove from the passed formula in the backends of this module.*
- void `clearPassedFormula ()`
- std::vector< `FormulaT` > `merge (const std::vector< FormulaT > &, const std::vector< FormulaT > &) const`

*Merges the two vectors of sets into the first one.*
- size\_t `determine_smallest_origin (const std::vector< FormulaT > &origins) const`
- bool `probablyLooping (const typename Poly::PolyType &_branchingPolynomial, const Rational &_← branchingValue) const`

*Checks whether given the current branching value and branching variable/polynomial it is (highly) probable that this branching is part of an infinite loop of branchings.*
- bool `branchAt (const Poly &_polynomial, bool _integral, const Rational &_value, std::vector< FormulaT > &&_premise, bool _leftCaseWeak=true, bool _preferLeftCase=true, bool _useReceivedFormulaAsPremise=false)`

*Adds a lemmas which provoke a branching for the given variable at the given value, if this module returns Unknown and there exists a preceding SATModule.*
- bool `branchAt (const Poly &_polynomial, bool _integral, const Rational &_value, bool _leftCaseWeak=true, bool _preferLeftCase=true, bool _useReceivedFormulaAsPremise=false, const std::vector< FormulaT > &← _premise=std::vector< FormulaT >())`
- bool `branchAt (carl::Variable::Arg _var, const Rational &_value, std::vector< FormulaT > &&_premise, bool _leftCaseWeak=true, bool _preferLeftCase=true, bool _useReceivedFormulaAsPremise=false)`
- bool `branchAt (carl::Variable::Arg _var, const Rational &_value, bool _leftCaseWeak=true, bool _preferLeftCase=true, bool _useReceivedFormulaAsPremise=false, const std::vector< FormulaT > &_premise=std::vector< FormulaT >())`
- void `splitUnequalConstraint (const FormulaT &)`

*Adds the following lemmas for the given constraint  $p \neq 0$ .*
- unsigned `checkModel () const`
- void `addInformationRelevantFormula (const FormulaT &formula)`

*Adds a formula to the InformationRelevantFormula.*
- const std::set< `FormulaT` > & `getInformationRelevantFormulas ()`

*Gets all InformationRelevantFormulas.*
- bool `isLemmaLevel (LemmaLevel level)`

*Checks if current lemma level is greater or equal to given level.*

## Static Protected Member Functions

- static bool `modelsDisjoint (const Model &_modelA, const Model &_modelB)`

*Checks whether there is no variable assigned by both models.*

## Protected Attributes

- std::vector< [FormulaSetT](#) > mInfeasibleSubsets
  - Stores the infeasible subsets.*
- Manager \*const mpManager
  - A reference to the manager.*
- Model mModel
  - Stores the assignment of the current satisfiable result, if existent.*
- std::vector< [Model](#) > mAllModels
  - Stores all satisfying assignments.*
- bool mModelComputed
  - True, if the model has already been computed.*
- bool mFinalCheck
  - true, if the check procedure should perform a final check which especially means not to postpone splitting decisions*
- bool mFullCheck
  - false, if this module should avoid too expensive procedures and rather return unknown instead.*
- carl::Variable mObjectiveVariable
  - Objective variable to be minimized. If set to NO\_VARIABLE, a normal sat check should be performed.*
- std::vector< [TheoryPropagation](#) > mTheoryPropagations
- std::atomic< [Answer](#) > mSolverState
  - States whether the received formula is known to be satisfiable or unsatisfiable otherwise it is set to unknown.*
- std::atomic\_bool \* mBackendsFoundAnswer
  - This flag is passed to any backend and if it determines an answer to a prior check call, this flag is fired.*
- Conditionals mFoundAnswer
  - Vector of Booleans: If any of them is true, we have to terminate a running check procedure.*
- std::vector< [Module](#) \* > mUsedBackends
  - The backends of this module which are currently used (conditions to use this module are fulfilled for the passed formula).*
- std::vector< [Module](#) \* > mAllBackends
  - The backends of this module which have been used.*
- std::vector< [Lemma](#) > mLemmas
  - Stores the lemmas being valid formulas this module or its backends made.*
- ModuleInput::iterator mFirstSubformulaToPass
  - Stores the position of the first sub-formula in the passed formula, which has not yet been considered for a consistency check of the backends.*
- carl::FastSet< [FormulaT](#) > mConstraintsToInform
  - Stores the constraints which the backends must be informed about.*
- carl::FastSet< [FormulaT](#) > mInformedConstraints
  - Stores the position of the first constraint of which no backend has been informed about.*
- ModuleInput::const\_iterator mFirstUncheckedReceivedSubformula
  - Stores the position of the first (by this module) unchecked sub-formula of the received formula.*
- unsigned mSmallerMusesCheckCounter
  - Counter used for the generation of the smt2 files to check for smaller muses.*
- std::vector< std::size\_t > mVariableCounters
  - Maps variables to the number of their occurrences.*

### 0.15.299.1 Detailed Description

```
template<class Settings>
class smrat::LRAModule< Settings >
```

A module which performs the Simplex method on the linear part of it's received formula.

### 0.15.299.2 Member Typedef Documentation

**0.15.299.2.1 ConstraintBoundsMap** template<class Settings >  
 typedef carl::FastMap<FormulaT, std::vector<const LRABound\*>> smtrat::LRAModule< Settings >::ConstraintBoundsMap  
 Maps constraint to the bounds it represents (e.g., equations represent two bounds)

**0.15.299.2.2 ConstraintContextMap** template<class Settings >  
 typedef carl::FastMap<FormulaT, Context> smtrat::LRAModule< Settings >::ConstraintContextMap  
 Stores the position of a received formula in the passed formula.

**0.15.299.2.3 ExVariableMap** template<class Settings >  
 typedef carl::FastPointerMap<typename Poly::PolyType, LRAVariable\*> smtrat::LRAModule< Settings >::ExVariableMap  
 Maps a linear polynomial to its corresponding **LRAModule** variable.

**0.15.299.2.4 LRABound** template<class Settings >  
 typedef lra::Bound<LRABoundType, LRAEntryType> smtrat::LRAModule< Settings >::LRABound  
 Type of a bound of a variable within the **LRAModule**.

**0.15.299.2.5 LRABoundType** template<class Settings >  
 typedef Settings::BoundType smtrat::LRAModule< Settings >::LRABoundType  
 Number type of the underlying value of a bound of a variable within the **LRAModule**.

**0.15.299.2.6 LRAEntryType** template<class Settings >  
 typedef Settings::EntryType smtrat::LRAModule< Settings >::LRAEntryType  
 Type of an entry within the tableau.

**0.15.299.2.7 LRATableau** template<class Settings >  
 typedef lra::Tableau<typename Settings::Tableau\_settings, LRABoundType, LRAEntryType> smtrat::LRAModule< Settings >::LRATableau  
 The tableau which is the main data structure maintained by the **LRAModule** responsible for the pivoting steps.

**0.15.299.2.8 LRAValue** template<class Settings >  
 typedef lra::Value<LRABoundType> smtrat::LRAModule< Settings >::LRAValue  
 The type of the assignment of a variable maintained by the **LRAModule**. It consists of a tuple of two values of the bound type.

**0.15.299.2.9 LRAVariable** template<class Settings >  
 typedef lra::Variable<LRABoundType, LRAEntryType> smtrat::LRAModule< Settings >::LRAVariable  
 A variable of the **LRAModule**, being either a original variable or a slack variable representing a linear polynomial.

**0.15.299.2.10 SettingsType** template<class Settings >  
 typedef Settings smtrat::LRAModule< Settings >::SettingsType

**0.15.299.2.11 VarVariableMap** template<class Settings >  
typedef carl::FastMap<carl::Variable, LRAVariable\*> smtrat::LRAModule< Settings >::VarVariableMap  
Maps an original variable to its corresponding [LRAModule](#) variable.

### 0.15.299.3 Member Enumeration Documentation

**0.15.299.3.1 LemmaType** enum smtrat::Module::LemmaType : unsigned [strong], [inherited]

Enumerator

|           |  |
|-----------|--|
| NORMAL    |  |
| PERMANENT |  |

### 0.15.299.4 Constructor & Destructor Documentation

**0.15.299.4.1 LRAModule()** template<class Settings >  
smtrat::LRAModule< Settings >::LRAModule (   
    const ModuleInput \* \_formula,  
    Conditionals & \_conditionals,  
    Manager \* \_manager = NULL )

Constructs a [LRAModule](#).

Parameters

|               |                                                                                             |
|---------------|---------------------------------------------------------------------------------------------|
| _type         | The type of this module being <a href="#">LRAModule</a> .                                   |
| _formula      | The formula passed to this module, called received formula.                                 |
| _settings     | [Not yet used.]                                                                             |
| _conditionals | Vector of Booleans: If any of them is true, we have to terminate a running check procedure. |
| _manager      | A reference to the manager of the solver using this module.                                 |

**0.15.299.4.2 ~LRAModule()** template<class Settings >  
virtual smtrat::LRAModule< Settings >::~LRAModule ( ) [virtual]  
Destructs this [LRAModule](#).

### 0.15.299.5 Member Function Documentation

**0.15.299.5.1 add()** bool smtrat::Module::add (   
    ModuleInput::const\_iterator \_subformula ) [inherited]

The module has to take the given sub-formula of the received formula into account.

Parameters

|             |                                                    |
|-------------|----------------------------------------------------|
| _subformula | The sub-formula to take additionally into account. |
|-------------|----------------------------------------------------|

**Returns**

false, if it can be easily decided that this sub-formula causes a conflict with the already considered sub-formulas; true, otherwise.

**0.15.299.5.2 addConstraintToInform()** `void smtrat::Module::addConstraintToInform (`

```
const FormulaT & _constraint) [protected], [virtual], [inherited]
```

Adds a constraint to the collection of constraints of this module, which are informed to a freshly generated backend.

**Parameters**

|                          |                        |
|--------------------------|------------------------|
| <code>_constraint</code> | The constraint to add. |
|--------------------------|------------------------|

Reimplemented in [smtrat::SATModule< Settings >](#).

**0.15.299.5.3 addCore()** `template<class Settings >`

```
bool smtrat::LRAbstractModule< Settings >::addCore (
 ModuleInput::const_iterator _subformula) [virtual]
```

The module has to take the given sub-formula of the received formula into account.

**Parameters**

|                          |                                                    |
|--------------------------|----------------------------------------------------|
| <code>_subformula</code> | The sub-formula to take additionally into account. |
|--------------------------|----------------------------------------------------|

**Returns**

false, if it can be easily decided that this sub-formula causes a conflict with the already considered sub-formulas; true, otherwise.

Reimplemented from [smtrat::Module](#).

**0.15.299.5.4 addInformationRelevantFormula()** `void smtrat::Module::addInformationRelevantFormula (`

```
const FormulaT & formula) [protected], [inherited]
```

Adds a formula to the InformationRelevantFormula.

**Parameters**

|                      |                |
|----------------------|----------------|
| <code>formula</code> | Formula to add |
|----------------------|----------------|

**0.15.299.5.5 addLemma()** `void smtrat::Module::addLemma (`

```
const FormulaT & _lemma,
```

```
const LemmaType & _lt = LemmaType::NORMAL,
```

```
const FormulaT & _preferredFormula = FormulaT(carl::FormulaType::TRUE)) [inline],
```

[inherited]

Stores a lemma being a valid formula.

**Parameters**

|                                |                                                                       |
|--------------------------------|-----------------------------------------------------------------------|
| <code>_lemma</code>            | The eduction/lemma to store.                                          |
| <code>_lt</code>               | The type of the lemma.                                                |
| <code>_preferredFormula</code> | Hint for the next decision, which formula should be assigned to true. |

**0.15.299.5.6 addOrigin()** `void smtrat::Module::addOrigin (`

```
 ModuleInput::iterator _formula,
 const FormulaT & _origin) [inline], [protected], [inherited]
```

Adds the given set of formulas in the received formula to the origins of the given passed formula.

**Parameters**

|                       |                                                           |
|-----------------------|-----------------------------------------------------------|
| <code>_formula</code> | The passed formula to set the origins for.                |
| <code>_origin</code>  | A set of formulas in the received formula of this module. |

**0.15.299.5.7 addReceivedSubformulaToPassedFormula()** `std::pair<ModuleInput::iterator, bool>`

```
smtrat::Module::addReceivedSubformulaToPassedFormula (
```

```
 ModuleInput::const_iterator _subformula) [inline], [protected], [inherited]
```

Copies the given sub-formula of the received formula to the passed formula.

Note, that there is always a link between sub-formulas of the passed formulas to sub-formulas of the received formulas, which are responsible for its occurrence.

**Parameters**

|                          |                                                  |
|--------------------------|--------------------------------------------------|
| <code>_subformula</code> | The sub-formula of the received formula to copy. |
|--------------------------|--------------------------------------------------|

**0.15.299.5.8 addSubformulaToPassedFormula() [1/3]** `std::pair<ModuleInput::iterator, bool>`

```
smtrat::Module::addSubformulaToPassedFormula (
```

```
 const FormulaT & _formula) [inline], [protected], [inherited]
```

Adds the given formula to the passed formula with no origin.

Note that in the next call of this module's removeSubformula, all formulas in the passed formula without origins will be removed.

**Parameters**

|                       |                                           |
|-----------------------|-------------------------------------------|
| <code>_formula</code> | The formula to add to the passed formula. |
|-----------------------|-------------------------------------------|

**Returns**

A pair to the position where the formula to add has been inserted (or its first sub-formula which has not yet been in the passed formula, in case the formula to add is a conjunction), and a Boolean stating whether anything has been added to the passed formula.

**0.15.299.5.9 addSubformulaToPassedFormula() [2/3]** `std::pair<ModuleInput::iterator, bool>`

```
smtrat::Module::addSubformulaToPassedFormula (
```

```
 const FormulaT & _formula,
```

```
 const FormulaT & _origin) [inline], [protected], [inherited]
```

Adds the given formula to the passed formula.

**Parameters**

|                       |                                                                                                                           |
|-----------------------|---------------------------------------------------------------------------------------------------------------------------|
| <code>_formula</code> | The formula to add to the passed formula.                                                                                 |
| <code>_origin</code>  | The sub-formula of the received formula being responsible for the occurrence of the formula to add to the passed formula. |

**Returns**

A pair to the position where the formula to add has been inserted (or its first sub-formula which has not yet been in the passed formula, in case the formula to add is a conjunction), and a Boolean stating whether anything has been added to the passed formula.

**0.15.299.5.10 addSubformulaToPassedFormula() [3/3] std::pair<ModuleInput::iterator,bool>**

```
smtrat::Module::addSubformulaToPassedFormula (
 const FormulaT & _formula,
 const std::shared_ptr< std::vector< FormulaT >> & _origins) [inline], [protected],
[inherited]
```

Adds the given formula to the passed formula.

**Parameters**

|                       |                                                                                                                                         |
|-----------------------|-----------------------------------------------------------------------------------------------------------------------------------------|
| <code>_formula</code> | The formula to add to the passed formula.                                                                                               |
| <code>_origins</code> | The link of the formula to add to the passed formula to sub-formulas of the received formulas, which are responsible for its occurrence |

**Returns**

A pair to the position where the formula to add has been inserted (or its first sub-formula which has not yet been in the passed formula, in case the formula to add is a conjunction), and a Boolean stating whether anything has been added to the passed formula.

**0.15.299.5.11 allModels() const std::vector<Model>& smtrat::Module::allModels () const [inline], [inherited]****Returns**

All satisfying assignments, if existent.

**0.15.299.5.12 anAnswerFound() bool smtrat::Module::anAnswerFound () const [inline], [protected], [inherited]**

Checks for all antecedent modules and those which run in parallel with the same antecedent modules, whether one of them has determined a result.

**Returns**

True, if one of them has determined a result.

**0.15.299.5.13 answerFound() const smtrat::Conditionals& smtrat::Module::answerFound () const [inline], [inherited]****Returns**

A vector of Booleans: If any of them is true, we have to terminate a running check procedure.

**0.15.299.5.14 backendsModel() const Model & smtrat::Module::backendsModel () const [protected], [inherited]**

Stores the model of a backend which determined satisfiability of the passed formula in the model of this module.

---

**0.15.299.5.15** **branchAt()** [1/4] `bool smrat::Module::branchAt (`

```
carl::Variable::Arg _var,
const Rational & _value,
bool _leftCaseWeak = true,
bool _preferLeftCase = true,
bool _useReceivedFormulaAsPremise = false,
const std::vector< FormulaT > & _premise = std::vector<FormulaT>()) [inline],
[protected], [inherited]
```

**0.15.299.5.16** **branchAt()** [2/4] `bool smrat::Module::branchAt (`

```
carl::Variable::Arg _var,
const Rational & _value,
std::vector< FormulaT > && _premise,
bool _leftCaseWeak = true,
bool _preferLeftCase = true,
bool _useReceivedFormulaAsPremise = false) [inline], [protected], [inherited]
```

**0.15.299.5.17** **branchAt()** [3/4] `bool smrat::Module::branchAt (`

```
const Poly & _polynomial,
bool _integral,
const Rational & _value,
bool _leftCaseWeak = true,
bool _preferLeftCase = true,
bool _useReceivedFormulaAsPremise = false,
const std::vector< FormulaT > & _premise = std::vector<FormulaT>()) [inline],
[protected], [inherited]
```

**0.15.299.5.18** **branchAt()** [4/4] `bool smrat::Module::branchAt (`

```
const Poly & _polynomial,
bool _integral,
const Rational & _value,
std::vector< FormulaT > && _premise,
bool _leftCaseWeak = true,
bool _preferLeftCase = true,
bool _useReceivedFormulaAsPremise = false) [protected], [inherited]
```

Adds a lemmas which provoke a branching for the given variable at the given value, if this module returns Unknown and there exists a preceding [SATModule](#).

Note that the given value is rounded down and up, if the given variable is integer-valued.

#### Parameters

|                                           |                                                                                                                                                                                                                |
|-------------------------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>_polynomial</code>                  | The variable to branch for.                                                                                                                                                                                    |
| <code>_integral</code>                    | A flag being true, if all variables in the polynomial to branch for are integral.                                                                                                                              |
| <code>_value</code>                       | The value to branch at.                                                                                                                                                                                        |
| <code>_premise</code>                     | The sub-formulas of the received formula from which the branch is followed. Note, that a premise is not necessary, as every branch is a valid formula. But a premise can prevent from branching unnecessarily. |
| <code>_leftCaseWeak</code>                | true, if a branching in the form of (or ( $\leq p b$ ) ( $> p b$ )) is desired. false, if a branching in the form of (or ( $< p b$ ) ( $\geq p b$ )) is desired.                                               |
| <code>_preferLeftCase</code>              | true, if the left case (polynomial less(or equal) 0 shall be chosen first. false, otherwise.                                                                                                                   |
| <code>_useReceivedFormulaAsPremise</code> | true, if the whole received formula should be used as premise                                                                                                                                                  |

```
0.15.299.5.19 check() Answer smtrat::Module::check (
 bool _final = false,
 bool _full = true,
 carl::Variable _objective = carl::Variable::NO_VARIABLE) [virtual], [inherited]
```

Checks the received formula for consistency.

Note, that this is an implementation of the satisfiability check of the conjunction of the so far received formulas, which does actually nothing but passing the problem to its backends. This implementation is only used internally and must be overwritten by any derived module.

#### Parameters

|                   |                                                                                                                                       |
|-------------------|---------------------------------------------------------------------------------------------------------------------------------------|
| <i>_final</i>     | true, if this satisfiability check will be the last one (for a global sat-check), if its result is SAT                                |
| <i>_full</i>      | false, if this module should avoid too expensive procedures and rather return unknown instead.                                        |
| <i>_objective</i> | if not set to NO_VARIABLE, the module should find an assignment minimizing this objective variable; otherwise any assignment is good. |

#### Returns

True, if the received formula is satisfiable; False, if the received formula is not satisfiable; Unknown, otherwise.

Reimplemented in [smtrat::PModule](#).

```
0.15.299.5.20 checkCore() template<class Settings >
Answer smtrat::LRAbstract< Settings >::checkCore () [virtual]
```

Checks the received formula for consistency.

#### Returns

SAT, if the received formula is satisfiable; UNSAT, if the received formula is not satisfiable; Unknown, otherwise.

Reimplemented from [smtrat::Module](#).

```
0.15.299.5.21 checkCore_old() template<class Settings >
Answer smtrat::LRAbstract< Settings >::checkCore_old ()
```

```
0.15.299.5.22 checkInfSubsetForMinimality() void smtrat::Module::checkInfSubsetForMinimality (
 std::vector< FormulaSetT >::const_iterator _infssubset,
 const std::string & _filename = "smaller_muses",
 unsigned _maxSizeDifference = 1) const [inherited]
```

Checks the given infeasible subset for minimality by storing all subsets of it, which have a smaller size which differs from the size of the infeasible subset not more than the given threshold.

#### Parameters

|                           |                                                                                                        |
|---------------------------|--------------------------------------------------------------------------------------------------------|
| <i>_infssubset</i>        | The infeasible subset to check for minimality.                                                         |
| <i>_filename</i>          | The name of the file to store the infeasible subsets in order to be able to check their infeasibility. |
| <i>_maxSizeDifference</i> | The maximal difference between the sizes of the subsets compared to the size of the infeasible subset. |

**0.15.299.5.23 checkModel()** `unsigned smtrat::Module::checkModel ( ) const [protected], [inherited]`

**Returns**

false, if the current model of this module does not satisfy the current given formula; true, if it cannot be said whether the model satisfies the given formula.

**0.15.299.5.24 checkNotEqualConstraints()** `template<class Settings >`

```
Answer smtrat::LRAModule< Settings >::checkNotEqualConstraints (
 Answer _result)
```

**0.15.299.5.25 cleanModel()** `void smtrat::Module::cleanModel ( ) const [inline], [protected], [inherited]`

Substitutes variable occurrences by its model value in the model values of other variables.

**0.15.299.5.26 clearLemmas()** `void smtrat::Module::clearLemmas ( ) [inline], [inherited]`

Deletes all yet found lemmas.

**0.15.299.5.27 clearModel()** `void smtrat::Module::clearModel ( ) const [inline], [protected], [inherited]`

Clears the assignment, if any was found.

**0.15.299.5.28 clearModels()** `void smtrat::Module::clearModels ( ) const [inline], [protected], [inherited]`

Clears all assignments, if any was found.

**0.15.299.5.29 clearPassedFormula()** `void smtrat::Module::clearPassedFormula ( ) [protected], [inherited]`

**0.15.299.5.30 collectOrigins() [1/2]** `void smtrat::Module::collectOrigins (
 const FormulaT & _formula,
 FormulaSetT & _origins ) const [inherited]`

**0.15.299.5.31 collectOrigins() [2/2]** `void smtrat::Module::collectOrigins (
 const FormulaT & _formula,
 FormulasT & _origins ) const [inherited]`

Collects the formulas in the given formula, which are part of the received formula.

If the given formula directly occurs in the received formula, it is inserted into the given set. Otherwise, the given formula must be of type AND and all its sub-formulas part of the received formula. Hence, they will be added to the given set.

**Parameters**

|                       |                                                                                                      |
|-----------------------|------------------------------------------------------------------------------------------------------|
| <code>_formula</code> | The formula from which to collect the formulas being sub-formulas of the received formula (origins). |
| <code>_origins</code> | The set in which to store the origins.                                                               |

**0.15.299.5.32 `collectTheoryPropagations()`** void smtrat::Module::collectTheoryPropagations ( )  
[inherited]

**0.15.299.5.33 `constraintsToInform()`** const carl::FastSet<[FormulaT](#)>& smtrat::Module::constraintsToInform ( ) const [inline], [inherited]

#### Returns

The constraints which the backends must be informed about.

**0.15.299.5.34 `createInfeasibleSubsets()`** template<class Settings >  
void smtrat::LRAbstractModule< Settings >::createInfeasibleSubsets (   
 lra::EntryID \_tableauEntry )

**0.15.299.5.35 `currentlySatisfied()`** template<class Settings >  
unsigned smtrat::LRAbstractModule< Settings >::currentlySatisfied (   
 const [FormulaT](#) & ) const [virtual]

#### Returns

0, if the given formula is conflicted by the current model; 1, if the given formula is satisfied by the current model; 2, otherwise

Reimplemented from [smtrat::Module](#).

**0.15.299.5.36 `currentlySatisfiedByBackend()`** unsigned smtrat::Module::currentlySatisfiedByBackend (   
 const [FormulaT](#) & \_formula ) const [inherited]

#### Returns

0, if the given formula is conflicted by the current model; 1, if the given formula is satisfied by the current model; 2, otherwise 3, if we do not know anything (default)

**0.15.299.5.37 `deinform()`** void smtrat::Module::deinform (   
 const [FormulaT](#) & \_constraint ) [inherited]

The inverse of informing about a constraint.

All data structures which were kept regarding this constraint are going to be removed. Note, that this makes only sense if it is not likely enough that a formula with this constraint must be solved again.

#### Parameters

|                          |                                                         |
|--------------------------|---------------------------------------------------------|
| <code>_constraint</code> | The constraint to remove from internal data structures. |
|--------------------------|---------------------------------------------------------|

**0.15.299.5.38 `deinformCore()`** template<class Settings >  
void smtrat::LRAbstractModule< Settings >::deinformCore (   
 const [FormulaT](#) & \_constraint ) [virtual]

The inverse of informing about a constraint.

All data structures which were kept regarding this constraint are going to be removed. Note, that this makes only sense if it is not likely enough that a formula with this constraint must be solved again.

**Parameters**

|                          |                                                         |
|--------------------------|---------------------------------------------------------|
| <code>_constraint</code> | The constraint to remove from internal data structures. |
|--------------------------|---------------------------------------------------------|

Reimplemented from [smrat::Module](#).

**0.15.299.5.39 `determine_smallest_origin()`** `size_t smrat::Module::determine_smallest_origin (const std::vector< FormulaT > & origins ) const [protected], [inherited]`

**Parameters**

|                      |                              |
|----------------------|------------------------------|
| <code>origins</code> | A vector of sets of origins. |
|----------------------|------------------------------|

**Returns**

The index of the smallest (regarding the size of the sets) element of origins

**0.15.299.5.40 `eraseSubformulaFromPassedFormula()`** `ModuleInput::iterator smrat::Module::eraseSubformulaFromPassedFormula (ModuleInput::iterator _subformula, bool _ignoreOrigins = false ) [protected], [virtual], [inherited]`

Removes everything related to the sub-formula to remove from the passed formula in the backends of this module. Afterwards the sub-formula is removed from the passed formula.

**Parameters**

|                             |                                                                                                              |
|-----------------------------|--------------------------------------------------------------------------------------------------------------|
| <code>_subformula</code>    | The sub-formula to remove from the passed formula.                                                           |
| <code>_ignoreOrigins</code> | True, if the sub-formula shall be removed regardless of its origins (should only be applied with expertise). |

**Returns**

Reimplemented in [smrat::ICPModule< Settings >](#), [smrat::ICPModule< ICPSettings4 >](#), and [smrat::ICPModule< ICPSettings1 >](#).

**0.15.299.5.41 `excludeNotReceivedVariablesFromModel()`** `void smrat::Module::excludeNotReceivedVariablesFromModel ( ) const [inherited]`

Excludes all variables from the current model, which do not occur in the received formula.

**0.15.299.5.42 `findBestOrigin()`** `std::vector< FormulaT >::const_iterator smrat::Module::findBestOrigin (const std::vector< FormulaT > & _origins ) const [protected], [inherited]`

**Parameters**

|                       |  |
|-----------------------|--|
| <code>_origins</code> |  |
|-----------------------|--|

Returns

**0.15.299.5.43 firstSubformulaToPass()** `ModuleInput::const_iterator smtrat::Module::firstSubformulaToPass () const [inline], [inherited]`

Returns

The position of the first sub-formula in the passed formula, which has not yet been considered for a consistency check of the backends.

**0.15.299.5.44 firstUncheckedReceivedSubformula()** `ModuleInput::const_iterator smtrat::Module::firstUncheckedReceivedSubformula () const [inline], [inherited]`

Returns

The position of the first (by this module) unchecked sub-formula of the received formula.

**0.15.299.5.45 freeSplittingVariable()** `static void smtrat::Module::freeSplittingVariable (const FormulaT & _splittingVariable ) [inline], [static], [inherited]`

**0.15.299.5.46 generateTrivialInfeasibleSubset()** `void smtrat::Module::generateTrivialInfeasibleSubset () [inline], [protected], [inherited]`

Stores the trivial infeasible subset being the set of received formulas.

**0.15.299.5.47 getBackendsAllModels()** `void smtrat::Module::getBackendsAllModels () const [protected], [inherited]`

Stores all models of a backend in the list of all models of this module.

**0.15.299.5.48 getBackendsModel()** `void smtrat::Module::getBackendsModel () const [protected], [inherited]`

**0.15.299.5.49 getInfeasibleSubsets() [1/2]** `void smtrat::Module::getInfeasibleSubsets () [protected], [inherited]`

Copies the infeasible subsets of the passed formula.

**0.15.299.5.50 getInfeasibleSubsets() [2/2]** `std::vector< FormulaSetT > smtrat::Module::getInfeasibleSubsets (const Module & _backend ) const [protected], [inherited]`

Get the infeasible subsets the given backend provides.

Note, that an infeasible subset in a backend contains sub formulas of the passed formula and an infeasible subset of this module contains sub formulas of the received formula. In this method the LATTER is returned.

Parameters

|                       |                                                          |
|-----------------------|----------------------------------------------------------|
| <code>_backend</code> | The backend from which to obtain the infeasible subsets. |
|-----------------------|----------------------------------------------------------|

**Returns**

The infeasible subsets the given backend provides.

**0.15.299.5.51 getInformationRelevantFormulas()** const std::set< [FormulaT](#) > & smtrat::Module::getInformationRelevantFormulas () [protected], [inherited]  
Gets all InformationRelevantFormulas.

**Returns**

Set of all formulas

**0.15.299.5.52 getModelEqualities()** std::list< std::vector< [carl::Variable](#) > > smtrat::Module::getModelEqualities () const [virtual], [inherited]  
Partition the variables from the current model into equivalence classes according to their assigned value.  
The result is a set of equivalence classes of variables where all variables within one class are assigned the same value. Note that the number of classes may not be minimal, i.e. two classes may actually be equivalent.

**Returns**

Equivalence classes.

**0.15.299.5.53 getOrigins() [1/3]** void smtrat::Module::getOrigins ( const [FormulaT](#) & *\_formula*, [FormulaSetT](#) & *\_origins* ) const [inline], [protected], [inherited]

**Parameters**

|                 |  |
|-----------------|--|
| <i>_formula</i> |  |
| <i>_origins</i> |  |

**0.15.299.5.54 getOrigins() [2/3]** void smtrat::Module::getOrigins ( const [FormulaT](#) & *\_formula*, [FormulasT](#) & *\_origins* ) const [inline], [protected], [inherited]

**Parameters**

|                 |  |
|-----------------|--|
| <i>_formula</i> |  |
| <i>_origins</i> |  |

**0.15.299.5.55 getOrigins() [3/3]** const [FormulaT](#)& smtrat::Module::getOrigins ( [ModuleInput::const\\_iterator](#) *\_formula* ) const [inline], [protected], [inherited]  
Gets the origins of the passed formula at the given position.

**Parameters**

|                 |                                                   |
|-----------------|---------------------------------------------------|
| <i>_formula</i> | The position of a formula in the passed formulas. |
|-----------------|---------------------------------------------------|

**Returns**

The origins of the passed formula at the given position.

**0.15.299.5.56 `getRationalModel()`** template<class Settings >  
 const RationalAssignment& smtrat::LRAutoModule< Settings >::getRationalModel ( ) const  
 Gives a rational model if the received formula is satisfiable.  
 Note, that it is calculated from scratch every time you call this method.

**Returns**

The rational model.

**0.15.299.5.57 `getReceivedFormulaSimplified()`** std::pair< bool, FormulaT > smtrat::Module::get<= ReceivedFormulaSimplified ( ) [virtual], [inherited]

**Returns**

A pair of a Boolean and a formula, where the Boolean is true, if the received formula could be simplified to an equisatisfiable formula. The formula is equisatisfiable to this module's received formula, if the Boolean is true.

Reimplemented in [smtrat::PModule](#).

**0.15.299.5.58 `getSlackVariable()`** template<class Settings >  
 const LRAVariable\* smtrat::LRAutoModule< Settings >::getSlackVariable (   
 const FormulaT & \_constraint ) const [inline]

**Parameters**

|                          |                                               |
|--------------------------|-----------------------------------------------|
| <code>_constraint</code> | The constraint to get the slack variable for. |
|--------------------------|-----------------------------------------------|

**Returns**

The slack variable constructed for the linear polynomial without the constant part in the given constraint.

**0.15.299.5.59 `getVariableBounds()`** template<class Settings >  
 EvalRationalIntervalMap smtrat::LRAutoModule< Settings >::getVariableBounds ( ) const  
 Returns the bounds of the variables as intervals.

**Returns**

The bounds of the variables as intervals.

**0.15.299.5.60 `hasLemmas()`** bool smtrat::Module::hasLemmas ( ) [inline], [inherited]  
 Checks whether this module or any of its backends provides any lemmas.

**0.15.299.5.61 `hasValidInfeasibleSubset()`** bool smtrat::Module::hasValidInfeasibleSubset ( ) const [inherited]

**Returns**

true, if the module has at least one valid infeasible subset, that is all its elements are sub-formulas of the received formula (pointer must be equal).

**0.15.299.5.62** `id()` `std::size_t smtrat::Module::id () const [inline], [inherited]`

**Returns**

A unique ID to identify this module instance.

**0.15.299.5.63** `infeasibleSubsets()` `const std::vector<FormulaSetT>& smtrat::Module::infeasibleSubsets () const [inline], [inherited]`

**Returns**

The infeasible subsets of the set of received formulas (empty, if this module has not detected unsatisfiability of the conjunction of received formulas).

**0.15.299.5.64** `inform()` `bool smtrat::Module::inform (const FormulaT & _constraint) [inherited]`

Informs the module about the given constraint.

It should be tried to inform this module about any constraint it could receive eventually before assertSubformula is called (preferably for the first time, but at least before adding a formula containing that constraint).

**Parameters**

|                          |                                 |
|--------------------------|---------------------------------|
| <code>_constraint</code> | The constraint to inform about. |
|--------------------------|---------------------------------|

**Returns**

false, if it can be easily decided whether the given constraint is inconsistent; true, otherwise.

**0.15.299.5.65** `informBackends()` `void smtrat::Module::informBackends (const FormulaT & _constraint) [inline], [protected], [inherited]`

Informs all backends of this module about the given constraint.

**Parameters**

|                          |                                 |
|--------------------------|---------------------------------|
| <code>_constraint</code> | The constraint to inform about. |
|--------------------------|---------------------------------|

**0.15.299.5.66** `informCore()` `template<class Settings> bool smtrat::LRAbstractModule<Settings>::informCore (const FormulaT & _constraint) [virtual]`

Informs this module about the existence of the given constraint, which means that it could be added in future.

**Parameters**

|                          |                                 |
|--------------------------|---------------------------------|
| <code>_constraint</code> | The constraint to inform about. |
|--------------------------|---------------------------------|

**Returns**

false, if the it can be determined that the constraint itself is conflicting; true, otherwise.

Reimplemented from [smtrat::Module](#).

**0.15.299.5.67 informedConstraints()** const carl::FastSet<[FormulaT](#)>& smtrat::Module::informedConstraints ( ) const [inline], [inherited]

#### Returns

The position of the first constraint of which no backend has been informed about.

**0.15.299.5.68 init()** template<class Settings >  
void [smtrat::LRAbstractModule](#)< Settings >::init ( ) [virtual]

Initializes the tableau according to all linear constraints, of which this module has been informed.  
Reimplemented from [smtrat::Module](#).

**0.15.299.5.69 is\_minimizing()** bool smtrat::Module::is\_minimizing ( ) const [inline], [inherited]

**0.15.299.5.70 isLemmaLevel()** bool smtrat::Module::isLemmaLevel ( [LemmaLevel](#) level ) [protected], [inherited]

Checks if current lemma level is greater or equal to given level.

#### Parameters

|              |                 |
|--------------|-----------------|
| <i>level</i> | Level to check. |
|--------------|-----------------|

**0.15.299.5.71 isPreprocessor()** bool smtrat::Module::isPreprocessor ( ) const [inline], [inherited]

#### Returns

true, if this module is a preprocessor that is a module, which simplifies its received formula to an equisatisfiable formula being passed to its backends. The simplified formula can be obtained with [getReceivedFormulaSimplified\(\)](#).

**0.15.299.5.72 lemmas()** const std::vector<[Lemma](#)>& smtrat::Module::lemmas ( ) const [inline], [inherited]

#### Returns

A constant reference to the lemmas being valid formulas this module or its backends made.

**0.15.299.5.73 merge()** std::vector< [FormulaT](#) > smtrat::Module::merge ( const std::vector< [FormulaT](#) > & *\_vecSetA*, const std::vector< [FormulaT](#) > & *\_vecSetB* ) const [protected], [inherited]

Merges the two vectors of sets into the first one.

({a,b},{a,c}) and ({b,d},{b}) -> ({a,b,d},{a,b},{a,b,c,d},{a,b,c})

#### Parameters

|                 |                                  |
|-----------------|----------------------------------|
| <i>_vecSetA</i> | A vector of sets of constraints. |
| <i>_vecSetB</i> | A vector of sets of constraints. |

**Returns**

The vector being the two given vectors merged.

**0.15.299.5.74 model()** const [Model](#)& smtrat::Module::model () const [inline], [inherited]**Returns**

The assignment of the current satisfiable result, if existent.

**0.15.299.5.75 modelsDisjoint()** bool smtrat::Module::modelsDisjoint (

```
const Model & _modelA,
const Model & _modelB) [static], [protected], [inherited]
```

Checks whether there is no variable assigned by both models.

**Parameters**

|         |                                |
|---------|--------------------------------|
| _modelA | The first model to check for.  |
| _modelB | The second model to check for. |

**Returns**

true, if there is no variable assigned by both models; false, otherwise.

**0.15.299.5.76 moduleName()** template<class Settings >

```
std::string smtrat::LRAModule< Settings >::moduleName () const [inline], [virtual]
```

**Returns**

The name of the given module type as name.

Reimplemented from [smtrat::Module](#).

**0.15.299.5.77 objective()** [carl::Variable](#) smtrat::Module::objective () const [inline], [inherited]**0.15.299.5.78 optimize()** template<class Settings >

```
Answer smtrat::LRAModule< Settings >::optimize (
 Answer _result)
```

**0.15.299.5.79 originalVariables()** template<class Settings >

```
const VarVariableMap& smtrat::LRAModule< Settings >::originalVariables () const [inline]
```

**Returns**

A constant reference to the original variables.

**0.15.299.5.80 originInReceivedFormula()** bool smtrat::Module::originInReceivedFormula (

```
const FormulaT & _origin) const [protected], [inherited]
```

**0.15.299.5.81 passedFormulaBegin()** `ModuleInput::iterator smtrat::Module::passedFormulaBegin ( )` [inline], [protected], [inherited]

#### Returns

An iterator to the end of the passed formula. TODO: disable this method

**0.15.299.5.82 passedFormulaEnd()** `ModuleInput::iterator smtrat::Module::passedFormulaEnd ( )` [inline], [protected], [inherited]

#### Returns

An iterator to the end of the passed formula.

**0.15.299.5.83 pPassedFormula()** `const ModuleInput* smtrat::Module::pPassedFormula ( ) const` [inline], [inherited]

#### Returns

A pointer to the formula passed to the backends of this module.

**0.15.299.5.84 pReceivedFormula()** `const ModuleInput* smtrat::Module::pReceivedFormula ( ) const` [inline], [inherited]

#### Returns

A pointer to the formula passed to this module.

**0.15.299.5.85 print()** `void smtrat::Module::print ( const std::string & _initiation = "***" ) const`

Prints everything relevant of the solver.

#### Parameters

|                          |                      |
|--------------------------|----------------------|
| <code>_initiation</code> | The line initiation. |
|--------------------------|----------------------|

**0.15.299.5.86 printAllModels()** `void smtrat::Module::printAllModels ( std::ostream & _out = std::cout )` [inherited]

Prints all assignments of this module satisfying its received formula if it satisfiable and this module could find an assignment.

#### Parameters

|                   |                                        |
|-------------------|----------------------------------------|
| <code>_out</code> | The stream to print the assignment on. |
|-------------------|----------------------------------------|

**0.15.299.5.87 printBoundCandidatesToPass()** `template<class Settings > void smtrat::LRAModule< Settings >::printBoundCandidatesToPass ( std::ostream & _out = std::cout, const std::string _init = "" ) const`

Prints the strictest bounds, which have to be passed the backend in case.

#### Parameters

|                    |                                      |
|--------------------|--------------------------------------|
| <code>_out</code>  | The output stream to print on.       |
| <code>_init</code> | The beginning of each line to print. |

```
0.15.299.5.88 printConstraintToBound() template<class Settings >
void smtrat::LRAModule< Settings >::printConstraintToBound (
 std::ostream & _out = std::cout,
 const std::string _init = "") const
```

Prints the mapping of constraints to their corresponding bounds.

#### Parameters

|                    |                                      |
|--------------------|--------------------------------------|
| <code>_out</code>  | The output stream to print on.       |
| <code>_init</code> | The beginning of each line to print. |

```
0.15.299.5.89 printInfeasibleSubsets() void smtrat::Module::printInfeasibleSubsets (
 const std::string & _initiation = "***") const [inherited]
```

Prints the infeasible subsets.

#### Parameters

|                          |                      |
|--------------------------|----------------------|
| <code>_initiation</code> | The line initiation. |
|--------------------------|----------------------|

```
0.15.299.5.90 printLinearConstraints() template<class Settings >
void smtrat::LRAModule< Settings >::printLinearConstraints (
 std::ostream & _out = std::cout,
 const std::string _init = "") const
```

Prints all linear constraints.

#### Parameters

|                    |                                      |
|--------------------|--------------------------------------|
| <code>_out</code>  | The output stream to print on.       |
| <code>_init</code> | The beginning of each line to print. |

```
0.15.299.5.91 printModel() void smtrat::Module::printModel (
 std::ostream & _out = std::cout) const [inherited]
```

Prints the assignment of this module satisfying its received formula if it satisfiable and this module could find an assignment.

#### Parameters

|                   |                                        |
|-------------------|----------------------------------------|
| <code>_out</code> | The stream to print the assignment on. |
|-------------------|----------------------------------------|

```
0.15.299.5.92 printNonlinearConstraints() template<class Settings >
void smtrat::LRAModule< Settings >::printNonlinearConstraints (
 std::ostream & _out = std::cout,
 const std::string _init = "") const
Prints all non-linear constraints.
```

**Parameters**

|              |                                      |
|--------------|--------------------------------------|
| <i>_out</i>  | The output stream to print on.       |
| <i>_init</i> | The beginning of each line to print. |

```
0.15.299.5.93 printPassedFormula() void smtrat::Module::printPassedFormula (
 const std::string & _initiation = "***") const [inherited]
Prints the vector of passed formula.
```

**Parameters**

|                    |                      |
|--------------------|----------------------|
| <i>_initiation</i> | The line initiation. |
|--------------------|----------------------|

```
0.15.299.5.94 printRationalModel() template<class Settings >
void smtrat::LRAModule< Settings >::printRationalModel (
 std::ostream & _out = std::cout,
 const std::string _init = "") const
Prints the current rational assignment.
```

**Parameters**

|              |                                      |
|--------------|--------------------------------------|
| <i>_out</i>  | The output stream to print on.       |
| <i>_init</i> | The beginning of each line to print. |

```
0.15.299.5.95 printReceivedFormula() void smtrat::Module::printReceivedFormula (
 const std::string & _initiation = "***") const [inherited]
Prints the vector of the received formula.
```

**Parameters**

|                    |                      |
|--------------------|----------------------|
| <i>_initiation</i> | The line initiation. |
|--------------------|----------------------|

```
0.15.299.5.96 printTableau() template<class Settings >
void smtrat::LRAModule< Settings >::printTableau (
 std::ostream & _out = std::cout,
 const std::string _init = "") const
Prints the current tableau.
```

**Parameters**

|              |                                      |
|--------------|--------------------------------------|
| <i>_out</i>  | The output stream to print on.       |
| <i>_init</i> | The beginning of each line to print. |

---

```
0.15.299.5.97 printVariables() template<class Settings >
void smtrat::LRAgent< Settings >::printVariables (
 std::ostream & _out = std::cout,
 const std::string _init = "") const
```

Prints all lra variables and their assignments.

#### Parameters

|              |                                      |
|--------------|--------------------------------------|
| <i>_out</i>  | The output stream to print on.       |
| <i>_init</i> | The beginning of each line to print. |

```
0.15.299.5.98 probablyLooping() bool smtrat::Module::probablyLooping (
 const typename Poly::PolyType & _branchingPolynomial,
 const Rational & _branchingValue) const [protected], [inherited]
```

Checks whether given the current branching value and branching variable/polynomial it is (highly) probable that this branching is part of an infinite loop of branchings.

#### Parameters

|                             |                                                                                     |
|-----------------------------|-------------------------------------------------------------------------------------|
| <i>_branchingPolynomial</i> | The polynomial to branch at (in most branching strategies this is just a variable). |
| <i>_branchingValue</i>      | The value to branch at.                                                             |

#### Returns

true, if this branching is probably part of an infinite loop of branchings; false, otherwise.

```
0.15.299.5.99 processLearnedBounds() template<class Settings >
void smtrat::LRAgent< Settings >::processLearnedBounds ()
```

```
0.15.299.5.100 processResult() template<class Settings >
Answer smtrat::LRAgent< Settings >::processResult (
 Answer _result)
```

```
0.15.299.5.101 receivedFormulaChecked() void smtrat::Module::receivedFormulaChecked () [inline],
[inherited]
```

Notifies that the received formulas has been checked.

```
0.15.299.5.102 receivedFormulasAsInfeasibleSubset() void smtrat::Module::receivedFormulasAs<→
InfeasibleSubset (
 ModuleInput::const_iterator _subformula) [inline], [protected], [inherited]
```

Stores an infeasible subset consisting only of the given received formula.

```
0.15.299.5.103 receivedVariable() bool smtrat::Module::receivedVariable (
 carl::Variable::Arg _var) const [inline], [inherited]
```

**0.15.299.5.104 remove()** `void smtrat::Module::remove (`  
 `ModuleInput::const_iterator _subformula ) [virtual], [inherited]`

Removes everything related to the given sub-formula of the received formula.

However, it is desired not to lose track of search spaces where no satisfying assignment can be found for the remaining sub-formulas.

#### Parameters

|                          |                                                    |
|--------------------------|----------------------------------------------------|
| <code>_subformula</code> | The sub formula of the received formula to remove. |
|--------------------------|----------------------------------------------------|

Reimplemented in [smtrat::PModule](#).

**0.15.299.5.105 removeCore()** `template<class Settings >`  
`void smtrat::LRAbstractModule< Settings >::removeCore (`  
 `ModuleInput::const_iterator _subformula ) [virtual]`

Removes everything related to the given sub-formula of the received formula.

#### Parameters

|                          |                                                    |
|--------------------------|----------------------------------------------------|
| <code>_subformula</code> | The sub formula of the received formula to remove. |
|--------------------------|----------------------------------------------------|

Reimplemented from [smtrat::Module](#).

**0.15.299.5.106 removeOrigin()** `std::pair<ModuleInput::iterator, bool> smtrat::Module::remove←`  
`Origin (`  
 `ModuleInput::iterator _formula,`  
 `const FormulaT & _origin ) [inline], [protected], [inherited]`

**0.15.299.5.107 removeOrigins()** `std::pair<ModuleInput::iterator, bool> smtrat::Module::remove←`  
`Origins (`  
 `ModuleInput::iterator _formula,`  
 `const std::shared_ptr< std::vector< FormulaT >> & _origins ) [inline], [protected],`  
`[inherited]`

**0.15.299.5.108 rPassedFormula()** `const ModuleInput& smtrat::Module::rPassedFormula ( ) const`  
`[inline], [inherited]`

#### Returns

A reference to the formula passed to the backends of this module.

**0.15.299.5.109 rReceivedFormula()** `const ModuleInput& smtrat::Module::rReceivedFormula ( ) const`  
`[inline], [inherited]`

#### Returns

A reference to the formula passed to this module.

**0.15.299.5.110 runBackends() [1/2]** `virtual Answer smtrat::Module::runBackends ( ) [inline],`  
`[protected], [virtual], [inherited]`

Reimplemented in [smtrat::PModule](#).

---

**0.15.299.5.111 runBackends()** [2/2] [Answer](#) smtrat::Module::runBackends (

```
 bool _final,
 bool _full,
 carl::Variable _objective) [protected], [virtual], [inherited]
```

Runs the backend solvers on the passed formula.

#### Parameters

|                         |                                                                                                                                       |
|-------------------------|---------------------------------------------------------------------------------------------------------------------------------------|
| <code>_final</code>     | true, if this satisfiability check will be the last one (for a global sat-check), if its result is SAT                                |
| <code>_full</code>      | false, if this module should avoid too expensive procedures and rather return unknown instead.                                        |
| <code>_objective</code> | if not set to NO_VARIABLE, the module should find an assignment minimizing this objective variable; otherwise any assignment is good. |

#### Returns

True, if the passed formula is consistent; False, if the passed formula is inconsistent; Unknown, otherwise.

Reimplemented in [smtrat::PModule](#).

**0.15.299.5.112 setId()** void smtrat::Module::setId (

```
 std::size_t _id) [inline], [inherited]
```

Sets this modules unique ID to identify itself.

#### Parameters

|                 |                                    |
|-----------------|------------------------------------|
| <code>id</code> | The id to set this module's id to. |
|-----------------|------------------------------------|

**0.15.299.5.113 setThreadPriority()** void smtrat::Module::setThreadPriority (

```
 thread_priority _threadPriority) [inline], [inherited]
```

Sets the priority of this module to get a thread for running its check procedure.

#### Parameters

|                              |                                                       |
|------------------------------|-------------------------------------------------------|
| <code>_threadPriority</code> | The priority to set this module's thread priority to. |
|------------------------------|-------------------------------------------------------|

**0.15.299.5.114 slackVariables()** template<class Settings >

```
const ExVariableMap& smtrat::LRAModule< Settings >::slackVariables () const [inline]
```

#### Returns

A constant reference to the slack variables.

**0.15.299.5.115 solverState()** [Answer](#) smtrat::Module::solverState ( ) const [inline], [inherited]

#### Returns

True, if this module is in a state, such that it has found a solution for its received formula; False, if this module is in a state, such that it has determined that there is no solution for its received formula; Unknown, otherwise.

**0.15.299.5.116 `splitUnequalConstraint()`** `void smtrat::Module::splitUnequalConstraint ( const FormulaT & _unequalConstraint )` [protected], [inherited]

Adds the following lemmas for the given constraint  $p \neq 0$ .

$(p \neq 0 \Leftrightarrow (p < 0 \text{ or } p > 0))$

and  $\neg(p < 0 \text{ and } p > 0)$

#### Parameters

|                                 |                                                  |
|---------------------------------|--------------------------------------------------|
| <code>_unequalConstraint</code> | A constraint having the relation symbol $\neq$ . |
|---------------------------------|--------------------------------------------------|

**0.15.299.5.117 `threadPriority()`** `thread_priority smtrat::Module::threadPriority () const` [inline], [inherited]

#### Returns

The priority of this module to get a thread for running its check procedure.

**0.15.299.5.118 `updateAllModels()`** `void smtrat::Module::updateAllModels ()` [virtual], [inherited]

Updates all satisfying models, if the solver has detected the consistency of the received formula, beforehand.

Reimplemented in [smtrat::SATModule< Settings >](#).

**0.15.299.5.119 `updateLemmas()`** `void smtrat::Module::updateLemmas ()` [inherited]

Stores all lemmas of any backend of this module in its own lemma vector.

**0.15.299.5.120 `updateModel()`** `template<class Settings >`

`void smtrat::LRAutoModule< Settings >::updateModel () const` [virtual]

Updates the model, if the solver has detected the consistency of the received formula, beforehand.

Reimplemented from [smtrat::Module](#).

**0.15.299.5.121 `usedBackends()`** `const std::vector<Module*>& smtrat::Module::usedBackends ()`

const [inline], [inherited]

#### Returns

The backends of this module which are currently used (conditions to use this module are fulfilled for the passed formula).

## 0.15.299.6 Field Documentation

**0.15.299.6.1 `mAllBackends`** `std::vector<Module*> smtrat::Module::mAllBackends` [protected], [inherited]

The backends of this module which have been used.

**0.15.299.6.2 `mAllModels`** `std::vector<Model> smtrat::Module::mAllModels` [mutable], [protected], [inherited]

Stores all satisfying assignments.

**0.15.299.6.3 mBackendsFoundAnswer** `std::atomic_bool* smrat::Module::mBackendsFoundAnswer`

[protected], [inherited]

This flag is passed to any backend and if it determines an answer to a prior check call, this flag is fired.

**0.15.299.6.4 mConstraintsToInform** `carl::FastSet<FormulaT> smrat::Module::mConstraintsToInform`

[protected], [inherited]

Stores the constraints which the backends must be informed about.

**0.15.299.6.5 mFinalCheck** `bool smrat::Module::mFinalCheck [protected], [inherited]`

true, if the check procedure should perform a final check which especially means not to postpone splitting decisions

**0.15.299.6.6 mFirstPosInLastBranches** `std::size_t smrat::Module::mFirstPosInLastBranches = 0`

[static], [inherited]

The beginning of the cyclic buffer storing the last branches.

**0.15.299.6.7 mFirstSubformulaToPass** `ModuleInput::iterator smrat::Module::mFirstSubformulaToPass [protected], [inherited]`

Stores the position of the first sub-formula in the passed formula, which has not yet been considered for a consistency check of the backends.

**0.15.299.6.8 mFirstUncheckedReceivedSubformula** `ModuleInput::const_iterator smrat::Module::mFirstUncheckedReceivedSubformula [protected], [inherited]`

Stores the position of the first (by this module) unchecked sub-formula of the received formula.

**0.15.299.6.9 mFoundAnswer** `Conditionals smrat::Module::mFoundAnswer [protected], [inherited]`

Vector of Booleans: If any of them is true, we have to terminate a running check procedure.

**0.15.299.6.10 mFullCheck** `bool smrat::Module::mFullCheck [protected], [inherited]`

false, if this module should avoid too expensive procedures and rather return unknown instead.

**0.15.299.6.11 mInfeasibleSubsets** `std::vector<FormulaSetT> smrat::Module::mInfeasibleSubsets`

[protected], [inherited]

Stores the infeasible subsets.

**0.15.299.6.12 mInformedConstraints** `carl::FastSet<FormulaT> smrat::Module::mInformedConstraints`

[protected], [inherited]

Stores the position of the first constraint of which no backend has been informed about.

**0.15.299.6.13 mLastBranches** `std::vector< Branching > smrat::Module::mLastBranches = std::vector<Branching>(mNumOfBranchVarsToStore, Branching(typename Poly::PolyType(), 0)) [static], [inherited]`

Stores the last branches in a cycle buffer.

**0.15.299.6.14 mLemmas** std::vector<[Lemma](#)> smtrat::Module::mLemmas [protected], [inherited]  
Stores the lemmas being valid formulas this module or its backends made.

**0.15.299.6.15 mModel** [Model](#) smtrat::Module::mModel [mutable], [protected], [inherited]  
Stores the assignment of the current satisfiable result, if existent.

**0.15.299.6.16 mModelComputed** bool smtrat::Module::mModelComputed [mutable], [protected], [inherited]  
True, if the model has already been computed.

**0.15.299.6.17 mNumOfBranchVarsToStore** std::size\_t smtrat::Module::mNumOfBranchVarsToStore = 5 [static], [inherited]  
The number of different variables to consider for a probable infinite loop of branchings.

**0.15.299.6.18 mObjectiveVariable** carl::Variable smtrat::Module::mObjectiveVariable [protected], [inherited]  
Objective variable to be minimized. If set to NO\_VARIABLE, a normal sat check should be performed.

**0.15.299.6.19 mOldSplittingVariables** std::vector< [FormulaT](#) > smtrat::Module::mOldSplittingVariables [static], [inherited]  
Reusable splitting variables.

**0.15.299.6.20 mpManager** [Manager](#)\* const smtrat::Module::mpManager [protected], [inherited]  
A reference to the manager.

**0.15.299.6.21 mSmallerMusesCheckCounter** unsigned smtrat::Module::mSmallerMusesCheckCounter [mutable], [protected], [inherited]  
Counter used for the generation of the smt2 files to check for smaller muses.

**0.15.299.6.22 mSolverState** std::atomic<[Answer](#)> smtrat::Module::mSolverState [protected], [inherited]  
States whether the received formula is known to be satisfiable or unsatisfiable otherwise it is set to unknown.

**0.15.299.6.23 mTheoryPropagations** std::vector<[TheoryPropagation](#)> smtrat::Module::mTheoryPropagations [protected], [inherited]

**0.15.299.6.24 mUsedBackends** std::vector<[Module](#)\*> smtrat::Module::mUsedBackends [protected], [inherited]  
The backends of this module which are currently used (conditions to use this module are fulfilled for the passed formula).

**0.15.299.6.25 mVariableCounters** std::vector<std::size\_t> smtrat::Module::mVariableCounters [protected], [inherited]  
Maps variables to the number of their occurrences.

## 0.15.300 smtrat::LVEModule < Settings > Class Template Reference

```
#include <LVEModule.h>
```

### Public Types

- `typedef Settings SettingsType`
- `enum class LemmaType : unsigned { NORMAL = 0 , PERMANENT = 1 }`

### Public Member Functions

*Adds the given formula to the passed formula.*
- std::pair< [ModuleInput::iterator](#), bool > [addSubformulaToPassedFormula](#) (const [FormulaT](#) &\_formula, const [FormulaT](#) &\_origin)
 

*Adds the given formula to the passed formula.*
- void [generateTrivialInfeasibleSubset](#) ()
 

*Stores the trivial infeasible subset being the set of received formulas.*
- void [receivedFormulasAsInfeasibleSubset](#) ([ModuleInput::const\\_iterator](#) \_subformula)
 

*Stores an infeasible subset consisting only of the given received formula.*
- std::vector< [FormulaT](#) >::const\_iterator [findBestOrigin](#) (const std::vector< [FormulaT](#) > &\_origins) const
 

*Copies the infeasible subsets of the passed formula.*
- std::vector< [FormulaSetT](#) > [getInfeasibleSubsets](#) (const [Module](#) &\_backend) const
 

*Get the infeasible subsets the given backend provides.*
- const [Model](#) & [backendsModel](#) () const
 

*Stores the model of a backend which determined satisfiability of the passed formula in the model of this module.*
- void [getBackendsModel](#) () const
 

*Stores all models of a backend in the list of all models of this module.*
- void [getBackendsAllModels](#) () const
 

*Checks whether given the current branching value and branching variable/polynomial it is (highly) probable that this branching is part of an infinite loop of branchings.*
- virtual [ModuleInput::iterator](#) [eraseSubformulaFromPassedFormula](#) ([ModuleInput::iterator](#) \_subformula, bool \_ignoreOrigins=false)
 

*Removes everything related to the sub-formula to remove from the passed formula in the backends of this module.*
- void [clearPassedFormula](#) ()
 

*Merges the two vectors of sets into the first one.*
- std::vector< [FormulaT](#) > [merge](#) (const std::vector< [FormulaT](#) > &, const std::vector< [FormulaT](#) > &) const
 

*Adds a lemmas which provoke a branching for the given variable at the given value, if this module returns Unknown and there exists a preceding SATModule.*
- bool [branchAt](#) (const [Poly](#) &\_polynomial, bool \_integral, const [Rational](#) &\_value, std::vector< [FormulaT](#) > &&\_premise, bool \_leftCaseWeak=true, bool \_preferLeftCase=true, bool \_useReceivedFormulaAsPremise=false)
 

*bool [branchAt](#) (const [Poly](#) &\_polynomial, bool \_integral, const [Rational](#) &\_value, bool \_leftCaseWeak=true, bool \_preferLeftCase=true, bool \_useReceivedFormulaAsPremise=false, const std::vector< [FormulaT](#) > &\_premise=std::vector< [FormulaT](#) >())
   
bool [branchAt](#) (carl::Variable::Arg \_var, const [Rational](#) &\_value, std::vector< [FormulaT](#) > &&\_premise, bool \_leftCaseWeak=true, bool \_preferLeftCase=true, bool \_useReceivedFormulaAsPremise=false)
   
bool [branchAt](#) (carl::Variable::Arg \_var, const [Rational](#) &\_value, bool \_leftCaseWeak=true, bool \_preferLeftCase=true, bool \_useReceivedFormulaAsPremise=false, const std::vector< [FormulaT](#) > &\_premise=std::vector< [FormulaT](#) >())
   
void [splitUnequalConstraint](#) (const [FormulaT](#) &)*

*Adds the following lemmas for the given constraint p!=0.*
- unsigned [checkModel](#) () const
 

*Adds a formula to the InformationRelevantFormula.*
- void [addInformationRelevantFormula](#) (const [FormulaT](#) &formula)
 

*Gets all InformationRelevantFormulas.*
- const std::set< [FormulaT](#) > & [getInformationRelevantFormulas](#) ()
 

*Checks if current lemma level is greater or equal to given level.*

## Static Protected Member Functions

- static bool `modelsDisjoint` (const `Model` &\_modelA, const `Model` &\_modelB)

*Checks whether there is no variable assigned by both models.*

## Protected Attributes

- `std::vector<FormulaSetT> mInfeasibleSubsets`

*Stores the infeasible subsets.*

- `Manager *const mpManager`

*A reference to the manager.*

- `Model mModel`

*Stores the assignment of the current satisfiable result, if existent.*

- `std::vector<Model> mAllModels`

*Stores all satisfying assignments.*

- `bool mModelComputed`

*True, if the model has already been computed.*

- `bool mFinalCheck`

*true, if the check procedure should perform a final check which especially means not to postpone splitting decisions*

- `bool mFullCheck`

*false, if this module should avoid too expensive procedures and rather return unknown instead.*

- `carl::Variable mObjectiveVariable`

*Objective variable to be minimized. If set to NO\_VARIABLE, a normal sat check should be performed.*

- `std::vector<TheoryPropagation> mTheoryPropagations`

- `std::atomic<Answer> mSolverState`

*States whether the received formula is known to be satisfiable or unsatisfiable otherwise it is set to unknown.*

- `std::atomic_bool * mBackendsFoundAnswer`

*This flag is passed to any backend and if it determines an answer to a prior check call, this flag is fired.*

- `Conditionals mFoundAnswer`

*Vector of Booleans: If any of them is true, we have to terminate a running check procedure.*

- `std::vector<Module *> mUsedBackends`

*The backends of this module which are currently used (conditions to use this module are fulfilled for the passed formula).*

- `std::vector<Module *> mAllBackends`

*The backends of this module which have been used.*

- `std::vector<Lemma> mLemmas`

*Stores the lemmas being valid formulas this module or its backends made.*

- `ModuleInput::iterator mFirstSubformulaToPass`

*Stores the position of the first sub-formula in the passed formula, which has not yet been considered for a consistency check of the backends.*

- `carl::FastSet<FormulaT> mConstraintsToInform`

*Stores the constraints which the backends must be informed about.*

- `carl::FastSet<FormulaT> mInformedConstraints`

*Stores the position of the first constraint of which no backend has been informed about.*

- `ModuleInput::const_iterator mFirstUncheckedReceivedSubformula`

*Stores the position of the first (by this module) unchecked sub-formula of the received formula.*

- `unsigned mSmallerMusesCheckCounter`

*Counter used for the generation of the smt2 files to check for smaller muses.*

- `std::vector<std::size_t> mVariableCounters`

*Maps variables to the number of their occurrences.*

`smtrat::LVEModule< Settings >::~LVEModule` ( )

### 0.15.300.4 Member Function Documentation

**0.15.300.4.1 add()** bool `smtrat::PModule::add` (  
`ModuleInput::const_iterator` `_subformula`) [inherited]

The module has to take the given sub-formula of the received formula into account.

Parameters

|                          |                                                    |
|--------------------------|----------------------------------------------------|
| <code>_subformula</code> | The sub-formula to take additionally into account. |
|--------------------------|----------------------------------------------------|

Returns

false, if it can be easily decided that this sub-formula causes a conflict with the already considered sub-formulas; true, otherwise.

**0.15.300.4.2 addConstraintToInform()** void `smtrat::Module::addConstraintToInform` (  
`const FormulaT` & `_constraint`) [protected], [virtual], [inherited]

Adds a constraint to the collection of constraints of this module, which are informed to a freshly generated backend.

**Parameters**

|                    |                        |
|--------------------|------------------------|
| <i>_constraint</i> | The constraint to add. |
|--------------------|------------------------|

Reimplemented in [smrat::SATModule< Settings >](#).

**0.15.300.4.3 addCore()** `virtual bool smrat::Module::addCore ( ModuleInput::const_iterator formula ) [inline], [protected], [virtual], [inherited]`

The module has to take the given sub-formula of the received formula into account.

**Parameters**

|                |                                                    |
|----------------|----------------------------------------------------|
| <i>formula</i> | The sub-formula to take additionally into account. |
|----------------|----------------------------------------------------|

**Returns**

false, if it can be easily decided that this sub-formula causes a conflict with the already considered sub-formulas; true, otherwise.

Reimplemented in [smrat::VSModule< Settings >](#), [smrat::SATModule< Settings >](#), [smrat::PFEModule< Settings >](#), [smrat::ICPModule< Settings >](#), [smrat::ICPModule< ICPSettings4 >](#), [smrat::ICPModule< ICPSettings1 >](#), [smrat::UnionFindModule< Settings >](#), [smrat::UFCegarModule< Settings >](#), [smrat::STropModule< Settings >](#), [smrat::PBPPModule< Settings >](#), [smrat::PBGaussModule< Settings >](#), [smrat::NRAILModule< Settings >](#), [smrat::NewCoveringModule< Settings >](#), [smrat::NewCADModule< Settings >](#), [smrat::LRAModule< Settings >](#), [smrat::LRAModule< LRASettingsICP >](#), [smrat::LRAModule< LRASettings1 >](#), [smrat::IntEqModule< Settings >](#), [smrat::IntBlastModule< Settings >](#), [smrat::IncWidthModule< Settings >](#), [smrat::ICEModule< Settings >](#), [smrat::FPPModule< Settings >](#), [smrat::FouMoModule< Settings >](#), [smrat::EQModule< Settings >](#), [smrat::CurryModule< Settings >](#), [smrat::CubeLIAModule< Settings >](#), [smrat::CSplitModule< Settings >](#), [smrat::BVModule< Settings >](#), and [smrat::GBModule< Settings >](#).

**0.15.300.4.4 addInformationRelevantFormula()** `void smrat::Module::addInformationRelevantFormula (`

`const FormulaT & formula ) [protected], [inherited]`

Adds a formula to the InformationRelevantFormula.

**Parameters**

|                |                |
|----------------|----------------|
| <i>formula</i> | Formula to add |
|----------------|----------------|

**0.15.300.4.5 addLemma()** `void smrat::Module::addLemma (`

`const FormulaT & _lemma,`

`const LemmaType & _lt = LemmaType::NORMAL,`

`const FormulaT & _preferredFormula = FormulaT( carl::FormulaType::TRUE ) ) [inline],`

`[inherited]`

Stores a lemma being a valid formula.

**Parameters**

|                          |                                                                       |
|--------------------------|-----------------------------------------------------------------------|
| <i>_lemma</i>            | The eduction/lemma to store.                                          |
| <i>_lt</i>               | The type of the lemma.                                                |
| <i>_preferredFormula</i> | Hint for the next decision, which formula should be assigned to true. |

**0.15.300.4.6 addOrigin()** void smtrat::Module::addOrigin (   
     ModuleInput::iterator \_formula,  
     const FormulaT & \_origin ) [inline], [protected], [inherited]  
 Adds the given set of formulas in the received formula to the origins of the given passed formula.

#### Parameters

|          |                                                           |
|----------|-----------------------------------------------------------|
| _formula | The passed formula to set the origins for.                |
| _origin  | A set of formulas in the received formula of this module. |

**0.15.300.4.7 addReceivedSubformulaToPassedFormula()** std::pair<ModuleInput::iterator,bool> smtrat::Module::addReceivedSubformulaToPassedFormula (   
     ModuleInput::const\_iterator \_subformula ) [inline], [protected], [inherited]

Copies the given sub-formula of the received formula to the passed formula.

Note, that there is always a link between sub-formulas of the passed formulas to sub-formulas of the received formulas, which are responsible for its occurrence.

#### Parameters

|             |                                                  |
|-------------|--------------------------------------------------|
| _subformula | The sub-formula of the received formula to copy. |
|-------------|--------------------------------------------------|

**0.15.300.4.8 addSubformulaToPassedFormula() [1/3]** std::pair<ModuleInput::iterator,bool> smtrat::Module::addSubformulaToPassedFormula (   
     const FormulaT & \_formula ) [inline], [protected], [inherited]

Adds the given formula to the passed formula with no origin.

Note that in the next call of this module's removeSubformula, all formulas in the passed formula without origins will be removed.

#### Parameters

|          |                                           |
|----------|-------------------------------------------|
| _formula | The formula to add to the passed formula. |
|----------|-------------------------------------------|

#### Returns

A pair to the position where the formula to add has been inserted (or its first sub-formula which has not yet been in the passed formula, in case the formula to add is a conjunction), and a Boolean stating whether anything has been added to the passed formula.

**0.15.300.4.9 addSubformulaToPassedFormula() [2/3]** std::pair<ModuleInput::iterator,bool> smtrat::Module::addSubformulaToPassedFormula (   
     const FormulaT & \_formula,  
     const FormulaT & \_origin ) [inline], [protected], [inherited]

Adds the given formula to the passed formula.

#### Parameters

|          |                                                                                                                           |
|----------|---------------------------------------------------------------------------------------------------------------------------|
| _formula | The formula to add to the passed formula.                                                                                 |
| _origin  | The sub-formula of the received formula being responsible for the occurrence of the formula to add to the passed formula. |

**Returns**

A pair to the position where the formula to add has been inserted (or its first sub-formula which has not yet been in the passed formula, in case the formula to add is a conjunction), and a Boolean stating whether anything has been added to the passed formula.

**0.15.300.4.10 addSubformulaToPassedFormula() [3/3] std::pair<ModuleInput::iterator,bool>**

```
smrat::Module::addSubformulaToPassedFormula (
 const FormulaT & _formula,
 const std::shared_ptr< std::vector< FormulaT >> & _origins) [inline], [protected],
[inherited]
```

Adds the given formula to the passed formula.

**Parameters**

|                       |                                                                                                                                         |
|-----------------------|-----------------------------------------------------------------------------------------------------------------------------------------|
| <code>_formula</code> | The formula to add to the passed formula.                                                                                               |
| <code>_origins</code> | The link of the formula to add to the passed formula to sub-formulas of the received formulas, which are responsible for its occurrence |

**Returns**

A pair to the position where the formula to add has been inserted (or its first sub-formula which has not yet been in the passed formula, in case the formula to add is a conjunction), and a Boolean stating whether anything has been added to the passed formula.

**0.15.300.4.11 allModels() const std::vector<Model>& smrat::Module::allModels () const [inline], [inherited]****Returns**

All satisfying assignments, if existent.

**0.15.300.4.12 anAnswerFound() bool smrat::Module::anAnswerFound () const [inline], [protected], [inherited]**

Checks for all antecedent modules and those which run in parallel with the same antecedent modules, whether one of them has determined a result.

**Returns**

True, if one of them has determined a result.

**0.15.300.4.13 answerFound() const smrat::Conditionals& smrat::Module::answerFound () const [inline], [inherited]****Returns**

A vector of Booleans: If any of them is true, we have to terminate a running check procedure.

**0.15.300.4.14 appliedPreprocessing() bool smrat::PModule::appliedPreprocessing () const [inline], [inherited]****Returns**

true, if the current received formula has been simplified and the result of this simplification is stored in the passed formula.

**0.15.300.4.15 `backendsModel()`** const `Model` & smtrat::Module::backendsModel () const [protected], [inherited]

Stores the model of a backend which determined satisfiability of the passed formula in the model of this module.

**0.15.300.4.16 `branchAt() [1/4]`** bool smtrat::Module::branchAt ( carl::Variable::Arg \_var, const Rational & \_value, bool \_leftCaseWeak = true, bool \_preferLeftCase = true, bool \_useReceivedFormulaAsPremise = false, const std::vector< `FormulaT` > & \_premise = std::vector<`FormulaT`>() ) [inline], [protected], [inherited]

**0.15.300.4.17 `branchAt() [2/4]`** bool smtrat::Module::branchAt ( carl::Variable::Arg \_var, const Rational & \_value, std::vector< `FormulaT` > && \_premise, bool \_leftCaseWeak = true, bool \_preferLeftCase = true, bool \_useReceivedFormulaAsPremise = false ) [inline], [protected], [inherited]

**0.15.300.4.18 `branchAt() [3/4]`** bool smtrat::Module::branchAt ( const Poly & \_polynomial, bool \_integral, const Rational & \_value, bool \_leftCaseWeak = true, bool \_preferLeftCase = true, bool \_useReceivedFormulaAsPremise = false, const std::vector< `FormulaT` > & \_premise = std::vector<`FormulaT`>() ) [inline], [protected], [inherited]

**0.15.300.4.19 `branchAt() [4/4]`** bool smtrat::Module::branchAt ( const Poly & \_polynomial, bool \_integral, const Rational & \_value, std::vector< `FormulaT` > && \_premise, bool \_leftCaseWeak = true, bool \_preferLeftCase = true, bool \_useReceivedFormulaAsPremise = false ) [protected], [inherited]

Adds a lemmas which provoke a branching for the given variable at the given value, if this module returns Unknown and there exists a preceding SATModule.

Note that the given value is rounded down and up, if the given variable is integer-valued.

#### Parameters

|                            |                                                                                                                                                                                                                |
|----------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>_polynomial</code>   | The variable to branch for.                                                                                                                                                                                    |
| <code>_integral</code>     | A flag being true, if all variables in the polynomial to branch for are integral.                                                                                                                              |
| <code>_value</code>        | The value to branch at.                                                                                                                                                                                        |
| <code>_premise</code>      | The sub-formulas of the received formula from which the branch is followed. Note, that a premise is not necessary, as every branch is a valid formula. But a premise can prevent from branching unnecessarily. |
| <code>_leftCaseWeak</code> | true, if a branching in the form of (or ( $\leq p b$ ) ( $> p b$ )) is desired. false, if a branching in the form of (or ( $< p b$ ) ( $\geq p b$ )) is desired.                                               |

**Parameters**

|                                           |                                                                                              |
|-------------------------------------------|----------------------------------------------------------------------------------------------|
| <code>_preferLeftCase</code>              | true, if the left case (polynomial less(or equal) 0 shall be chosen first. false, otherwise. |
| <code>_useReceivedFormulaAsPremise</code> | true, if the whole received formula should be used as premise                                |

**0.15.300.4.20 `check()`** `Answer smrat::PModule::check (`

```
 bool _final = false,
 bool _full = true,
 carl::Variable _objective = carl::Variable::NO_VARIABLE) [virtual], [inherited]
```

Checks the received formula for consistency.

Note, that this is an implementation of the satisfiability check of the conjunction of the so far received formulas, which does actually nothing but passing the problem to its backends. This implementation is only used internally and must be overwritten by any derived module.

**Parameters**

|                         |                                                                                                                                       |
|-------------------------|---------------------------------------------------------------------------------------------------------------------------------------|
| <code>_final</code>     | true, if this satisfiability check will be the last one (for a global sat-check), if its result is SAT                                |
| <code>_full</code>      | false, if this module should avoid too expensive procedures and rather return unknown instead.                                        |
| <code>_objective</code> | if not set to NO_VARIABLE, the module should find an assignment minimizing this objective variable; otherwise any assignment is good. |

**Returns**

True, if the received formula is satisfiable; False, if the received formula is not satisfiable; Unknown, otherwise.

Reimplemented from [smrat::Module](#).

**0.15.300.4.21 `checkCore()`** `template<typename Settings >`

```
Answer smrat::LVEModule< Settings >::checkCore () [virtual]
```

Checks the received formula for consistency.

**Returns**

True, if the received formula is satisfiable; False, if the received formula is not satisfiable; Unknown, otherwise.

Reimplemented from [smrat::Module](#).

**0.15.300.4.22 `checkInfeasibleSubsetForMinimality()`** `void smrat::Module::checkInfeasibleSubsetForMinimality (`

```
 std::vector< FormulaSet >::const_iterator _infssubset,
 const std::string & _filename = "smaller_muses",
 unsigned _maxSizeDifference = 1) const [inherited]
```

Checks the given infeasible subset for minimality by storing all subsets of it, which have a smaller size which differs from the size of the infeasible subset not more than the given threshold.

**Parameters**

|                                 |                                                                                                        |
|---------------------------------|--------------------------------------------------------------------------------------------------------|
| <code>_infssubset</code>        | The infeasible subset to check for minimality.                                                         |
| <code>_filename</code>          | The name of the file to store the infeasible subsets in order to be able to check their infeasibility. |
| <code>_maxSizeDifference</code> | The maximal difference between the sizes of the subsets compared to the size of the infeasible subset. |

**0.15.300.4.23 `checkModel()`** `unsigned smtrat::Module::checkModel ( ) const [protected], [inherited]`

**Returns**

false, if the current model of this module does not satisfy the current given formula; true, if it cannot be said whether the model satisfies the given formula.

**0.15.300.4.24 `cleanModel()`** `void smtrat::Module::cleanModel ( ) const [inline], [protected], [inherited]`

Substitutes variable occurrences by its model value in the model values of other variables.

**0.15.300.4.25 `clearLemmas()`** `void smtrat::Module::clearLemmas ( ) [inline], [inherited]`  
Deletes all yet found lemmas.

**0.15.300.4.26 `clearModel()`** `void smtrat::Module::clearModel ( ) const [inline], [protected], [inherited]`

Clears the assignment, if any was found.

**0.15.300.4.27 `clearModels()`** `void smtrat::Module::clearModels ( ) const [inline], [protected], [inherited]`

Clears all assignments, if any was found.

**0.15.300.4.28 `clearPassedFormula()`** `void smtrat::Module::clearPassedFormula ( ) [protected], [inherited]`

**0.15.300.4.29 `collectOrigins() [1/2]`** `void smtrat::Module::collectOrigins ( const FormulaT & _formula, FormulaSetT & _origins ) const [inherited]`

**0.15.300.4.30 `collectOrigins() [2/2]`** `void smtrat::Module::collectOrigins ( const FormulaT & _formula, FormulasT & _origins ) const [inherited]`

Collects the formulas in the given formula, which are part of the received formula.

If the given formula directly occurs in the received formula, it is inserted into the given set. Otherwise, the given formula must be of type AND and all its sub-formulas part of the received formula. Hence, they will be added to the given set.

**Parameters**

|                       |                                                                                                      |
|-----------------------|------------------------------------------------------------------------------------------------------|
| <code>_formula</code> | The formula from which to collect the formulas being sub-formulas of the received formula (origins). |
| <code>_origins</code> | The set in which to store the origins.                                                               |

**0.15.300.4.31 `collectTheoryPropagations()`** `void smtrat::Module::collectTheoryPropagations ( ) [inherited]`

**0.15.300.4.32 constraintsToInform()** const carl::FastSet<[FormulaT](#)>& smrat::Module::constraintsToInform( ) const [inline], [inherited]

**Returns**

The constraints which the backends must be informed about.

**0.15.300.4.33 currentlySatisfied()** virtual unsigned smrat::Module::currentlySatisfied( const [FormulaT](#) & ) const [inline], [virtual], [inherited]

**Returns**

0, if the given formula is conflicted by the current model; 1, if the given formula is satisfied by the current model; 2, otherwise; 3, if we do not know anything (default)

Reimplemented in [smrat::LRAbstractModule< Settings >](#), [smrat::LRAbstractModule< LRASettingsICP >](#), and [smrat::LRAbstractModule< LRASettings >](#)

**0.15.300.4.34 currentlySatisfiedByBackend()** unsigned smrat::Module::currentlySatisfiedByBackend( const [FormulaT](#) & \_formula ) const [inherited]

**Returns**

0, if the given formula is conflicted by the current model; 1, if the given formula is satisfied by the current model; 2, otherwise 3, if we do not know anything (default)

**0.15.300.4.35 deinform()** void smrat::Module::deinform( const [FormulaT](#) & \_constraint ) [inherited]

The inverse of informing about a constraint.

All data structures which were kept regarding this constraint are going to be removed. Note, that this makes only sense if it is not likely enough that a formula with this constraint must be solved again.

**Parameters**

|                          |                                                         |
|--------------------------|---------------------------------------------------------|
| <code>_constraint</code> | The constraint to remove from internal data structures. |
|--------------------------|---------------------------------------------------------|

**0.15.300.4.36 deinformCore()** virtual void smrat::Module::deinformCore( const [FormulaT](#) & \_constraint ) [inline], [protected], [virtual], [inherited]

The inverse of informing about a constraint.

All data structures which were kept regarding this constraint are going to be removed. Note, that this makes only sense if it is not likely enough that a formula with this constraint must be solved again.

**Parameters**

|                          |                                                         |
|--------------------------|---------------------------------------------------------|
| <code>_constraint</code> | The constraint to remove from internal data structures. |
|--------------------------|---------------------------------------------------------|

Reimplemented in [smrat::LRAbstractModule< Settings >](#), [smrat::LRAbstractModule< LRASettingsICP >](#), and [smrat::LRAbstractModule< LRASettings >](#)

**0.15.300.4.37 determine\_smallest\_origin()** size\_t smrat::Module::determine\_smallest\_origin( const std::vector< [FormulaT](#) > & origins ) const [protected], [inherited]

## Parameters

|                       |                              |
|-----------------------|------------------------------|
| <code>_origins</code> | A vector of sets of origins. |
|-----------------------|------------------------------|

## Returns

The index of the smallest (regarding the size of the sets) element of origins

**0.15.300.4.38 `eraseSubformulaFromPassedFormula()`** `ModuleInput::iterator smtrat::Module::erase<SubformulaFromPassedFormula (`

```
 ModuleInput::iterator _subformula,
 bool _ignoreOrigins = false) [protected], [virtual], [inherited]
```

Removes everything related to the sub-formula to remove from the passed formula in the backends of this module. Afterwards the sub-formula is removed from the passed formula.

## Parameters

|                             |                                                                                                              |
|-----------------------------|--------------------------------------------------------------------------------------------------------------|
| <code>_subformula</code>    | The sub-formula to remove from the passed formula.                                                           |
| <code>_ignoreOrigins</code> | True, if the sub-formula shall be removed regardless of its origins (should only be applied with expertise). |

## Returns

Reimplemented in `smtrat::ICPModule< Settings >`, `smtrat::ICPModule< ICPSettings4 >`, and `smtrat::ICPModule< ICPSettings1 >`.

**0.15.300.4.39 `excludeNotReceivedVariablesFromModel()`** `void smtrat::Module::excludeNotReceived<VariablesFromModel ( ) const [inherited]`

Excludes all variables from the current model, which do not occur in the received formula.

**0.15.300.4.40 `findBestOrigin()`** `std::vector< FormulaT >::const_iterator smtrat::Module::find<BestOrigin (`

```
 const std::vector< FormulaT > & _origins) const [protected], [inherited]
```

## Parameters

|                       |  |
|-----------------------|--|
| <code>_origins</code> |  |
|-----------------------|--|

## Returns

**0.15.300.4.41 `firstSubformulaToPass()`** `ModuleInput::const_iterator smtrat::Module::firstSubformula<ToPass ( ) const [inline], [inherited]`

## Returns

The position of the first sub-formula in the passed formula, which has not yet been considered for a consistency check of the backends.

**0.15.300.4.42 firstUncheckedReceivedSubformula()** `ModuleInput::const_iterator smtrat::Module::firstUncheckedReceivedSubformula ( ) const [inline], [inherited]`

**Returns**

The position of the first (by this module) unchecked sub-formula of the received formula.

**0.15.300.4.43 freeSplittingVariable()** `static void smtrat::Module::freeSplittingVariable ( const FormulaT & _splittingVariable ) [inline], [static], [inherited]`

**0.15.300.4.44 generateTrivialInfeasibleSubset()** `void smtrat::Module::generateTrivialInfeasibleSubset ( ) [inline], [protected], [inherited]`

Stores the trivial infeasible subset being the set of received formulas.

**0.15.300.4.45 getBackendsAllModels()** `void smtrat::Module::getBackendsAllModels ( ) const [protected], [inherited]`

Stores all models of a backend in the list of all models of this module.

**0.15.300.4.46 getBackendsModel()** `void smtrat::Module::getBackendsModel ( ) const [protected], [inherited]`

**0.15.300.4.47 getInfeasibleSubsets() [1/2]** `void smtrat::Module::getInfeasibleSubsets ( ) [protected], [inherited]`

Copies the infeasible subsets of the passed formula.

**0.15.300.4.48 getInfeasibleSubsets() [2/2]** `std::vector< FormulaSetT > smtrat::Module::getInfeasibleSubsets (`

`const Module & _backend ) const [protected], [inherited]`

Get the infeasible subsets the given backend provides.

Note, that an infeasible subset in a backend contains sub formulas of the passed formula and an infeasible subset of this module contains sub formulas of the received formula. In this method the LATTER is returned.

**Parameters**

|                       |                                                          |
|-----------------------|----------------------------------------------------------|
| <code>_backend</code> | The backend from which to obtain the infeasible subsets. |
|-----------------------|----------------------------------------------------------|

**Returns**

The infeasible subsets the given backend provides.

**0.15.300.4.49 getInformationRelevantFormulas()** `const std::set< FormulaT > & smtrat::Module::getInformationRelevantFormulas ( ) [protected], [inherited]`

Gets all InformationRelevantFormulas.

**Returns**

Set of all formulas

**0.15.300.4.50 `getModelEqualities()`** `std::list< std::vector< carl::Variable > > smtrat::Module::getModelEqualities ( ) const [virtual], [inherited]`

Partition the variables from the current model into equivalence classes according to their assigned value.

The result is a set of equivalence classes of variables where all variables within one class are assigned the same value. Note that the number of classes may not be minimal, i.e. two classes may actually be equivalent.

#### Returns

Equivalence classes.

**0.15.300.4.51 `getOrigins() [1/3]`** `void smtrat::Module::getOrigins (`

```
const FormulaT & _formula,
FormulaSetT & _origins) const [inline], [protected], [inherited]
```

#### Parameters

|                       |  |
|-----------------------|--|
| <code>_formula</code> |  |
| <code>_origins</code> |  |

**0.15.300.4.52 `getOrigins() [2/3]`** `void smtrat::Module::getOrigins (`

```
const FormulaT & _formula,
FormulasT & _origins) const [inline], [protected], [inherited]
```

#### Parameters

|                       |  |
|-----------------------|--|
| <code>_formula</code> |  |
| <code>_origins</code> |  |

**0.15.300.4.53 `getOrigins() [3/3]`** `const FormulaT& smtrat::Module::getOrigins (`

```
ModuleInput::const_iterator _formula) const [inline], [protected], [inherited]
```

Gets the origins of the passed formula at the given position.

#### Parameters

|                       |                                                   |
|-----------------------|---------------------------------------------------|
| <code>_formula</code> | The position of a formula in the passed formulas. |
|-----------------------|---------------------------------------------------|

#### Returns

The origins of the passed formula at the given position.

**0.15.300.4.54 `getReceivedFormulaSimplified()`** `std::pair< bool, FormulaT > smtrat::PModule::getReceivedFormulaSimplified ( ) [virtual], [inherited]`

#### Returns

A pair of a Boolean and a formula, where the Boolean is true, if the received formula could be simplified to an equisatisfiable formula. The formula is equisatisfiable to this module's received formula, if the Boolean is true.

Reimplemented from [smtrat::Module](#).

**0.15.300.4.55 hasLemmas()** `bool smrat::Module::hasLemmas () [inline], [inherited]`  
Checks whether this module or any of its backends provides any lemmas.

**0.15.300.4.56 hasValidInfeasibleSubset()** `bool smrat::Module::hasValidInfeasibleSubset () const [inherited]`

**Returns**

true, if the module has at least one valid infeasible subset, that is all its elements are sub-formulas of the received formula (pointer must be equal).

**0.15.300.4.57 id()** `std::size_t smrat::Module::id () const [inline], [inherited]`

**Returns**

A unique ID to identify this module instance.

**0.15.300.4.58 infeasibleSubsets()** `const std::vector<FormulaSetT>& smrat::Module::infeasibleSubsets () const [inline], [inherited]`

**Returns**

The infeasible subsets of the set of received formulas (empty, if this module has not detected unsatisfiability of the conjunction of received formulas).

**0.15.300.4.59 inform()** `bool smrat::Module::inform (const FormulaT & _constraint) [inherited]`

Informs the module about the given constraint.

It should be tried to inform this module about any constraint it could receive eventually before assertSubformula is called (preferably for the first time, but at least before adding a formula containing that constraint).

**Parameters**

|                          |                                 |
|--------------------------|---------------------------------|
| <code>_constraint</code> | The constraint to inform about. |
|--------------------------|---------------------------------|

**Returns**

false, if it can be easily decided whether the given constraint is inconsistent; true, otherwise.

**0.15.300.4.60 informBackends()** `void smrat::Module::informBackends (const FormulaT & _constraint) [inline], [protected], [inherited]`

Informs all backends of this module about the given constraint.

**Parameters**

|                          |                                 |
|--------------------------|---------------------------------|
| <code>_constraint</code> | The constraint to inform about. |
|--------------------------|---------------------------------|

**0.15.300.4.61 informCore()** `virtual bool smrat::Module::informCore (const FormulaT & _constraint) [inline], [protected], [virtual], [inherited]`

Informs the module about the given constraint.

It should be tried to inform this module about any constraint it could receive eventually before assertSubformula is called (preferably for the first time, but at least before adding a formula containing that constraint).

#### Parameters

|                          |                                 |
|--------------------------|---------------------------------|
| <code>_constraint</code> | The constraint to inform about. |
|--------------------------|---------------------------------|

#### Returns

`false`, if it can be easily decided whether the given constraint is inconsistent; `true`, otherwise.

Reimplemented in [smrat::UnionFindModule< Settings >](#), [smrat::PBPPModule< Settings >](#), [smrat::PBGaussModule< Settings >](#), [smrat::NRAILModule< Settings >](#), [smrat::NewCoveringModule< Settings >](#), [smrat::NewCADModule< Settings >](#), [smrat::LRAModule< Settings >](#), [smrat::LRAModule< LRASettingsICP >](#), [smrat::LRAModule< LRASettings1 >](#), [smrat::IntBlastModule< Settings >](#), [smrat::FPPModule< Settings >](#), [smrat::EQModule< Settings >](#), [smrat::CurryModule< Settings >](#), [smrat::BVMModule< Settings >](#), [smrat::ICPModule< Settings >](#), [smrat::ICPModule< ICPSettings4 >](#), and [smrat::ICPModule< ICPSettings1 >](#).

#### 0.15.300.4.62 informedConstraints()

```
const carl::FastSet<FormulaT>& smrat::Module::informed<→
Constraints () const [inline], [inherited]
```

#### Returns

The position of the first constraint of which no backend has been informed about.

#### 0.15.300.4.63 init()

```
void smrat::Module::init () [virtual], [inherited]
```

Informs all backends about the so far encountered constraints, which have not yet been communicated.

This method must not be called twice and only before the first runBackends call.

Reimplemented in [smrat::PBPPModule< Settings >](#), [smrat::PBGaussModule< Settings >](#), [smrat::NRAILModule< Settings >](#), [smrat::NewCoveringModule< Settings >](#), [smrat::NewCADModule< Settings >](#), [smrat::LRAModule< Settings >](#), [smrat::LRAModule< LRASettingsICP >](#), [smrat::LRAModule< LRASettings1 >](#), [smrat::IntBlastModule< Settings >](#), [smrat::FPPModule< Settings >](#), [smrat::EQModule< Settings >](#), [smrat::CurryModule< Settings >](#), and [smrat::BVMModule< Settings >](#).

#### 0.15.300.4.64 is\_minimizing()

```
bool smrat::Module::is_minimizing () const [inline], [inherited]
```

#### 0.15.300.4.65 isLemmaLevel()

```
bool smrat::Module::isLemmaLevel (
 LemmaLevel level) [protected], [inherited]
```

Checks if current lemma level is greater or equal to given level.

#### Parameters

|                    |                 |
|--------------------|-----------------|
| <code>level</code> | Level to check. |
|--------------------|-----------------|

#### 0.15.300.4.66 isPreprocessor()

```
bool smrat::PModule::isPreprocessor () const [inline], [inherited]
```

#### Returns

`true`, if this module is a preprocessor that is a module, which simplifies its received formula to an equisatisfiable formula being passed to its backends. The simplified formula can be obtained with [getReceivedFormulaSimplified\(\)](#).

**0.15.300.4.67 lemmas()** const std::vector<[Lemma](#)>& smtrat::Module::lemmas ( ) const [inline], [inherited]

**Returns**

A constant reference to the lemmas being valid formulas this module or its backends made.

**0.15.300.4.68 merge()** std::vector< [FormulaT](#) > smtrat::Module::merge ( const std::vector< [FormulaT](#) > & [\\_vecSetA](#), const std::vector< [FormulaT](#) > & [\\_vecSetB](#) ) const [protected], [inherited]

Merges the two vectors of sets into the first one.

({a,b},{a,c}) and ({b,d},{b}) -> ({a,b,d},{a,b},{a,b,c,d},{a,b,c})

**Parameters**

|                          |                                  |
|--------------------------|----------------------------------|
| <a href="#">_vecSetA</a> | A vector of sets of constraints. |
| <a href="#">_vecSetB</a> | A vector of sets of constraints. |

**Returns**

The vector being the two given vectors merged.

**0.15.300.4.69 model()** const [Model](#)& smtrat::Module::model ( ) const [inline], [inherited]

**Returns**

The assignment of the current satisfiable result, if existent.

**0.15.300.4.70 modelsDisjoint()** bool smtrat::Module::modelsDisjoint ( const [Model](#) & [\\_modelA](#), const [Model](#) & [\\_modelB](#) ) [static], [protected], [inherited]

Checks whether there is no variable assigned by both models.

**Parameters**

|                         |                                |
|-------------------------|--------------------------------|
| <a href="#">_modelA</a> | The first model to check for.  |
| <a href="#">_modelB</a> | The second model to check for. |

**Returns**

true, if there is no variable assigned by both models; false, otherwise.

**0.15.300.4.71 moduleName()** template<typename Settings > std::string smtrat::LVEModule< [Settings](#) >::moduleName ( ) const [inline], [virtual]

**Returns**

The name of the given module type as name.

Reimplemented from [smtrat::Module](#).

**0.15.300.4.72 `objective()`** `carl::Variable smrat::Module::objective ( ) const [inline], [inherited]`

**0.15.300.4.73 `originInReceivedFormula()`** `bool smrat::Module::originInReceivedFormula ( const FormulaT & _origin ) const [protected], [inherited]`

**0.15.300.4.74 `passedFormulaBegin()`** `ModuleInput::iterator smrat::Module::passedFormulaBegin ( ) [inline], [protected], [inherited]`

**Returns**

An iterator to the end of the passed formula. TODO: disable this method

**0.15.300.4.75 `passedFormulaEnd()`** `ModuleInput::iterator smrat::Module::passedFormulaEnd ( ) [inline], [protected], [inherited]`

**Returns**

An iterator to the end of the passed formula.

**0.15.300.4.76 `pPassedFormula()`** `const ModuleInput* smrat::Module::pPassedFormula ( ) const [inline], [inherited]`

**Returns**

A pointer to the formula passed to the backends of this module.

**0.15.300.4.77 `pReceivedFormula()`** `const ModuleInput* smrat::Module::pReceivedFormula ( ) const [inline], [inherited]`

**Returns**

A pointer to the formula passed to this module.

**0.15.300.4.78 `print()`** `void smrat::Module::print ( const std::string & _initiation = "***" ) const [inherited]`

Prints everything relevant of the solver.

**Parameters**

|                          |                      |
|--------------------------|----------------------|
| <code>_initiation</code> | The line initiation. |
|--------------------------|----------------------|

**0.15.300.4.79 `printAllModels()`** `void smrat::Module::printAllModels ( std::ostream & _out = std::cout ) [inherited]`

Prints all assignments of this module satisfying its received formula if it satisfiable and this module could find an assignment.

**Parameters**

|                   |                                        |
|-------------------|----------------------------------------|
| <code>_out</code> | The stream to print the assignment on. |
|-------------------|----------------------------------------|

**0.15.300.4.80 printInfeasibleSubsets()** void smtrat::Module::printInfeasibleSubsets ( const std::string & *\_initiation* = "\*\*\*" ) const [inherited]  
Prints the infeasible subsets.

Parameters

|                    |                      |
|--------------------|----------------------|
| <i>_initiation</i> | The line initiation. |
|--------------------|----------------------|

**0.15.300.4.81 printModel()** void smtrat::Module::printModel ( std::ostream & *\_out* = std::cout ) const [inherited]  
Prints the assignment of this module satisfying its received formula if it satisfiable and this module could find an assignment.

Parameters

|             |                                        |
|-------------|----------------------------------------|
| <i>_out</i> | The stream to print the assignment on. |
|-------------|----------------------------------------|

**0.15.300.4.82 printPassedFormula()** void smtrat::Module::printPassedFormula ( const std::string & *\_initiation* = "\*\*\*" ) const [inherited]  
Prints the vector of passed formula.

Parameters

|                    |                      |
|--------------------|----------------------|
| <i>_initiation</i> | The line initiation. |
|--------------------|----------------------|

**0.15.300.4.83 printReceivedFormula()** void smtrat::Module::printReceivedFormula ( const std::string & *\_initiation* = "\*\*\*" ) const [inherited]  
Prints the vector of the received formula.

Parameters

|                    |                      |
|--------------------|----------------------|
| <i>_initiation</i> | The line initiation. |
|--------------------|----------------------|

**0.15.300.4.84 probablyLooping()** bool smtrat::Module::probablyLooping ( const typename Poly::PolyType & *\_branchingPolynomial*, const Rational & *\_branchingValue* ) const [protected], [inherited]  
Checks whether given the current branching value and branching variable/polynomial it is (highly) probable that this branching is part of an infinite loop of branchings.

Parameters

|                             |                                                                                     |
|-----------------------------|-------------------------------------------------------------------------------------|
| <i>_branchingPolynomial</i> | The polynomial to branch at (in most branching strategies this is just a variable). |
| <i>_branchingValue</i>      | The value to branch at.                                                             |

**Returns**

true, if this branching is probably part of an infinite loop of branchings; false, otherwise.

**0.15.300.4.85 receivedFormulaChecked()** void smrat::Module::receivedFormulaChecked () [inline], [inherited]

Notifies that the received formulas has been checked.

**0.15.300.4.86 receivedFormulasAsInfeasibleSubset()** void smrat::Module::receivedFormulasAsInfeasibleSubset (

    ModuleInput::const\_iterator \_subformula ) [inline], [protected], [inherited]

Stores an infeasible subset consisting only of the given received formula.

**0.15.300.4.87 receivedVariable()** bool smrat::Module::receivedVariable (

    carl::Variable::Arg \_var ) const [inline], [inherited]

**0.15.300.4.88 remove()** void smrat::PModule::remove (

    ModuleInput::const\_iterator \_subformula ) [virtual], [inherited]

Removes everything related to the given sub-formula of the received formula.

However, it is desired not to lose track of search spaces where no satisfying assignment can be found for the remaining sub-formulas.

**Parameters**

|             |                                                    |
|-------------|----------------------------------------------------|
| _subformula | The sub formula of the received formula to remove. |
|-------------|----------------------------------------------------|

Reimplemented from [smrat::Module](#).

**0.15.300.4.89 removeCore()** virtual void smrat::Module::removeCore (

    ModuleInput::const\_iterator formula ) [inline], [protected], [virtual], [inherited]

Removes everything related to the given sub-formula of the received formula.

However, it is desired not to lose track of search spaces where no satisfying assignment can be found for the remaining sub-formulas.

**Parameters**

|         |                                                    |
|---------|----------------------------------------------------|
| formula | The sub formula of the received formula to remove. |
|---------|----------------------------------------------------|

Reimplemented in [smrat::VSModule< Settings >](#), [smrat::SATModule< Settings >](#), [smrat::PFEModule< Settings >](#), [smrat::ICPModule< Settings >](#), [smrat::ICPModule< ICPSettings4 >](#), [smrat::ICPModule< ICPSettings1 >](#), [smrat::UnionFindModule< Settings >](#), [smrat::UFCegarModule< Settings >](#), [smrat::STropModule< Settings >](#), [smrat::PBPPModule< Settings >](#), [smrat::PBGaussModule< Settings >](#), [smrat::NRAILModule< Settings >](#), [smrat::NewCoveringModule< Settings >](#), [smrat::NewCADModule< Settings >](#), [smrat::LRAModule< Settings >](#), [smrat::LRAModule< LRASettingsICP >](#), [smrat::LRAModule< LRASettings1 >](#), [smrat::IntEqModule< Settings >](#), [smrat::IntBlastModule< Settings >](#), [smrat::IncWidthModule< Settings >](#), [smrat::ICEModule< Settings >](#), [smrat::FPPModule< Settings >](#), [smrat::FouMoModule< Settings >](#), [smrat::EQModule< Settings >](#), [smrat::CurryModule< Settings >](#), [smrat::CubeLIAModule< Settings >](#), [smrat::CSplitModule< Settings >](#), [smrat::BVModule< Settings >](#), and [smrat::GBModule< Settings >](#).

**0.15.300.4.90 removeOrigin()** std::pair<ModuleInput::iterator, bool> smrat::Module::removeOrigin (

```
Origin (
 ModuleInput::iterator _formula,
 const FormulaT & _origin) [inline], [protected], [inherited]
```

**0.15.300.4.91 removeOrigins()** std::pair<ModuleInput::iterator, bool> smtrat::Module::removeOrigins (

```
 ModuleInput::iterator _formula,
 const std::shared_ptr< std::vector< FormulaT >> & _origins) [inline], [protected],
[inherited]
```

**0.15.300.4.92 rPassedFormula()** const ModuleInput& smtrat::Module::rPassedFormula ( ) const [inline], [inherited]

**Returns**

A reference to the formula passed to the backends of this module.

**0.15.300.4.93 rReceivedFormula()** const ModuleInput& smtrat::Module::rReceivedFormula ( ) const [inline], [inherited]

**Returns**

A reference to the formula passed to this module.

**0.15.300.4.94 runBackends() [1/2]** virtual Answer smtrat::PModule::runBackends ( ) [inline], [virtual], [inherited]

Reimplemented from [smtrat::Module](#).

**0.15.300.4.95 runBackends() [2/2]** Answer smtrat::PModule::runBackends (

```
 bool _final,
 bool _full,
 carl::Variable _objective) [virtual], [inherited]
```

Runs the backend solvers on the passed formula.

**Parameters**

|                         |                                                                                                                                       |
|-------------------------|---------------------------------------------------------------------------------------------------------------------------------------|
| <code>_final</code>     | true, if this satisfiability check will be the last one (for a global sat-check), if its result is SAT.                               |
| <code>_full</code>      | false, if this module should avoid too expensive procedures and rather return unknown instead.                                        |
| <code>_objective</code> | if not set to NO_VARIABLE, the module should find an assignment minimizing this objective variable; otherwise any assignment is good. |

**Returns**

True, if the passed formula is consistent; False, if the passed formula is inconsistent; Unknown, otherwise.

Reimplemented from [smtrat::Module](#).

**0.15.300.4.96 setId()** void smtrat::Module::setId (

```
 std::size_t _id) [inline], [inherited]
```

Sets this modules unique ID to identify itself.

## Parameters

|                         |                                    |
|-------------------------|------------------------------------|
| $\leftrightarrow$       | The id to set this module's id to. |
| $\underline{\text{id}}$ |                                    |

**0.15.300.4.97 `setThreadPriority()`** `void smtrat::Module::setThreadPriority ( thread_priority _threadPriority )` [inline], [inherited]

Sets the priority of this module to get a thread for running its check procedure.

## Parameters

|                              |                                                       |
|------------------------------|-------------------------------------------------------|
| <code>_threadPriority</code> | The priority to set this module's thread priority to. |
|------------------------------|-------------------------------------------------------|

**0.15.300.4.98 `solverState()`** `Answer smtrat::Module::solverState ( ) const` [inline], [inherited]

## Returns

True, if this module is in a state, such that it has found a solution for its received formula; False, if this module is in a state, such that it has determined that there is no solution for its received formula; Unknown, otherwise.

**0.15.300.4.99 `splitUnequalConstraint()`** `void smtrat::Module::splitUnequalConstraint ( const FormulaT & _unequalConstraint )` [protected], [inherited]

Adds the following lemmas for the given constraint  $p \neq 0$ .

$(p \neq 0 \leftrightarrow (p < 0 \text{ or } p > 0))$

and  $\neg(p < 0 \text{ and } p > 0)$

## Parameters

|                                 |                                                  |
|---------------------------------|--------------------------------------------------|
| <code>_unequalConstraint</code> | A constraint having the relation symbol $\neq$ . |
|---------------------------------|--------------------------------------------------|

**0.15.300.4.100 `threadPriority()`** `thread_priority smtrat::Module::threadPriority ( ) const` [inline], [inherited]

## Returns

The priority of this module to get a thread for running its check procedure.

**0.15.300.4.101 `updateAllModels()`** `void smtrat::Module::updateAllModels ( )` [virtual], [inherited]

Updates all satisfying models, if the solver has detected the consistency of the received formula, beforehand.

Reimplemented in [smtrat::SATModule< Settings >](#).

**0.15.300.4.102 `updateLemmas()`** `void smtrat::Module::updateLemmas ( )` [inherited]

Stores all lemmas of any backend of this module in its own lemma vector.

**0.15.300.4.103 updateModel()** template<typename Settings>  
void smrat::LVEModule<Settings>::updateModel() const [virtual]

Updates the current assignment into the model.

Note, that this is a unique but possibly symbolic assignment maybe containing newly introduced variables.

Reimplemented from [smrat::Module](#).

**0.15.300.4.104 usedBackends()** const std::vector<[Module](#)\*>& smrat::Module::usedBackends() const [inline], [inherited]

**Returns**

The backends of this module which are currently used (conditions to use this module are fulfilled for the passed formula).

## 0.15.300.5 Field Documentation

**0.15.300.5.1 mAllBackends** std::vector<[Module](#)\*> smrat::Module::mAllBackends [protected], [inherited]

The backends of this module which have been used.

**0.15.300.5.2 mAllModels** std::vector<[Model](#)> smrat::Module::mAllModels [mutable], [protected], [inherited]

Stores all satisfying assignments.

**0.15.300.5.3 mBackendsFoundAnswer** std::atomic\_bool\* smrat::Module::mBackendsFoundAnswer [protected], [inherited]

This flag is passed to any backend and if it determines an answer to a prior check call, this flag is fired.

**0.15.300.5.4 mConstraintsToInform** carl::FastSet<[FormulaT](#)> smrat::Module::mConstraintsToInform [protected], [inherited]

Stores the constraints which the backends must be informed about.

**0.15.300.5.5 mFinalCheck** bool smrat::Module::mFinalCheck [protected], [inherited]

true, if the check procedure should perform a final check which especially means not to postpone splitting decisions

**0.15.300.5.6 mFirstPosInLastBranches** std::size\_t smrat::Module::mFirstPosInLastBranches = 0 [static], [inherited]

The beginning of the cyclic buffer storing the last branches.

**0.15.300.5.7 mFirstSubformulaToPass** [ModuleInput](#)::iterator smrat::Module::mFirstSubformulaToPass [protected], [inherited]

Stores the position of the first sub-formula in the passed formula, which has not yet been considered for a consistency check of the backends.

**0.15.300.5.8 mFirstUncheckedReceivedSubformula** [ModuleInput](#)::const\_iterator smrat::Module::mFirstUncheckedReceivedSubformula [protected], [inherited]

Stores the position of the first (by this module) unchecked sub-formula of the received formula.

**0.15.300.5.9 mFoundAnswer** `Conditionals` `smtrat::Module::mFoundAnswer` [protected], [inherited]  
Vector of Booleans: If any of them is true, we have to terminate a running check procedure.

**0.15.300.5.10 mFullCheck** `bool` `smtrat::Module::mFullCheck` [protected], [inherited]  
false, if this module should avoid too expensive procedures and rather return unknown instead.

**0.15.300.5.11 mInfeasibleSubsets** `std::vector<FormulaSetT>` `smtrat::Module::mInfeasibleSubsets` [protected], [inherited]  
Stores the infeasible subsets.

**0.15.300.5.12 mInformedConstraints** `carl::FastSet<FormulaT>` `smtrat::Module::mInformedConstraints` [protected], [inherited]  
Stores the position of the first constraint of which no backend has been informed about.

**0.15.300.5.13 mLastBranches** `std::vector<Branching>` `smtrat::Module::mLastBranches = std::vector<Branching>(mNumOfBranchVarsToStore, Branching(typename Poly::PolyType(), 0))` [static], [inherited]  
Stores the last branches in a cycle buffer.

**0.15.300.5.14 mLemmas** `std::vector<Lemma>` `smtrat::Module::mLemmas` [protected], [inherited]  
Stores the lemmas being valid formulas this module or its backends made.

**0.15.300.5.15 mModel** `Model` `smtrat::Module::mModel` [mutable], [protected], [inherited]  
Stores the assignment of the current satisfiable result, if existent.

**0.15.300.5.16 mModelComputed** `bool` `smtrat::Module::mModelComputed` [mutable], [protected], [inherited]  
True, if the model has already been computed.

**0.15.300.5.17 mNumOfBranchVarsToStore** `std::size_t` `smtrat::Module::mNumOfBranchVarsToStore = 5` [static], [inherited]  
The number of different variables to consider for a probable infinite loop of branchings.

**0.15.300.5.18 mObjectiveVariable** `carl::Variable` `smtrat::Module::mObjectiveVariable` [protected], [inherited]  
Objective variable to be minimized. If set to NO\_VARIABLE, a normal sat check should be performed.

**0.15.300.5.19 mOldSplittingVariables** `std::vector<FormulaT>` `smtrat::Module::mOldSplittingVariables` [static], [inherited]  
Reusable splitting variables.

**0.15.300.5.20 mpManager** `Manager*` `const smtrat::Module::mpManager` [protected], [inherited]  
A reference to the manager.

**0.15.300.5.21 mSmallerMusesCheckCounter** `unsigned smtrat::Module::mSmallerMusesCheckCounter`  
[mutable], [protected], [inherited]  
Counter used for the generation of the smt2 files to check for smaller muses.

**0.15.300.5.22 mSolverState** `std::atomic<Answer> smtrat::Module::mSolverState` [protected],  
[inherited]

States whether the received formula is known to be satisfiable or unsatisfiable otherwise it is set to unknown.

**0.15.300.5.23 mTheoryPropagations** `std::vector<TheoryPropagation> smtrat::Module::mTheory←Propagations` [protected], [inherited]

**0.15.300.5.24 mUsedBackends** `std::vector<Module*> smtrat::Module::mUsedBackends` [protected],  
[inherited]

The backends of this module which are currently used (conditions to use this module are fulfilled for the passed formula).

**0.15.300.5.25 mVariableCounters** `std::vector<std::size_t> smtrat::Module::mVariableCounters`  
[protected], [inherited]

Maps variables to the number of their occurrences.

## 0.15.301 smtrat::Manager Class Reference

Base class for solvers.

```
#include <Manager.h>
```

### Public Member Functions

**0.15.301.3 Member Function Documentation****0.15.301.3.1 add()** `bool smtrat::Manager::add (`  
`const FormulaT & _subformula,`  
`bool _containsUnknownConstraints = true )`

Adds the given formula to the conjunction of formulas, which will be considered for the next satisfiability check.

**Parameters**

|                                          |                                                                                                 |
|------------------------------------------|-------------------------------------------------------------------------------------------------|
| <code>_subformula</code>                 | The formula to add.                                                                             |
| <code>_containsUnknownConstraints</code> | true, if the formula to add contains constraints, about which this solver was not yet informed. |

**Returns**

false, if it is easy to decide whether adding this formula creates a conflict; true, otherwise.

**0.15.301.3.2 addBackend() [1/2]** `template<typename Module >`  
`BackendLink smtrat::Manager::addBackend (`  
`const BackendLink & backend ) [inline], [protected]`**0.15.301.3.3 addBackend() [2/2]** `template<typename Module >`  
`BackendLink smtrat::Manager::addBackend (`  
`const std::initializer_list< BackendLink > & backends = {} ) [inline], [protected]`**0.15.301.3.4 addEdge()** `BackendLink& smtrat::Manager::addEdge (`  
`std::size_t from,`  
`std::size_t to ) [inline], [protected]`

**0.15.301.3.5 addInformationRelevantFormula()** void smtrat::Manager::addInformationRelevantFormula ( const FormulaT & formula ) [inline]  
 Adds formula to InformationRelevantFormula.

**Parameters**

|                |                |
|----------------|----------------|
| <i>formula</i> | Formula to add |
|----------------|----------------|

**0.15.301.3.6 allModels()** const std::vector<Model>& smtrat::Manager::allModels ( ) const [inline]

**Returns**

A list of all assignments, such that they satisfy the conjunction of the so far added formulas.

Note, that an assignment is only provided if the conjunction of so far added formulas is satisfiable. Furthermore, when solving non-linear real arithmetic formulas the assignment could contain other variables or freshly introduced variables.

**0.15.301.3.7 check()** Answer smtrat::Manager::check ( bool \_full = true )

Checks the so far added formulas for satisfiability.

**Returns**

True, if the conjunction of the so far added formulas is satisfiable; False, if it not satisfiable; Unknown, if this solver cannot decide whether it is satisfiable or not.

**0.15.301.3.8 clear()** void smtrat::Manager::clear ( ) [inline]

**0.15.301.3.9 clearInformationRelevantFormula()** void smtrat::Manager::clearInformationRelevantFormula ( ) [inline]  
 Deletes all InformationRelevantFormula.

**0.15.301.3.10 deinform()** void smtrat::Manager::deinform ( const FormulaT & \_constraint )

The inverse of informing about a constraint.

All data structures which were kept regarding this constraint are going to be removed. Note, that this makes only sense if it is not likely enough that a formula with this constraint must be solved again.

**Parameters**

|                    |                                                         |
|--------------------|---------------------------------------------------------|
| <i>_constraint</i> | The constraint to remove from internal data structures. |
|--------------------|---------------------------------------------------------|

**0.15.301.3.11 formula()** const ModuleInput& smtrat::Manager::formula ( ) const [inline]

**Returns**

The conjunction of so far added formulas.

**0.15.301.3.12 formulaBegin()** `ModuleInput::iterator smrat::Manager::formulaBegin ( ) [inline]`

**0.15.301.3.13 formulaEnd()** `ModuleInput::iterator smrat::Manager::formulaEnd ( ) [inline]`

**0.15.301.3.14 getAllBackends()** `std::vector<Module*> smrat::Manager::getAllBackends ( Module * _module ) const [inline], [protected]`

Gets all backends so far instantiated according the strategy and all previous enquiries of the given module.

**Parameters**

|                      |                                                                                                                      |
|----------------------|----------------------------------------------------------------------------------------------------------------------|
| <code>_module</code> | The module to get all backends so far instantiated according the strategy and all previous enquiries of this module. |
|----------------------|----------------------------------------------------------------------------------------------------------------------|

**Returns**

All backends so far instantiated according the strategy and all previous enquiries of the given module.

**0.15.301.3.15 getAllGeneratedModules()** `const std::vector<Module*>& smrat::Manager::getAllGeneratedModules ( ) const [inline]`

**Returns**

All instantiated modules of the solver belonging to this manager.

**0.15.301.3.16 getBackends()** `std::vector<Module * > smrat::Manager::getBackends ( Module * _requiredBy, std::atomic_bool * _foundAnswer ) [protected]`

Get the backends to call for the given problem instance required by the given module.

**Parameters**

|                           |                                  |
|---------------------------|----------------------------------|
| <code>_requiredBy</code>  | The module asking for a backend. |
| <code>_foundAnswer</code> | A conditional                    |

**Returns**

A vector of modules, which the module defined by `_requiredBy` calls in parallel to achieve an answer to the given instance.

**0.15.301.3.17 getInformationRelevantFormulas()** `const std::set<FormulaT>& smrat::Manager::getInformationRelevantFormulas ( ) [inline], [protected]`

Gets all InformationRelevantFormulas.

**Returns**

Set of all formulas

**0.15.301.3.18 getInputSimplified()** `std::pair< bool, FormulaT > smrat::Manager::getInputSimplified ( )`

**Returns**

A pair of a Boolean and a formula, where the Boolean is true, if the input formula could be simplified to an equisatisfiable formula. The formula is equisatisfiable to this solver's input formula, if the Boolean is true.

**0.15.301.3.19 `getModelEqualities()`** `std::list< std::vector< carl::Variable > > smtrat::Manager::getModelEqualities( ) const`  
 Determines variables assigned by the currently found satisfying assignment to an equal value in their domain.

**Returns**

A list of vectors of variables, stating that the variables in one vector are assigned to equal values.

**0.15.301.3.20 `infeasibleSubsets()`** `const std::vector< FormulaSetT > & smtrat::Manager::infeasibleSubsets( ) const`

**Returns**

All infeasible subsets of the set so far added formulas.

Note, that the conjunction of the so far added formulas must be inconsistent to receive an infeasible subset.

**0.15.301.3.21 `inform()`** `bool smtrat::Manager::inform( const FormulaT & _constraint )`

Informs the solver about a constraint.

Optimally, it should be informed about all constraints, which it will receive eventually, before any of them is added as part of a formula with the interface add(..).

**Parameters**

|                          |                                 |
|--------------------------|---------------------------------|
| <code>_constraint</code> | The constraint to inform about. |
|--------------------------|---------------------------------|

**Returns**

false, if it is easy to decide (for any module used of this solver), whether the constraint itself is inconsistent; true, otherwise.

**0.15.301.3.22 `isLemmaLevel()`** `bool smtrat::Manager::isLemmaLevel( LemmaLevel level ) [inline]`

Checks if current lemma level is greater or equal to given level.

**Parameters**

|                    |                 |
|--------------------|-----------------|
| <code>level</code> | Level to check. |
|--------------------|-----------------|

**0.15.301.3.23 `lemmas()`** `std::vector< FormulaT > smtrat::Manager::lemmas( )`  
 Returns the lemmas/tautologies which were made during the last solving provoked by [check\(\)](#).  
 These lemmas can be used in the same manner as infeasible subsets are used.

**Returns**

The lemmas/tautologies made during solving.

**0.15.301.3.24 logic()** auto smtrat::Manager::logic ( ) const [inline]

Returns

A constant reference to the logic this solver considers.

**0.15.301.3.25 model()** const Model & smtrat::Manager::model ( ) const

Returns

An assignment of the variables, which occur in the so far added formulas, to values of their domains, such that it satisfies the conjunction of these formulas.

Note, that an assignment is only provided if the conjunction of so far added formulas is satisfiable. Furthermore, when solving non-linear real arithmetic formulas the assignment could contain other variables or freshly introduced variables.

**0.15.301.3.26 objectiveVariable()** const carl::Variable& smtrat::Manager::objectiveVariable ( ) const [inline]

**0.15.301.3.27 pop() [1/2]** bool smtrat::Manager::pop ( void )

Pops a backtrack point from the stack of backtrack points.

This provokes, that all formulas which have been added after that backtrack point are removed.

Note, that this interface has not necessarily be used to apply a solver constructed with SMT-RAT, but is often required by state-of-the-art SMT solvers when embedding a theory solver constructed with SMT-RAT into them.

**0.15.301.3.28 pop() [2/2]** void smtrat::Manager::pop ( size\_t \_levels )

**0.15.301.3.29 printAllAssignments()** void smtrat::Manager::printAllAssignments ( std::ostream & \_out = std::cout ) [inline]

Prints all assignments of variables occurring in the so far added formulas to values of their domains, if the conjunction of these formulas is satisfiable.

Parameters

|             |                         |
|-------------|-------------------------|
| <i>_out</i> | The stream to print on. |
|-------------|-------------------------|

**0.15.301.3.30 printAssignment()** void smtrat::Manager::printAssignment ( ) const

Prints the currently found assignment of variables occurring in the so far added formulas to values of their domains, if the conjunction of these formulas is satisfiable.

**0.15.301.3.31 printBackTrackStack()** void smtrat::Manager::printBackTrackStack ( std::ostream & \_out = std::cout ) const

Prints the stack of backtrack points.

Parameters

|             |                         |
|-------------|-------------------------|
| <i>_out</i> | The stream to print on. |
|-------------|-------------------------|

```
0.15.301.3.32 printInfeasibleSubset() void smtrat::Manager::printInfeasibleSubset (
 std::ostream & _out = std::cout) const
```

Prints the first found infeasible subset of the set of received formulas.

#### Parameters

|                   |                         |
|-------------------|-------------------------|
| <code>_out</code> | The stream to print on. |
|-------------------|-------------------------|

```
0.15.301.3.33 printStrategyGraph() void smtrat::Manager::printStrategyGraph (
 std::ostream & _out = std::cout) const [inline]
```

Prints the strategy of the solver maintained by this manager.

#### Parameters

|                   |                         |
|-------------------|-------------------------|
| <code>_out</code> | The stream to print on. |
|-------------------|-------------------------|

```
0.15.301.3.34 push() void smtrat::Manager::push (
 void) [inline]
```

Pushes a backtrack point to the stack of backtrack points.

Note, that this interface has not necessarily be used to apply a solver constructed with SMT-RAT, but is often required by state-of-the-art SMT solvers when embedding a theory solver constructed with SMT-RAT into them.

```
0.15.301.3.35 rDebugOutputChannel() std::ostream& smtrat::Manager::rDebugOutputChannel () [inline]
```

#### Returns

The stream to print the debug information on.

```
0.15.301.3.36 remove() [1/2] ModuleInput::iterator smtrat::Manager::remove (
 const FormulaT & _subformula) [inline]
```

Temporarily added: (TODO: Discuss with Gereon) Removes the given formula in the conjunction of formulas, which will be considered for the next satisfiability check.

#### Parameters

|                          |                        |
|--------------------------|------------------------|
| <code>_subformula</code> | The formula to remove. |
|--------------------------|------------------------|

#### Returns

An iterator to the formula after the position of the just removed formula. If the removed formula has been the last element, the end of the conjunction of formulas, which will be considered for the next satisfiability check is returned.

```
0.15.301.3.37 remove() [2/2] ModuleInput::iterator smtrat::Manager::remove (
 ModuleInput::iterator _subformula)
```

Removes the formula at the given position in the conjunction of formulas, which will be considered for the next satisfiability check.

**Parameters**

|                          |                                        |
|--------------------------|----------------------------------------|
| <code>_subformula</code> | The position of the formula to remove. |
|--------------------------|----------------------------------------|

**Returns**

An iterator to the formula after the position of the just removed formula. If the removed formula has been the last element, the end of the conjunction of formulas, which will be considered for the next satisfiability check is returned.

**0.15.301.3.38 `reset()`** `void smtrat::Manager::reset ( )`**0.15.301.3.39 `rLogic()`** `auto& smtrat::Manager::rLogic ( ) [inline]`**Returns**

A reference to the logic this solver considers.

**0.15.301.3.40 `setLemmaLevel()`** `void smtrat::Manager::setLemmaLevel ( LemmaLevel level ) [inline]`

Sets the current level for lemma generation.

**Parameters**

|                    |       |
|--------------------|-------|
| <code>level</code> | Level |
|--------------------|-------|

**0.15.301.3.41 `setObjectiveVariable()`** `void smtrat::Manager::setObjectiveVariable ( carl::Variable var ) [inline]`**0.15.301.3.42 `setStrategy()` [1/2]** `void smtrat::Manager::setStrategy ( const BackendLink & backend ) [inline], [protected]`**0.15.301.3.43 `setStrategy()` [2/2]** `void smtrat::Manager::setStrategy ( const std::initializer_list< BackendLink > & backends ) [inline], [protected]`**0.15.301.4 Friends And Related Function Documentation****0.15.301.4.1 `Module`** `friend class Module [friend]`**0.15.302 Minisat::Map< K, D, H, E > Class Template Reference**

### 0.15.303.1 Detailed Description

Tool wrapper for [MathSAT](#) for SMT-LIB.

### 0.15.303.2 Constructor & Destructor Documentation

**0.15.303.2.1 [MathSAT\(\)](#)** benchmax::MathSAT::MathSAT (

```
 const fs::path & binary,
 const std::string & arguments) [inline]
```

New [MathSAT](#) tool.

### 0.15.303.3 Member Function Documentation

**0.15.303.3.1 [additionalResults\(\)](#)** virtual void benchmax::MathSAT::additionalResults (

```
 const fs::path & ,
 BenchmarkResult & result) const [inline], [override], [virtual]
```

Computes the answer string from the exit code and parses statistics output.

Reimplemented from [benchmax::Tool](#).

**0.15.303.3.2 [attributeHash\(\)](#)** std::size\_t benchmax::Tool::attributeHash () const [inline], [inherited]

Hash of the attributes.

**0.15.303.3.3 attributes()** const std::map<std::string, std::string>& benchmax::Tool::attributes () const [inline], [inherited]  
A set of attributes, for example compilation options.

**0.15.303.3.4 binary()** fs::path benchmax::Tool::binary () const [inline], [inherited]  
Full path to the binary.

**0.15.303.3.5 canHandle()** virtual bool benchmax::MathSAT::canHandle (const fs::path & path) const [inline], [override], [virtual]  
Only handle .smt2 files.  
Reimplemented from [benchmax::Tool](#).

**0.15.303.3.6 getCommandLine() [1/2]** virtual std::string benchmax::Tool::getCommandLine (const std::string & file) const [inline], [virtual], [inherited]  
Compose commandline for this tool and the given input file.

**0.15.303.3.7 getCommandLine() [2/2]** virtual std::string benchmax::Tool::getCommandLine (const std::string & file, const std::string & localBinary) const [inline], [virtual], [inherited]  
Compose commandline for this tool with another binary name and the given input file.

**0.15.303.3.8 name()** std::string benchmax::Tool::name () const [inline], [inherited]  
Common name of this tool.

**0.15.303.3.9 parseCommandLine()** virtual std::optional<std::string> benchmax::Tool::parseCommandline (const std::string & cmdline) const [inline], [virtual], [inherited]  
Compose commandline for this tool and the given input file.

**0.15.303.3.10 resolveDependencies()** std::vector<std::string> benchmax::Tool::resolveDependencies () const [inline], [inherited]  
Get dependencies of binary required to run it (via ldd)

## 0.15.303.4 Field Documentation

**0.15.303.4.1 mArguments** std::string benchmax::Tool::mArguments [protected], [inherited]  
Command line arguments that should be passed to the binary.

**0.15.303.4.2 mAttributes** std::map<std::string, std::string> benchmax::Tool::mAttributes [protected], [inherited]  
Attributes of the tool obtained by introspection of the binary.

**0.15.303.4.3 mBinary** fs::path benchmax::Tool::mBinary [protected], [inherited]  
Path to the binary.

**0.15.303.4.4 mName** std::string benchmax::Tool::mName [protected], [inherited]  
 (Non-unique) identifier for the tool.

## 0.15.304 smtrat::mcsat::fm::MaxSizeComparator Struct Reference

This heuristic chooses the explanation excluding the largest interval.

```
#include <ConflictGenerator.h>
```

### Public Member Functions

*Adds a lemmas which provoke a branching for the given variable at the given value, if this module returns Unknown and there exists a preceding SATModule.*
- void [splitUnequalConstraint](#) (const [FormulaT](#) &)
 

*Adds the following lemmas for the given constraint p!=0.*
- unsigned [checkModel](#) () const
 

*Gets all InformationRelevantFormulas.*
- void [addInformationRelevantFormula](#) (const [FormulaT](#) &formula)
 

*Adds a formula to the InformationRelevantFormula.*
- const std::set< [FormulaT](#) > & [getInformationRelevantFormulas](#) ()
 

*Gets all InformationRelevantFormulas.*
- bool [isLemmaLevel](#) ([LemmaLevel](#) level)
 

*Checks if current lemma level is greater or equal to given level.*

## Static Protected Member Functions

- static bool `modelsDisjoint` (const `Model` &\_modelA, const `Model` &\_modelB)

*Checks whether there is no variable assigned by both models.*

## Protected Attributes

- `std::vector<FormulaSetT> mInfeasibleSubsets`

*Stores the infeasible subsets.*

- `Manager *const mpManager`

*A reference to the manager.*

- `Model mModel`

*Stores the assignment of the current satisfiable result, if existent.*

- `std::vector<Model> mAllModels`

*Stores all satisfying assignments.*

- `bool mModelComputed`

*True, if the model has already been computed.*

- `bool mFinalCheck`

*true, if the check procedure should perform a final check which especially means not to postpone splitting decisions*

- `bool mFullCheck`

*false, if this module should avoid too expensive procedures and rather return unknown instead.*

- `carl::Variable mObjectiveVariable`

*Objective variable to be minimized. If set to NO\_VARIABLE, a normal sat check should be performed.*

- `std::vector<TheoryPropagation> mTheoryPropagations`

- `std::atomic<Answer> mSolverState`

*States whether the received formula is known to be satisfiable or unsatisfiable otherwise it is set to unknown.*

- `std::atomic_bool * mBackendsFoundAnswer`

*This flag is passed to any backend and if it determines an answer to a prior check call, this flag is fired.*

- `Conditionals mFoundAnswer`

*Vector of Booleans: If any of them is true, we have to terminate a running check procedure.*

- `std::vector<Module*> mUsedBackends`

*The backends of this module which are currently used (conditions to use this module are fulfilled for the passed formula).*

- `std::vector<Module*> mAllBackends`

*The backends of this module which have been used.*

- `std::vector<Lemma> mLemmas`

*Stores the lemmas being valid formulas this module or its backends made.*

- `ModuleInput::iterator mFirstSubformulaToPass`

*Stores the position of the first sub-formula in the passed formula, which has not yet been considered for a consistency check of the backends.*

- `carl::FastSet<FormulaT> mConstraintsToInform`

*Stores the constraints which the backends must be informed about.*

- `carl::FastSet<FormulaT> mInformedConstraints`

*Stores the position of the first constraint of which no backend has been informed about.*

- `ModuleInput::const_iterator mFirstUncheckedReceivedSubformula`

*Stores the position of the first (by this module) unchecked sub-formula of the received formula.*

- `unsigned mSmallerMusesCheckCounter`

*Counter used for the generation of the smt2 files to check for smaller muses.*

- `std::vector<std::size_t> mVariableCounters`

*Maps variables to the number of their occurrences.*

`smtrat::MCBModule< Settings >::~MCBModule` ( )

### 0.15.310.4 Member Function Documentation

**0.15.310.4.1 add()** bool `smtrat::PModule::add` (  
   `ModuleInput::const_iterator` `_subformula` ) [inherited]

The module has to take the given sub-formula of the received formula into account.

Parameters

|                          |                                                    |
|--------------------------|----------------------------------------------------|
| <code>_subformula</code> | The sub-formula to take additionally into account. |
|--------------------------|----------------------------------------------------|

Returns

false, if it can be easily decided that this sub-formula causes a conflict with the already considered sub-formulas; true, otherwise.

**0.15.310.4.2 addConstraintToInform()** void `smtrat::Module::addConstraintToInform` (  
   const `FormulaT` & `_constraint` ) [protected], [virtual], [inherited]

Adds a constraint to the collection of constraints of this module, which are informed to a freshly generated backend.

**Parameters**

|                    |                        |
|--------------------|------------------------|
| <i>_constraint</i> | The constraint to add. |
|--------------------|------------------------|

Reimplemented in [smrat::SATModule< Settings >](#).

**0.15.310.4.3 addCore()** `virtual bool smrat::Module::addCore (`

`ModuleInput::const_iterator formula ) [inline], [protected], [virtual], [inherited]`

The module has to take the given sub-formula of the received formula into account.

**Parameters**

|                |                                                    |
|----------------|----------------------------------------------------|
| <i>formula</i> | The sub-formula to take additionally into account. |
|----------------|----------------------------------------------------|

**Returns**

false, if it can be easily decided that this sub-formula causes a conflict with the already considered sub-formulas; true, otherwise.

Reimplemented in [smrat::VSModule< Settings >](#), [smrat::SATModule< Settings >](#), [smrat::PFEModule< Settings >](#), [smrat::ICPModule< Settings >](#), [smrat::ICPModule< ICPSettings4 >](#), [smrat::ICPModule< ICPSettings1 >](#), [smrat::UnionFindModule< Settings >](#), [smrat::UFCegarModule< Settings >](#), [smrat::STropModule< Settings >](#), [smrat::PBPPModule< Settings >](#), [smrat::PBGaussModule< Settings >](#), [smrat::NRAILModule< Settings >](#), [smrat::NewCoveringModule< Settings >](#), [smrat::NewCADModule< Settings >](#), [smrat::LRAModule< Settings >](#), [smrat::LRAModule< LRASettingsICP >](#), [smrat::LRAModule< LRASettings1 >](#), [smrat::IntEqModule< Settings >](#), [smrat::IntBlastModule< Settings >](#), [smrat::IncWidthModule< Settings >](#), [smrat::ICEModule< Settings >](#), [smrat::FPPModule< Settings >](#), [smrat::FouMoModule< Settings >](#), [smrat::EQModule< Settings >](#), [smrat::CurryModule< Settings >](#), [smrat::CubeLIAModule< Settings >](#), [smrat::CSplitModule< Settings >](#), [smrat::BVModule< Settings >](#), and [smrat::GBModule< Settings >](#).

**0.15.310.4.4 addInformationRelevantFormula()** `void smrat::Module::addInformationRelevantFormula (`

`const FormulaT & formula ) [protected], [inherited]`

Adds a formula to the InformationRelevantFormula.

**Parameters**

|                |                |
|----------------|----------------|
| <i>formula</i> | Formula to add |
|----------------|----------------|

**0.15.310.4.5 addLemma()** `void smrat::Module::addLemma (`

`const FormulaT & _lemma,`

`const LemmaType & _lt = LemmaType::NORMAL,`

`const FormulaT & _preferredFormula = FormulaT( carl::FormulaType::TRUE ) ) [inline],`

`[inherited]`

Stores a lemma being a valid formula.

**Parameters**

|                          |                                                                       |
|--------------------------|-----------------------------------------------------------------------|
| <i>_lemma</i>            | The eduction/lemma to store.                                          |
| <i>_lt</i>               | The type of the lemma.                                                |
| <i>_preferredFormula</i> | Hint for the next decision, which formula should be assigned to true. |

**0.15.310.4.6 addOrigin()** void smtrat::Module::addOrigin (   
     ModuleInput::iterator \_formula,  
     const FormulaT & \_origin ) [inline], [protected], [inherited]  
 Adds the given set of formulas in the received formula to the origins of the given passed formula.

#### Parameters

|          |                                                           |
|----------|-----------------------------------------------------------|
| _formula | The passed formula to set the origins for.                |
| _origin  | A set of formulas in the received formula of this module. |

**0.15.310.4.7 addReceivedSubformulaToPassedFormula()** std::pair<ModuleInput::iterator,bool> smtrat::Module::addReceivedSubformulaToPassedFormula (   
     ModuleInput::const\_iterator \_subformula ) [inline], [protected], [inherited]

Copies the given sub-formula of the received formula to the passed formula.

Note, that there is always a link between sub-formulas of the passed formulas to sub-formulas of the received formulas, which are responsible for its occurrence.

#### Parameters

|             |                                                  |
|-------------|--------------------------------------------------|
| _subformula | The sub-formula of the received formula to copy. |
|-------------|--------------------------------------------------|

**0.15.310.4.8 addSubformulaToPassedFormula() [1/3]** std::pair<ModuleInput::iterator,bool> smtrat::Module::addSubformulaToPassedFormula (   
     const FormulaT & \_formula ) [inline], [protected], [inherited]

Adds the given formula to the passed formula with no origin.

Note that in the next call of this module's removeSubformula, all formulas in the passed formula without origins will be removed.

#### Parameters

|          |                                           |
|----------|-------------------------------------------|
| _formula | The formula to add to the passed formula. |
|----------|-------------------------------------------|

#### Returns

A pair to the position where the formula to add has been inserted (or its first sub-formula which has not yet been in the passed formula, in case the formula to add is a conjunction), and a Boolean stating whether anything has been added to the passed formula.

**0.15.310.4.9 addSubformulaToPassedFormula() [2/3]** std::pair<ModuleInput::iterator,bool> smtrat::Module::addSubformulaToPassedFormula (   
     const FormulaT & \_formula,  
     const FormulaT & \_origin ) [inline], [protected], [inherited]

Adds the given formula to the passed formula.

#### Parameters

|          |                                                                                                                           |
|----------|---------------------------------------------------------------------------------------------------------------------------|
| _formula | The formula to add to the passed formula.                                                                                 |
| _origin  | The sub-formula of the received formula being responsible for the occurrence of the formula to add to the passed formula. |

**Returns**

A pair to the position where the formula to add has been inserted (or its first sub-formula which has not yet been in the passed formula, in case the formula to add is a conjunction), and a Boolean stating whether anything has been added to the passed formula.

**0.15.310.4.10 addSubformulaToPassedFormula() [3/3] std::pair<ModuleInput::iterator,bool>**

```
smrat::Module::addSubformulaToPassedFormula (
 const FormulaT & _formula,
 const std::shared_ptr< std::vector< FormulaT >> & _origins) [inline], [protected],
[inherited]
```

Adds the given formula to the passed formula.

**Parameters**

|                       |                                                                                                                                         |
|-----------------------|-----------------------------------------------------------------------------------------------------------------------------------------|
| <code>_formula</code> | The formula to add to the passed formula.                                                                                               |
| <code>_origins</code> | The link of the formula to add to the passed formula to sub-formulas of the received formulas, which are responsible for its occurrence |

**Returns**

A pair to the position where the formula to add has been inserted (or its first sub-formula which has not yet been in the passed formula, in case the formula to add is a conjunction), and a Boolean stating whether anything has been added to the passed formula.

**0.15.310.4.11 allModels() const std::vector<Model>& smrat::Module::allModels () const [inline], [inherited]****Returns**

All satisfying assignments, if existent.

**0.15.310.4.12 anAnswerFound() bool smrat::Module::anAnswerFound () const [inline], [protected], [inherited]**

Checks for all antecedent modules and those which run in parallel with the same antecedent modules, whether one of them has determined a result.

**Returns**

True, if one of them has determined a result.

**0.15.310.4.13 answerFound() const smrat::Conditionals& smrat::Module::answerFound () const [inline], [inherited]****Returns**

A vector of Booleans: If any of them is true, we have to terminate a running check procedure.

**0.15.310.4.14 appliedPreprocessing() bool smrat::PModule::appliedPreprocessing () const [inline], [inherited]****Returns**

true, if the current received formula has been simplified and the result of this simplification is stored in the passed formula.

**0.15.310.4.15 `backendsModel()`** const `Model` & smtrat::Module::backendsModel () const [protected], [inherited]

Stores the model of a backend which determined satisfiability of the passed formula in the model of this module.

**0.15.310.4.16 `branchAt() [1/4]`** bool smtrat::Module::branchAt ( carl::Variable::Arg \_var, const Rational & \_value, bool \_leftCaseWeak = true, bool \_preferLeftCase = true, bool \_useReceivedFormulaAsPremise = false, const std::vector< `FormulaT` > & \_premise = std::vector<`FormulaT`>() ) [inline], [protected], [inherited]

**0.15.310.4.17 `branchAt() [2/4]`** bool smtrat::Module::branchAt ( carl::Variable::Arg \_var, const Rational & \_value, std::vector< `FormulaT` > && \_premise, bool \_leftCaseWeak = true, bool \_preferLeftCase = true, bool \_useReceivedFormulaAsPremise = false ) [inline], [protected], [inherited]

**0.15.310.4.18 `branchAt() [3/4]`** bool smtrat::Module::branchAt ( const Poly & \_polynomial, bool \_integral, const Rational & \_value, bool \_leftCaseWeak = true, bool \_preferLeftCase = true, bool \_useReceivedFormulaAsPremise = false, const std::vector< `FormulaT` > & \_premise = std::vector<`FormulaT`>() ) [inline], [protected], [inherited]

**0.15.310.4.19 `branchAt() [4/4]`** bool smtrat::Module::branchAt ( const Poly & \_polynomial, bool \_integral, const Rational & \_value, std::vector< `FormulaT` > && \_premise, bool \_leftCaseWeak = true, bool \_preferLeftCase = true, bool \_useReceivedFormulaAsPremise = false ) [protected], [inherited]

Adds a lemmas which provoke a branching for the given variable at the given value, if this module returns Unknown and there exists a preceding SATModule.

Note that the given value is rounded down and up, if the given variable is integer-valued.

#### Parameters

|                            |                                                                                                                                                                                                                |
|----------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>_polynomial</code>   | The variable to branch for.                                                                                                                                                                                    |
| <code>_integral</code>     | A flag being true, if all variables in the polynomial to branch for are integral.                                                                                                                              |
| <code>_value</code>        | The value to branch at.                                                                                                                                                                                        |
| <code>_premise</code>      | The sub-formulas of the received formula from which the branch is followed. Note, that a premise is not necessary, as every branch is a valid formula. But a premise can prevent from branching unnecessarily. |
| <code>_leftCaseWeak</code> | true, if a branching in the form of (or ( $\leq p b$ ) ( $> p b$ )) is desired. false, if a branching in the form of (or ( $< p b$ ) ( $\geq p b$ )) is desired.                                               |

**Parameters**

|                                           |                                                                                              |
|-------------------------------------------|----------------------------------------------------------------------------------------------|
| <code>_preferLeftCase</code>              | true, if the left case (polynomial less(or equal) 0 shall be chosen first. false, otherwise. |
| <code>_useReceivedFormulaAsPremise</code> | true, if the whole received formula should be used as premise                                |

**0.15.310.4.20 `check()`** `Answer smtrat::PModule::check (`

```
 bool _final = false,
 bool _full = true,
 carl::Variable _objective = carl::Variable::NO_VARIABLE) [virtual], [inherited]
```

Checks the received formula for consistency.

Note, that this is an implementation of the satisfiability check of the conjunction of the so far received formulas, which does actually nothing but passing the problem to its backends. This implementation is only used internally and must be overwritten by any derived module.

**Parameters**

|                         |                                                                                                                                       |
|-------------------------|---------------------------------------------------------------------------------------------------------------------------------------|
| <code>_final</code>     | true, if this satisfiability check will be the last one (for a global sat-check), if its result is SAT                                |
| <code>_full</code>      | false, if this module should avoid too expensive procedures and rather return unknown instead.                                        |
| <code>_objective</code> | if not set to NO_VARIABLE, the module should find an assignment minimizing this objective variable; otherwise any assignment is good. |

**Returns**

True, if the received formula is satisfiable; False, if the received formula is not satisfiable; Unknown, otherwise.

Reimplemented from [smtrat::Module](#).

**0.15.310.4.21 `checkCore()`** `template<typename Settings >`

```
Answer smtrat::MCBModule< Settings >::checkCore () [virtual]
```

Checks the received formula for consistency.

**Returns**

SAT, if the received formula is satisfiable; UNSAT, if the received formula is not satisfiable; Unknown, otherwise.

Reimplemented from [smtrat::Module](#).

**0.15.310.4.22 `checkInfSubsetForMinimality()`** `void smtrat::Module::checkInfSubsetForMinimality (`

```
 std::vector< FormulaSet >::const_iterator _infssubset,
 const std::string & _filename = "smaller_muses",
 unsigned _maxSizeDifference = 1) const [inherited]
```

Checks the given infeasible subset for minimality by storing all subsets of it, which have a smaller size which differs from the size of the infeasible subset not more than the given threshold.

**Parameters**

|                                 |                                                                                                        |
|---------------------------------|--------------------------------------------------------------------------------------------------------|
| <code>_infssubset</code>        | The infeasible subset to check for minimality.                                                         |
| <code>_filename</code>          | The name of the file to store the infeasible subsets in order to be able to check their infeasibility. |
| <code>_maxSizeDifference</code> | The maximal difference between the sizes of the subsets compared to the size of the infeasible subset. |

**0.15.310.4.23 `checkModel()`** `unsigned smtrat::Module::checkModel ( ) const [protected], [inherited]`

**Returns**

false, if the current model of this module does not satisfy the current given formula; true, if it cannot be said whether the model satisfies the given formula.

**0.15.310.4.24 `cleanModel()`** `void smtrat::Module::cleanModel ( ) const [inline], [protected], [inherited]`

Substitutes variable occurrences by its model value in the model values of other variables.

**0.15.310.4.25 `clearLemmas()`** `void smtrat::Module::clearLemmas ( ) [inline], [inherited]`  
Deletes all yet found lemmas.

**0.15.310.4.26 `clearModel()`** `void smtrat::Module::clearModel ( ) const [inline], [protected], [inherited]`

Clears the assignment, if any was found.

**0.15.310.4.27 `clearModels()`** `void smtrat::Module::clearModels ( ) const [inline], [protected], [inherited]`

Clears all assignments, if any was found.

**0.15.310.4.28 `clearPassedFormula()`** `void smtrat::Module::clearPassedFormula ( ) [protected], [inherited]`

**0.15.310.4.29 `collectOrigins() [1/2]`** `void smtrat::Module::collectOrigins ( const FormulaT & _formula, FormulaSetT & _origins ) const [inherited]`

**0.15.310.4.30 `collectOrigins() [2/2]`** `void smtrat::Module::collectOrigins ( const FormulaT & _formula, FormulasT & _origins ) const [inherited]`

Collects the formulas in the given formula, which are part of the received formula.

If the given formula directly occurs in the received formula, it is inserted into the given set. Otherwise, the given formula must be of type AND and all its sub-formulas part of the received formula. Hence, they will be added to the given set.

**Parameters**

|                       |                                                                                                      |
|-----------------------|------------------------------------------------------------------------------------------------------|
| <code>_formula</code> | The formula from which to collect the formulas being sub-formulas of the received formula (origins). |
| <code>_origins</code> | The set in which to store the origins.                                                               |

**0.15.310.4.31 `collectTheoryPropagations()`** `void smtrat::Module::collectTheoryPropagations ( ) [inherited]`

**0.15.310.4.32 constraintsToInform()** const carl::FastSet<[FormulaT](#)>& smrat::Module::constraintsToInform( ) const [inline], [inherited]

**Returns**

The constraints which the backends must be informed about.

**0.15.310.4.33 currentlySatisfied()** virtual unsigned smrat::Module::currentlySatisfied( const [FormulaT](#) & ) const [inline], [virtual], [inherited]

**Returns**

0, if the given formula is conflicted by the current model; 1, if the given formula is satisfied by the current model; 2, otherwise; 3, if we do not know anything (default)

Reimplemented in [smrat::LRAbstractModule< Settings >](#), [smrat::LRAbstractModule< LRASettingsICP >](#), and [smrat::LRAbstractModule< LRASettings >](#)

**0.15.310.4.34 currentlySatisfiedByBackend()** unsigned smrat::Module::currentlySatisfiedByBackend( const [FormulaT](#) & \_formula ) const [inherited]

**Returns**

0, if the given formula is conflicted by the current model; 1, if the given formula is satisfied by the current model; 2, otherwise 3, if we do not know anything (default)

**0.15.310.4.35 deinform()** void smrat::Module::deinform( const [FormulaT](#) & \_constraint ) [inherited]

The inverse of informing about a constraint.

All data structures which were kept regarding this constraint are going to be removed. Note, that this makes only sense if it is not likely enough that a formula with this constraint must be solved again.

**Parameters**

|                          |                                                         |
|--------------------------|---------------------------------------------------------|
| <code>_constraint</code> | The constraint to remove from internal data structures. |
|--------------------------|---------------------------------------------------------|

**0.15.310.4.36 deinformCore()** virtual void smrat::Module::deinformCore( const [FormulaT](#) & \_constraint ) [inline], [protected], [virtual], [inherited]

The inverse of informing about a constraint.

All data structures which were kept regarding this constraint are going to be removed. Note, that this makes only sense if it is not likely enough that a formula with this constraint must be solved again.

**Parameters**

|                          |                                                         |
|--------------------------|---------------------------------------------------------|
| <code>_constraint</code> | The constraint to remove from internal data structures. |
|--------------------------|---------------------------------------------------------|

Reimplemented in [smrat::LRAbstractModule< Settings >](#), [smrat::LRAbstractModule< LRASettingsICP >](#), and [smrat::LRAbstractModule< LRASettings >](#)

**0.15.310.4.37 determine\_smallest\_origin()** size\_t smrat::Module::determine\_smallest\_origin( const std::vector< [FormulaT](#) > & origins ) const [protected], [inherited]

## Parameters

|                       |                              |
|-----------------------|------------------------------|
| <code>_origins</code> | A vector of sets of origins. |
|-----------------------|------------------------------|

## Returns

The index of the smallest (regarding the size of the sets) element of origins

**0.15.310.4.38 `eraseSubformulaFromPassedFormula()`** `ModuleInput::iterator smtrat::Module::eraseSubformulaFromPassedFormula (`

```
ModuleInput::iterator _subformula,
bool _ignoreOrigins = false) [protected], [virtual], [inherited]
```

Removes everything related to the sub-formula to remove from the passed formula in the backends of this module. Afterwards the sub-formula is removed from the passed formula.

## Parameters

|                             |                                                                                                              |
|-----------------------------|--------------------------------------------------------------------------------------------------------------|
| <code>_subformula</code>    | The sub-formula to remove from the passed formula.                                                           |
| <code>_ignoreOrigins</code> | True, if the sub-formula shall be removed regardless of its origins (should only be applied with expertise). |

## Returns

Reimplemented in `smtrat::ICPModule< Settings >`, `smtrat::ICPModule< ICPSettings4 >`, and `smtrat::ICPModule< ICPSettings1 >`.

**0.15.310.4.39 `excludeNotReceivedVariablesFromModel()`** `void smtrat::Module::excludeNotReceivedVariablesFromModel ( ) const [inherited]`

Excludes all variables from the current model, which do not occur in the received formula.

**0.15.310.4.40 `findBestOrigin()`** `std::vector< FormulaT >::const_iterator smtrat::Module::findBestOrigin (`

```
const std::vector< FormulaT > & _origins) const [protected], [inherited]
```

## Parameters

|                       |  |
|-----------------------|--|
| <code>_origins</code> |  |
|-----------------------|--|

## Returns

**0.15.310.4.41 `firstSubformulaToPass()`** `ModuleInput::const_iterator smtrat::Module::firstSubformulaToPass ( ) const [inline], [inherited]`

## Returns

The position of the first sub-formula in the passed formula, which has not yet been considered for a consistency check of the backends.

**0.15.310.4.42 firstUncheckedReceivedSubformula()** `ModuleInput::const_iterator smtrat::Module::firstUncheckedReceivedSubformula ( ) const [inline], [inherited]`

**Returns**

The position of the first (by this module) unchecked sub-formula of the received formula.

**0.15.310.4.43 freeSplittingVariable()** `static void smtrat::Module::freeSplittingVariable ( const FormulaT & _splittingVariable ) [inline], [static], [inherited]`

**0.15.310.4.44 generateTrivialInfeasibleSubset()** `void smtrat::Module::generateTrivialInfeasibleSubset ( ) [inline], [protected], [inherited]`

Stores the trivial infeasible subset being the set of received formulas.

**0.15.310.4.45 getBackendsAllModels()** `void smtrat::Module::getBackendsAllModels ( ) const [protected], [inherited]`

Stores all models of a backend in the list of all models of this module.

**0.15.310.4.46 getBackendsModel()** `void smtrat::Module::getBackendsModel ( ) const [protected], [inherited]`

**0.15.310.4.47 getInfeasibleSubsets() [1/2]** `void smtrat::Module::getInfeasibleSubsets ( ) [protected], [inherited]`

Copies the infeasible subsets of the passed formula.

**0.15.310.4.48 getInfeasibleSubsets() [2/2]** `std::vector< FormulaSetT > smtrat::Module::getInfeasibleSubsets (`

`const Module & _backend ) const [protected], [inherited]`

Get the infeasible subsets the given backend provides.

Note, that an infeasible subset in a backend contains sub formulas of the passed formula and an infeasible subset of this module contains sub formulas of the received formula. In this method the LATTER is returned.

**Parameters**

|                       |                                                          |
|-----------------------|----------------------------------------------------------|
| <code>_backend</code> | The backend from which to obtain the infeasible subsets. |
|-----------------------|----------------------------------------------------------|

**Returns**

The infeasible subsets the given backend provides.

**0.15.310.4.49 getInformationRelevantFormulas()** `const std::set< FormulaT > & smtrat::Module::getInformationRelevantFormulas ( ) [protected], [inherited]`

Gets all InformationRelevantFormulas.

**Returns**

Set of all formulas

**0.15.310.4.50 `getModelEqualities()`** `std::list< std::vector< carl::Variable > > smtrat::Module::getModelEqualities ( ) const [virtual], [inherited]`

Partition the variables from the current model into equivalence classes according to their assigned value.

The result is a set of equivalence classes of variables where all variables within one class are assigned the same value. Note that the number of classes may not be minimal, i.e. two classes may actually be equivalent.

#### Returns

Equivalence classes.

**0.15.310.4.51 `getOrigins() [1/3]`** `void smtrat::Module::getOrigins (`

```
const FormulaT & _formula,
FormulaSetT & _origins) const [inline], [protected], [inherited]
```

#### Parameters

|                       |  |
|-----------------------|--|
| <code>_formula</code> |  |
| <code>_origins</code> |  |

**0.15.310.4.52 `getOrigins() [2/3]`** `void smtrat::Module::getOrigins (`

```
const FormulaT & _formula,
FormulasT & _origins) const [inline], [protected], [inherited]
```

#### Parameters

|                       |  |
|-----------------------|--|
| <code>_formula</code> |  |
| <code>_origins</code> |  |

**0.15.310.4.53 `getOrigins() [3/3]`** `const FormulaT& smtrat::Module::getOrigins (`

```
ModuleInput::const_iterator _formula) const [inline], [protected], [inherited]
```

Gets the origins of the passed formula at the given position.

#### Parameters

|                       |                                                   |
|-----------------------|---------------------------------------------------|
| <code>_formula</code> | The position of a formula in the passed formulas. |
|-----------------------|---------------------------------------------------|

#### Returns

The origins of the passed formula at the given position.

**0.15.310.4.54 `getReceivedFormulaSimplified()`** `std::pair< bool, FormulaT > smtrat::PModule::getReceivedFormulaSimplified ( ) [virtual], [inherited]`

#### Returns

A pair of a Boolean and a formula, where the Boolean is true, if the received formula could be simplified to an equisatisfiable formula. The formula is equisatisfiable to this module's received formula, if the Boolean is true.

Reimplemented from [smtrat::Module](#).

**0.15.310.4.55 hasLemmas()** `bool smrat::Module::hasLemmas () [inline], [inherited]`  
Checks whether this module or any of its backends provides any lemmas.

**0.15.310.4.56 hasValidInfeasibleSubset()** `bool smrat::Module::hasValidInfeasibleSubset () const [inherited]`

**Returns**

true, if the module has at least one valid infeasible subset, that is all its elements are sub-formulas of the received formula (pointer must be equal).

**0.15.310.4.57 id()** `std::size_t smrat::Module::id () const [inline], [inherited]`

**Returns**

A unique ID to identify this module instance.

**0.15.310.4.58 infeasibleSubsets()** `const std::vector<FormulaSetT>& smrat::Module::infeasibleSubsets () const [inline], [inherited]`

**Returns**

The infeasible subsets of the set of received formulas (empty, if this module has not detected unsatisfiability of the conjunction of received formulas).

**0.15.310.4.59 inform()** `bool smrat::Module::inform (const FormulaT & _constraint) [inherited]`

Informs the module about the given constraint.

It should be tried to inform this module about any constraint it could receive eventually before assertSubformula is called (preferably for the first time, but at least before adding a formula containing that constraint).

**Parameters**

|                          |                                 |
|--------------------------|---------------------------------|
| <code>_constraint</code> | The constraint to inform about. |
|--------------------------|---------------------------------|

**Returns**

false, if it can be easily decided whether the given constraint is inconsistent; true, otherwise.

**0.15.310.4.60 informBackends()** `void smrat::Module::informBackends (const FormulaT & _constraint) [inline], [protected], [inherited]`

Informs all backends of this module about the given constraint.

**Parameters**

|                          |                                 |
|--------------------------|---------------------------------|
| <code>_constraint</code> | The constraint to inform about. |
|--------------------------|---------------------------------|

**0.15.310.4.61 informCore()** `virtual bool smrat::Module::informCore (const FormulaT & _constraint) [inline], [protected], [virtual], [inherited]`

Informs the module about the given constraint.

It should be tried to inform this module about any constraint it could receive eventually before assertSubformula is called (preferably for the first time, but at least before adding a formula containing that constraint).

#### Parameters

|                          |                                 |
|--------------------------|---------------------------------|
| <code>_constraint</code> | The constraint to inform about. |
|--------------------------|---------------------------------|

#### Returns

`false`, if it can be easily decided whether the given constraint is inconsistent; `true`, otherwise.

Reimplemented in [smrat::UnionFindModule< Settings >](#), [smrat::PBPPModule< Settings >](#), [smrat::PBGaussModule< Settings >](#), [smrat::NRAILModule< Settings >](#), [smrat::NewCoveringModule< Settings >](#), [smrat::NewCADModule< Settings >](#), [smrat::LRAModule< Settings >](#), [smrat::LRAModule< LRASettingsICP >](#), [smrat::LRAModule< LRASettings1 >](#), [smrat::IntBlastModule< Settings >](#), [smrat::FPPModule< Settings >](#), [smrat::EQModule< Settings >](#), [smrat::CurryModule< Settings >](#), [smrat::BVMModule< Settings >](#), [smrat::ICPModule< Settings >](#), [smrat::ICPModule< ICPSettings4 >](#), and [smrat::ICPModule< ICPSettings1 >](#).

#### 0.15.310.4.62 informedConstraints()

```
const carl::FastSet<FormulaT>& smrat::Module::informed<→
Constraints () const [inline], [inherited]
```

#### Returns

The position of the first constraint of which no backend has been informed about.

#### 0.15.310.4.63 init()

```
void smrat::Module::init () [virtual], [inherited]
```

Informs all backends about the so far encountered constraints, which have not yet been communicated.

This method must not be called twice and only before the first runBackends call.

Reimplemented in [smrat::PBPPModule< Settings >](#), [smrat::PBGaussModule< Settings >](#), [smrat::NRAILModule< Settings >](#), [smrat::NewCoveringModule< Settings >](#), [smrat::NewCADModule< Settings >](#), [smrat::LRAModule< Settings >](#), [smrat::LRAModule< LRASettingsICP >](#), [smrat::LRAModule< LRASettings1 >](#), [smrat::IntBlastModule< Settings >](#), [smrat::FPPModule< Settings >](#), [smrat::EQModule< Settings >](#), [smrat::CurryModule< Settings >](#), and [smrat::BVMModule< Settings >](#).

#### 0.15.310.4.64 is\_minimizing()

```
bool smrat::Module::is_minimizing () const [inline], [inherited]
```

#### 0.15.310.4.65 isLemmaLevel()

```
bool smrat::Module::isLemmaLevel (
```

`LemmaLevel level`) [protected], [inherited]

Checks if current lemma level is greater or equal to given level.

#### Parameters

|                    |                 |
|--------------------|-----------------|
| <code>level</code> | Level to check. |
|--------------------|-----------------|

#### 0.15.310.4.66 isPreprocessor()

```
bool smrat::PModule::isPreprocessor () const [inline], [inherited]
```

#### Returns

`true`, if this module is a preprocessor that is a module, which simplifies its received formula to an equisatisfiable formula being passed to its backends. The simplified formula can be obtained with [getReceivedFormulaSimplified\(\)](#).

**0.15.310.4.67 lemmas()** const std::vector<[Lemma](#)>& smtrat::Module::lemmas ( ) const [inline], [inherited]

**Returns**

A constant reference to the lemmas being valid formulas this module or its backends made.

**0.15.310.4.68 merge()** std::vector< [FormulaT](#) > smtrat::Module::merge ( const std::vector< [FormulaT](#) > & [\\_vecSetA](#), const std::vector< [FormulaT](#) > & [\\_vecSetB](#) ) const [protected], [inherited]

Merges the two vectors of sets into the first one.

({a,b},{a,c}) and ({b,d},{b}) -> ({a,b,d},{a,b},{a,b,c,d},{a,b,c})

**Parameters**

|                          |                                  |
|--------------------------|----------------------------------|
| <a href="#">_vecSetA</a> | A vector of sets of constraints. |
| <a href="#">_vecSetB</a> | A vector of sets of constraints. |

**Returns**

The vector being the two given vectors merged.

**0.15.310.4.69 model()** const [Model](#)& smtrat::Module::model ( ) const [inline], [inherited]

**Returns**

The assignment of the current satisfiable result, if existent.

**0.15.310.4.70 modelsDisjoint()** bool smtrat::Module::modelsDisjoint ( const [Model](#) & [\\_modelA](#), const [Model](#) & [\\_modelB](#) ) [static], [protected], [inherited]

Checks whether there is no variable assigned by both models.

**Parameters**

|                         |                                |
|-------------------------|--------------------------------|
| <a href="#">_modelA</a> | The first model to check for.  |
| <a href="#">_modelB</a> | The second model to check for. |

**Returns**

true, if there is no variable assigned by both models; false, otherwise.

**0.15.310.4.71 moduleName()** virtual std::string smtrat::Module::moduleName ( ) const [inline], [virtual], [inherited]

**Returns**

The name of the given module type as name.

Reimplemented in `smrat::VSModule< Settings >`, `smrat::UnionFindModule< Settings >`, `smrat::UFCegarModule< Settings >`, `smrat::STropModule< Settings >`, `smrat::SplitSOSModule< Settings >`, `smrat::PBPPModule< Settings >`, `smrat::PBGaussModule< Settings >`, `smrat::NRAILModule< Settings >`, `smrat::NewCADModule< Settings >`, `smrat::LVEModule< Settings >`, `smrat::LRAModule< Settings >`, `smrat::LRAModule< LRASettingsICP >`, `smrat::LRAModule< LRASettings1 >`, `smrat::IntEqModule< Settings >`, `smrat::IntBlastModule< Settings >`, `smrat::IncWidthModule< Settings >`, `smrat::ICPModule< Settings >`, `smrat::ICPModule< ICPSettings4 >`, `smrat::ICPModule< ICPSettings1 >`, `smrat::GBModule< Settings >`, `smrat::FouMoModule< Settings >`, `smrat::EQPreprocessingModule< Settings >`, `smrat::EQModule< Settings >`, `smrat::CurryModule< Settings >`, `smrat::CubeLIAModule< Settings >`, `smrat::CSplitModule< Settings >`, `smrat::BVMModule< Settings >`, and `smrat::BEModule< Settings >`.

**0.15.310.4.72 `objective()`** `carl::Variable smrat::Module::objective ( ) const [inline], [inherited]`**0.15.310.4.73 `originInReceivedFormula()`** `bool smrat::Module::originInReceivedFormula ( const FormulaT & _origin ) const [protected], [inherited]`**0.15.310.4.74 `passedFormulaBegin()`** `ModuleInput::iterator smrat::Module::passedFormulaBegin ( ) [inline], [protected], [inherited]`**Returns**

An iterator to the end of the passed formula. TODO: disable this method

**0.15.310.4.75 `passedFormulaEnd()`** `ModuleInput::iterator smrat::Module::passedFormulaEnd ( ) [inline], [protected], [inherited]`**Returns**

An iterator to the end of the passed formula.

**0.15.310.4.76 `pPassedFormula()`** `const ModuleInput* smrat::Module::pPassedFormula ( ) const [inline], [inherited]`**Returns**

A pointer to the formula passed to the backends of this module.

**0.15.310.4.77 `pReceivedFormula()`** `const ModuleInput* smrat::Module::pReceivedFormula ( ) const [inline], [inherited]`**Returns**

A pointer to the formula passed to this module.

**0.15.310.4.78 `print()`** `void smrat::Module::print ( const std::string & _initiation = "***" ) const [inherited]`

Prints everything relevant of the solver.

**Parameters**

|                    |                      |
|--------------------|----------------------|
| <i>_initiation</i> | The line initiation. |
|--------------------|----------------------|

**0.15.310.4.79 printAllModels()** void smtrat::Module::printAllModels ( std::ostream & *\_out* = std::cout ) const [inherited]

Prints all assignments of this module satisfying its received formula if it satisfiable and this module could find an assignment.

**Parameters**

|             |                                        |
|-------------|----------------------------------------|
| <i>_out</i> | The stream to print the assignment on. |
|-------------|----------------------------------------|

**0.15.310.4.80 printInfeasibleSubsets()** void smtrat::Module::printInfeasibleSubsets ( const std::string & *\_initiation* = "\*\*\*" ) const [inherited]

Prints the infeasible subsets.

**Parameters**

|                    |                      |
|--------------------|----------------------|
| <i>_initiation</i> | The line initiation. |
|--------------------|----------------------|

**0.15.310.4.81 printModel()** void smtrat::Module::printModel ( std::ostream & *\_out* = std::cout ) const [inherited]

Prints the assignment of this module satisfying its received formula if it satisfiable and this module could find an assignment.

**Parameters**

|             |                                        |
|-------------|----------------------------------------|
| <i>_out</i> | The stream to print the assignment on. |
|-------------|----------------------------------------|

**0.15.310.4.82 printPassedFormula()** void smtrat::Module::printPassedFormula ( const std::string & *\_initiation* = "\*\*\*" ) const [inherited]

Prints the vector of passed formula.

**Parameters**

|                    |                      |
|--------------------|----------------------|
| <i>_initiation</i> | The line initiation. |
|--------------------|----------------------|

**0.15.310.4.83 printReceivedFormula()** void smtrat::Module::printReceivedFormula ( const std::string & *\_initiation* = "\*\*\*" ) const [inherited]

Prints the vector of the received formula.

**Parameters**

|                    |                      |
|--------------------|----------------------|
| <i>_initiation</i> | The line initiation. |
|--------------------|----------------------|

```
0.15.310.4.84 probablyLooping() bool smtrat::Module::probablyLooping (
 const typename Poly::PolyType & _branchingPolynomial,
 const Rational & _branchingValue) const [protected], [inherited]
```

Checks whether given the current branching value and branching variable/polynomial it is (highly) probable that this branching is part of an infinite loop of branchings.

#### Parameters

|                                   |                                                                                     |
|-----------------------------------|-------------------------------------------------------------------------------------|
| <code>_branchingPolynomial</code> | The polynomial to branch at (in most branching strategies this is just a variable). |
| <code>_branchingValue</code>      | The value to branch at.                                                             |

#### Returns

true, if this branching is probably part of an infinite loop of branchings; false, otherwise.

```
0.15.310.4.85 receivedFormulaChecked() void smtrat::Module::receivedFormulaChecked () [inline], [inherited]
```

Notifies that the received formulas has been checked.

```
0.15.310.4.86 receivedFormulasAsInfeasibleSubset() void smtrat::Module::receivedFormulasAs<-
InfeasibleSubset (
```

```
 ModuleInput::const_iterator _subformula) [inline], [protected], [inherited]
```

Stores an infeasible subset consisting only of the given received formula.

```
0.15.310.4.87 receivedVariable() bool smtrat::Module::receivedVariable (
 carl::Variable::Arg _var) const [inline], [inherited]
```

```
0.15.310.4.88 remove() void smtrat::PModule::remove (
```

```
 ModuleInput::const_iterator _subformula) [virtual], [inherited]
```

Removes everything related to the given sub-formula of the received formula.

However, it is desired not to lose track of search spaces where no satisfying assignment can be found for the remaining sub-formulas.

#### Parameters

|                          |                                                    |
|--------------------------|----------------------------------------------------|
| <code>_subformula</code> | The sub formula of the received formula to remove. |
|--------------------------|----------------------------------------------------|

Reimplemented from [smtrat::Module](#).

```
0.15.310.4.89 removeCore() virtual void smtrat::Module::removeCore (
 ModuleInput::const_iterator formula) [inline], [protected], [virtual], [inherited]
```

Removes everything related to the given sub-formula of the received formula.

However, it is desired not to lose track of search spaces where no satisfying assignment can be found for the remaining sub-formulas.

#### Parameters

|                      |                                                    |
|----------------------|----------------------------------------------------|
| <code>formula</code> | The sub formula of the received formula to remove. |
|----------------------|----------------------------------------------------|

Reimplemented in [smrat::VSModule< Settings >](#), [smrat::SATModule< Settings >](#), [smrat::PFEModule< Settings >](#), [smrat::ICPModule< Settings >](#), [smrat::ICPModule< ICPSettings4 >](#), [smrat::ICPModule< ICPSettings1 >](#), [smrat::UnionFindModule< Settings >](#), [smrat::UFCegarModule< Settings >](#), [smrat::STropModule< Settings >](#), [smrat::PBPPModule< Settings >](#), [smrat::PBGaussModule< Settings >](#), [smrat::NRAILModule< Settings >](#), [smrat::NewCoveringModule< Settings >](#), [smrat::NewCADModule< Settings >](#), [smrat::LRAModule< Settings >](#), [smrat::LRAModule< LRASettingsICP >](#), [smrat::LRAModule< LRASettings1 >](#), [smrat::IntEqModule< Settings >](#), [smrat::IntBlastModule< Settings >](#), [smrat::IncWidthModule< Settings >](#), [smrat::ICEModule< Settings >](#), [smrat::FPPModule< Settings >](#), [smrat::FouMoModule< Settings >](#), [smrat::EQModule< Settings >](#), [smrat::CurryModule< Settings >](#), [smrat::CubeLIAModule< Settings >](#), [smrat::CSplitModule< Settings >](#), [smrat::BVMModule< Settings >](#), and [smrat::GBModule< Settings >](#).

**0.15.310.4.90 removeOrigin()** `std::pair<ModuleInput::iterator,bool> smrat::Module::removeOrigin (`

```
 ModuleInput::iterator _formula,
 const FormulaT & _origin) [inline], [protected], [inherited]
```

**0.15.310.4.91 removeOrigins()** `std::pair<ModuleInput::iterator,bool> smrat::Module::removeOrigins (`

```
 ModuleInput::iterator _formula,
 const std::shared_ptr< std::vector< FormulaT >> & _origins) [inline], [protected],
[inherited]
```

**0.15.310.4.92 rPassedFormula()** `const ModuleInput& smrat::Module::rPassedFormula ( ) const`

[inline], [inherited]

#### Returns

A reference to the formula passed to the backends of this module.

**0.15.310.4.93 rReceivedFormula()** `const ModuleInput& smrat::Module::rReceivedFormula ( ) const`

[inline], [inherited]

#### Returns

A reference to the formula passed to this module.

**0.15.310.4.94 runBackends() [1/2]** `virtual Answer smrat::PModule::runBackends ( ) [inline], [virtual], [inherited]`

Reimplemented from [smrat::Module](#).

**0.15.310.4.95 runBackends() [2/2]** `Answer smrat::PModule::runBackends (`

```
 bool _final,
 bool _full,
 carl::Variable _objective) [virtual], [inherited]
```

Runs the backend solvers on the passed formula.

#### Parameters

|                         |                                                                                                                                       |
|-------------------------|---------------------------------------------------------------------------------------------------------------------------------------|
| <code>_final</code>     | true, if this satisfiability check will be the last one (for a global sat-check), if its result is SAT.                               |
| <code>_full</code>      | false, if this module should avoid too expensive procedures and rather return unknown instead.                                        |
| <code>_objective</code> | if not set to NO_VARIABLE, the module should find an assignment minimizing this objective variable; otherwise any assignment is good. |

**Returns**

True, if the passed formula is consistent; False, if the passed formula is inconsistent; Unknown, otherwise.

Reimplemented from [smtrat::Module](#).

**0.15.310.4.96 setId()** `void smtrat::Module::setId ( std::size_t _id ) [inline], [inherited]`  
 Sets this modules unique ID to identify itself.

**Parameters**

|              |                                    |
|--------------|------------------------------------|
| $\leftarrow$ | The id to set this module's id to. |
| $\_id$       |                                    |

**0.15.310.4.97 setThreadPriority()** `void smtrat::Module::setThreadPriority ( thread_priority _threadPriority ) [inline], [inherited]`  
 Sets the priority of this module to get a thread for running its check procedure.

**Parameters**

|                    |                                                       |
|--------------------|-------------------------------------------------------|
| $\_threadPriority$ | The priority to set this module's thread priority to. |
|--------------------|-------------------------------------------------------|

**0.15.310.4.98 solverState()** `Answer smtrat::Module::solverState ( ) const [inline], [inherited]`

**Returns**

True, if this module is in a state, such that it has found a solution for its received formula; False, if this module is in a state, such that it has determined that there is no solution for its received formula; Unknown, otherwise.

**0.15.310.4.99 splitUnequalConstraint()** `void smtrat::Module::splitUnequalConstraint ( const FormulaT & _unequalConstraint ) [protected], [inherited]`

Adds the following lemmas for the given constraint  $p \neq 0$ .

$(p \neq 0 \leftrightarrow (p < 0 \text{ or } p > 0))$

and  $\neg(p < 0 \text{ and } p > 0)$

**Parameters**

|                       |                                                  |
|-----------------------|--------------------------------------------------|
| $\_unequalConstraint$ | A constraint having the relation symbol $\neq$ . |
|-----------------------|--------------------------------------------------|

**0.15.310.4.100 threadPriority()** `thread_priority smtrat::Module::threadPriority ( ) const [inline], [inherited]`

**Returns**

The priority of this module to get a thread for running its check procedure.

**0.15.310.4.101 updateAllModels()** void smrat::Module::updateAllModels () [virtual], [inherited]  
Updates all satisfying models, if the solver has detected the consistency of the received formula, beforehand.  
Reimplemented in [smrat::SATModule< Settings >](#).

**0.15.310.4.102 updateLemmas()** void smrat::Module::updateLemmas () [inherited]  
Stores all lemmas of any backend of this module in its own lemma vector.

**0.15.310.4.103 updateModel()** template<typename Settings >  
void [smrat::MCBModule< Settings >](#)::updateModel () const [virtual]  
Updates the model, if the solver has detected the consistency of the received formula, beforehand.  
Reimplemented from [smrat::Module](#).

**0.15.310.4.104 usedBackends()** const std::vector<[Module\\*](#)>& smrat::Module::usedBackends ()  
const [inline], [inherited]

**Returns**

The backends of this module which are currently used (conditions to use this module are fulfilled for the passed formula).

## 0.15.310.5 Field Documentation

**0.15.310.5.1 mAllBackends** std::vector<[Module\\*](#)> smrat::Module::mAllBackends [protected], [inherited]  
The backends of this module which have been used.

**0.15.310.5.2 mAllModels** std::vector<[Model](#)> smrat::Module::mAllModels [mutable], [protected], [inherited]  
Stores all satisfying assignments.

**0.15.310.5.3 mBackendsFoundAnswer** std::atomic\_bool\* smrat::Module::mBackendsFoundAnswer [protected], [inherited]  
This flag is passed to any backend and if it determines an answer to a prior check call, this flag is fired.

**0.15.310.5.4 mConstraintsToInform** carl::FastSet<[FormulaT](#)> smrat::Module::mConstraintsToInform [protected], [inherited]  
Stores the constraints which the backends must be informed about.

**0.15.310.5.5 mFinalCheck** bool smrat::Module::mFinalCheck [protected], [inherited]  
true, if the check procedure should perform a final check which especially means not to postpone splitting decisions

**0.15.310.5.6 mFirstPosInLastBranches** std::size\_t smrat::Module::mFirstPosInLastBranches = 0 [static], [inherited]  
The beginning of the cyclic buffer storing the last branches.

**0.15.310.5.7 mFirstSubformulaToPass** `ModuleInput::iterator smrat::Module::mFirstSubformulaToPass` [protected], [inherited]

Stores the position of the first sub-formula in the passed formula, which has not yet been considered for a consistency check of the backends.

**0.15.310.5.8 mFirstUncheckedReceivedSubformula** `ModuleInput::const_iterator smrat::Module::mFirstUncheckedReceivedSubformula` [protected], [inherited]

Stores the position of the first (by this module) unchecked sub-formula of the received formula.

**0.15.310.5.9 mFoundAnswer** `Conditionals smrat::Module::mFoundAnswer` [protected], [inherited]

Vector of Booleans: If any of them is true, we have to terminate a running check procedure.

**0.15.310.5.10 mFullCheck** `bool smrat::Module::mFullCheck` [protected], [inherited]

false, if this module should avoid too expensive procedures and rather return unknown instead.

**0.15.310.5.11 mInfeasibleSubsets** `std::vector<FormulaSetT> smrat::Module::mInfeasibleSubsets`

[protected], [inherited]

Stores the infeasible subsets.

**0.15.310.5.12 mInformedConstraints** `carl::FastSet<FormulaT> smrat::Module::mInformedConstraints`

[protected], [inherited]

Stores the position of the first constraint of which no backend has been informed about.

**0.15.310.5.13 mLastBranches** `std::vector< Branching > smrat::Module::mLastBranches = std::vector<Branching> (mNumOfBranchVarsToStore, Branching(typename Poly::PolyType(), 0))` [static], [inherited]

Stores the last branches in a cycle buffer.

**0.15.310.5.14 mLemmas** `std::vector<Lemma> smrat::Module::mLemmas` [protected], [inherited]

Stores the lemmas being valid formulas this module or its backends made.

**0.15.310.5.15 mModel** `Model smrat::Module::mModel` [mutable], [protected], [inherited]

Stores the assignment of the current satisfiable result, if existent.

**0.15.310.5.16 mModelComputed** `bool smrat::Module::mModelComputed` [mutable], [protected], [inherited]

True, if the model has already been computed.

**0.15.310.5.17 mNumOfBranchVarsToStore** `std::size_t smrat::Module::mNumOfBranchVarsToStore = 5` [static], [inherited]

The number of different variables to consider for a probable infinite loop of branchings.

**0.15.310.5.18 mObjectiveVariable** carl::Variable smrat::Module::mObjectiveVariable [protected], [inherited]  
Objective variable to be minimized. If set to NO\_VARIABLE, a normal sat check should be performed.

**0.15.310.5.19 mOldSplittingVariables** std::vector< [FormulaT](#) > smrat::Module::mOldSplittingVariables [static], [inherited]  
Reusable splitting variables.

**0.15.310.5.20 mpManager** Manager\* const smrat::Module::mpManager [protected], [inherited]  
A reference to the manager.

**0.15.310.5.21 mSmallerMusesCheckCounter** unsigned smrat::Module::mSmallerMusesCheckCounter [mutable], [protected], [inherited]  
Counter used for the generation of the smt2 files to check for smaller muses.

**0.15.310.5.22 mSolverState** std::atomic<[Answer](#)> smrat::Module::mSolverState [protected], [inherited]  
States whether the received formula is known to be satisfiable or unsatisfiable otherwise it is set to unknown.

**0.15.310.5.23 mTheoryPropagations** std::vector<[TheoryPropagation](#)> smrat::Module::mTheoryPropagations [protected], [inherited]

**0.15.310.5.24 mUsedBackends** std::vector<[Module](#)\*> smrat::Module::mUsedBackends [protected], [inherited]  
The backends of this module which are currently used (conditions to use this module are fulfilled for the passed formula).

**0.15.310.5.25 mVariableCounters** std::vector<std::size\_t> smrat::Module::mVariableCounters [protected], [inherited]  
Maps variables to the number of their occurrences.

## 0.15.311 smrat::mcsat::MCASATBackend< Settings > Class Template Reference

### 0.15.312.1 Constructor & Destructor Documentation

```
0.15.312.1.1 MCSATMixin() template<typename Settings >
template<typename BaseModule >
smrat::mcsat::MCSATMixin< Settings >::MCSATMixin (
 BaseModule & baseModule) [inline], [explicit]
```

### 0.15.312.2 Member Function Documentation

**0.15.312.2.1 addBooleanVariable()** template<typename Settings >  
std::size\_t smtrat::mcsat::MCSATMixin< Settings >::addBooleanVariable (  
    Minisat::Var variable )

Add a variable, return the level it was inserted on.

**0.15.312.2.2 assignedAtTrailIndex()** template<typename Settings >  
int smtrat::mcsat::MCSATMixin< Settings >::assignedAtTrailIndex (  
    Minisat::Var variable ) const [inline]

**0.15.312.2.3 backtrackTo()** template<typename Settings >  
bool smtrat::mcsat::MCSATMixin< Settings >::backtrackTo (  
    Minisat::Lit literal )

Backtracks to the theory decision represented by the given literal.

**0.15.312.2.4 carlVar()** template<typename Settings >  
const carl::Variable& smtrat::mcsat::MCSATMixin< Settings >::carlVar (  
    Minisat::Var v ) const [inline]

**0.15.312.2.5 computeTheoryLevel() [1/2]** template<typename Settings >  
std::size\_t smtrat::mcsat::MCSATMixin< Settings >::computeTheoryLevel (  
    const FormulaT & f ) const [inline]

**0.15.312.2.6 computeTheoryLevel() [2/2]** template<typename Settings >  
std::size\_t smtrat::mcsat::MCSATMixin< Settings >::computeTheoryLevel (  
    Minisat::Var var ) const [inline]

**0.15.312.2.7 current() [1/2]** template<typename Settings >  
TheoryLevel& smtrat::mcsat::MCSATMixin< Settings >::current () [inline]

**0.15.312.2.8 current() [2/2]** template<typename Settings >  
const TheoryLevel& smtrat::mcsat::MCSATMixin< Settings >::current () const [inline]  
Returns the current theory level.

**0.15.312.2.9 decisionLevel()** template<typename Settings >  
int smtrat::mcsat::MCSATMixin< Settings >::decisionLevel (  
    Minisat::Var v ) const [inline]

**0.15.312.2.10 doBooleanAssignment()** template<typename Settings >  
void smtrat::mcsat::MCSATMixin< Settings >::doBooleanAssignment (  
    Minisat::Lit lit ) [inline]

Add a new constraint.

**0.15.312.2.11 evaluateLiteral()** template<typename Settings >  
Minisat::lbool smtrat::mcsat::MCSATMixin< Settings >::evaluateLiteral (  
    Minisat::Lit lit ) const

Evaluate a literal in the theory, set lastReason to last theory decision involved.

---

**0.15.312.2.12 `explainInconsistency()`** template<typename Settings >  
`std::optional<Explanation> smtrat::mcsat::MCSATMixin< Settings >::explainInconsistency ( )`  
`[inline]`

Checks if the trail is consistent after the assignment on the current level.

The trail must be consistent on the previous level.

Returns std::nullopt if consistent and an explanation.

**0.15.312.2.13 `explainTheoryPropagation()`** template<typename Settings >  
`Explanation smtrat::mcsat::MCSATMixin< Settings >::explainTheoryPropagation (`  
`Minisat::Lit literal ) [inline]`

**0.15.312.2.14 `fullConsistencyCheck()`** template<typename Settings >  
`bool smtrat::mcsat::MCSATMixin< Settings >::fullConsistencyCheck ( ) const [inline]`

**0.15.312.2.15 `get()`** template<typename Settings >  
`const TheoryLevel& smtrat::mcsat::MCSATMixin< Settings >::get (`  
`std::size_t level ) const [inline]`

Returns the respective theory level.

**0.15.312.2.16 `getDecisionLiteral()`** template<typename Settings >  
`Minisat::Lit smtrat::mcsat::MCSATMixin< Settings >::getDecisionLiteral (`  
`Minisat::Var var ) const [inline]`

**0.15.312.2.17 `hasUnassignedDep()`** template<typename Settings >  
`bool smtrat::mcsat::MCSATMixin< Settings >::hasUnassignedDep (`  
`Minisat::Var v ) const [inline]`

**0.15.312.2.18 `initVariables()`** template<typename Settings >  
`template<typename Constraints >`  
`void smtrat::mcsat::MCSATMixin< Settings >::initVariables (`  
`const Constraints & c ) [inline]`

**0.15.312.2.19 `is_consistent() [1/2]`** template<typename Settings >  
`bool smtrat::mcsat::MCSATMixin< Settings >::is_consistent ( ) [inline]`  
 Checks if any inconsistency was detected.

**0.15.312.2.20 `is_consistent() [2/2]`** template<typename Settings >  
`bool smtrat::mcsat::MCSATMixin< Settings >::is_consistent (`  
`Minisat::Var v ) [inline]`

*Full path to the binary.*
  - `const std::map< std::string, std::string > & attributes () const`  
*A set of attributes, for example compilation options.*
  - `std::vector< std::string > resolveDependencies () const`  
*Get dependencies of binary required to run it (via ldd)*
  - `std::size_t attributeHash () const`  
*Hash of the attributes.*
  - `virtual std::string getCommandline (const std::string &file) const`  
*Compose commandline for this tool and the given input file.*
  - `virtual std::string getCommandline (const std::string &file, const std::string &localBinary) const`  
*Compose commandline for this tool with another binary name and the given input file.*
  - `virtual std::optional< std::string > parseCommandline (const std::string &cmdline) const`  
*Compose commandline for this tool and the given input file.*

## Protected Attributes

- `std::string mName`  
*(Non-unique) identifier for the tool.*
- `fs::path mBinary`  
*Path to the binary.*
- `std::string mArguments`  
*Command line arguments that should be passed to the binary.*
- `std::map< std::string, std::string > mAttributes`  
*Attributes of the tool obtained by introspection of the binary.*

### 0.15.314.1 Detailed Description

Tool wrapper for a [Minisat](#) solver.

### 0.15.314.2 Constructor & Destructor Documentation

**0.15.314.2.1 Minisat()** `benchmax::Minisat::Minisat (`  
    `const fs::path & binary,`  
    `const std::string & arguments ) [inline]`

Create tool.

### 0.15.314.3 Member Function Documentation

**0.15.314.3.1 additionalResults()** `virtual void benchmax::Minisat::additionalResults (`  
    `const fs::path & ,`  
    `BenchmarkResult & result ) const [inline], [override], [virtual]`

Parse results from stdout.

Reimplemented from [benchmax::Tool](#).

**0.15.314.3.2 attributeHash()** `std::size_t benchmax::Tool::attributeHash ( ) const [inline], [inherited]`

Hash of the attributes.

**0.15.314.3.3 attributes()** const std::map<std::string, std::string>& benchmax::Tool::attributes () const [inline], [inherited]  
A set of attributes, for example compilation options.

**0.15.314.3.4 binary()** fs::path benchmax::Tool::binary () const [inline], [inherited]  
Full path to the binary.

**0.15.314.3.5 canHandle()** virtual bool benchmax::Minisat::canHandle (const fs::path & path) const [inline], [override], [virtual]  
Only handles .opb files.  
Reimplemented from [benchmax::Tool](#).

**0.15.314.3.6 getCommandLine() [1/2]** virtual std::string benchmax::Tool::getCommandLine (const std::string & file) const [inline], [virtual], [inherited]  
Compose commandline for this tool and the given input file.

**0.15.314.3.7 getCommandLine() [2/2]** virtual std::string benchmax::Tool::getCommandLine (const std::string & file, const std::string & localBinary) const [inline], [virtual], [inherited]  
Compose commandline for this tool with another binary name and the given input file.

**0.15.314.3.8 name()** std::string benchmax::Tool::name () const [inline], [inherited]  
Common name of this tool.

**0.15.314.3.9 parseCommandLine()** virtual std::optional<std::string> benchmax::Tool::parseCommandline (const std::string & cmdline) const [inline], [virtual], [inherited]  
Compose commandline for this tool and the given input file.

**0.15.314.3.10 resolveDependencies()** std::vector<std::string> benchmax::Tool::resolveDependencies () const [inline], [inherited]  
Get dependencies of binary required to run it (via ldd)

## 0.15.314.4 Field Documentation

**0.15.314.4.1 mArguments** std::string benchmax::Tool::mArguments [protected], [inherited]  
Command line arguments that should be passed to the binary.

**0.15.314.4.2 mAttributes** std::map<std::string, std::string> benchmax::Tool::mAttributes [protected], [inherited]  
Attributes of the tool obtained by introspection of the binary.

**0.15.314.4.3 mBinary** fs::path benchmax::Tool::mBinary [protected], [inherited]  
Path to the binary.

**0.15.314.4.4 mName** std::string benchmax::Tool::mName [protected], [inherited]  
(Non-unique) identifier for the tool.

## 0.15.315 benchmax::Minisatp Class Reference

Tool wrapper for the [Minisatp](#) solver for pseudo-Boolean problems.

```
#include <Minisatp.h>
```

### Public Member Functions

- **Minisatp** (const fs::path &[binary](#), const std::string &[arguments](#))

- virtual std::optional< std::string > [parseCommandline](#) (const std::string &[cmdline](#)) const  
*Compose commandline for this tool and the given input file.*

### Protected Attributes

- std::string [mName](#)  
(Non-unique) identifier for the tool.
- fs::path [mBinary](#)  
Path to the binary.
- std::string [mArguments](#)  
Command line arguments that should be passed to the binary.
- std::map< std::string, std::string > [mAttributes](#)  
Attributes of the tool obtained by introspection of the binary.

### 0.15.315.1 Detailed Description

Tool wrapper for the [Minisatp](#) solver for pseudo-Boolean problems.

### 0.15.315.2 Constructor & Destructor Documentation

```
0.15.315.2.1 Minisatp() benchmax::Minisatp::Minisatp (
 const fs::path & binary,
 const std::string & arguments) [inline]
```

Create tool, add "-v0" to arguments.

### 0.15.315.3 Member Function Documentation

```
0.15.315.3.1 additionalResults() virtual void benchmax::Minisatp::additionalResults (
 const fs::path & ,
 BenchmarkResult & result) const [inline], [override], [virtual]
```

Parse results from stdout.

Reimplemented from [benchmax::Tool](#).

```
0.15.315.3.2 attributeHash() std::size_t benchmax::Tool::attributeHash () const [inline],
[inherited]
```

Hash of the attributes.

```
0.15.315.3.3 attributes() const std::map<std::string, std::string>& benchmax::Tool::attributes (
) const [inline], [inherited]
```

A set of attributes, for example compilation options.

```
0.15.315.3.4 binary() fs::path benchmax::Tool::binary () const [inline], [inherited]
```

Full path to the binary.

```
0.15.315.3.5 canHandle() virtual bool benchmax::Minisatp::canHandle (
 const fs::path & path) const [inline], [override], [virtual]
```

Only handles .opb files.

Reimplemented from [benchmax::Tool](#).

```
0.15.315.3.6 getCommandLine() [1/2] virtual std::string benchmax::Tool::getCommandLine (
 const std::string & file) const [inline], [virtual], [inherited]
```

Compose commandline for this tool and the given input file.

```
0.15.315.3.7 getCommandLine() [2/2] virtual std::string benchmax::Tool::getCommandLine (
 const std::string & file,
 const std::string & localBinary) const [inline], [virtual], [inherited]
```

Compose commandline for this tool with another binary name and the given input file.

```
0.15.315.3.8 name() std::string benchmax::Tool::name () const [inline], [inherited]
```

Common name of this tool.

```
0.15.315.3.9 parseCommandLine() virtual std::optional<std::string> benchmax::Tool::parseCommandline (
 const std::string & cmdline) const [inline], [virtual], [inherited]
```

Compose commandline for this tool and the given input file.

**0.15.315.3.10 resolveDependencies()** std::vector<std::string> benchmax::Tool::resolveDependencies()  
() const [inline], [inherited]  
Get dependencies of binary required to run it (via ldd)

#### 0.15.315.4 Field Documentation

**0.15.315.4.1 mArguments** std::string benchmax::Tool::mArguments [protected], [inherited]  
Command line arguments that should be passed to the binary.

**0.15.315.4.2 mAttributes** std::map<std::string, std::string> benchmax::Tool::mAttributes [protected],  
[inherited]  
Attributes of the tool obtained by introspection of the binary.

**0.15.315.4.3 mBinary** fs::path benchmax::Tool::mBinary [protected], [inherited]  
Path to the binary.

**0.15.315.4.4 mName** std::string benchmax::Tool::mName [protected], [inherited]  
(Non-unique) identifier for the tool.

### 0.15.316 smtrat::mcsat::fm::MinSizeComparator Struct Reference

This heuristic chooses the explanation excluding the smallest interval.

```
#include <ConflictGenerator.h>
```

#### Public Member Functions

- bool [operator\(\)](#) (const [Bound](#) &b1, const [Bound](#) &b2) const

#### Data Fields

- bool [symmetric](#) = true

#### 0.15.316.1 Detailed Description

This heuristic chooses the explanation excluding the smallest interval.

#### 0.15.316.2 Member Function Documentation

**0.15.316.2.1 operator()** bool smtrat::mcsat::fm::MinSizeComparator::operator() (const [Bound](#) & b1, const [Bound](#) & b2) const [inline]

#### 0.15.316.3 Field Documentation

**0.15.316.3.1 symmetric** bool smtrat::mcsat::fm::MinSizeComparator::symmetric = true

### 0.15.317 smtrat::mcsat::fm::MinVarCountComparator Struct Reference

This heuristic tries to minimize the number of variables occurring in the explanation.

```
#include <ConflictGenerator.h>
```

#### Public Member Functions

- bool `operator()` (const `Bound` &`b1`, const `Bound` &`b2`) const

#### Data Fields

- bool `symmetric` = false

#### 0.15.317.1 Detailed Description

This heuristic tries to minimize the number of variables occurring in the explanation.  
It is a 2-approximation to the lowest possible number of variables in an explanation.

#### 0.15.317.2 Member Function Documentation

```
0.15.317.2.1 operator() bool smtrat::mcsat::fm::MinVarCountComparator::operator() (
 const Bound & b1,
 const Bound & b2) const [inline]
```

#### 0.15.317.3 Field Documentation

```
0.15.317.3.1 symmetric bool smtrat::mcsat::fm::MinVarCountComparator::symmetric = false
```

### 0.15.318 smtrat::cad::MISGeneration< heuristic > Class Template Reference

```
#include <MISGeneration.h>
```

#### Public Member Functions

```

## 0.15.319 smtrat::MixedSignEncoder Class Reference

```
#include <MixedSignEncoder.h>
```

### Public Member Functions

- `MixedSignEncoder ()`
- `bool canEncode (const ConstraintT &constraint)`
- `Rational encodingSize (const ConstraintT &constraint)`
- `std::string name ()`
- `std::optional< FormulaT > encode (const ConstraintT &constraint)`

*Encodes an arbitrary constraint.*

### Data Fields

- `std::size_t problem_size`

### Protected Member Functions

- `std::optional< FormulaT > doEncode (const ConstraintT &constraint)`
- `FormulaT generateVarChain (const std::set< carl::Variable > &vars, carl::FormulaType type)`

### 0.15.319.1 Constructor & Destructor Documentation

**0.15.319.1.1 MixedSignEncoder()** smtrat::MixedSignEncoder::MixedSignEncoder ( ) [inline]

### 0.15.319.2 Member Function Documentation

**0.15.319.2.1 canEncode()** bool smtrat::MixedSignEncoder::canEncode ( const ConstraintT & constraint ) [virtual]  
Implements [smtrat::PseudoBoolEncoder](#).

**0.15.319.2.2 doEncode()** std::optional< [FormulaT](#) > smtrat::MixedSignEncoder::doEncode ( const ConstraintT & constraint ) [protected], [virtual]  
Implements [smtrat::PseudoBoolEncoder](#).

**0.15.319.2.3 encode()** std::optional< [FormulaT](#) > smtrat::PseudoBoolEncoder::encode ( const ConstraintT & constraint ) [inherited]  
Encodes an arbitrary constraint.

Returns

encoded formula

**0.15.319.2.4 encodingSize()** Rational smtrat::MixedSignEncoder::encodingSize ( const ConstraintT & constraint ) [virtual]  
Reimplemented from [smtrat::PseudoBoolEncoder](#).

**0.15.319.2.5 generateVarChain()** [FormulaT](#) smtrat::PseudoBoolEncoder::generateVarChain ( const std::set< carl::Variable > & vars, carl::FormulaType type ) [protected], [inherited]

**0.15.319.2.6 name()** std::string smtrat::MixedSignEncoder::name ( ) [inline], [virtual]  
Reimplemented from [smtrat::PseudoBoolEncoder](#).

### 0.15.319.3 Field Documentation

**0.15.319.3.1 problem\_size** std::size\_t smtrat::PseudoBoolEncoder::problem\_size [inherited]

**0.15.320 smtrat::cad::ModelBasedProjection< incrementality, backtracking, Settings > Class Template Reference**

#include <Projection.h>

## Public Member Functions

- `std::size_t dim () const`  
*Returns the dimension of the projection.*
- `const auto & vars () const`  
*Returns the variables used for projection.*

*Additional info on projection, projection levels and projection polynomials.*
- `ProjectionOperator mOperator`  
*The projection operator.*
- std::function< void(std::size\_t, const `SampleLiftedWith` &) > `mRemoveCallback`  
*Callback to be called when polynomials are removed. The arguments are the projection level and a bitset that indicate which polynomials were removed in this level.*

### 0.15.320.1 Member Typedef Documentation

**0.15.320.1.1 Constraints** template<typename Settings >  
using `smtrat::cad::BaseProjection< Settings >`::`Constraints` = `CADConstraints<Settings::backtracking>`  
[protected], [inherited]

### 0.15.320.2 Member Function Documentation

**0.15.320.2.1 addEqConstraint() [1/2]** template<typename Settings >  
carl::Bitset `smtrat::cad::BaseProjection< Settings >`::`addEqConstraint` (  
  const `Poly` & `p`,  
  std::size\_t `cid`,  
  bool `isBound`) [inline], [inherited]

Adds the given polynomial of an equational constraint to the projection. Converts to a UPoly and calls the appropriate overload.

**0.15.320.2.2 addEqConstraint() [2/2]** template<typename Settings >  
virtual carl::Bitset `smtrat::cad::BaseProjection< Settings >`::`addEqConstraint` (  
  const `UPoly` & `p`,  
  std::size\_t `cid`,  
  bool `isBound`) [inline], [virtual], [inherited]

Adds the given polynomial of an equational constraint to the projection.

Reimplemented in `smtrat::cad::Projection< Incrementality::FULL, Backtracking::HIDE, Settings >`.

**0.15.320.2.3 addPolynomial() [1/2]** template<typename Settings >  
carl::Bitset `smtrat::cad::BaseProjection< Settings >`::`addPolynomial` (  
  const `Poly` & `p`,  
  std::size\_t `cid`,  
  bool `isBound`) [inline], [inherited]

Adds the given polynomial to the projection. Converts to a UPoly and calls the appropriate overload.

**0.15.320.2.4 addPolynomial() [2/2]** template<typename Settings >  
virtual carl::Bitset `smtrat::cad::BaseProjection< Settings >`::`addPolynomial` (  
  const `UPoly` & `p`,  
  std::size\_t `cid`,  
  bool `isBound`) [pure virtual], [inherited]

Adds the given polynomial to the projection.

Implemented in `smrat::cad::Projection< Incrementality::NONE, Backtracking::UNORDERED, Settings >`, `smrat::cad::Projection< Incrementality::NONE, Backtracking::ORDERED, Settings >`, `smrat::cad::Projection< Incrementality::FULL, Backtracking::HIDE, Settings >`, and `smrat::cad::Projection< Incrementality::SIMPLE, Backtracking::HIDE, Settings >`.

**0.15.320.2.5 `callRemoveCallback()`** template<typename Settings>  
void `smrat::cad::BaseProjection< Settings >`::`callRemoveCallback` (  
    std::size\_t level,  
    const `SampleLiftedWith` & slw) const [inline], [protected], [inherited]

**0.15.320.2.6 `canBePurgedByBounds()`** template<typename Settings>  
bool `smrat::cad::BaseProjection< Settings >`::`canBePurgedByBounds` (  
    const `UPoly` & p) const [inline], [protected], [inherited]

Checks whether a polynomial can safely be ignored due to the bounds.

**0.15.320.2.7 `dim()`** template<typename Settings>  
std::size\_t `smrat::cad::BaseProjection< Settings >`::`dim` () const [inline], [inherited]

Returns the dimension of the projection.

**0.15.320.2.8 `empty() [1/2]`** template<typename Settings>  
virtual bool `smrat::cad::BaseProjection< Settings >`::`empty` () [inline], [virtual], [inherited]

**0.15.320.2.9 `empty() [2/2]`** template<typename Settings>  
virtual bool `smrat::cad::BaseProjection< Settings >`::`empty` (  
    std::size\_t level) const [pure virtual], [inherited]

Implemented in `smrat::qe::cad::Projection< Settings >`, `smrat::cad::Projection< Incrementality::NONE, Backtracking::UNORDERED, Settings >`, `smrat::cad::Projection< Incrementality::NONE, Backtracking::ORDERED, Settings >`, `smrat::cad::ModelBasedProjection< Incrementality::NONE, Backtracking::HIDE, Settings >`, `smrat::cad::Projection< Incrementality::FULL, BT, Settings >`, and `smrat::cad::Projection< Incrementality::FULL, Backtracking::HIDE, Settings >`.

**0.15.320.2.10 `exportAsDot()`** template<typename Settings>  
virtual void `smrat::cad::BaseProjection< Settings >`::`exportAsDot` (  
    std::ostream & ) const [inline], [virtual], [inherited]

Reimplemented in `smrat::cad::Projection< Incrementality::FULL, BT, Settings >`, and `smrat::cad::Projection< Incrementality::FULL, Backtracking::HIDE, Settings >`.

**0.15.320.2.11 `freeID()`** template<typename Settings>  
void `smrat::cad::BaseProjection< Settings >`::`freeID` (  
    std::size\_t level,  
    std::size\_t id) [inline], [protected], [inherited]

Frees a currently used polynomial id for the given level.

**0.15.320.2.12 `getID()`** template<typename Settings>  
std::size\_t `smrat::cad::BaseProjection< Settings >`::`getID` (  
    std::size\_t level) [inline], [protected], [inherited]

Returns a fresh polynomial id for the given level.

**0.15.320.2.13 `getOrigin()`** template<typename Settings >  
 virtual `Origin smtrat::cad::BaseProjection< Settings >::getOrigin (`  
 `std::size_t level,`  
 `std::size_t id ) const [inline], [virtual], [inherited]`  
 Reimplemented in `smtrat::cad::Projection< Incrementality::FULL, BT, Settings >`.

**0.15.320.2.14 `getPolyForLifting()`** template<typename Settings >  
`OptionalID smtrat::cad::BaseProjection< Settings >::getPolyForLifting (`  
 `std::size_t level,`  
 `SampleLiftedWith & slw ) [inline], [inherited]`  
 Get a polynomial from this level suited for lifting.

**0.15.320.2.15 `getPolynomialById()`** template<typename Settings >  
 virtual const `UPoly& smtrat::cad::BaseProjection< Settings >::getPolynomialById (`  
 `std::size_t level,`  
 `std::size_t id ) const [pure virtual], [inherited]`

Retrieves a polynomial from its id.

Implemented in `smtrat::qe::cad::Projection< Settings >`, `smtrat::cad::Projection< Incrementality::NONE, Backtracking::UNORDERED, smtrat::cad::Projection< Incrementality::NONE, Backtracking::ORDERED, Settings >`, `smtrat::cad::ModelBasedProjection< Incrementality::SIMPLE, BT, Settings >`, `smtrat::cad::Projection< Incrementality::FULL, BT, Settings >`, and `smtrat::cad::Projection< Incrementality::FULL, Backtracking::HIDE, Settings >`.

**0.15.320.2.16 `hasPolynomialById()`** template<typename Settings >  
 virtual bool `smtrat::cad::BaseProjection< Settings >::hasPolynomialById (`  
 `std::size_t level,`  
 `std::size_t id ) const [pure virtual], [inherited]`

Implemented in `smtrat::qe::cad::Projection< Settings >`, `smtrat::cad::Projection< Incrementality::NONE, Backtracking::UNORDERED, smtrat::cad::Projection< Incrementality::NONE, Backtracking::ORDERED, Settings >`, `smtrat::cad::ModelBasedProjection< Incrementality::SIMPLE, BT, Settings >`, `smtrat::cad::Projection< Incrementality::FULL, BT, Settings >`, and `smtrat::cad::Projection< Incrementality::FULL, Backtracking::HIDE, Settings >`.

**0.15.320.2.17 `isPurged()`** template<typename Settings >  
 bool `smtrat::cad::BaseProjection< Settings >::isPurged (`  
 `std::size_t level,`  
 `std::size_t id ) [inline], [protected], [inherited]`

**0.15.320.2.18 `removePolynomial()` [1/2]** template<typename Settings >  
 void `smtrat::cad::BaseProjection< Settings >::removePolynomial (`  
 `const Poly & p,`  
 `std::size_t cid,`  
 `bool isBound ) [inline], [inherited]`

Removes the given polynomial from the projection. Converts to a UPoly and calls the appropriate overload.

**0.15.320.2.19 `removePolynomial()` [2/2]** template<typename Settings >  
 virtual void `smtrat::cad::BaseProjection< Settings >::removePolynomial (`  
 `const UPoly & p,`  
 `std::size_t cid,`  
 `bool isBound ) [pure virtual], [inherited]`

Removes the given polynomial from the projection.

Implemented in `smtrat::cad::Projection< Incrementality::NONE, Backtracking::ORDERED, Settings >`, `smtrat::cad::ModelBasedProjection< Incrementality::SIMPLE, BT, Settings >`, `smtrat::cad::Projection< Incrementality::FULL, BT, Settings >`, `smtrat::cad::Projection< Incrementality::FULL, Backtracking::HIDE, Settings >`, `smtrat::cad::Projection< Incrementality::SIMPLE, BT, Settings >`, and `smtrat::cad::Projection< Incrementality::NONE, Backtracking::HIDE, Settings >`.

**0.15.320.2.20 `reset()`** template<typename Settings >  
void `smtrat::cad::BaseProjection< Settings >::reset ( )` [inline], [inherited]  
Resets all datastructures, use the given variables from now on.

**0.15.320.2.21 `setRemoveCallback()`** template<typename Settings >  
template<typename F >  
void `smtrat::cad::BaseProjection< Settings >::setRemoveCallback (`  
    `F && f )` [inline], [inherited]  
Sets a callback that is called whenever polynomials are removed.

**0.15.320.2.22 `size() [1/2]`** template<typename Settings >  
`std::size_t smtrat::cad::BaseProjection< Settings >::size ( ) const` [inline], [inherited]

**0.15.320.2.23 `size() [2/2]`** template<typename Settings >  
virtual `std::size_t smtrat::cad::BaseProjection< Settings >::size (`  
    `std::size_t level ) const` [pure virtual], [inherited]

Implemented in `smtrat::qe::cad::Projection< Settings >`, `smtrat::cad::Projection< Incrementality::NONE, Backtracking::UNORDERED >`, `smtrat::cad::Projection< Incrementality::NONE, Backtracking::ORDERED, Settings >`, `smtrat::cad::ModelBasedProjection< Incrementality::INCREMENTAL, Backtracking::UNORDERED >`, `smtrat::cad::Projection< Incrementality::FULL, BT, Settings >`, and `smtrat::cad::Projection< Incrementality::FULL, Backtracking::HIDDEN >`.

**0.15.320.2.24 `var()`** template<typename Settings >  
carl::Variable `smtrat::cad::BaseProjection< Settings >::var (`  
    `std::size_t level ) const` [inline], [protected], [inherited]  
Returns the variable that corresponds to the given level, that is the variable eliminated in this level.

**0.15.320.2.25 `vars()`** template<typename Settings >  
const auto& `smtrat::cad::BaseProjection< Settings >::vars ( ) const` [inline], [inherited]  
Returns the variables used for projection.

### 0.15.320.3 Field Documentation

**0.15.320.3.1 `mConstraints`** template<typename Settings >  
const `Constraints& smtrat::cad::BaseProjection< Settings >::mConstraints` [protected], [inherited]

**0.15.320.3.2 `mInfo`** template<typename Settings >  
`ProjectionInformation smtrat::cad::BaseProjection< Settings >::mInfo` [protected], [inherited]  
Additional info on projection, projection levels and projection polynomials.

**0.15.320.3.3 `mLiftingQueues`** template<typename Settings >  
`std::vector<PolynomialLiftingQueue<BaseProjection> > smtrat::cad::BaseProjection< Settings >::mLiftingQueues` [protected], [inherited]  
List of lifting queues that can be used for incremental projection.

**0.15.320.3.4 `mOperator`** template<typename Settings >  
`ProjectionOperator smtrat::cad::BaseProjection< Settings >::mOperator` [protected], [inherited]  
The projection operator.

**0.15.320.3.5 mRemoveCallback** template<typename Settings >  
 std::function<void(std::size\_t, const SampleLiftedWith&) > smtrat::cad::BaseProjection< Settings >::mRemoveCallback [protected], [inherited]  
 Callback to be called when polynomials are removed. The arguments are the projection level and a bitset that indicate which polynomials were removed in this level.

### 0.15.321 smtrat::cad::ModelBasedProjection< Incrementality::NONE, Backtracking::ORDERED, Settings > Class Template Reference

This class implements a projection that supports no incrementality and expects backtracking to be in order.  
`#include <Projection_Model.h>`

#### 0.15.321.1 Detailed Description

```
template<typename Settings>
class smrat::cad::ModelBasedProjection< Incrementality::NONE, Backtracking::ORDERED, Settings >
```

This class implements a projection that supports no incrementality and expects backtracking to be in order.  
It is based on the following data structures:

- `mPolynomialIDs`: maps polynomials to a (per level) unique id
- `mPolynomials`: stores polynomials as a list (per level) with their origin

The origin of a polynomial in level zero is the id of the corresponding constraint. For all other levels, it is the id of some polynomial from level zero such that the polynomial must be removed if the origin is removed. For a single projection operation, the resulting origin is the largest of the participating polynomials. If a polynomial is derived from multiple projection operations, the origin is the earliest and thus smallest, at least for this non-incremental setting.

#### 0.15.321.2 Constructor & Destructor Documentation

```
0.15.321.2.1 ModelBasedProjection() template<typename Settings >
smrat::cad::ModelBasedProjection< Incrementality::NONE, Backtracking::ORDERED, Settings >::
::ModelBasedProjection (
 const Constraints & c,
 const Model & model) [inline]
```

### 0.15.321.3 Member Function Documentation

**0.15.321.3.1 addEqConstraint() [1/2]** template<typename Settings >
carl::Bitset smrat::cad::BaseProjection< Settings >::addEqConstraint (
 const Poly & p,
 std::size\_t cid,
 bool isBound ) [inline], [inherited]

Adds the given polynomial of an equational constraint to the projection. Converts to a UPoly and calls the appropriate overload.

**0.15.321.3.2 addEqConstraint() [2/2]** template<typename Settings >
virtual carl::Bitset smrat::cad::BaseProjection< Settings >::addEqConstraint (
 const UPoly & p,
 std::size\_t cid,
 bool isBound ) [inline], [virtual], [inherited]

Adds the given polynomial of an equational constraint to the projection.

Reimplemented in [smrat::cad::Projection< Incrementality::FULL, Backtracking::HIDE, Settings >](#).

**0.15.321.3.3 addPolynomial() [1/2]** template<typename Settings >
carl::Bitset smrat::cad::BaseProjection< Settings >::addPolynomial (
 const Poly & p,
 std::size\_t cid,
 bool isBound ) [inline], [inherited]

Adds the given polynomial to the projection. Converts to a UPoly and calls the appropriate overload.

**0.15.321.3.4 addPolynomial() [2/2]** template<typename Settings >
carl::Bitset smrat::cad::ModelBasedProjection< Incrementality::NONE, Backtracking::ORDERED,
Settings >::addPolynomial (
 const UPoly & p,
 std::size\_t cid,
 bool ) [inline], [override], [virtual]

Adds the given polynomial to the projection with the given constraint id as origin.

Asserts that the main variable of the polynomial is the first variable.

Implements [smrat::cad::BaseProjection< Settings >](#).

**0.15.321.3.5 callRemoveCallback()** template<typename Settings >
void smrat::cad::BaseProjection< Settings >::callRemoveCallback (
 std::size\_t level,
 const SampleLiftedWith & slw ) const [inline], [protected], [inherited]

**0.15.321.3.6 canBePurgedByBounds()** template<typename Settings >
bool smrat::cad::BaseProjection< Settings >::canBePurgedByBounds (
 const UPoly & p ) const [inline], [protected], [inherited]

Checks whether a polynomial can safely be ignored due to the bounds.

**0.15.321.3.7 dim() [1/2]** template<typename Settings >  
std::size\_t smtrat::cad::BaseProjection< Settings >::dim () const [inline], [inherited]  
Returns the dimension of the projection.

**0.15.321.3.8 dim() [2/2]** template<typename Settings >  
std::size\_t smtrat::cad::BaseProjection< Settings >::dim [inline]  
Returns the dimension of the projection.

**0.15.321.3.9 empty() [1/2]** template<typename Settings >  
virtual bool smtrat::cad::BaseProjection< Settings >::empty () [inline], [virtual], [inherited]

**0.15.321.3.10 empty() [2/2]** template<typename Settings >  
bool smtrat::cad::ModelBasedProjection< Incrementality::NONE, Backtracking::ORDERED, Settings >::empty (  
 std::size\_t level ) const [inline], [override], [virtual]

Returns whether the number of polynomials in this level is zero.

Implements smtrat::cad::BaseProjection< Settings >.

**0.15.321.3.11 exportAsDot()** template<typename Settings >  
virtual void smtrat::cad::BaseProjection< Settings >::exportAsDot (

std::ostream & ) const [inline], [virtual], [inherited]

Reimplemented in smtrat::cad::Projection< Incrementality::FULL, BT, Settings >, and smtrat::cad::Projection< Incrementality::FULL,

**0.15.321.3.12 freeID()** template<typename Settings >  
void smtrat::cad::BaseProjection< Settings >::freeID (

std::size\_t level,

std::size\_t id ) [inline], [protected], [inherited]

Frees a currently used polynomial id for the given level.

**0.15.321.3.13 getID()** template<typename Settings >  
std::size\_t smtrat::cad::BaseProjection< Settings >::getID (

std::size\_t level ) [inline], [protected], [inherited]

Returns a fresh polynomial id for the given level.

**0.15.321.3.14 getOrigin()** template<typename Settings >  
virtual Origin smtrat::cad::BaseProjection< Settings >::getOrigin (

std::size\_t level,

std::size\_t id ) const [inline], [virtual], [inherited]

Reimplemented in smtrat::cad::Projection< Incrementality::FULL, BT, Settings >.

**0.15.321.3.15 getPolyForLifting()** template<typename Settings >  
OptionalID smtrat::cad::BaseProjection< Settings >::getPolyForLifting (

std::size\_t level,

SampleLiftedWith & slw ) [inline], [inherited]

Get a polynomial from this level suited for lifting.

**0.15.321.3.16 `getPolynomialById()`** template<typename Settings >  
 const UPoly& smtrat::cad::ModelBasedProjection< Incrementality::NONE, Backtracking::ORDERED, Settings >::getPolynomialById ( std::size\_t level, std::size\_t id ) const [inline], [override], [virtual]  
 Get the polynomial from this level with the given id.  
 Implements smtrat::cad::BaseProjection< Settings >.

**0.15.321.3.17 `hasPolynomialById()`** template<typename Settings >  
 bool smtrat::cad::ModelBasedProjection< Incrementality::NONE, Backtracking::ORDERED, Settings >::hasPolynomialById ( std::size\_t level, std::size\_t id ) const [inline], [override], [virtual]  
 Implements smtrat::cad::BaseProjection< Settings >.

**0.15.321.3.18 `isPurged()`** template<typename Settings >  
 bool smtrat::cad::BaseProjection< Settings >::isPurged ( std::size\_t level, std::size\_t id ) [inline], [protected], [inherited]

**0.15.321.3.19 `projectNewPolynomial()`** template<typename Settings >  
 carl::Bitset smtrat::cad::ModelBasedProjection< Incrementality::NONE, Backtracking::ORDERED, Settings >::projectNewPolynomial ( const ConstraintSelection & = carl::Bitset(true) ) [inline]  
 Returns false, as the projection is not incremental.

**0.15.321.3.20 `projectNextLevel()`** template<typename Settings >  
 void smtrat::cad::ModelBasedProjection< Incrementality::NONE, Backtracking::ORDERED, Settings >::projectNextLevel ( std::size\_t level ) [inline]  
 Performs the projection model-based for one level, using only polynomials with closest roots.

**0.15.321.3.21 `removePolynomial()` [1/2]** template<typename Settings >  
 void smtrat::cad::BaseProjection< Settings >::removePolynomial ( const Poly & p, std::size\_t cid, bool isBound ) [inline], [inherited]

Removes the given polynomial from the projection. Converts to a UPoly and calls the appropriate overload.

**0.15.321.3.22 `removePolynomial()` [2/2]** template<typename Settings >  
 void smtrat::cad::ModelBasedProjection< Incrementality::NONE, Backtracking::ORDERED, Settings >::removePolynomial ( const UPoly & p, std::size\_t cid, bool ) [inline], [override], [virtual]

Removed the given polynomial from the projection.

Asserts that this polynomial was the one added last and has the given constraint id as origin. Calls the callback function for every level with a mask designating the polynomials removed from this level.

Implements smtrat::cad::BaseProjection< Settings >.

**0.15.321.3.23 `reset()`** template<typename Settings >  
void smrat::cad::ModelBasedProjection< Incrementality::NONE, Backtracking::ORDERED, Settings >::reset () [inline]  
Resets all datastructures, use the given variables from now on.

**0.15.321.3.24 `setRemoveCallback()`** template<typename Settings >  
template<typename F >  
void smrat::cad::BaseProjection< Settings >::setRemoveCallback (  
 F && f ) [inline], [inherited]  
Sets a callback that is called whenever polynomials are removed.

**0.15.321.3.25 `size() [1/4]`** template<typename Settings >  
std::size\_t smrat::cad::BaseProjection< Settings >::size () const [inline], [inherited]

**0.15.321.3.26 `size() [2/4]`** template<typename Settings >  
std::size\_t smrat::cad::BaseProjection< Settings >::size (  
 void ) [inline]

**0.15.321.3.27 `size() [3/4]`** template<typename Settings >  
std::size\_t smrat::cad::ModelBasedProjection< Incrementality::NONE, Backtracking::ORDERED, Settings >::size (  
 std::size\_t level ) const [inline], [override], [virtual]  
Returns the number of polynomials in this level.  
Implements `smrat::cad::BaseProjection< Settings >`.

**0.15.321.3.28 `size() [4/4]`** template<typename Settings >  
virtual std::size\_t smrat::cad::BaseProjection< Settings >::size (  
 void )

**0.15.321.3.29 `var()`** template<typename Settings >  
carl::Variable smrat::cad::BaseProjection< Settings >::var (  
 std::size\_t level ) const [inline], [protected], [inherited]  
Returns the variable that corresponds to the given level, that is the variable eliminated in this level.

**0.15.321.3.30 `vars()`** template<typename Settings >  
const auto& smrat::cad::BaseProjection< Settings >::vars () const [inline], [inherited]  
Returns the variables used for projection.

## 0.15.321.4 Friends And Related Function Documentation

**0.15.321.4.1 `operator<<`** template<typename Settings >  
template<typename S >  
std::ostream& operator<< (  
 std::ostream & os,  
 const ModelBasedProjection< Incrementality::NONE, Backtracking::ORDERED, S > & p  
) [friend]

### 0.15.321.5 Field Documentation

**0.15.321.5.1 mConstraints** template<typename Settings >  
 const [Constraints](#)& [smtrat::cad::BaseProjection](#)< Settings >::mConstraints [protected], [inherited]

**0.15.321.5.2 mInfo** template<typename Settings >  
[ProjectionInformation](#) [smtrat::cad::BaseProjection](#)< Settings >::mInfo [protected], [inherited]  
 Additional info on projection, projection levels and projection polynomials.

**0.15.321.5.3 mRemoveCallback** template<typename Settings >  
 std::function<void(std::size\_t, const [SampleLiftedWith](#)&)> [smtrat::cad::BaseProjection](#)< Settings >::mRemoveCallback [protected], [inherited]  
 Callback to be called when polynomials are removed. The arguments are the projection level and a bitset that indicate which polynomials were removed in this level.

## 0.15.322 smtrat::Module Class Reference

A base class for all kind of theory solving methods.

```
#include <Module.h>
```

### Data Structures

- struct [Lemma](#)
- struct [ModuleStatistics](#)
- struct [TheoryPropagation](#)

### Public Types

*Prints all assignments of this module satisfying its received formula if it satisfiable and this module could find an assignment.*

### Static Public Member Functions

- static void **freeSplittingVariable** (const FormulaT &\_splittingVariable)

### Static Public Attributes

- static size\_t **mNumOfBranchVarsToStore** = 5  
*The number of different variables to consider for a probable infinite loop of branchings.*
- static std::vector< Branching > **mLastBranches** = std::vector<Branching>(mNumOfBranchVarsToStore, Branching(typename Poly::PolyType(), 0))  
*Stores the last branches in a cycle buffer.*
- static size\_t **mFirstPosInLastBranches** = 0  
*The beginning of the cyclic buffer storing the last branches.*
- static std::vector< FormulaT > **mOldSplittingVariables**  
*Reusable splitting variables.*

### Protected Member Functions

- virtual bool **informCore** (const FormulaT &\_constraint)  
*Informs the module about the given constraint.*
- virtual void **deinformCore** (const FormulaT &\_constraint)  
*The inverse of informing about a constraint.*
- virtual bool **addCore** (ModuleInput::const\_iterator formula)  
*The module has to take the given sub-formula of the received formula into account.*
- virtual **Answer checkCore** ()  
*Checks the received formula for consistency.*
- virtual void **removeCore** (ModuleInput::const\_iterator formula)  
*Removes everything related to the given sub-formula of the received formula.*
- bool **anAnswerFound** () const  
*Checks for all antecedent modules and those which run in parallel with the same antecedent modules, whether one of them has determined a result.*
- void **clearModel** () const  
*Clears the assignment, if any was found.*
- void **clearModels** () const  
*Clears all assignments, if any was found.*
- void **cleanModel** () const

- Substitutes variable occurrences by its model value in the model values of other variables.*
- `ModuleInput::iterator passedFormulaBegin ()`
  - `ModuleInput::iterator passedFormulaEnd ()`
  - `void addOrigin (ModuleInput::iterator _formula, const FormulaT &_origin)`

*Adds the given set of formulas in the received formula to the origins of the given passed formula.*
  - `const FormulaT & getOrigins (ModuleInput::const_iterator _formula) const`

*Gets the origins of the passed formula at the given position.*
  - `std::pair< ModuleInput::iterator, bool > removeOrigin (ModuleInput::iterator _formula, const FormulaT &_origin)`
  - `std::pair< ModuleInput::iterator, bool > removeOrigins (ModuleInput::iterator _formula, const std::shared_ptr< std::vector< FormulaT >> &_origins)`
  - `void informBackends (const FormulaT &_constraint)`

*Informs all backends of this module about the given constraint.*
  - `virtual void addConstraintToInform (const FormulaT &_constraint)`

*Adds a constraint to the collection of constraints of this module, which are informed to a freshly generated backend.*
  - `std::pair< ModuleInput::iterator, bool > addReceivedSubformulaToPassedFormula (ModuleInput::const_iterator _subformula)`

*Copies the given sub-formula of the received formula to the passed formula.*
  - `bool originInReceivedFormula (const FormulaT &_origin) const`
  - `std::pair< ModuleInput::iterator, bool > addSubformulaToPassedFormula (const FormulaT &_formula)`

*Adds the given formula to the passed formula with no origin.*
  - `std::pair< ModuleInput::iterator, bool > addSubformulaToPassedFormula (const FormulaT &_formula, const std::shared_ptr< std::vector< FormulaT >> &_origins)`

*Adds the given formula to the passed formula.*
  - `std::pair< ModuleInput::iterator, bool > addSubformulaToPassedFormula (const FormulaT &_formula, const FormulaT &_origin)`

*Adds the given formula to the passed formula.*
  - `void generateTrivialInfeasibleSubset ()`

*Stores the trivial infeasible subset being the set of received formulas.*
  - `void receivedFormulasAsInfeasibleSubset (ModuleInput::const_iterator _subformula)`

*Stores an infeasible subset consisting only of the given received formula.*
  - `std::vector< FormulaT >::const_iterator findBestOrigin (const std::vector< FormulaT > &_origins) const`
  - `void getOrigins (const FormulaT &_formula, FormulasT &_origins) const`
  - `void getOrigins (const FormulaT &_formula, FormulaSetT &_origins) const`
  - `void getInfeasibleSubsets ()`

*Copies the infeasible subsets of the passed formula.*
  - `const Model & backendsModel () const`

*Stores the model of a backend which determined satisfiability of the passed formula in the model of this module.*
  - `void getBackendsModel () const`
  - `void getBackendsAllModels () const`

*Stores all models of a backend in the list of all models of this module.*
  - `virtual Answer runBackends (bool _final, bool _full, carl::Variable _objective)`

*Runs the backend solvers on the passed formula.*
  - `virtual Answer runBackends ()`
  - `virtual ModuleInput::iterator eraseSubformulaFromPassedFormula (ModuleInput::iterator _subformula, bool _ignoreOrigins=false)`

*Removes everything related to the sub-formula to remove from the passed formula in the backends of this module.*
  - `void clearPassedFormula ()`
  - `std::vector< FormulaSetT > getInfeasibleSubsets (const Module &backend) const`

*Get the infeasible subsets the given backend provides.*
  - `std::vector< FormulaT > merge (const std::vector< FormulaT > &, const std::vector< FormulaT > &) const`

*Merges the two vectors of sets into the first one.*

- size\_t `determine_smallest_origin` (const std::vector< `FormulaT` > &origins) const
- bool `probablyLooping` (const typename `Poly::PolyType` &`_branchingPolynomial`, const `Rational` &`_branchingValue`) const
 

*Checks whether given the current branching value and branching variable/polynomial it is (highly) probable that this branching is part of an infinite loop of branchings.*
- bool `branchAt` (const `Poly` &`_polynomial`, bool `_integral`, const `Rational` &`_value`, std::vector< `FormulaT` > &&`_premise`, bool `_leftCaseWeak=true`, bool `_preferLeftCase=true`, bool `_useReceivedFormulaAsPremise=false`)
 

*Adds a lemmas which provoke a branching for the given variable at the given value, if this module returns Unknown and there exists a preceding `SATModule`.*
- bool `branchAt` (const `Poly` &`_polynomial`, bool `_integral`, const `Rational` &`_value`, bool `_leftCaseWeak=true`, bool `_preferLeftCase=true`, bool `_useReceivedFormulaAsPremise=false`, const std::vector< `FormulaT` > &`_premise=std::vector< FormulaT >()`)
 

*Adds a lemmas which provoke a branching for the given variable at the given value, if this module returns Unknown and there exists a preceding `SATModule`.*
- bool `branchAt` (carl::Variable::Arg `_var`, const `Rational` &`_value`, std::vector< `FormulaT` > &&`_premise`, bool `_leftCaseWeak=true`, bool `_preferLeftCase=true`, bool `_useReceivedFormulaAsPremise=false`)
 

*Adds a lemmas which provoke a branching for the given variable at the given value, if this module returns Unknown and there exists a preceding `SATModule`.*
- bool `branchAt` (carl::Variable::Arg `_var`, const `Rational` &`_value`, bool `_leftCaseWeak=true`, bool `_preferLeftCase=true`, bool `_useReceivedFormulaAsPremise=false`, const std::vector< `FormulaT` > &`_premise=std::vector< FormulaT >()`)
 

*Adds a lemmas which provoke a branching for the given variable at the given value, if this module returns Unknown and there exists a preceding `SATModule`.*
- void `splitUnequalConstraint` (const `FormulaT` &)
 

*Adds the following lemmas for the given constraint `p!=0`.*
- unsigned `checkModel` () const
- void `addInformationRelevantFormula` (const `FormulaT` &`formula`)
 

*Adds a formula to the `InformationRelevantFormula`.*
- const std::set< `FormulaT` > & `getInformationRelevantFormulas` ()
 

*Gets all `InformationRelevantFormulas`.*
- bool `isLemmaLevel` (`LemmaLevel` `level`)
 

*Checks if current lemma level is greater or equal to given level.*

## Static Protected Member Functions

- static bool `modelsDisjoint` (const `Model` &`_modelA`, const `Model` &`_modelB`)
 

*Checks whether there is no variable assigned by both models.*

## Protected Attributes

- std::vector< `FormulaSetT` > `mInfeasibleSubsets`

*Stores the infeasible subsets.*
- `Manager` \*const `mpManager`

*A reference to the manager.*
- `Model` `mModel`

*Stores the assignment of the current satisfiable result, if existent.*
- std::vector< `Model` > `mAllModels`

*Stores all satisfying assignments.*
- bool `mModelComputed`

*True, if the model has already been computed.*
- bool `mFinalCheck`

*true, if the check procedure should perform a final check which especially means not to postpone splitting decisions*
- bool `mFullCheck`

*false, if this module should avoid too expensive procedures and rather return unknown instead.*
- carl::Variable `mObjectiveVariable`

*Objective variable to be minimized. If set to NO\_VARIABLE, a normal sat check should be performed.*
- std::vector< `TheoryPropagation` > `mTheoryPropagations`
- std::atomic< `Answer` > `mSolverState`

*States whether the received formula is known to be satisfiable or unsatisfiable otherwise it is set to unknown.*

- `std::atomic_bool * mBackendsFoundAnswer`  
*This flag is passed to any backend and if it determines an answer to a prior check call, this flag is fired.*
- `Conditionals mFoundAnswer`  
*Vector of Booleans: If any of them is true, we have to terminate a running check procedure.*
- `std::vector< Module * > mUsedBackends`  
*The backends of this module which are currently used (conditions to use this module are fulfilled for the passed formula).*
- `std::vector< Module * > mAllBackends`  
*The backends of this module which have been used.*
- `std::vector< Lemma > mLemmas`  
*Stores the lemmas being valid formulas this module or its backends made.*
- `ModuleInput::iterator mFirstSubformulaToPass`  
*Stores the position of the first sub-formula in the passed formula, which has not yet been considered for a consistency check of the backends.*
- `carl::FastSet< FormulaT > mConstraintsToInform`  
*Stores the constraints which the backends must be informed about.*
- `carl::FastSet< FormulaT > mInformedConstraints`  
*Stores the position of the first constraint of which no backend has been informed about.*
- `ModuleInput::const_iterator mFirstUncheckedReceivedSubformula`  
*Stores the position of the first (by this module) unchecked sub-formula of the received formula.*
- `unsigned mSmallerMusesCheckCounter`  
*Counter used for the generation of the smt2 files to check for smaller muses.*
- `std::vector< std::size_t > mVariableCounters`  
*Maps variables to the number of their occurrences.*

### 0.15.322.1 Detailed Description

A base class for all kind of theory solving methods.

### 0.15.322.2 Member Enumeration Documentation

#### 0.15.322.2.1 LemmaType `enum smtrat::Module::LemmaType : unsigned [strong]`

Enumerator

|           |  |
|-----------|--|
| NORMAL    |  |
| PERMANENT |  |

### 0.15.322.3 Constructor & Destructor Documentation

#### 0.15.322.3.1 Module() `smtrat::Module::Module (`

```
 const ModuleInput * _formula,
 Conditionals & _foundAnswer,
 Manager * _manager = nullptr,
 std::string module_name = "Module")
```

Constructs a module.

#### Parameters

|                       |                                                             |
|-----------------------|-------------------------------------------------------------|
| <code>_formula</code> | The formula passed to this module, called received formula. |
|-----------------------|-------------------------------------------------------------|

**Parameters**

|                           |                                                                                             |
|---------------------------|---------------------------------------------------------------------------------------------|
| <code>_foundAnswer</code> | Vector of Booleans: If any of them is true, we have to terminate a running check procedure. |
| <code>_manager</code>     | A reference to the manager of the solver using this module.                                 |
| <code>module_name</code>  | Name of this module as string for printing.                                                 |

**0.15.322.3.2 ~Module()** `smtrat::Module::~Module () [virtual]`  
Destructs a module.

**0.15.322.4 Member Function Documentation**

**0.15.322.4.1 add()** `bool smtrat::Module::add (ModuleInput::const_iterator _subformula )`

The module has to take the given sub-formula of the received formula into account.

**Parameters**

|                          |                                                    |
|--------------------------|----------------------------------------------------|
| <code>_subformula</code> | The sub-formula to take additionally into account. |
|--------------------------|----------------------------------------------------|

**Returns**

false, if it can be easily decided that this sub-formula causes a conflict with the already considered sub-formulas; true, otherwise.

**0.15.322.4.2 addConstraintToInform()** `void smtrat::Module::addConstraintToInform (const FormulaT & _constraint ) [protected], [virtual]`

Adds a constraint to the collection of constraints of this module, which are informed to a freshly generated backend.

**Parameters**

|                          |                        |
|--------------------------|------------------------|
| <code>_constraint</code> | The constraint to add. |
|--------------------------|------------------------|

Reimplemented in [smtrat::SATModule< Settings >](#).

**0.15.322.4.3 addCore()** `virtual bool smtrat::Module::addCore (ModuleInput::const_iterator formula ) [inline], [protected], [virtual]`

The module has to take the given sub-formula of the received formula into account.

**Parameters**

|                      |                                                    |
|----------------------|----------------------------------------------------|
| <code>formula</code> | The sub-formula to take additionally into account. |
|----------------------|----------------------------------------------------|

**Returns**

false, if it can be easily decided that this sub-formula causes a conflict with the already considered sub-formulas; true, otherwise.

Reimplemented in [smtrat::VSModule< Settings >](#), [smtrat::SATModule< Settings >](#), [smtrat::PFEModule< Settings >](#), [smtrat::ICPModule< Settings >](#), [smtrat::ICPModule< ICPSettings4 >](#), [smtrat::ICPModule< ICPSettings1 >](#),

`smrat::UnionFindModule< Settings >, smrat::UFCegarModule< Settings >, smrat::STropModule< Settings >, smrat::PBPPModule< Settings >, smrat::PBGaussModule< Settings >, smrat::NRAILModule< Settings >, smrat::NewCoveringModule< Settings >, smrat::NewCADModule< Settings >, smrat::LRAModule< Settings >, smrat::LRAModule< LRASettingsICP >, smrat::LRAModule< LRASettings1 >, smrat::IntEqModule< Settings >, smrat::IntBlastModule< Settings >, smrat::IncWidthModule< Settings >, smrat::ICEModule< Settings >, smrat::FPPModule< Settings >, smrat::FouMoModule< Settings >, smrat::EQModule< Settings >, smrat::CurryModule< Settings >, smrat::CubeLIAModule< Settings >, smrat::CSplitModule< Settings >, smrat::BVMModule< Settings >, and smrat::GBModule< Settings >.`

#### 0.15.322.4.4 `addInformationRelevantFormula()` `void smrat::Module::addInformationRelevantFormula(`

`const FormulaT & formula ) [protected]`

Adds a formula to the InformationRelevantFormula.

##### Parameters

|                      |                |
|----------------------|----------------|
| <code>formula</code> | Formula to add |
|----------------------|----------------|

#### 0.15.322.4.5 `addLemma()` `void smrat::Module::addLemma(`

`const FormulaT & _lemma,`

`const LemmaType & _lt = LemmaType::NORMAL,`

`const FormulaT & _preferredFormula = FormulaT( carl::FormulaType::TRUE ) ) [inline]`

Stores a lemma being a valid formula.

##### Parameters

|                                |                                                                       |
|--------------------------------|-----------------------------------------------------------------------|
| <code>_lemma</code>            | The eduction/lemma to store.                                          |
| <code>_lt</code>               | The type of the lemma.                                                |
| <code>_preferredFormula</code> | Hint for the next decision, which formula should be assigned to true. |

#### 0.15.322.4.6 `addOrigin()` `void smrat::Module::addOrigin(`

`ModuleInput::iterator _formula,`

`const FormulaT & _origin ) [inline], [protected]`

Adds the given set of formulas in the received formula to the origins of the given passed formula.

##### Parameters

|                       |                                                           |
|-----------------------|-----------------------------------------------------------|
| <code>_formula</code> | The passed formula to set the origins for.                |
| <code>_origin</code>  | A set of formulas in the received formula of this module. |

#### 0.15.322.4.7 `addReceivedSubformulaToPassedFormula()` `std::pair<ModuleInput::iterator,bool>`

`smrat::Module::addReceivedSubformulaToPassedFormula(`

`ModuleInput::const_iterator _subformula ) [inline], [protected]`

Copies the given sub-formula of the received formula to the passed formula.

Note, that there is always a link between sub-formulas of the passed formulas to sub-formulas of the received formulas, which are responsible for its occurrence.

##### Parameters

|                          |                                                  |
|--------------------------|--------------------------------------------------|
| <code>_subformula</code> | The sub-formula of the received formula to copy. |
|--------------------------|--------------------------------------------------|

```
0.15.322.4.8 addSubformulaToPassedFormula() [1/3] std::pair<ModuleInput::iterator,bool> smtrat→
::Module::addSubformulaToPassedFormula (
 const FormulaT & _formula) [inline], [protected]
```

Adds the given formula to the passed formula with no origin.

Note that in the next call of this module's removeSubformula, all formulas in the passed formula without origins will be removed.

#### Parameters

|                 |                                           |
|-----------------|-------------------------------------------|
| <i>_formula</i> | The formula to add to the passed formula. |
|-----------------|-------------------------------------------|

#### Returns

A pair to the position where the formula to add has been inserted (or its first sub-formula which has not yet been in the passed formula, in case the formula to add is a conjunction), and a Boolean stating whether anything has been added to the passed formula.

```
0.15.322.4.9 addSubformulaToPassedFormula() [2/3] std::pair<ModuleInput::iterator,bool> smtrat→
::Module::addSubformulaToPassedFormula (
 const FormulaT & _formula,
 const FormulaT & _origin) [inline], [protected]
```

Adds the given formula to the passed formula.

#### Parameters

|                 |                                                                                                                           |
|-----------------|---------------------------------------------------------------------------------------------------------------------------|
| <i>_formula</i> | The formula to add to the passed formula.                                                                                 |
| <i>_origin</i>  | The sub-formula of the received formula being responsible for the occurrence of the formula to add to the passed formula. |

#### Returns

A pair to the position where the formula to add has been inserted (or its first sub-formula which has not yet been in the passed formula, in case the formula to add is a conjunction), and a Boolean stating whether anything has been added to the passed formula.

```
0.15.322.4.10 addSubformulaToPassedFormula() [3/3] std::pair<ModuleInput::iterator,bool>
smtrat::Module::addSubformulaToPassedFormula (
 const FormulaT & _formula,
 const std::shared_ptr< std::vector< FormulaT >> & _origins) [inline], [protected]
```

Adds the given formula to the passed formula.

#### Parameters

|                 |                                                                                                                                         |
|-----------------|-----------------------------------------------------------------------------------------------------------------------------------------|
| <i>_formula</i> | The formula to add to the passed formula.                                                                                               |
| <i>_origins</i> | The link of the formula to add to the passed formula to sub-formulas of the received formulas, which are responsible for its occurrence |

**Returns**

A pair to the position where the formula to add has been inserted (or its first sub-formula which has not yet been in the passed formula, in case the formula to add is a conjunction), and a Boolean stating whether anything has been added to the passed formula.

**0.15.322.4.11 allModels()** const std::vector<[Model](#)>& smtrat::Module::allModels () const [inline]**Returns**

All satisfying assignments, if existent.

**0.15.322.4.12 anAnswerFound()** bool smtrat::Module::anAnswerFound () const [inline], [protected]  
Checks for all antecedent modules and those which run in parallel with the same antecedent modules, whether one of them has determined a result.**Returns**

True, if one of them has determined a result.

**0.15.322.4.13 answerFound()** const [smtusat::Conditionals](#)& smtrat::Module::answerFound () const [inline]**Returns**

A vector of Booleans: If any of them is true, we have to terminate a running check procedure.

**0.15.322.4.14 backendsModel()** const [Model](#) & smtrat::Module::backendsModel () const [protected]  
Stores the model of a backend which determined satisfiability of the passed formula in the model of this module.**0.15.322.4.15 branchAt() [1/4]** bool smtrat::Module::branchAt ( carl::Variable::Arg \_var, const [Rational](#) & \_value, bool \_leftCaseWeak = true, bool \_preferLeftCase = true, bool \_useReceivedFormulaAsPremise = false, const std::vector< [FormulaT](#) > & \_premise = std::vector<[FormulaT](#)>() ) [inline], [protected]**0.15.322.4.16 branchAt() [2/4]** bool smtrat::Module::branchAt ( carl::Variable::Arg \_var, const [Rational](#) & \_value, std::vector< [FormulaT](#) > && \_premise, bool \_leftCaseWeak = true, bool \_preferLeftCase = true, bool \_useReceivedFormulaAsPremise = false ) [inline], [protected]

```
0.15.322.4.17 branchAt() [3/4] bool smtrat::Module::branchAt (
 const Poly & _polynomial,
 bool _integral,
 const Rational & _value,
 bool _leftCaseWeak = true,
 bool _preferLeftCase = true,
 bool _useReceivedFormulaAsPremise = false,
 const std::vector< FormulaT > & _premise = std::vector< FormulaT >()) [inline],
[protected]
```

```
0.15.322.4.18 branchAt() [4/4] bool smtrat::Module::branchAt (
 const Poly & _polynomial,
 bool _integral,
 const Rational & _value,
 std::vector< FormulaT > && _premise,
 bool _leftCaseWeak = true,
 bool _preferLeftCase = true,
 bool _useReceivedFormulaAsPremise = false) [protected]
```

Adds a lemmas which provoke a branching for the given variable at the given value, if this module returns Unknown and there exists a preceding [SATModule](#).

Note that the given value is rounded down and up, if the given variable is integer-valued.

#### Parameters

|                                           |                                                                                                                                                                                                                |
|-------------------------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>_polynomial</code>                  | The variable to branch for.                                                                                                                                                                                    |
| <code>_integral</code>                    | A flag being true, if all variables in the polynomial to branch for are integral.                                                                                                                              |
| <code>_value</code>                       | The value to branch at.                                                                                                                                                                                        |
| <code>_premise</code>                     | The sub-formulas of the received formula from which the branch is followed. Note, that a premise is not necessary, as every branch is a valid formula. But a premise can prevent from branching unnecessarily. |
| <code>_leftCaseWeak</code>                | true, if a branching in the form of (or ( $\leq p b$ ) ( $> p b$ )) is desired. false, if a branching in the form of (or ( $< p b$ ) ( $\geq p b$ )) is desired.                                               |
| <code>_preferLeftCase</code>              | true, if the left case (polynomial less(or equal) 0 shall be chosen first. false, otherwise.                                                                                                                   |
| <code>_useReceivedFormulaAsPremise</code> | true, if the whole received formula should be used as premise                                                                                                                                                  |

```
0.15.322.4.19 check() Answer smtrat::Module::check (
```

```
 bool _final = false,
 bool _full = true,
 carl::Variable _objective = carl::Variable::NO_VARIABLE) [virtual]
```

Checks the received formula for consistency.

Note, that this is an implementation of the satisfiability check of the conjunction of the so far received formulas, which does actually nothing but passing the problem to its backends. This implementation is only used internally and must be overwritten by any derived module.

#### Parameters

|                         |                                                                                                                                       |
|-------------------------|---------------------------------------------------------------------------------------------------------------------------------------|
| <code>_final</code>     | true, if this satisfiability check will be the last one (for a global sat-check), if its result is SAT                                |
| <code>_full</code>      | false, if this module should avoid too expensive procedures and rather return unknown instead.                                        |
| <code>_objective</code> | if not set to NO_VARIABLE, the module should find an assignment minimizing this objective variable; otherwise any assignment is good. |

**Returns**

True, if the received formula is satisfiable; False, if the received formula is not satisfiable; Unknown, otherwise.

Reimplemented in [smrat::PModule](#).

**0.15.322.4.20 checkCore()** [Answer](#) `smrat::Module::checkCore () [protected], [virtual]`

Checks the received formula for consistency.

Note, that this is an implementation of the satisfiability check of the conjunction of the so far received formulas, which does actually nothing but passing the problem to its backends. This implementation is only used internally and must be overwritten by any derived module.

**Returns**

True, if the received formula is satisfiable; False, if the received formula is not satisfiable; Unknown, otherwise.

Reimplemented in [smrat::VSModule< Settings >](#), [smrat::UnionFindModule< Settings >](#), [smrat::UFCegarModule< Settings >](#), [smrat::SymmetryModule< Settings >](#), [smrat::STropModule< Settings >](#), [smrat::SplitSOSModule< Settings >](#), [smrat::SATModule< Settings >](#), [smrat::PFEModule< Settings >](#), [smrat::PBPPModule< Settings >](#), [smrat::PBGaussModule< Settings >](#), [smrat::NRAILModule< Settings >](#), [smrat::NewCoveringModule< Settings >](#), [smrat::NewCADModule< Settings >](#), [smrat::MCBModule< Settings >](#), [smrat::LVEModule< Settings >](#), [smrat::LRAModule< Settings >](#), [smrat::LRAModule< LRASettings1 >](#), [smrat::IntEqModule< Settings >](#), [smrat::IntBlastModule< Settings >](#), [smrat::IncWidthModule< Settings >](#), [smrat::ICPModule< Settings >](#), [smrat::ICPModule< ICPSettings4 >](#), [smrat::ICPModule< ICPSettings1 >](#), [smrat::ICEModule< Settings >](#), [smrat::GBPPModule< Settings >](#), [smrat::GBModule< Settings >](#), [smrat::FPPModule< Settings >](#), [smrat::FouMoModule< Settings >](#), [smrat::ESModule< Settings >](#), [smrat::EQPreprocessingModule< Settings >](#), [smrat::EQModule< Settings >](#), [smrat::EMModule< Settings >](#), [smrat::CurryModule< Settings >](#), [smrat::CubeLIAModule< Settings >](#), [smrat::CSplitModule< Settings >](#), [smrat::CNFerModule](#), [smrat::BVMModule< Settings >](#), and [smrat::BEModule< Settings >](#).

**0.15.322.4.21 checkInfSubsetForMinimality()** `void smrat::Module::checkInfSubsetForMinimality (`

```
 std::vector< FormulaSetT >::const_iterator _infsSubset,
 const std::string & _filename = "smaller_muses",
 unsigned _maxSizeDifference = 1) const
```

Checks the given infeasible subset for minimality by storing all subsets of it, which have a smaller size which differs from the size of the infeasible subset not more than the given threshold.

**Parameters**

|                                 |                                                                                                        |
|---------------------------------|--------------------------------------------------------------------------------------------------------|
| <code>_infsSubset</code>        | The infeasible subset to check for minimality.                                                         |
| <code>_filename</code>          | The name of the file to store the infeasible subsets in order to be able to check their infeasibility. |
| <code>_maxSizeDifference</code> | The maximal difference between the sizes of the subsets compared to the size of the infeasible subset. |

**0.15.322.4.22 checkModel()** `unsigned smrat::Module::checkModel () const [protected]`**Returns**

false, if the current model of this module does not satisfy the current given formula; true, if it cannot be said whether the model satisfies the given formula.

**0.15.322.4.23 cleanModel()** `void smrat::Module::cleanModel () const [inline], [protected]`

Substitutes variable occurrences by its model value in the model values of other variables.

**0.15.322.4.24 `clearLemmas()`** `void smtrat::Module::clearLemmas () [inline]`  
 Deletes all yet found lemmas.

**0.15.322.4.25 `clearModel()`** `void smtrat::Module::clearModel () const [inline], [protected]`  
 Clears the assignment, if any was found.

**0.15.322.4.26 `clearModels()`** `void smtrat::Module::clearModels () const [inline], [protected]`  
 Clears all assignments, if any was found.

**0.15.322.4.27 `clearPassedFormula()`** `void smtrat::Module::clearPassedFormula () [protected]`

**0.15.322.4.28 `collectOrigins() [1/2]`** `void smtrat::Module::collectOrigins (`  
`const FormulaT & _formula,`  
`FormulaSetT & _origins ) const`

**0.15.322.4.29 `collectOrigins() [2/2]`** `void smtrat::Module::collectOrigins (`  
`const FormulaT & _formula,`  
`FormulasT & _origins ) const`

Collects the formulas in the given formula, which are part of the received formula.

If the given formula directly occurs in the received formula, it is inserted into the given set. Otherwise, the given formula must be of type AND and all its sub-formulas part of the received formula. Hence, they will be added to the given set.

#### Parameters

|                       |                                                                                                      |
|-----------------------|------------------------------------------------------------------------------------------------------|
| <code>_formula</code> | The formula from which to collect the formulas being sub-formulas of the received formula (origins). |
| <code>_origins</code> | The set in which to store the origins.                                                               |

**0.15.322.4.30 `collectTheoryPropagations()`** `void smtrat::Module::collectTheoryPropagations ()`

**0.15.322.4.31 `constraintsToInform()`** `const carl::FastSet<FormulaT>& smtrat::Module::constraintsToInform () const [inline]`

#### Returns

The constraints which the backends must be informed about.

**0.15.322.4.32 `currentlySatisfied()`** `virtual unsigned smtrat::Module::currentlySatisfied (`  
`const FormulaT & ) const [inline], [virtual]`

#### Returns

0, if the given formula is conflicted by the current model; 1, if the given formula is satisfied by the current model; 2, otherwise; 3, if we do not know anything (default)

Reimplemented in `smtrat::LRAModule< Settings >`, `smtrat::LRAModule< LRASettingsICP >`, and `smtrat::LRAModule< LRASettings >`

**0.15.322.4.33 currentlySatisfiedByBackend()** `unsigned smtrat::Module::currentlySatisfiedByBackend ( const FormulaT & _formula ) const`

**Returns**

0, if the given formula is conflicted by the current model; 1, if the given formula is satisfied by the current model; 2, otherwise 3, if we do not know anything (default)

**0.15.322.4.34 deinform()** `void smtrat::Module::deinform ( const FormulaT & _constraint )`

The inverse of informing about a constraint.

All data structures which were kept regarding this constraint are going to be removed. Note, that this makes only sense if it is not likely enough that a formula with this constraint must be solved again.

**Parameters**

|                          |                                                         |
|--------------------------|---------------------------------------------------------|
| <code>_constraint</code> | The constraint to remove from internal data structures. |
|--------------------------|---------------------------------------------------------|

**0.15.322.4.35 deinformCore()** `virtual void smtrat::Module::deinformCore ( const FormulaT & _constraint ) [inline], [protected], [virtual]`

The inverse of informing about a constraint.

All data structures which were kept regarding this constraint are going to be removed. Note, that this makes only sense if it is not likely enough that a formula with this constraint must be solved again.

**Parameters**

|                          |                                                         |
|--------------------------|---------------------------------------------------------|
| <code>_constraint</code> | The constraint to remove from internal data structures. |
|--------------------------|---------------------------------------------------------|

Reimplemented in [smtrat::LRAModule< Settings >](#), [smtrat::LRAModule< LRASettingsICP >](#), and [smtrat::LRAModule< LRASetting >](#)

**0.15.322.4.36 determine\_smallest\_origin()** `size_t smtrat::Module::determine_smallest_origin ( const std::vector< FormulaT > & origins ) const [protected]`

**Parameters**

|                      |                              |
|----------------------|------------------------------|
| <code>origins</code> | A vector of sets of origins. |
|----------------------|------------------------------|

**Returns**

The index of the smallest (regarding the size of the sets) element of origins

**0.15.322.4.37 eraseSubformulaFromPassedFormula()** `ModuleInput::iterator smtrat::Module::eraseSubformulaFromPassedFormula ( ModuleInput::iterator _subformula, bool _ignoreOrigins = false ) [protected], [virtual]`

Removes everything related to the sub-formula to remove from the passed formula in the backends of this module. Afterwards the sub-formula is removed from the passed formula.

**Parameters**

|                          |                                                    |
|--------------------------|----------------------------------------------------|
| <code>_subformula</code> | The sub-formula to remove from the passed formula. |
|--------------------------|----------------------------------------------------|

**Parameters**

|                             |                                                                                                              |
|-----------------------------|--------------------------------------------------------------------------------------------------------------|
| <code>_ignoreOrigins</code> | True, if the sub-formula shall be removed regardless of its origins (should only be applied with expertise). |
|-----------------------------|--------------------------------------------------------------------------------------------------------------|

**Returns**

Reimplemented in [smtrat::ICPModule< Settings >](#), [smtrat::ICPModule< ICPSettings4 >](#), and [smtrat::ICPModule< ICPSettings1 >](#).

**0.15.322.4.38 `excludeNotReceivedVariablesFromModel()`** `void smtrat::Module::excludeNotReceivedVariablesFromModel() const`  
Excludes all variables from the current model, which do not occur in the received formula.

**0.15.322.4.39 `findBestOrigin()`** `std::vector< FormulaT >::const_iterator smtrat::Module::findBestOrigin(`  
`const std::vector< FormulaT > & _origins ) const [protected]`

**Parameters**

|                       |  |
|-----------------------|--|
| <code>_origins</code> |  |
|-----------------------|--|

**Returns**

**0.15.322.4.40 `firstSubformulaToPass()`** `ModuleInput::const_iterator smtrat::Module::firstSubformulaToPass() const [inline]`

**Returns**

The position of the first sub-formula in the passed formula, which has not yet been considered for a consistency check of the backends.

**0.15.322.4.41 `firstUncheckedReceivedSubformula()`** `ModuleInput::const_iterator smtrat::Module::firstUncheckedReceivedSubformula() const [inline]`

**Returns**

The position of the first (by this module) unchecked sub-formula of the received formula.

**0.15.322.4.42 `freeSplittingVariable()`** `static void smtrat::Module::freeSplittingVariable(`  
`const FormulaT & _splittingVariable ) [inline], [static]`

**0.15.322.4.43 `generateTrivialInfeasibleSubset()`** `void smtrat::Module::generateTrivialInfeasibleSubset() [inline], [protected]`  
Stores the trivial infeasible subset being the set of received formulas.

**0.15.322.4.44 getBackendsAllModels()** void smtrat::Module::getBackendsAllModels () const [protected]  
Stores all models of a backend in the list of all models of this module.

**0.15.322.4.45 getBackendsModel()** void smtrat::Module::getBackendsModel () const [protected]

**0.15.322.4.46 getInfeasibleSubsets() [1/2]** void smtrat::Module::getInfeasibleSubsets () const [protected]  
Copies the infeasible subsets of the passed formula.

**0.15.322.4.47 getInfeasibleSubsets() [2/2]** std::vector< [FormulaSetT](#) > smtrat::Module::getInfeasibleSubsets (const [Module](#) & [\\_backend](#)) const [protected]  
Get the infeasible subsets the given backend provides.  
Note, that an infeasible subset in a backend contains sub formulas of the passed formula and an infeasible subset of this module contains sub formulas of the received formula. In this method the LATTER is returned.

#### Parameters

|                          |                                                          |
|--------------------------|----------------------------------------------------------|
| <a href="#">_backend</a> | The backend from which to obtain the infeasible subsets. |
|--------------------------|----------------------------------------------------------|

#### Returns

The infeasible subsets the given backend provides.

**0.15.322.4.48 getInformationRelevantFormulas()** const std::set< [FormulaT](#) > & smtrat::Module::getInformationRelevantFormulas () const [protected]  
Gets all InformationRelevantFormulas.

#### Returns

Set of all formulas

**0.15.322.4.49 getModelEqualities()** std::list< std::vector< [carl::Variable](#) > > smtrat::Module::getModelEqualities () const [virtual]  
Partition the variables from the current model into equivalence classes according to their assigned value.  
The result is a set of equivalence classes of variables where all variables within one class are assigned the same value. Note that the number of classes may not be minimal, i.e. two classes may actually be equivalent.

#### Returns

Equivalence classes.

**0.15.322.4.50 getOrigins() [1/3]** void smtrat::Module::getOrigins (const [FormulaT](#) & [\\_formula](#), [FormulaSetT](#) & [\\_origins](#)) const [inline], [protected]

#### Parameters

|                          |  |
|--------------------------|--|
| <a href="#">_formula</a> |  |
| <a href="#">_origins</a> |  |

```
0.15.322.4.51 getOrigins() [2/3] void smtrat::Module::getOrigins (
 const FormulaT & _formula,
 FormulasT & _origins) const [inline], [protected]
```

#### Parameters

|                       |  |
|-----------------------|--|
| <code>_formula</code> |  |
| <code>_origins</code> |  |

```
0.15.322.4.52 getOrigins() [3/3] const FormulaT& smtrat::Module::getOrigins (
 ModuleInput::const_iterator _formula) const [inline], [protected]
```

Gets the origins of the passed formula at the given position.

#### Parameters

|                       |                                                   |
|-----------------------|---------------------------------------------------|
| <code>_formula</code> | The position of a formula in the passed formulas. |
|-----------------------|---------------------------------------------------|

#### Returns

The origins of the passed formula at the given position.

```
0.15.322.4.53 getReceivedFormulaSimplified() std::pair< bool, FormulaT > smtrat::Module::get<-
ReceivedFormulaSimplified () [virtual]
```

#### Returns

A pair of a Boolean and a formula, where the Boolean is true, if the received formula could be simplified to an equisatisfiable formula. The formula is equisatisfiable to this module's received formula, if the Boolean is true.

Reimplemented in [smtrat::PModule](#).

```
0.15.322.4.54 hasLemmas() bool smtrat::Module::hasLemmas () [inline]
```

Checks whether this module or any of its backends provides any lemmas.

```
0.15.322.4.55 hasValidInfeasibleSubset() bool smtrat::Module::hasValidInfeasibleSubset () const
```

#### Returns

true, if the module has at least one valid infeasible subset, that is all its elements are sub-formulas of the received formula (pointer must be equal).

```
0.15.322.4.56 id() std::size_t smtrat::Module::id () const [inline]
```

#### Returns

A unique ID to identify this module instance.

**0.15.322.4.57 infeasibleSubsets()** const std::vector<[FormulaSetT](#)>& smtrat::Module::infeasibleSubsets ( ) const [inline]

#### Returns

The infeasible subsets of the set of received formulas (empty, if this module has not detected unsatisfiability of the conjunction of received formulas).

**0.15.322.4.58 inform()** bool smtrat::Module::inform ( const [FormulaT](#) & \_constraint )

Informs the module about the given constraint.

It should be tried to inform this module about any constraint it could receive eventually before assertSubformula is called (preferably for the first time, but at least before adding a formula containing that constraint).

#### Parameters

|                          |                                 |
|--------------------------|---------------------------------|
| <code>_constraint</code> | The constraint to inform about. |
|--------------------------|---------------------------------|

#### Returns

false, if it can be easily decided whether the given constraint is inconsistent; true, otherwise.

**0.15.322.4.59 informBackends()** void smtrat::Module::informBackends ( const [FormulaT](#) & \_constraint ) [inline], [protected]

Informs all backends of this module about the given constraint.

#### Parameters

|                          |                                 |
|--------------------------|---------------------------------|
| <code>_constraint</code> | The constraint to inform about. |
|--------------------------|---------------------------------|

**0.15.322.4.60 informCore()** virtual bool smtrat::Module::informCore ( const [FormulaT](#) & \_constraint ) [inline], [protected], [virtual]

Informs the module about the given constraint.

It should be tried to inform this module about any constraint it could receive eventually before assertSubformula is called (preferably for the first time, but at least before adding a formula containing that constraint).

#### Parameters

|                          |                                 |
|--------------------------|---------------------------------|
| <code>_constraint</code> | The constraint to inform about. |
|--------------------------|---------------------------------|

#### Returns

false, if it can be easily decided whether the given constraint is inconsistent; true, otherwise.

Reimplemented in [smtrat::UnionFindModule< Settings >](#), [smtrat::PBPPModule< Settings >](#), [smtrat::PBGaussModule< Settings >](#), [smtrat::NRAILModule< Settings >](#), [smtrat::NewCoveringModule< Settings >](#), [smtrat::NewCADModule< Settings >](#), [smtrat::LRAModule< Settings >](#), [smtrat::LRAModule< LRASettingsICP >](#), [smtrat::LRAModule< LRASettings1 >](#), [smtrat::IntBlastModule< Settings >](#), [smtrat::FPPModule< Settings >](#), [smtrat::EQModule< Settings >](#), [smtrat::CurryModule< Settings >](#), [smtrat::BVMModule< Settings >](#), [smtrat::ICPModule< Settings >](#), [smtrat::ICPModule< ICPSettings4 >](#), and [smtrat::ICPModule< ICPSettings1 >](#).

**0.15.322.4.61 informedConstraints()** const carl::FastSet<[FormulaT](#)>& smtrat::Module::informedConstraints ( ) const [inline]

#### Returns

The position of the first constraint of which no backend has been informed about.

**0.15.322.4.62 init()** void smtrat::Module::init ( ) [virtual]

Informs all backends about the so far encountered constraints, which have not yet been communicated.

This method must not be called twice and only before the first runBackends call.

Reimplemented in [smtrat::PBPPModule< Settings >](#), [smtrat::PBGaussModule< Settings >](#), [smtrat::NRAILModule< Settings >](#), [smtrat::NewCoveringModule< Settings >](#), [smtrat::NewCADModule< Settings >](#), [smtrat::LRAModule< Settings >](#), [smtrat::LRAModule< LRASettingsICP >](#), [smtrat::LRAModule< LRASettings1 >](#), [smtrat::IntBlastModule< Settings >](#), [smtrat::FPPModule< Settings >](#), [smtrat::EQModule< Settings >](#), [smtrat::CurryModule< Settings >](#), and [smtrat::BVModule< Settings >](#).

**0.15.322.4.63 is\_minimizing()** bool smtrat::Module::is\_minimizing ( ) const [inline]

**0.15.322.4.64 isLemmaLevel()** bool smtrat::Module::isLemmaLevel (

[LemmaLevel](#) level ) [protected]

Checks if current lemma level is greater or equal to given level.

#### Parameters

|              |                 |
|--------------|-----------------|
| <i>level</i> | Level to check. |
|--------------|-----------------|

**0.15.322.4.65 isPreprocessor()** bool smtrat::Module::isPreprocessor ( ) const [inline]

#### Returns

true, if this module is a preprocessor that is a module, which simplifies its received formula to an equisatisfiable formula being passed to its backends. The simplified formula can be obtained with [getReceivedFormulaSimplified\(\)](#).

**0.15.322.4.66 lemmas()** const std::vector<[Lemma](#)>& smtrat::Module::lemmas ( ) const [inline]

#### Returns

A constant reference to the lemmas being valid formulas this module or its backends made.

**0.15.322.4.67 merge()** std::vector< [FormulaT](#) > smtrat::Module::merge (

const std::vector< [FormulaT](#) > & \_vecSetA,

const std::vector< [FormulaT](#) > & \_vecSetB ) const [protected]

Merges the two vectors of sets into the first one.

({a,b},{a,c}) and ({b,d},{b}) -> ({a,b,d},{a,b},{a,b,c,d},{a,b,c})

#### Parameters

|                 |                                  |
|-----------------|----------------------------------|
| <i>_vecSetA</i> | A vector of sets of constraints. |
| <i>_vecSetB</i> | A vector of sets of constraints. |

**Returns**

The vector being the two given vectors merged.

**0.15.322.4.68 model()** const `Model&` `smtrat::Module::model()` const [inline]**Returns**

The assignment of the current satisfiable result, if existent.

**0.15.322.4.69 modelsDisjoint()** bool `smtrat::Module::modelsDisjoint()`

```
const Model & _modelA,
 const Model & _modelB) [static], [protected]
```

Checks whether there is no variable assigned by both models.

**Parameters**

|                      |                                |
|----------------------|--------------------------------|
| <code>_modelA</code> | The first model to check for.  |
| <code>_modelB</code> | The second model to check for. |

**Returns**

true, if there is no variable assigned by both models; false, otherwise.

**0.15.322.4.70 moduleName()** virtual std::string `smtrat::Module::moduleName()` const [inline], [virtual]**Returns**

The name of the given module type as name.

Reimplemented in `smtrat::VSModule< Settings >`, `smtrat::UnionFindModule< Settings >`, `smtrat::UFCegarModule< Settings >`, `smtrat::STropModule< Settings >`, `smtrat::SplitSOSModule< Settings >`, `smtrat::PBPPModule< Settings >`, `smtrat::PBGaussModule< Settings >`, `smtrat::NRAILModule< Settings >`, `smtrat::NewCADModule< Settings >`, `smtrat::LVEModule< Settings >`, `smtrat::LRAModule< Settings >`, `smtrat::LRAModule< LRASettingsICP >`, `smtrat::LRAModule< LRASettings1 >`, `smtrat::IntEqModule< Settings >`, `smtrat::IntBlastModule< Settings >`, `smtrat::IncWidthModule< Settings >`, `smtrat::ICPModule< Settings >`, `smtrat::ICPModule< ICPSettings4 >`, `smtrat::ICPModule< ICPSettings1 >`, `smtrat::GBModule< Settings >`, `smtrat::FouMoModule< Settings >`, `smtrat::EQPreprocessingModule< Settings >`, `smtrat::EQModule< Settings >`, `smtrat::CurryModule< Settings >`, `smtrat::CubeLIAModule< Settings >`, `smtrat::CSplitModule< Settings >`, `smtrat::BVModule< Settings >`, and `smtrat::BEModule< Settings >`.

**0.15.322.4.71 objective()** carl::Variable `smtrat::Module::objective()` const [inline]**0.15.322.4.72 originInReceivedFormula()** bool `smtrat::Module::originInReceivedFormula()`

```
const FormulaT & _origin) const [protected]
```

**0.15.322.4.73 passedFormulaBegin()** `ModuleInput::iterator` `smtrat::Module::passedFormulaBegin()` [inline], [protected]**Returns**

An iterator to the end of the passed formula. TODO: disable this method

**0.15.322.4.74 passedFormulaEnd()** `ModuleInput::iterator smtrat::Module::passedFormulaEnd ()`  
[inline], [protected]

**Returns**

An iterator to the end of the passed formula.

**0.15.322.4.75 pPassedFormula()** `const ModuleInput* smtrat::Module::pPassedFormula () const`  
[inline]

**Returns**

A pointer to the formula passed to the backends of this module.

**0.15.322.4.76 pReceivedFormula()** `const ModuleInput* smtrat::Module::pReceivedFormula () const`  
[inline]

**Returns**

A pointer to the formula passed to this module.

**0.15.322.4.77 print()** `void smtrat::Module::print (`  
`const std::string & _initiation = "***" ) const`  
Prints everything relevant of the solver.

**Parameters**

|                          |                      |
|--------------------------|----------------------|
| <code>_initiation</code> | The line initiation. |
|--------------------------|----------------------|

**0.15.322.4.78 printAllModels()** `void smtrat::Module::printAllModels (`  
`std::ostream & _out = std::cout )`

Prints all assignments of this module satisfying its received formula if it satisfiable and this module could find an assignment.

**Parameters**

|                   |                                        |
|-------------------|----------------------------------------|
| <code>_out</code> | The stream to print the assignment on. |
|-------------------|----------------------------------------|

**0.15.322.4.79 printInfeasibleSubsets()** `void smtrat::Module::printInfeasibleSubsets (`  
`const std::string & _initiation = "***" ) const`

Prints the infeasible subsets.

**Parameters**

|                          |                      |
|--------------------------|----------------------|
| <code>_initiation</code> | The line initiation. |
|--------------------------|----------------------|

**0.15.322.4.80 printModel()** `void smtrat::Module::printModel (`  
`std::ostream & _out = std::cout ) const`

Prints the assignment of this module satisfying its received formula if it satisfiable and this module could find an assignment.

Parameters

|                   |                                        |
|-------------------|----------------------------------------|
| <code>_out</code> | The stream to print the assignment on. |
|-------------------|----------------------------------------|

**0.15.322.4.81 `printPassedFormula()`** `void smtrat::Module::printPassedFormula ( const std::string & _initiation = "***" ) const`

Prints the vector of passed formula.

Parameters

|                          |                      |
|--------------------------|----------------------|
| <code>_initiation</code> | The line initiation. |
|--------------------------|----------------------|

**0.15.322.4.82 `printReceivedFormula()`** `void smtrat::Module::printReceivedFormula ( const std::string & _initiation = "***" ) const`

Prints the vector of the received formula.

Parameters

|                          |                      |
|--------------------------|----------------------|
| <code>_initiation</code> | The line initiation. |
|--------------------------|----------------------|

**0.15.322.4.83 `probablyLooping()`** `bool smtrat::Module::probablyLooping ( const typename Poly::PolyType & _branchingPolynomial, const Rational & _branchingValue ) const [protected]`

Checks whether given the current branching value and branching variable/polynomial it is (highly) probable that this branching is part of an infinite loop of branchings.

Parameters

|                                   |                                                                                     |
|-----------------------------------|-------------------------------------------------------------------------------------|
| <code>_branchingPolynomial</code> | The polynomial to branch at (in most branching strategies this is just a variable). |
| <code>_branchingValue</code>      | The value to branch at.                                                             |

Returns

true, if this branching is probably part of an infinite loop of branchings; false, otherwise.

**0.15.322.4.84 `receivedFormulaChecked()`** `void smtrat::Module::receivedFormulaChecked ( ) [inline]`

Notifies that the received formulas has been checked.

**0.15.322.4.85 `receivedFormulasAsInfeasibleSubset()`** `void smtrat::Module::receivedFormulasAsInfeasibleSubset ( ModuleInput::const_iterator _subformula ) [inline], [protected]`

Stores an infeasible subset consisting only of the given received formula.

**0.15.322.4.86 receivedVariable()** `bool smrat::Module::receivedVariable ( carl::Variable::Arg _var ) const [inline]`

**0.15.322.4.87 remove()** `void smrat::Module::remove ( ModuleInput::const_iterator _subformula ) [virtual]`

Removes everything related to the given sub-formula of the received formula.

However, it is desired not to lose track of search spaces where no satisfying assignment can be found for the remaining sub-formulas.

#### Parameters

|                          |                                                    |
|--------------------------|----------------------------------------------------|
| <code>_subformula</code> | The sub formula of the received formula to remove. |
|--------------------------|----------------------------------------------------|

Reimplemented in [smrat::PModule](#).

**0.15.322.4.88 removeCore()** `virtual void smrat::Module::removeCore ( ModuleInput::const_iterator formula ) [inline], [protected], [virtual]`

Removes everything related to the given sub-formula of the received formula.

However, it is desired not to lose track of search spaces where no satisfying assignment can be found for the remaining sub-formulas.

#### Parameters

|                      |                                                    |
|----------------------|----------------------------------------------------|
| <code>formula</code> | The sub formula of the received formula to remove. |
|----------------------|----------------------------------------------------|

Reimplemented in [smrat::VSModule< Settings >](#), [smrat::SATModule< Settings >](#), [smrat::PFEModule< Settings >](#), [smrat::ICPModule< Settings >](#), [smrat::ICPModule< ICPSettings4 >](#), [smrat::ICPModule< ICPSettings1 >](#), [smrat::UnionFindModule< Settings >](#), [smrat::UFCegarModule< Settings >](#), [smrat::STropModule< Settings >](#), [smrat::PBPPModule< Settings >](#), [smrat::PBGaussModule< Settings >](#), [smrat::NRAILModule< Settings >](#), [smrat::NewCoveringModule< Settings >](#), [smrat::NewCADModule< Settings >](#), [smrat::LRAModule< Settings >](#), [smrat::LRAModule< LRASettingsICP >](#), [smrat::LRAModule< LRASettings1 >](#), [smrat::IntEqModule< Settings >](#), [smrat::IntBlastModule< Settings >](#), [smrat::IncWidthModule< Settings >](#), [smrat::ICEModule< Settings >](#), [smrat::FPPModule< Settings >](#), [smrat::FouMoModule< Settings >](#), [smrat::EQModule< Settings >](#), [smrat::CurryModule< Settings >](#), [smrat::CubeLIAModule< Settings >](#), [smrat::CSplitModule< Settings >](#), [smrat::BVMModule< Settings >](#), and [smrat::GBModule< Settings >](#).

**0.15.322.4.89 removeOrigin()** `std::pair<ModuleInput::iterator,bool> smrat::Module::removeOrigin ( ModuleInput::iterator _formula, const FormulaT & _origin ) [inline], [protected]`

**0.15.322.4.90 removeOrigins()** `std::pair<ModuleInput::iterator,bool> smrat::Module::removeOrigins ( ModuleInput::iterator _formula, const std::shared_ptr< std::vector< FormulaT >> & _origins ) [inline], [protected]`

**0.15.322.4.91 rPassedFormula()** `const ModuleInput& smrat::Module::rPassedFormula ( ) const [inline]`

#### Returns

A reference to the formula passed to the backends of this module.

**0.15.322.4.92 rReceivedFormula()** `const ModuleInput& smtrat::Module::rReceivedFormula ( ) const [inline]`

**Returns**

A reference to the formula passed to this module.

**0.15.322.4.93 runBackends() [1/2]** `virtual Answer smtrat::Module::runBackends ( ) [inline], [protected], [virtual]`  
Reimplemented in [smtrat::PModule](#).

**0.15.322.4.94 runBackends() [2/2]** `Answer smtrat::Module::runBackends ( bool _final, bool _full, carl::Variable _objective ) [protected], [virtual]`

Runs the backend solvers on the passed formula.

**Parameters**

|                         |                                                                                                                                       |
|-------------------------|---------------------------------------------------------------------------------------------------------------------------------------|
| <code>_final</code>     | true, if this satisfiability check will be the last one (for a global sat-check), if its result is SAT                                |
| <code>_full</code>      | false, if this module should avoid too expensive procedures and rather return unknown instead.                                        |
| <code>_objective</code> | if not set to NO_VARIABLE, the module should find an assignment minimizing this objective variable; otherwise any assignment is good. |

**Returns**

True, if the passed formula is consistent; False, if the passed formula is inconsistent; Unknown, otherwise.

Reimplemented in [smtrat::PModule](#).

**0.15.322.4.95 setId()** `void smtrat::Module::setId ( std::size_t _id ) [inline]`

Sets this modules unique ID to identify itself.

**Parameters**

|                                                                       |                                    |
|-----------------------------------------------------------------------|------------------------------------|
| $\leftrightarrow$<br>$\underline{\leftrightarrow}$<br><code>id</code> | The id to set this module's id to. |
|-----------------------------------------------------------------------|------------------------------------|

**0.15.322.4.96 setThreadPriority()** `void smtrat::Module::setThreadPriority ( thread_priority _threadPriority ) [inline]`

Sets the priority of this module to get a thread for running its check procedure.

**Parameters**

|                              |                                                       |
|------------------------------|-------------------------------------------------------|
| <code>_threadPriority</code> | The priority to set this module's thread priority to. |
|------------------------------|-------------------------------------------------------|

**0.15.322.4.97 solverState()** `Answer smtrat::Module::solverState ( ) const [inline]`

**Returns**

True, if this module is in a state, such that it has found a solution for its received formula; False, if this module is in a state, such that it has determined that there is no solution for its received formula; Unknown, otherwise.

**0.15.322.4.98 splitUnequalConstraint()** `void smtrat::Module::splitUnequalConstraint (`

`const FormulaT & _unequalConstraint ) [protected]`

Adds the following lemmas for the given constraint  $p \neq 0$ .

$(p \neq 0 \leftrightarrow (p < 0 \text{ or } p > 0))$

and  $\neg(p < 0 \text{ and } p > 0)$

**Parameters**

|                                 |                                                  |
|---------------------------------|--------------------------------------------------|
| <code>_unequalConstraint</code> | A constraint having the relation symbol $\neq$ . |
|---------------------------------|--------------------------------------------------|

**0.15.322.4.99 threadPriority()** `thread_priority smtrat::Module::threadPriority ( ) const [inline]`**Returns**

The priority of this module to get a thread for running its check procedure.

**0.15.322.4.100 updateAllModels()** `void smtrat::Module::updateAllModels ( ) [virtual]`

Updates all satisfying models, if the solver has detected the consistency of the received formula, beforehand.

Reimplemented in [smtrat::SATModule< Settings >](#).

**0.15.322.4.101 updateLemmas()** `void smtrat::Module::updateLemmas ( )`

Stores all lemmas of any backend of this module in its own lemma vector.

**0.15.322.4.102 updateModel()** `void smtrat::Module::updateModel ( ) const [virtual]`

Updates the model, if the solver has detected the consistency of the received formula, beforehand.

Reimplemented in [smtrat::PModule](#), [smtrat::VSMModule< Settings >](#), [smtrat::UnionFindModule< Settings >](#), [smtrat::UFCegarModule< Settings >](#), [smtrat::STropModule< Settings >](#), [smtrat::SATModule< Settings >](#), [smtrat::PBPPModule< Settings >](#), [smtrat::PBGaussModule< Settings >](#), [smtrat::NRAILModule< Settings >](#), [smtrat::NewCoveringModule< Settings >](#), [smtrat::NewCADModule< Settings >](#), [smtrat::MCBModule< Settings >](#), [smtrat::LVEModule< Settings >](#), [smtrat::LRAModule< Settings >](#), [smtrat::LRAModule< LRASettingsICP >](#), [smtrat::LRAModule< LRASettings1 >](#), [smtrat::IntEqModule< Settings >](#), [smtrat::IntBlastModule< Settings >](#), [smtrat::IncWidthModule< Settings >](#), [smtrat::ICPModule< Settings >](#), [smtrat::ICPModule< ICPSettings4 >](#), [smtrat::ICPModule< ICPSettings1 >](#), [smtrat::GBPPModule< Settings >](#), [smtrat::FPPModule< Settings >](#), [smtrat::FouMoModule< Settings >](#), [smtrat::ESModule< Settings >](#), [smtrat::EQPreprocessingModule< Settings >](#), [smtrat::EQModule< Settings >](#), [smtrat::CurryModule< Settings >](#), [smtrat::CubeLIAModule< Settings >](#), [smtrat::CSplitModule< Settings >](#), and [smtrat::BVMModule< Settings >](#).

**0.15.322.4.103 usedBackends()** `const std::vector<Module*>& smtrat::Module::usedBackends ( )`

`const [inline]`

**Returns**

The backends of this module which are currently used (conditions to use this module are fulfilled for the passed formula).

### 0.15.322.5 Field Documentation

**0.15.322.5.1 mAllBackends** `std::vector<Module*> smtrat::Module::mAllBackends` [protected]  
The backends of this module which have been used.

**0.15.322.5.2 mAllModels** `std::vector<Model> smtrat::Module::mAllModels` [mutable], [protected]  
Stores all satisfying assignments.

**0.15.322.5.3 mBackendsFoundAnswer** `std::atomic_bool* smtrat::Module::mBackendsFoundAnswer` [protected]  
This flag is passed to any backend and if it determines an answer to a prior check call, this flag is fired.

**0.15.322.5.4 mConstraintsToInform** `carl::FastSet<FormulaT> smtrat::Module::mConstraintsToInform` [protected]  
Stores the constraints which the backends must be informed about.

**0.15.322.5.5 mFinalCheck** `bool smtrat::Module::mFinalCheck` [protected]  
true, if the check procedure should perform a final check which especially means not to postpone splitting decisions

**0.15.322.5.6 mFirstPosInLastBranches** `std::size_t smtrat::Module::mFirstPosInLastBranches = 0` [static]  
The beginning of the cyclic buffer storing the last branches.

**0.15.322.5.7 mFirstSubformulaToPass** `ModuleInput::iterator smtrat::Module::mFirstSubformulaToPass` [protected]  
Stores the position of the first sub-formula in the passed formula, which has not yet been considered for a consistency check of the backends.

**0.15.322.5.8 mFirstUncheckedReceivedSubformula** `ModuleInput::const_iterator smtrat::Module::mFirstUncheckedReceivedSubformula` [protected]  
Stores the position of the first (by this module) unchecked sub-formula of the received formula.

**0.15.322.5.9 mFoundAnswer** `Conditionals smtrat::Module::mFoundAnswer` [protected]  
Vector of Booleans: If any of them is true, we have to terminate a running check procedure.

**0.15.322.5.10 mFullCheck** `bool smtrat::Module::mFullCheck` [protected]  
false, if this module should avoid too expensive procedures and rather return unknown instead.

**0.15.322.5.11 mInfeasibleSubsets** `std::vector<FormulaSetT> smtrat::Module::mInfeasibleSubsets` [protected]  
Stores the infeasible subsets.

**0.15.322.5.12 mInformedConstraints** `carl::FastSet<FormulaT> smtrat::Module::mInformedConstraints` [protected]  
Stores the position of the first constraint of which no backend has been informed about.

**0.15.322.5.13 mLastBranches** `std::vector< Branching > smtrat::Module::mLastBranches = std::vector<Branching> (mNumOfBranchVarsToStore, Branching(typename Poly::PolyType(), 0))` [static]  
Stores the last branches in a cycle buffer.

**0.15.322.5.14 mLemmas** `std::vector<Lemma> smtrat::Module::mLemmas` [protected]  
Stores the lemmas being valid formulas this module or its backends made.

**0.15.322.5.15 mModel** `Model smtrat::Module::mModel` [mutable], [protected]  
Stores the assignment of the current satisfiable result, if existent.

**0.15.322.5.16 mModelComputed** `bool smtrat::Module::mModelComputed` [mutable], [protected]  
True, if the model has already been computed.

**0.15.322.5.17 mNumOfBranchVarsToStore** `std::size_t smtrat::Module::mNumOfBranchVarsToStore = 5` [static]  
The number of different variables to consider for a probable infinite loop of branchings.

**0.15.322.5.18 mObjectiveVariable** `carl::Variable smtrat::Module::mObjectiveVariable` [protected]  
Objective variable to be minimized. If set to NO\_VARIABLE, a normal sat check should be performed.

**0.15.322.5.19 mOldSplittingVariables** `std::vector< FormulaT > smtrat::Module::mOldSplittingVariables` [static]  
Reusable splitting variables.

**0.15.322.5.20 mpManager** `Manager* const smtrat::Module::mpManager` [protected]  
A reference to the manager.

**0.15.322.5.21 mSmallerMusesCheckCounter** `unsigned smtrat::Module::mSmallerMusesCheckCounter` [mutable], [protected]  
Counter used for the generation of the smt2 files to check for smaller muses.

**0.15.322.5.22 mSolverState** `std::atomic<Answer> smtrat::Module::mSolverState` [protected]  
States whether the received formula is known to be satisfiable or unsatisfiable otherwise it is set to unknown.

**0.15.322.5.23 mTheoryPropagations** `std::vector<TheoryPropagation> smtrat::Module::mTheoryPropagations` [protected]

**0.15.322.5.24 mUsedBackends** std::vector<[Module](#)\*> smrat::Module::mUsedBackends [protected]  
The backends of this module which are currently used (conditions to use this module are fulfilled for the passed formula).

**0.15.322.5.25 mVariableCounters** std::vector<std::size\_t> smrat::Module::mVariableCounters [protected]  
Maps variables to the number of their occurrences.

## Friends

- class `Module`
- class `Manager`

### 0.15.324.1 Detailed Description

The input formula a module has to consider for it's satisfiability check.  
It is a list of formulas and semantically considered as their conjunction.

### 0.15.324.2 Member Typedef Documentation

#### 0.15.324.2.1 `const_iterator` `typedef super::const_iterator smtrat::ModuleInput::const_iterator`

Passing through the list::const\_iterator.

#### 0.15.324.2.2 `iterator` `typedef super::iterator smtrat::ModuleInput::iterator`

Passing through the list::iterator.

### 0.15.324.3 Constructor & Destructor Documentation

#### 0.15.324.3.1 `ModuleInput()` `smtrat::ModuleInput::ModuleInput ( ) [inline]`

Constructs a module input.

### 0.15.324.4 Member Function Documentation

#### 0.15.324.4.1 `add() [1/4]` `std::pair<iterator,bool> smtrat::ModuleInput::add ( const FormulaT & _formula, bool _hasSingleOrigin, const FormulaT & _origin, const std::shared_ptr< FormulasT > & _origins, bool _mightBeConjunction = true )`

#### 0.15.324.4.2 `add() [2/4]` `std::pair<iterator,bool> smtrat::ModuleInput::add ( const FormulaT & _formula, bool _mightBeConjunction = true ) [inline]`

#### 0.15.324.4.3 `add() [3/4]` `std::pair<iterator,bool> smtrat::ModuleInput::add ( const FormulaT & _formula, const FormulaT & _origins, bool _mightBeConjunction = true ) [inline]`

#### 0.15.324.4.4 `add() [4/4]` `std::pair<iterator,bool> smtrat::ModuleInput::add ( const FormulaT & _formula, const std::shared_ptr< FormulasT > & _origins, bool _mightBeConjunction = true ) [inline]`

#### 0.15.324.4.5 `addOrigin()` `void smtrat::ModuleInput::addOrigin ( iterator _formula, const FormulaT & _origin ) [inline]`

**0.15.324.4.6 `back()`** `const auto& smtrat::ModuleInput::back ( ) const [inline]`

**0.15.324.4.7 `begin() [1/2]`** `iterator smtrat::ModuleInput::begin ( ) [inline]`

**0.15.324.4.8 `begin() [2/2]`** `const_iterator smtrat::ModuleInput::begin ( ) const [inline]`

**0.15.324.4.9 `clearOrigins()`** `void smtrat::ModuleInput::clearOrigins ( iterator _formula ) [inline]`

**0.15.324.4.10 `contains()`** `bool smtrat::ModuleInput::contains ( const FormulaT & _subformula ) const [inline]`

**Returns**

|                          |                                                                          |
|--------------------------|--------------------------------------------------------------------------|
| <code>_subformula</code> | The formula for which to check whether it is one of the stored formulas. |
|--------------------------|--------------------------------------------------------------------------|

**Returns**

true, if the given formula is one of the stored formulas; false, otherwise.

**0.15.324.4.11 `containsBitVectorConstraints()`** `bool smtrat::ModuleInput::containsBitVectorConstraints ( ) const [inline]`

**Returns**

true, if this formula contains bit vector constraints; false, otherwise.

**0.15.324.4.12 `containsBooleanVariables()`** `bool smtrat::ModuleInput::containsBooleanVariables ( ) const [inline]`

**Returns**

true, if this formula contains Boolean variables; false, otherwise.

**0.15.324.4.13 `containsIntegerVariables()`** `bool smtrat::ModuleInput::containsIntegerVariables ( ) const [inline]`

**Returns**

true, if this formula contains Boolean variables; false, otherwise.

**0.15.324.4.14 `containsRealVariables()`** `bool smtrat::ModuleInput::containsRealVariables ( ) const [inline]`

**Returns**

true, if this formula contains Boolean variables; false, otherwise.

**0.15.324.4.15 containsUninterpretedEquations()** `bool smtrat::ModuleInput::containsUninterpretedEquations () const [inline]`

**Returns**

true, if this formula contains uninterpreted equations; false, otherwise.

**0.15.324.4.16 empty()** `bool smtrat::ModuleInput::empty () const [inline]`

**0.15.324.4.17 end() [1/2]** `iterator smtrat::ModuleInput::end () [inline]`

**0.15.324.4.18 end() [2/2]** `const_iterator smtrat::ModuleInput::end () const [inline]`

**0.15.324.4.19 erase()** `ModuleInput::iterator smtrat::ModuleInput::erase ( iterator _formula )`

**0.15.324.4.20 find() [1/4]** `ModuleInput::iterator smtrat::ModuleInput::find ( const FormulaT & _formula )`

**0.15.324.4.21 find() [2/4]** `ModuleInput::const_iterator smtrat::ModuleInput::find ( const FormulaT & _formula ) const`

**0.15.324.4.22 find() [3/4]** `ModuleInput::iterator smtrat::ModuleInput::find ( const_iterator _hint, const FormulaT & _formula )`

**0.15.324.4.23 find() [4/4]** `ModuleInput::const_iterator smtrat::ModuleInput::find ( const_iterator _hint, const FormulaT & _formula ) const`

**0.15.324.4.24 gatherVariables()** `void smtrat::ModuleInput::gatherVariables ( carl::carlVariables & vars ) const [inline]`

**0.15.324.4.25 is\_constraint\_conjunction()** `bool smtrat::ModuleInput::is_constraint_conjunction () const [inline]`

**Returns**

true, if this formula is a conjunction of constraints; false, otherwise.

**0.15.324.4.26 is\_integer\_constraint\_conjunction()** `bool smtrat::ModuleInput::is_integer_constraint_conjunction () const [inline]`

**Returns**

true, if this formula is a conjunction of integer constraints; false, otherwise.

**0.15.324.4.27 `is_only_propositional()`** `bool smtrat::ModuleInput::is_only_propositional () const [inline]`

**Returns**

true, if this formula is propositional; false, otherwise.

**0.15.324.4.28 `is_real_constraint_conjunction()`** `bool smtrat::ModuleInput::is_real_constraint_conjunction () const [inline]`

**Returns**

true, if this formula is a conjunction of real constraints; false, otherwise.

**0.15.324.4.29 `isConstraintLiteralConjunction()`** `bool smtrat::ModuleInput::isConstraintLiteralConjunction () const [inline]`

**Returns**

true, if this formula is a conjunction of literals of constraints; false, otherwise.

**0.15.324.4.30 `isIntegerConstraintLiteralConjunction()`** `bool smtrat::ModuleInput::isIntegerConstraintLiteralConjunction () const [inline]`

**Returns**

true, if this formula is a conjunction of literals of integer constraints; false, otherwise.

**0.15.324.4.31 `isRealConstraintLiteralConjunction()`** `bool smtrat::ModuleInput::isRealConstraintLiteralConjunction () const [inline]`

**Returns**

true, if this formula is a conjunction of literals of real constraints; false, otherwise.

**0.15.324.4.32 `operator FormulaT()`** `smtrat::ModuleInput::operator FormulaT () const [inline], [explicit]`

**0.15.324.4.33 `properties()`** `carl::Condition smtrat::ModuleInput::properties () const [inline]`

**Returns**

All known properties of the underlying formula of this module input.

**0.15.324.4.34 `rbegin()`** `auto smtrat::ModuleInput::rbegin () const [inline]`

**0.15.324.4.35 `removeOrigin()`** `bool smtrat::ModuleInput::removeOrigin ( iterator _formula, const FormulaT & _origin )`

**0.15.324.4.36 `removeOrigins()`** `bool smtrat::ModuleInput::removeOrigins ( iterator _formula, const std::shared_ptr< FormulasT > & _origins )`

**0.15.324.4.37 `rend()`** `auto smtrat::ModuleInput::rend ( ) const [inline]`

**0.15.324.4.38 `satisfiedBy() [1/2]`** `unsigned smtrat::ModuleInput::satisfiedBy ( const Model & _assignment ) const`

**Parameters**

|                          |                                                                |
|--------------------------|----------------------------------------------------------------|
| <code>_assignment</code> | The model to check conjunction of the stored formulas against. |
|--------------------------|----------------------------------------------------------------|

**Returns**

1, if the conjunction of the stored formulas is satisfied by the given model; 0, if the given model conflicts the conjunction of the stored formulas; 2, if it cannot be determined cheaply, whether the given model conflicts or satisfies the conjunction of the stored formulas.

**0.15.324.4.39 `satisfiedBy() [2/2]`** `unsigned smtrat::ModuleInput::satisfiedBy ( const RationalAssignment & _assignment ) const`

**Parameters**

|                          |                                                                     |
|--------------------------|---------------------------------------------------------------------|
| <code>_assignment</code> | The assignment to check conjunction of the stored formulas against. |
|--------------------------|---------------------------------------------------------------------|

**Returns**

1, if the conjunction of the stored formulas is satisfied by the given assignment; 0, if the given assignment conflicts the conjunction of the stored formulas; 2, if it cannot be determined cheaply, whether the given assignment conflicts or satisfies the conjunction of the stored formulas.

**0.15.324.4.40 `size()`** `size_t smtrat::ModuleInput::size ( void ) const [inline]`

**0.15.324.4.41 `updateProperties()`** `void smtrat::ModuleInput::updateProperties ( )`  
Updates all properties of the formula underlying this module input.

## 0.15.328 smrat::subtropical::Moment Struct Reference

Represents the normal vector component and the sign variable assigned to a variable in an original constraint.  
`#include <Subtropical.h>`

### Public Member Functions

- `Moment ()`

### Data Fields

- `const carl::Variable normal_vector`  
*Normal vector component of the separating hyperplane.*
- `const carl::Variable sign_variant`  
*Boolean variable representing the sign variant.*

#### 0.15.328.1 Detailed Description

Represents the normal vector component and the sign variable assigned to a variable in an original constraint.

#### 0.15.328.2 Constructor & Destructor Documentation

##### 0.15.328.2.1 Moment() smrat::subtropical::Moment::Moment ( ) [inline]

#### 0.15.328.3 Field Documentation

**0.15.328.3.1 normal\_vector** `const carl::Variable smrat::subtropical::Moment::normal_vector`  
Normal vector component of the separating hyperplane.

**0.15.328.3.2 sign\_variant** `const carl::Variable smrat::subtropical::Moment::sign_variant`  
Boolean variable representing the sign variant.

Reimplemented from `smtrat::expression::simplifier::BaseSimplifier`.

## 0.15.332 `smtrat::NewCADModule`< `Settings` > Class Template Reference

```
#include <NewCADModule.h>
```

### Public Types

- `typedef Settings SettingsType`
- `enum class LemmaType : unsigned { NORMAL = 0 , PERMANENT = 1 }`

### Public Member Functions

- `std::string moduleName () const`
- `NewCADModule (const ModuleInput *_formula, Conditionals &_conditionals, Manager *_manager=nullptr)`
- `~NewCADModule ()`
- `bool informCore (const FormulaT &_constraint)`

*Informs the module about the given constraint.*
- `void init ()`

*Informs all backends about the so far encountered constraints, which have not yet been communicated.*
- `bool addCore (ModuleInput::const_iterator _subformula)`

*The module has to take the given sub-formula of the received formula into account.*
- `void removeCore (ModuleInput::const_iterator _subformula)`

*Removes the subformula of the received formula at the given position to the considered ones of this module.*
- `void updateModel () const`

*Updates the current assignment into the model.*
- `Answer checkCore ()`

*Checks the received formula for consistency.*
- `bool inform (const FormulaT &_constraint)`

*Informs the module about the given constraint.*
- `void deform (const FormulaT &_constraint)`

*The inverse of informing about a constraint.*
- `bool add (ModuleInput::const_iterator _subformula)`

*The module has to take the given sub-formula of the received formula into account.*
- `virtual Answer check (bool _final=false, bool _full=true, carl::Variable _objective=carl::Variable::NO_VARIABLE)`

*Checks the received formula for consistency.*
- `virtual void remove (ModuleInput::const_iterator _subformula)`

*Removes everything related to the given sub-formula of the received formula.*
- `virtual void updateAllModels ()`

*Updates all satisfying models, if the solver has detected the consistency of the received formula, beforehand.*
- `virtual std::list< std::vector< carl::Variable > > getModelEqualities () const`

*Partition the variables from the current model into equivalence classes according to their assigned value.*
- `unsigned currentlySatisfiedByBackend (const FormulaT &_formula) const`
- `virtual unsigned currentlySatisfied (const FormulaT &) const`
- `bool receivedVariable (carl::Variable::Arg _var) const`

- `Answer solverState () const`
- `std::size_t id () const`
- `void setId (std::size_t _id)`

*Sets this module's unique ID to identify itself.*
- `thread_priority threadPriority () const`
- `void setThreadPriority (thread_priority _threadPriority)`

*Sets the priority of this module to get a thread for running its check procedure.*
- `const ModuleInput * pReceivedFormula () const`
- `const ModuleInput & rReceivedFormula () const`
- `const ModuleInput * pPassedFormula () const`
- `const ModuleInput & rPassedFormula () const`
- `const Model & model () const`
- `const std::vector< Model > & allModels () const`
- `const std::vector< FormulaSetT > & infeasibleSubsets () const`
- `const std::vector< Module * > & usedBackends () const`
- `const carl::FastSet< FormulaT > & constraintsToInform () const`
- `const carl::FastSet< FormulaT > & informedConstraints () const`
- `void addLemma (const FormulaT &_lemma, const LemmaType &_lt=LemmaType::NORMAL, const FormulaT &_preferredFormula=FormulaT(carl::FormulaType::TRUE))`

*Stores a lemma being a valid formula.*
- `bool hasLemmas ()`

*Checks whether this module or any of its backends provides any lemmas.*
- `void clearLemmas ()`

*Deletes all yet found lemmas.*
- `const std::vector< Lemma > & lemmas () const`
- `ModuleInput::const_iterator firstUncheckedReceivedSubformula () const`
- `ModuleInput::const_iterator firstSubformulaToPass () const`
- `void receivedFormulaChecked ()`

*Notifies that the received formulas has been checked.*
- `const smtrat::Conditionals & answerFound () const`
- `bool isPreprocessor () const`
- `carl::Variable objective () const`
- `bool is_minimizing () const`
- `void excludeNotReceivedVariablesFromModel () const`

*Excludes all variables from the current model, which do not occur in the received formula.*
- `void updateLemmas ()`

*Stores all lemmas of any backend of this module in its own lemma vector.*
- `void collectTheoryPropagations ()`
- `void collectOrigins (const FormulaT &_formula, FormulasT &_origins) const`

*Collects the formulas in the given formula, which are part of the received formula.*
- `void collectOrigins (const FormulaT &_formula, FormulaSetT &_origins) const`
- `bool hasValidInfeasibleSubset () const`
- `void checkInfSubsetForMinimality (std::vector< FormulaSetT >::const_iterator _infsSubset, const std::string &_filename="smaller_muses", unsigned _maxSizeDifference=1) const`

*Checks the given infeasible subset for minimality by storing all subsets of it, which have a smaller size which differs from the size of the infeasible subset not more than the given threshold.*
- `virtual std::pair< bool, FormulaT > getReceivedFormulaSimplified ()`
- `void print (const std::string &_initiation="***") const`

*Prints everything relevant of the solver.*
- `void printReceivedFormula (const std::string &_initiation="***") const`

*Prints the vector of the received formula.*
- `void printPassedFormula (const std::string &_initiation="***") const`

*Prints the vector of passed formula.*

- void `printInfeasibleSubsets` (const std::string &\_initiation="\*\*\*") const  
*Prints the infeasible subsets.*
- void `printModel` (std::ostream &\_out=std::cout) const  
*Prints the assignment of this module satisfying its received formula if it satisfiable and this module could find an assignment.*
- void `printAllModels` (std::ostream &\_out=std::cout)  
*Prints all assignments of this module satisfying its received formula if it satisfiable and this module could find an assignment.*

### Static Public Member Functions

- static void `freeSplittingVariable` (const `FormulaT` &\_splittingVariable)

### Static Public Attributes

- static size\_t `mNumOfBranchVarsToStore` = 5  
*The number of different variables to consider for a probable infinite loop of branchings.*
- static std::vector<`Branching`> `mLastBranches` = std::vector<`Branching`>(mNumOfBranchVarsToStore, `Branching`(typename Poly::PolyType(), 0))  
*Stores the last branches in a cycle buffer.*
- static size\_t `mFirstPosInLastBranches` = 0  
*The beginning of the cyclic buffer storing the last branches.*
- static std::vector<`FormulaT`> `mOldSplittingVariables`  
*Reusable splitting variables.*

### Protected Member Functions

- virtual void `deinformCore` (const `FormulaT` &\_constraint)  
*The inverse of informing about a constraint.*
- bool `anAnswerFound` () const  
*Checks for all antecedent modules and those which run in parallel with the same antecedent modules, whether one of them has determined a result.*
- void `clearModel` () const  
*Clears the assignment, if any was found.*
- void `clearModels` () const  
*Clears all assignments, if any was found.*
- void `cleanModel` () const  
*Substitutes variable occurrences by its model value in the model values of other variables.*
- `ModuleInput::iterator` `passedFormulaBegin` ()
- `ModuleInput::iterator` `passedFormulaEnd` ()
- void `addOrigin` (`ModuleInput::iterator` \_formula, const `FormulaT` &\_origin)  
*Adds the given set of formulas in the received formula to the origins of the given passed formula.*
- const `FormulaT` & `getOrigins` (`ModuleInput::const_iterator` \_formula) const  
*Gets the origins of the passed formula at the given position.*

- std::pair< `ModuleInput::iterator`, bool > `addSubformulaToPassedFormula` (const `FormulaT` &\_formula)
 

*Adds the given formula to the passed formula with no origin.*
- std::pair< `ModuleInput::iterator`, bool > `addSubformulaToPassedFormula` (const `FormulaT` &\_formula, const std::shared\_ptr< std::vector< `FormulaT` >> &\_origins)
 

*Adds the given formula to the passed formula.*
- std::pair< `ModuleInput::iterator`, bool > `addSubformulaToPassedFormula` (const `FormulaT` &\_formula, const `FormulaT` &\_origin)
 

*Adds the given formula to the passed formula.*
- void `generateTrivialInfeasibleSubset` ()
 

*Stores the trivial infeasible subset being the set of received formulas.*
- void `receivedFormulasAsInfeasibleSubset` (`ModuleInput::const_iterator` \_subformula)
 

*Stores an infeasible subset consisting only of the given received formula.*
- std::vector< `FormulaT` >::const\_iterator `findBestOrigin` (const std::vector< `FormulaT` > &\_origins) const
- void `getInfeasibleSubsets` ()
 

*Copies the infeasible subsets of the passed formula.*
- std::vector< `FormulaSetT` > `getInfeasibleSubsets` (const `Module` &\_backend) const
 

*Get the infeasible subsets the given backend provides.*
- const `Model` & `backendsModel` () const
 

*Stores the model of a backend which determined satisfiability of the passed formula in the model of this module.*
- void `getBackendsModel` () const
- void `getBackendsAllModels` () const
 

*Stores all models of a backend in the list of all models of this module.*
- virtual `Answer runBackends` (bool \_final, bool \_full, carl::Variable \_objective)
 

*Runs the backend solvers on the passed formula.*
- virtual `Answer runBackends` ()
- virtual `ModuleInput::iterator eraseSubformulaFromPassedFormula` (`ModuleInput::iterator` \_subformula, bool \_ignoreOrigins=false)
 

*Removes everything related to the sub-formula to remove from the passed formula in the backends of this module.*
- void `clearPassedFormula` ()
- std::vector< `FormulaT` > `merge` (const std::vector< `FormulaT` > &, const std::vector< `FormulaT` > &) const
 

*Merges the two vectors of sets into the first one.*
- size\_t `determine_smallest_origin` (const std::vector< `FormulaT` > &origins) const
- bool `probablyLooping` (const typename Poly::PolyType &\_branchingPolynomial, const Rational &\_branchingValue) const
 

*Checks whether given the current branching value and branching variable/polynomial it is (highly) probable that this branching is part of an infinite loop of branchings.*
- bool `branchAt` (const Poly &\_polynomial, bool \_integral, const Rational &\_value, std::vector< `FormulaT` > &&\_premise, bool \_leftCaseWeak=true, bool \_preferLeftCase=true, bool \_useReceivedFormulaAsPremise=false)
 

*Adds a lemmas which provoke a branching for the given variable at the given value, if this module returns Unknown and there exists a preceding SATModule.*
- bool `branchAt` (const Poly &\_polynomial, bool \_integral, const Rational &\_value, bool \_leftCaseWeak=true, bool \_preferLeftCase=true, bool \_useReceivedFormulaAsPremise=false, const std::vector< `FormulaT` > &←\_premise=std::vector< `FormulaT` >())
 

*Adds a lemmas which provoke a branching for the given variable at the given value, if this module returns Unknown and there exists a preceding SATModule.*
- bool `branchAt` (carl::Variable::Arg \_var, const Rational &\_value, std::vector< `FormulaT` > &&\_premise, bool \_leftCaseWeak=true, bool \_preferLeftCase=true, bool \_useReceivedFormulaAsPremise=false)
 

*Adds a lemmas which provoke a branching for the given variable at the given value, if this module returns Unknown and there exists a preceding SATModule.*
- bool `branchAt` (carl::Variable::Arg \_var, const Rational &\_value, bool \_leftCaseWeak=true, bool \_preferLeftCase=true, bool \_useReceivedFormulaAsPremise=false, const std::vector< `FormulaT` > &\_premise=std::vector< `FormulaT` >())
 

*Adds a lemmas which provoke a branching for the given variable at the given value, if this module returns Unknown and there exists a preceding SATModule.*

- void `splitUnequalConstraint` (const `FormulaT` &)
 

*Adds the following lemmas for the given constraint  $p \neq 0$ .*
- unsigned `checkModel` () const
- void `addInformationRelevantFormula` (const `FormulaT` &`formula`)
 

*Adds a formula to the InformationRelevantFormula.*
- const std::set< `FormulaT` > & `getInformationRelevantFormulas` ()
 

*Gets all InformationRelevantFormulas.*
- bool `isLemmaLevel` (`LemmaLevel` level)
 

*Checks if current lemma level is greater or equal to given level.*

### Static Protected Member Functions

- static bool `modelsDisjoint` (const `Model` &`_modelA`, const `Model` &`_modelB`)
 

*Checks whether there is no variable assigned by both models.*

### Protected Attributes

- std::vector< `FormulaSetT` > `mInfeasibleSubsets`

*Stores the infeasible subsets.*
- `Manager` \*const `mpManager`

*A reference to the manager.*
- `Model` `mModel`

*Stores the assignment of the current satisfiable result, if existent.*
- std::vector< `Model` > `mAllModels`

*Stores all satisfying assignments.*
- bool `mModelComputed`

*True, if the model has already been computed.*
- bool `mFinalCheck`

*true, if the check procedure should perform a final check which especially means not to postpone splitting decisions*
- bool `mFullCheck`

*false, if this module should avoid too expensive procedures and rather return unknown instead.*
- carl::Variable `mObjectiveVariable`

*Objective variable to be minimized. If set to NO\_VARIABLE, a normal sat check should be performed.*
- std::vector< `TheoryPropagation` > `mTheoryPropagations`
- std::atomic< `Answer` > `mSolverState`

*States whether the received formula is known to be satisfiable or unsatisfiable otherwise it is set to unknown.*
- std::atomic\_bool \* `mBackendsFoundAnswer`

*This flag is passed to any backend and if it determines an answer to a prior check call, this flag is fired.*
- Conditionals `mFoundAnswer`

*Vector of Booleans: If any of them is true, we have to terminate a running check procedure.*
- std::vector< `Module` \* > `mUsedBackends`

*The backends of this module which are currently used (conditions to use this module are fulfilled for the passed formula).*
- std::vector< `Module` \* > `mAllBackends`

*The backends of this module which have been used.*
- std::vector< `Lemma` > `mLemmas`

*Stores the lemmas being valid formulas this module or its backends made.*
- `ModuleInput`::iterator `mFirstSubformulaToPass`

*Stores the position of the first sub-formula in the passed formula, which has not yet been considered for a consistency check of the backends.*
- carl::FastSet< `FormulaT` > `mConstraintsToInform`

*Stores the constraints which the backends must be informed about.*

- `carl::FastSet< FormulaT > mInformedConstraints`  
*Stores the position of the first constraint of which no backend has been informed about.*
- `ModuleInput::const_iterator mFirstUncheckedReceivedSubformula`  
*Stores the position of the first (by this module) unchecked sub-formula of the received formula.*
- `unsigned mSmallerMusesCheckCounter`  
*Counter used for the generation of the smt2 files to check for smaller muses.*
- `std::vector< std::size_t > mVariableCounters`  
*Maps variables to the number of their occurrences.*

### 0.15.332.4 Member Function Documentation

**0.15.332.4.1 add()** `bool smtrat::Module::add (`  
`ModuleInput::const_iterator _subformula ) [inherited]`

The module has to take the given sub-formula of the received formula into account.

Parameters

|                          |                                                    |
|--------------------------|----------------------------------------------------|
| <code>_subformula</code> | The sub-formula to take additionally into account. |
|--------------------------|----------------------------------------------------|

**Returns**

false, if it can be easily decided that this sub-formula causes a conflict with the already considered sub-formulas; true, otherwise.

**0.15.332.4.2 addConstraintToInform()** `void smtrat::Module::addConstraintToInform (`

```
const FormulaT & _constraint) [protected], [virtual], [inherited]
```

Adds a constraint to the collection of constraints of this module, which are informed to a freshly generated backend.

**Parameters**

|                          |                        |
|--------------------------|------------------------|
| <code>_constraint</code> | The constraint to add. |
|--------------------------|------------------------|

Reimplemented in [smtrat::SATModule< Settings >](#).

**0.15.332.4.3 addCore()** `template<typename Settings >`

```
bool smtrat::NewCADModule< Settings >::addCore (
 ModuleInput::const_iterator _subformula) [virtual]
```

The module has to take the given sub-formula of the received formula into account.

**Parameters**

|                          |                                                    |
|--------------------------|----------------------------------------------------|
| <code>_subformula</code> | The sub-formula to take additionally into account. |
|--------------------------|----------------------------------------------------|

**Returns**

false, if it can be easily decided that this sub-formula causes a conflict with the already considered sub-formulas; true, otherwise.

Reimplemented from [smtrat::Module](#).

**0.15.332.4.4 addInformationRelevantFormula()** `void smtrat::Module::addInformationRelevantFormula`

```
(
```

```
const FormulaT & formula) [protected], [inherited]
```

Adds a formula to the InformationRelevantFormula.

**Parameters**

|                      |                |
|----------------------|----------------|
| <code>formula</code> | Formula to add |
|----------------------|----------------|

**0.15.332.4.5 addLemma()** `void smtrat::Module::addLemma (`

```
const FormulaT & _lemma,
```

```
const LemmaType & _lt = LemmaType::NORMAL,
```

```
const FormulaT & _preferredFormula = FormulaT(carl::FormulaType::TRUE)) [inline],
```

```
[inherited]
```

Stores a lemma being a valid formula.

**Parameters**

|                                |                                                                       |
|--------------------------------|-----------------------------------------------------------------------|
| <code>_lemma</code>            | The eduction/lemma to store.                                          |
| <code>_lt</code>               | The type of the lemma.                                                |
| <code>_preferredFormula</code> | Hint for the next decision, which formula should be assigned to true. |

**0.15.332.4.6 addOrigin()** `void smtrat::Module::addOrigin (`

```
 ModuleInput::iterator _formula,
 const FormulaT & _origin) [inline], [protected], [inherited]
```

Adds the given set of formulas in the received formula to the origins of the given passed formula.

**Parameters**

|                       |                                                           |
|-----------------------|-----------------------------------------------------------|
| <code>_formula</code> | The passed formula to set the origins for.                |
| <code>_origin</code>  | A set of formulas in the received formula of this module. |

**0.15.332.4.7 addReceivedSubformulaToPassedFormula()** `std::pair<ModuleInput::iterator, bool>`

```
smtrat::Module::addReceivedSubformulaToPassedFormula (
```

```
 ModuleInput::const_iterator _subformula) [inline], [protected], [inherited]
```

Copies the given sub-formula of the received formula to the passed formula.

Note, that there is always a link between sub-formulas of the passed formulas to sub-formulas of the received formulas, which are responsible for its occurrence.

**Parameters**

|                          |                                                  |
|--------------------------|--------------------------------------------------|
| <code>_subformula</code> | The sub-formula of the received formula to copy. |
|--------------------------|--------------------------------------------------|

**0.15.332.4.8 addSubformulaToPassedFormula() [1/3]** `std::pair<ModuleInput::iterator, bool>`

```
smtrat::Module::addSubformulaToPassedFormula (
```

```
 const FormulaT & _formula) [inline], [protected], [inherited]
```

Adds the given formula to the passed formula with no origin.

Note that in the next call of this module's removeSubformula, all formulas in the passed formula without origins will be removed.

**Parameters**

|                       |                                           |
|-----------------------|-------------------------------------------|
| <code>_formula</code> | The formula to add to the passed formula. |
|-----------------------|-------------------------------------------|

**Returns**

A pair to the position where the formula to add has been inserted (or its first sub-formula which has not yet been in the passed formula, in case the formula to add is a conjunction), and a Boolean stating whether anything has been added to the passed formula.

**0.15.332.4.9 addSubformulaToPassedFormula() [2/3]** `std::pair<ModuleInput::iterator, bool>`

```
smtrat::Module::addSubformulaToPassedFormula (
```

```
 const FormulaT & _formula,
```

```
 const FormulaT & _origin) [inline], [protected], [inherited]
```

Adds the given formula to the passed formula.

**Parameters**

|                       |                                                                                                                           |
|-----------------------|---------------------------------------------------------------------------------------------------------------------------|
| <code>_formula</code> | The formula to add to the passed formula.                                                                                 |
| <code>_origin</code>  | The sub-formula of the received formula being responsible for the occurrence of the formula to add to the passed formula. |

**Returns**

A pair to the position where the formula to add has been inserted (or its first sub-formula which has not yet been in the passed formula, in case the formula to add is a conjunction), and a Boolean stating whether anything has been added to the passed formula.

**0.15.332.4.10 addSubformulaToPassedFormula() [3/3] std::pair<ModuleInput::iterator,bool>**

```
smtrat::Module::addSubformulaToPassedFormula (
 const FormulaT & _formula,
 const std::shared_ptr< std::vector< FormulaT >> & _origins) [inline], [protected],
[inherited]
```

Adds the given formula to the passed formula.

**Parameters**

|                       |                                                                                                                                         |
|-----------------------|-----------------------------------------------------------------------------------------------------------------------------------------|
| <code>_formula</code> | The formula to add to the passed formula.                                                                                               |
| <code>_origins</code> | The link of the formula to add to the passed formula to sub-formulas of the received formulas, which are responsible for its occurrence |

**Returns**

A pair to the position where the formula to add has been inserted (or its first sub-formula which has not yet been in the passed formula, in case the formula to add is a conjunction), and a Boolean stating whether anything has been added to the passed formula.

**0.15.332.4.11 allModels() const std::vector<Model>& smtrat::Module::allModels () const [inline], [inherited]****Returns**

All satisfying assignments, if existent.

**0.15.332.4.12 anAnswerFound() bool smtrat::Module::anAnswerFound () const [inline], [protected], [inherited]**

Checks for all antecedent modules and those which run in parallel with the same antecedent modules, whether one of them has determined a result.

**Returns**

True, if one of them has determined a result.

**0.15.332.4.13 answerFound() const smtrat::Conditionals& smtrat::Module::answerFound () const [inline], [inherited]****Returns**

A vector of Booleans: If any of them is true, we have to terminate a running check procedure.

**0.15.332.4.14 backendsModel() const Model & smtrat::Module::backendsModel () const [protected], [inherited]**

Stores the model of a backend which determined satisfiability of the passed formula in the model of this module.

---

**0.15.332.4.15 branchAt() [1/4]** bool smrat::Module::branchAt (

```
carl::Variable::Arg _var,
const Rational & _value,
bool _leftCaseWeak = true,
bool _preferLeftCase = true,
bool _useReceivedFormulaAsPremise = false,
const std::vector< FormulaT > & _premise = std::vector<FormulaT>()) [inline],
[protected], [inherited]
```

**0.15.332.4.16 branchAt() [2/4]** bool smrat::Module::branchAt (

```
carl::Variable::Arg _var,
const Rational & _value,
std::vector< FormulaT > && _premise,
bool _leftCaseWeak = true,
bool _preferLeftCase = true,
bool _useReceivedFormulaAsPremise = false) [inline], [protected], [inherited]
```

**0.15.332.4.17 branchAt() [3/4]** bool smrat::Module::branchAt (

```
const Poly & _polynomial,
bool _integral,
const Rational & _value,
bool _leftCaseWeak = true,
bool _preferLeftCase = true,
bool _useReceivedFormulaAsPremise = false,
const std::vector< FormulaT > & _premise = std::vector<FormulaT>()) [inline],
[protected], [inherited]
```

**0.15.332.4.18 branchAt() [4/4]** bool smrat::Module::branchAt (

```
const Poly & _polynomial,
bool _integral,
const Rational & _value,
std::vector< FormulaT > && _premise,
bool _leftCaseWeak = true,
bool _preferLeftCase = true,
bool _useReceivedFormulaAsPremise = false) [protected], [inherited]
```

Adds a lemmas which provoke a branching for the given variable at the given value, if this module returns Unknown and there exists a preceding [SATModule](#).

Note that the given value is rounded down and up, if the given variable is integer-valued.

#### Parameters

|                                           |                                                                                                                                                                                                                |
|-------------------------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>_polynomial</code>                  | The variable to branch for.                                                                                                                                                                                    |
| <code>_integral</code>                    | A flag being true, if all variables in the polynomial to branch for are integral.                                                                                                                              |
| <code>_value</code>                       | The value to branch at.                                                                                                                                                                                        |
| <code>_premise</code>                     | The sub-formulas of the received formula from which the branch is followed. Note, that a premise is not necessary, as every branch is a valid formula. But a premise can prevent from branching unnecessarily. |
| <code>_leftCaseWeak</code>                | true, if a branching in the form of (or ( $\leq p b$ ) ( $> p b$ )) is desired. false, if a branching in the form of (or ( $< p b$ ) ( $\geq p b$ )) is desired.                                               |
| <code>_preferLeftCase</code>              | true, if the left case (polynomial less(or equal) 0 shall be chosen first. false, otherwise.                                                                                                                   |
| <code>_useReceivedFormulaAsPremise</code> | true, if the whole received formula should be used as premise                                                                                                                                                  |

```
0.15.332.4.19 check() Answer smtrat::Module::check (
 bool _final = false,
 bool _full = true,
 carl::Variable _objective = carl::Variable::NO_VARIABLE) [virtual], [inherited]
```

Checks the received formula for consistency.

Note, that this is an implementation of the satisfiability check of the conjunction of the so far received formulas, which does actually nothing but passing the problem to its backends. This implementation is only used internally and must be overwritten by any derived module.

#### Parameters

|                   |                                                                                                                                       |
|-------------------|---------------------------------------------------------------------------------------------------------------------------------------|
| <i>_final</i>     | true, if this satisfiability check will be the last one (for a global sat-check), if its result is SAT                                |
| <i>_full</i>      | false, if this module should avoid too expensive procedures and rather return unknown instead.                                        |
| <i>_objective</i> | if not set to NO_VARIABLE, the module should find an assignment minimizing this objective variable; otherwise any assignment is good. |

#### Returns

True, if the received formula is satisfiable; False, if the received formula is not satisfiable; Unknown, otherwise.

Reimplemented in [smtrat::PModule](#).

```
0.15.332.4.20 checkCore() template<typename Settings >
Answer smtrat::NewCADModule< Settings >::checkCore () [virtual]
```

Checks the received formula for consistency.

#### Parameters

|                   |                                                                                                                                       |
|-------------------|---------------------------------------------------------------------------------------------------------------------------------------|
| <i>_full</i>      | false, if this module should avoid too expensive procedures and rather return unknown instead.                                        |
| <i>_objective</i> | if not set to NO_VARIABLE, the module should find an assignment minimizing this objective variable; otherwise any assignment is good. |

#### Returns

True, if the received formula is satisfiable; False, if the received formula is not satisfiable; Unknown, otherwise.

Reimplemented from [smtrat::Module](#).

```
0.15.332.4.21 checkInfSubsetForMinimality() void smtrat::Module::checkInfSubsetForMinimality (
 std::vector< FormulaSetT >::const_iterator _infsSubset,
 const std::string & _filename = "smaller_muses",
 unsigned _maxSizeDifference = 1) const [inherited]
```

Checks the given infeasible subset for minimality by storing all subsets of it, which have a smaller size which differs from the size of the infeasible subset not more than the given threshold.

#### Parameters

|                           |                                                                                                        |
|---------------------------|--------------------------------------------------------------------------------------------------------|
| <i>_infsSubset</i>        | The infeasible subset to check for minimality.                                                         |
| <i>_filename</i>          | The name of the file to store the infeasible subsets in order to be able to check their infeasibility. |
| <i>_maxSizeDifference</i> | The maximal difference between the sizes of the subsets compared to the size of the infeasible subset. |

**0.15.332.4.22 checkModel()** `unsigned smtrat::Module::checkModel ( ) const [protected], [inherited]`

Returns

false, if the current model of this module does not satisfy the current given formula; true, if it cannot be said whether the model satisfies the given formula.

**0.15.332.4.23 cleanModel()** `void smtrat::Module::cleanModel ( ) const [inline], [protected], [inherited]`

Substitutes variable occurrences by its model value in the model values of other variables.

**0.15.332.4.24 clearLemmas()** `void smtrat::Module::clearLemmas ( ) [inline], [inherited]`  
Deletes all yet found lemmas.

**0.15.332.4.25 clearModel()** `void smtrat::Module::clearModel ( ) const [inline], [protected], [inherited]`

Clears the assignment, if any was found.

**0.15.332.4.26 clearModels()** `void smtrat::Module::clearModels ( ) const [inline], [protected], [inherited]`

Clears all assignments, if any was found.

**0.15.332.4.27 clearPassedFormula()** `void smtrat::Module::clearPassedFormula ( ) [protected], [inherited]`

**0.15.332.4.28 collectOrigins() [1/2]** `void smtrat::Module::collectOrigins ( const FormulaT & _formula, FormulaSetT & _origins ) const [inherited]`

**0.15.332.4.29 collectOrigins() [2/2]** `void smtrat::Module::collectOrigins ( const FormulaT & _formula, FormulasT & _origins ) const [inherited]`

Collects the formulas in the given formula, which are part of the received formula.

If the given formula directly occurs in the received formula, it is inserted into the given set. Otherwise, the given formula must be of type AND and all its sub-formulas part of the received formula. Hence, they will be added to the given set.

Parameters

|                       |                                                                                                      |
|-----------------------|------------------------------------------------------------------------------------------------------|
| <code>_formula</code> | The formula from which to collect the formulas being sub-formulas of the received formula (origins). |
| <code>_origins</code> | The set in which to store the origins.                                                               |

**0.15.332.4.30 collectTheoryPropagations()** `void smtrat::Module::collectTheoryPropagations ( ) [inherited]`

**0.15.332.4.31 constraintsToInform()** const carl::FastSet<[FormulaT](#)>& smrat::Module::constraintsToInform( ) const [inline], [inherited]

#### Returns

The constraints which the backends must be informed about.

**0.15.332.4.32 currentlySatisfied()** virtual unsigned smrat::Module::currentlySatisfied( const [FormulaT](#) & ) const [inline], [virtual], [inherited]

#### Returns

0, if the given formula is conflicted by the current model; 1, if the given formula is satisfied by the current model; 2, otherwise; 3, if we do not know anything (default)

Reimplemented in [smrat::LRAModule< Settings >](#), [smrat::LRAModule< LRASettingsICP >](#), and [smrat::LRAModule< LRASettings >](#)

**0.15.332.4.33 currentlySatisfiedByBackend()** unsigned smrat::Module::currentlySatisfiedByBackend( const [FormulaT](#) & \_formula ) const [inherited]

#### Returns

0, if the given formula is conflicted by the current model; 1, if the given formula is satisfied by the current model; 2, otherwise 3, if we do not know anything (default)

**0.15.332.4.34 deinform()** void smrat::Module::deinform( const [FormulaT](#) & \_constraint ) [inherited]

The inverse of informing about a constraint.

All data structures which were kept regarding this constraint are going to be removed. Note, that this makes only sense if it is not likely enough that a formula with this constraint must be solved again.

#### Parameters

|                          |                                                         |
|--------------------------|---------------------------------------------------------|
| <code>_constraint</code> | The constraint to remove from internal data structures. |
|--------------------------|---------------------------------------------------------|

**0.15.332.4.35 deinformCore()** virtual void smrat::Module::deinformCore( const [FormulaT](#) & \_constraint ) [inline], [protected], [virtual], [inherited]

The inverse of informing about a constraint.

All data structures which were kept regarding this constraint are going to be removed. Note, that this makes only sense if it is not likely enough that a formula with this constraint must be solved again.

#### Parameters

|                          |                                                         |
|--------------------------|---------------------------------------------------------|
| <code>_constraint</code> | The constraint to remove from internal data structures. |
|--------------------------|---------------------------------------------------------|

Reimplemented in [smrat::LRAModule< Settings >](#), [smrat::LRAModule< LRASettingsICP >](#), and [smrat::LRAModule< LRASettings >](#)

**0.15.332.4.36 determine\_smallest\_origin()** size\_t smrat::Module::determine\_smallest\_origin( const std::vector< [FormulaT](#) > & origins ) const [protected], [inherited]

**Parameters**

|                |                              |
|----------------|------------------------------|
| <i>origins</i> | A vector of sets of origins. |
|----------------|------------------------------|

**Returns**

The index of the smallest (regarding the size of the sets) element of origins

**0.15.332.4.37 `eraseSubformulaFromPassedFormula()`** `ModuleInput::iterator smtrat::Module::erase<SubformulaFromPassedFormula (`

`ModuleInput::iterator _subformula,`  
`bool _ignoreOrigins = false ) [protected], [virtual], [inherited]`

Removes everything related to the sub-formula to remove from the passed formula in the backends of this module.  
Afterwards the sub-formula is removed from the passed formula.

**Parameters**

|                       |                                                                                                              |
|-----------------------|--------------------------------------------------------------------------------------------------------------|
| <i>_subformula</i>    | The sub-formula to remove from the passed formula.                                                           |
| <i>_ignoreOrigins</i> | True, if the sub-formula shall be removed regardless of its origins (should only be applied with expertise). |

**Returns**

Reimplemented in `smtrat::ICPModule< Settings >`, `smtrat::ICPModule< ICPSettings4 >`, and `smtrat::ICPModule< ICPSettings1 >`.

**0.15.332.4.38 `excludeNotReceivedVariablesFromModel()`** `void smtrat::Module::excludeNotReceived<VariablesFromModel ( ) const [inherited]`

Excludes all variables from the current model, which do not occur in the received formula.

**0.15.332.4.39 `findBestOrigin()`** `std::vector< FormulaT >::const_iterator smtrat::Module::find<BestOrigin (`

`const std::vector< FormulaT > & _origins ) const [protected], [inherited]`

**Parameters**

|                 |  |
|-----------------|--|
| <i>_origins</i> |  |
|-----------------|--|

**Returns**

**0.15.332.4.40 `firstSubformulaToPass()`** `ModuleInput::const_iterator smtrat::Module::firstSubformula<ToPass ( ) const [inline], [inherited]`

**Returns**

The position of the first sub-formula in the passed formula, which has not yet been considered for a consistency check of the backends.

**0.15.332.4.41 firstUncheckedReceivedSubformula()** `ModuleInput::const_iterator smtrat::Module::firstUncheckedReceivedSubformula ( ) const [inline], [inherited]`

#### Returns

The position of the first (by this module) unchecked sub-formula of the received formula.

**0.15.332.4.42 freeSplittingVariable()** `static void smtrat::Module::freeSplittingVariable ( const FormulaT & _splittingVariable ) [inline], [static], [inherited]`

**0.15.332.4.43 generateTrivialInfeasibleSubset()** `void smtrat::Module::generateTrivialInfeasibleSubset ( ) [inline], [protected], [inherited]`

Stores the trivial infeasible subset being the set of received formulas.

**0.15.332.4.44 getBackendsAllModels()** `void smtrat::Module::getBackendsAllModels ( ) const [protected], [inherited]`

Stores all models of a backend in the list of all models of this module.

**0.15.332.4.45 getBackendsModel()** `void smtrat::Module::getBackendsModel ( ) const [protected], [inherited]`

**0.15.332.4.46 getInfeasibleSubsets() [1/2]** `void smtrat::Module::getInfeasibleSubsets ( ) [protected], [inherited]`

Copies the infeasible subsets of the passed formula.

**0.15.332.4.47 getInfeasibleSubsets() [2/2]** `std::vector< FormulaSetT > smtrat::Module::getInfeasibleSubsets (`

`const Module & _backend ) const [protected], [inherited]`

Get the infeasible subsets the given backend provides.

Note, that an infeasible subset in a backend contains sub formulas of the passed formula and an infeasible subset of this module contains sub formulas of the received formula. In this method the LATTER is returned.

#### Parameters

|                       |                                                          |
|-----------------------|----------------------------------------------------------|
| <code>_backend</code> | The backend from which to obtain the infeasible subsets. |
|-----------------------|----------------------------------------------------------|

#### Returns

The infeasible subsets the given backend provides.

**0.15.332.4.48 getInformationRelevantFormulas()** `const std::set< FormulaT > & smtrat::Module::getInformationRelevantFormulas ( ) [protected], [inherited]`

Gets all InformationRelevantFormulas.

#### Returns

Set of all formulas

**0.15.332.4.49 getModelEqualities()** `std::list< std::vector< carl::Variable > > smtrat::Module::getModelEqualities ( ) const [virtual], [inherited]`

Partition the variables from the current model into equivalence classes according to their assigned value.

The result is a set of equivalence classes of variables where all variables within one class are assigned the same value. Note that the number of classes may not be minimal, i.e. two classes may actually be equivalent.

#### Returns

Equivalence classes.

**0.15.332.4.50 getOrigins() [1/3]** `void smtrat::Module::getOrigins (`

```
const FormulaT & _formula,
FormulaSetT & _origins) const [inline], [protected], [inherited]
```

#### Parameters

|                       |  |
|-----------------------|--|
| <code>_formula</code> |  |
| <code>_origins</code> |  |

**0.15.332.4.51 getOrigins() [2/3]** `void smtrat::Module::getOrigins (`

```
const FormulaT & _formula,
FormulasT & _origins) const [inline], [protected], [inherited]
```

#### Parameters

|                       |  |
|-----------------------|--|
| <code>_formula</code> |  |
| <code>_origins</code> |  |

**0.15.332.4.52 getOrigins() [3/3]** `const FormulaT& smtrat::Module::getOrigins (`

```
ModuleInput::const_iterator _formula) const [inline], [protected], [inherited]
```

Gets the origins of the passed formula at the given position.

#### Parameters

|                       |                                                   |
|-----------------------|---------------------------------------------------|
| <code>_formula</code> | The position of a formula in the passed formulas. |
|-----------------------|---------------------------------------------------|

#### Returns

The origins of the passed formula at the given position.

**0.15.332.4.53 getReceivedFormulaSimplified()** `std::pair< bool, FormulaT > smtrat::Module::getReceivedFormulaSimplified ( ) [virtual], [inherited]`

#### Returns

A pair of a Boolean and a formula, where the Boolean is true, if the received formula could be simplified to an equisatisfiable formula. The formula is equisatisfiable to this module's received formula, if the Boolean is true.

Reimplemented in [smtrat::PModule](#).

**0.15.332.4.54 hasLemmas()** `bool smtrat::Module::hasLemmas () [inline], [inherited]`  
Checks whether this module or any of its backends provides any lemmas.

**0.15.332.4.55 hasValidInfeasibleSubset()** `bool smtrat::Module::hasValidInfeasibleSubset () const [inherited]`

**Returns**

true, if the module has at least one valid infeasible subset, that is all its elements are sub-formulas of the received formula (pointer must be equal).

**0.15.332.4.56 id()** `std::size_t smtrat::Module::id () const [inline], [inherited]`

**Returns**

A unique ID to identify this module instance.

**0.15.332.4.57 infeasibleSubsets()** `const std::vector<FormulaSetT>& smtrat::Module::infeasibleSubsets () const [inline], [inherited]`

**Returns**

The infeasible subsets of the set of received formulas (empty, if this module has not detected unsatisfiability of the conjunction of received formulas).

**0.15.332.4.58 inform()** `bool smtrat::Module::inform (const FormulaT & _constraint) [inherited]`

Informs the module about the given constraint.

It should be tried to inform this module about any constraint it could receive eventually before assertSubformula is called (preferably for the first time, but at least before adding a formula containing that constraint).

**Parameters**

|                          |                                 |
|--------------------------|---------------------------------|
| <code>_constraint</code> | The constraint to inform about. |
|--------------------------|---------------------------------|

**Returns**

false, if it can be easily decided whether the given constraint is inconsistent; true, otherwise.

**0.15.332.4.59 informBackends()** `void smtrat::Module::informBackends (const FormulaT & _constraint) [inline], [protected], [inherited]`

Informs all backends of this module about the given constraint.

**Parameters**

|                          |                                 |
|--------------------------|---------------------------------|
| <code>_constraint</code> | The constraint to inform about. |
|--------------------------|---------------------------------|

**0.15.332.4.60 informCore()** `template<typename Settings > bool smtrat::NewCADModule< Settings >::informCore (`

```
 const FormulaT & _constraint) [virtual]
```

Informs the module about the given constraint.

It should be tried to inform this module about any constraint it could receive eventually before assertSubformula is called (preferably for the first time, but at least before adding a formula containing that constraint).

#### Parameters

|                          |                                 |
|--------------------------|---------------------------------|
| <code>_constraint</code> | The constraint to inform about. |
|--------------------------|---------------------------------|

#### Returns

`false`, if it can be easily decided whether the given constraint is inconsistent; `true`, otherwise.

Reimplemented from [smtrat::Module](#).

**0.15.332.4.61 informedConstraints()** `const carl::FastSet<FormulaT>& smtrat::Module::informedConstraints ( ) const [inline], [inherited]`

#### Returns

The position of the first constraint of which no backend has been informed about.

**0.15.332.4.62 init()** `template<typename Settings > void smtrat::NewCADModule< Settings >::init ( ) [virtual]`

Informs all backends about the so far encountered constraints, which have not yet been communicated.

This method must not and will not be called more than once and only before the first runBackends call.

Reimplemented from [smtrat::Module](#).

**0.15.332.4.63 is\_minimizing()** `bool smtrat::Module::is_minimizing ( ) const [inline], [inherited]`

**0.15.332.4.64 isLemmaLevel()** `bool smtrat::Module::isLemmaLevel (`

```
 LemmaLevel level) [protected], [inherited]
```

Checks if current lemma level is greater or equal to given level.

#### Parameters

|                    |                 |
|--------------------|-----------------|
| <code>level</code> | Level to check. |
|--------------------|-----------------|

**0.15.332.4.65 isPreprocessor()** `bool smtrat::Module::isPreprocessor ( ) const [inline], [inherited]`

#### Returns

`true`, if this module is a preprocessor that is a module, which simplifies its received formula to an equisatisfiable formula being passed to its backends. The simplified formula can be obtained with [getReceivedFormulaSimplified\(\)](#).

**0.15.332.4.66 lemmas()** `const std::vector<Lemma>& smtrat::Module::lemmas ( ) const [inline], [inherited]`

**Returns**

A constant reference to the lemmas being valid formulas this module or its backends made.

**0.15.332.4.67 merge()** std::vector< [FormulaT](#) > smtrat::Module::merge ( const std::vector< [FormulaT](#) > & [\\_vecSetA](#), const std::vector< [FormulaT](#) > & [\\_vecSetB](#) ) const [protected], [inherited]  
Merges the two vectors of sets into the first one.  
({a,b},{a,c}) and ({b,d},{b}) -> ({a,b,d},{a,b},{a,b,c,d},{a,b,c})

**Parameters**

|                          |                                  |
|--------------------------|----------------------------------|
| <a href="#">_vecSetA</a> | A vector of sets of constraints. |
| <a href="#">_vecSetB</a> | A vector of sets of constraints. |

**Returns**

The vector being the two given vectors merged.

**0.15.332.4.68 model()** const [Model&](#) smtrat::Module::model ( ) const [inline], [inherited]

**Returns**

The assignment of the current satisfiable result, if existent.

**0.15.332.4.69 modelsDisjoint()** bool smtrat::Module::modelsDisjoint ( const [Model](#) & [\\_modelA](#), const [Model](#) & [\\_modelB](#) ) [static], [protected], [inherited]  
Checks whether there is no variable assigned by both models.

**Parameters**

|                         |                                |
|-------------------------|--------------------------------|
| <a href="#">_modelA</a> | The first model to check for.  |
| <a href="#">_modelB</a> | The second model to check for. |

**Returns**

true, if there is no variable assigned by both models; false, otherwise.

**0.15.332.4.70 moduleName()** template<typename Settings > std::string smtrat::NewCADModule< [Settings](#) >::moduleName ( ) const [inline], [virtual]

**Returns**

The name of the given module type as name.

Reimplemented from [smtrat::Module](#).

**0.15.332.4.71 objective()** carl::Variable smtrat::Module::objective ( ) const [inline], [inherited]

**0.15.332.4.72 originInReceivedFormula()** `bool smtrat::Module::originInReceivedFormula (`  
    `const FormulaT & _origin ) const [protected], [inherited]`

**0.15.332.4.73 passedFormulaBegin()** `ModuleInput::iterator smtrat::Module::passedFormulaBegin (`  
    `) [inline], [protected], [inherited]`

**Returns**

An iterator to the end of the passed formula. TODO: disable this method

**0.15.332.4.74 passedFormulaEnd()** `ModuleInput::iterator smtrat::Module::passedFormulaEnd ( )`  
[inline], [protected], [inherited]

**Returns**

An iterator to the end of the passed formula.

**0.15.332.4.75 pPassedFormula()** `const ModuleInput* smtrat::Module::pPassedFormula ( ) const`  
[inline], [inherited]

**Returns**

A pointer to the formula passed to the backends of this module.

**0.15.332.4.76 pReceivedFormula()** `const ModuleInput* smtrat::Module::pReceivedFormula ( ) const`  
[inline], [inherited]

**Returns**

A pointer to the formula passed to this module.

**0.15.332.4.77 print()** `void smtrat::Module::print (`  
    `const std::string & _initiation = "***" ) const [inherited]`

Prints everything relevant of the solver.

**Parameters**

|                          |                      |
|--------------------------|----------------------|
| <code>_initiation</code> | The line initiation. |
|--------------------------|----------------------|

**0.15.332.4.78 printAllModels()** `void smtrat::Module::printAllModels (`  
    `std::ostream & _out = std::cout ) [inherited]`

Prints all assignments of this module satisfying its received formula if it satisfiable and this module could find an assignment.

**Parameters**

|                   |                                        |
|-------------------|----------------------------------------|
| <code>_out</code> | The stream to print the assignment on. |
|-------------------|----------------------------------------|

**0.15.332.4.79 printInfeasibleSubsets()** void smtrat::Module::printInfeasibleSubsets ( const std::string & *\_initiation* = "\*\*\*" ) const [inherited]  
Prints the infeasible subsets.

#### Parameters

|                    |                      |
|--------------------|----------------------|
| <i>_initiation</i> | The line initiation. |
|--------------------|----------------------|

**0.15.332.4.80 printModel()** void smtrat::Module::printModel ( std::ostream & *\_out* = std::cout ) const [inherited]

Prints the assignment of this module satisfying its received formula if it satisfiable and this module could find an assignment.

#### Parameters

|             |                                        |
|-------------|----------------------------------------|
| <i>_out</i> | The stream to print the assignment on. |
|-------------|----------------------------------------|

**0.15.332.4.81 printPassedFormula()** void smtrat::Module::printPassedFormula ( const std::string & *\_initiation* = "\*\*\*" ) const [inherited]

Prints the vector of passed formula.

#### Parameters

|                    |                      |
|--------------------|----------------------|
| <i>_initiation</i> | The line initiation. |
|--------------------|----------------------|

**0.15.332.4.82 printReceivedFormula()** void smtrat::Module::printReceivedFormula ( const std::string & *\_initiation* = "\*\*\*" ) const [inherited]

Prints the vector of the received formula.

#### Parameters

|                    |                      |
|--------------------|----------------------|
| <i>_initiation</i> | The line initiation. |
|--------------------|----------------------|

**0.15.332.4.83 probablyLooping()** bool smtrat::Module::probablyLooping ( const typename Poly::PolyType & *\_branchingPolynomial*, const Rational & *\_branchingValue* ) const [protected], [inherited]

Checks whether given the current branching value and branching variable/polynomial it is (highly) probable that this branching is part of an infinite loop of branchings.

#### Parameters

|                             |                                                                                     |
|-----------------------------|-------------------------------------------------------------------------------------|
| <i>_branchingPolynomial</i> | The polynomial to branch at (in most branching strategies this is just a variable). |
| <i>_branchingValue</i>      | The value to branch at.                                                             |

#### Returns

true, if this branching is probably part of an infinite loop of branchings; false, otherwise.

**0.15.332.4.84 receivedFormulaChecked()** void smtrat::Module::receivedFormulaChecked () [inline], [inherited]  
Notifies that the received formulas has been checked.

**0.15.332.4.85 receivedFormulasAsInfeasibleSubset()** void smtrat::Module::receivedFormulasAsInfeasibleSubset ( ModuleInput::const\_iterator \_subformula ) [inline], [protected], [inherited]  
Stores an infeasible subset consisting only of the given received formula.

**0.15.332.4.86 receivedVariable()** bool smtrat::Module::receivedVariable ( carl::Variable::Arg \_var ) const [inline], [inherited]

**0.15.332.4.87 remove()** void smtrat::Module::remove ( ModuleInput::const\_iterator \_subformula ) [virtual], [inherited]

Removes everything related to the given sub-formula of the received formula.  
However, it is desired not to lose track of search spaces where no satisfying assignment can be found for the remaining sub-formulas.

#### Parameters

|             |                                                    |
|-------------|----------------------------------------------------|
| _subformula | The sub formula of the received formula to remove. |
|-------------|----------------------------------------------------|

Reimplemented in [smtrat::PModule](#).

**0.15.332.4.88 removeCore()** template<typename Settings >  
void smtrat::NewCADModule< Settings >::removeCore ( ModuleInput::const\_iterator \_subformula ) [virtual]

Removes the subformula of the received formula at the given position to the considered ones of this module.  
Note that this includes every stored calculation which depended on this subformula, but should keep the other stored calculation, if possible, untouched.

#### Parameters

|             |                                           |
|-------------|-------------------------------------------|
| _subformula | The position of the subformula to remove. |
|-------------|-------------------------------------------|

Reimplemented from [smtrat::Module](#).

**0.15.332.4.89 removeOrigin()** std::pair<ModuleInput::iterator,bool> smtrat::Module::removeOrigin ( ModuleInput::iterator \_formula, const FormulaT & \_origin ) [inline], [protected], [inherited]

**0.15.332.4.90 removeOrigins()** std::pair<ModuleInput::iterator,bool> smtrat::Module::removeOrigins ( ModuleInput::iterator \_formula, const std::shared\_ptr< std::vector< FormulaT >> & \_origins ) [inline], [protected], [inherited]

**0.15.332.4.91 rPassedFormula()** const ModuleInput& smtrat::Module::rPassedFormula () const

[inline], [inherited]

#### Returns

A reference to the formula passed to the backends of this module.

**0.15.332.4.92 rReceivedFormula()** `const ModuleInput& smtrat::Module::rReceivedFormula () const`  
 [inline], [inherited]

#### Returns

A reference to the formula passed to this module.

**0.15.332.4.93 runBackends() [1/2]** `virtual Answer smtrat::Module::runBackends () [inline], [protected], [virtual], [inherited]`  
 Reimplemented in [smtrat::PModule](#).

**0.15.332.4.94 runBackends() [2/2]** `Answer smtrat::Module::runBackends (`

```
 bool _final,
 bool _full,
 carl::Variable _objective) [protected], [virtual], [inherited]
```

Runs the backend solvers on the passed formula.

#### Parameters

|                         |                                                                                                                                       |
|-------------------------|---------------------------------------------------------------------------------------------------------------------------------------|
| <code>_final</code>     | true, if this satisfiability check will be the last one (for a global sat-check), if its result is SAT                                |
| <code>_full</code>      | false, if this module should avoid too expensive procedures and rather return unknown instead.                                        |
| <code>_objective</code> | if not set to NO_VARIABLE, the module should find an assignment minimizing this objective variable; otherwise any assignment is good. |

#### Returns

True, if the passed formula is consistent; False, if the passed formula is inconsistent; Unknown, otherwise.

Reimplemented in [smtrat::PModule](#).

**0.15.332.4.95 setId()** `void smtrat::Module::setId (`  
`std::size_t _id ) [inline], [inherited]`

Sets this modules unique ID to identify itself.

#### Parameters

|                 |                                    |
|-----------------|------------------------------------|
| <code>id</code> | The id to set this module's id to. |
|-----------------|------------------------------------|

**0.15.332.4.96 setThreadPriority()** `void smtrat::Module::setThreadPriority (`  
`thread_priority _threadPriority ) [inline], [inherited]`

Sets the priority of this module to get a thread for running its check procedure.

**Parameters**

|                              |                                                       |
|------------------------------|-------------------------------------------------------|
| <code>_threadPriority</code> | The priority to set this module's thread priority to. |
|------------------------------|-------------------------------------------------------|

**0.15.332.4.97 `solverState()`** Answer smtrat::Module::solverState ( ) const [inline], [inherited]**Returns**

True, if this module is in a state, such that it has found a solution for its received formula; False, if this module is in a state, such that it has determined that there is no solution for its received formula; Unknown, otherwise.

**0.15.332.4.98 `splitUnequalConstraint()`** void smtrat::Module::splitUnequalConstraint ( const FormulaT & \_unequalConstraint ) [protected], [inherited]

Adds the following lemmas for the given constraint  $p \neq 0$ .

$$(p \neq 0 \Leftrightarrow (p < 0 \text{ or } p > 0))$$

and  $\neg(p < 0 \text{ and } p > 0)$

**Parameters**

|                                 |                                                  |
|---------------------------------|--------------------------------------------------|
| <code>_unequalConstraint</code> | A constraint having the relation symbol $\neq$ . |
|---------------------------------|--------------------------------------------------|

**0.15.332.4.99 `threadPriority()`** thread\_priority smtrat::Module::threadPriority ( ) const [inline], [inherited]**Returns**

The priority of this module to get a thread for running its check procedure.

**0.15.332.4.100 `updateAllModels()`** void smtrat::Module::updateAllModels ( ) [virtual], [inherited]

Updates all satisfying models, if the solver has detected the consistency of the received formula, beforehand.

Reimplemented in [smtrat::SATModule< Settings >](#).

**0.15.332.4.101 `updateLemmas()`** void smtrat::Module::updateLemmas ( ) [inherited]

Stores all lemmas of any backend of this module in its own lemma vector.

**0.15.332.4.102 `updateModel()`** template<typename Settings > void smtrat::NewCADModule< Settings >::updateModel ( ) const [virtual]

Updates the current assignment into the model.

Note, that this is a unique but possibly symbolic assignment maybe containing newly introduced variables.

Reimplemented from [smtrat::Module](#).

**0.15.332.4.103 `usedBackends()`** const std::vector<Module\*>& smtrat::Module::usedBackends ( ) const [inline], [inherited]**Returns**

The backends of this module which are currently used (conditions to use this module are fulfilled for the passed formula).

### 0.15.332.5 Field Documentation

**0.15.332.5.1 mAllBackends** std::vector<[Module](#)\*> smrat::Module::mAllBackends [protected], [inherited]

The backends of this module which have been used.

**0.15.332.5.2 mAllModels** std::vector<[Model](#)> smrat::Module::mAllModels [mutable], [protected], [inherited]

Stores all satisfying assignments.

**0.15.332.5.3 mBackendsFoundAnswer** std::atomic\_bool\* smrat::Module::mBackendsFoundAnswer [protected], [inherited]

This flag is passed to any backend and if it determines an answer to a prior check call, this flag is fired.

**0.15.332.5.4 mConstraintsToInform** carl::FastSet<[FormulaT](#)> smrat::Module::mConstraintsToInform [protected], [inherited]

Stores the constraints which the backends must be informed about.

**0.15.332.5.5 mFinalCheck** bool smrat::Module::mFinalCheck [protected], [inherited]

true, if the check procedure should perform a final check which especially means not to postpone splitting decisions

**0.15.332.5.6 mFirstPosInLastBranches** std::size\_t smrat::Module::mFirstPosInLastBranches = 0 [static], [inherited]

The beginning of the cyclic buffer storing the last branches.

**0.15.332.5.7 mFirstSubformulaToPass** [ModuleInput](#)::iterator smrat::Module::mFirstSubformulaToPass [protected], [inherited]

Stores the position of the first sub-formula in the passed formula, which has not yet been considered for a consistency check of the backends.

**0.15.332.5.8 mFirstUncheckedReceivedSubformula** [ModuleInput](#)::const\_iterator smrat::Module::mFirstUncheckedReceivedSubformula [protected], [inherited]

Stores the position of the first (by this module) unchecked sub-formula of the received formula.

**0.15.332.5.9 mFoundAnswer** [Conditionals](#) smrat::Module::mFoundAnswer [protected], [inherited]

Vector of Booleans: If any of them is true, we have to terminate a running check procedure.

**0.15.332.5.10 mFullCheck** bool smrat::Module::mFullCheck [protected], [inherited]

false, if this module should avoid too expensive procedures and rather return unknown instead.

**0.15.332.5.11 mInfeasibleSubsets** std::vector<[FormulaSetT](#)> smrat::Module::mInfeasibleSubsets [protected], [inherited]

Stores the infeasible subsets.

**0.15.332.5.12 mInformedConstraints** `carl::FastSet<FormulaT> smtrat::Module::mInformedConstraints` [protected], [inherited]  
Stores the position of the first constraint of which no backend has been informed about.

**0.15.332.5.13 mLastBranches** `std::vector<Branching> smtrat::Module::mLastBranches = std::vector<Branching>(mNumOfBranchVarsToStore, Branching(typename Poly::PolyType(), 0))` [static], [inherited]  
Stores the last branches in a cycle buffer.

**0.15.332.5.14 mLemmas** `std::vector<Lemma> smtrat::Module::mLemmas` [protected], [inherited]  
Stores the lemmas being valid formulas this module or its backends made.

**0.15.332.5.15 mModel** `Model smtrat::Module::mModel` [mutable], [protected], [inherited]  
Stores the assignment of the current satisfiable result, if existent.

**0.15.332.5.16 mModelComputed** `bool smtrat::Module::mModelComputed` [mutable], [protected], [inherited]  
True, if the model has already been computed.

**0.15.332.5.17 mNumOfBranchVarsToStore** `std::size_t smtrat::Module::mNumOfBranchVarsToStore = 5` [static], [inherited]  
The number of different variables to consider for a probable infinite loop of branchings.

**0.15.332.5.18 mObjectiveVariable** `carl::Variable smtrat::Module::mObjectiveVariable` [protected], [inherited]  
Objective variable to be minimized. If set to NO\_VARIABLE, a normal sat check should be performed.

**0.15.332.5.19 mOldSplittingVariables** `std::vector<FormulaT> smtrat::Module::mOldSplittingVariables` [static], [inherited]  
Reusable splitting variables.

**0.15.332.5.20 mpManager** `Manager* const smtrat::Module::mpManager` [protected], [inherited]  
A reference to the manager.

**0.15.332.5.21 mSmallerMusesCheckCounter** `unsigned smtrat::Module::mSmallerMusesCheckCounter` [mutable], [protected], [inherited]  
Counter used for the generation of the smt2 files to check for smaller muses.

**0.15.332.5.22 mSolverState** `std::atomic<Answer> smtrat::Module::mSolverState` [protected], [inherited]  
States whether the received formula is known to be satisfiable or unsatisfiable otherwise it is set to unknown.

**0.15.332.5.23 mTheoryPropagations** `std::vector<TheoryPropagation> smtrat::Module::mTheoryPropagations` [protected], [inherited]

**0.15.332.5.24 mUsedBackends** std::vector<Module\*> smtrat::Module::mUsedBackends [protected], [inherited]

The backends of this module which are currently used (conditions to use this module are fulfilled for the passed formula).

**0.15.332.5.25 mVariableCounters** std::vector<std::size\_t> smtrat::Module::mVariableCounters [protected], [inherited]

Maps variables to the number of their occurrences.

## 0.15.333 smtrat::NewCoveringModule< Settings > Class Template Reference

```
#include <NewCoveringModule.h>
```

### Public Types

- using `SettingsType = Settings`
- enum class `LemmaType` : unsigned { `NORMAL` = 0 , `PERMANENT` = 1 }

### Public Member Functions

- `NewCoveringModule` (const `ModuleInput` \*\_formula, `Conditionals` &\_conditionals, `Manager` \*\_manager= nullptr)
 

*Informs the module about the given constraint.*
- `~NewCoveringModule` ()
 

*The module has to take the given sub-formula of the received formula into account.*
- `bool informCore` (const `FormulaT` &\_constraint)
 

*Informs all backends about the so far encountered constraints, which have not yet been communicated.*
- `bool addCore` (`ModuleInput::const_iterator` \_subformula)
 

*Updates the current assignment into the model.*
- `void removeCore` (`ModuleInput::const_iterator` \_subformula)
 

*Removes the subformula of the received formula at the given position to the considered ones of this module.*
- `void updateModel` () const
 

*Updates the current assignment into the model.*
- `Answer checkCore` ()
 

*Processes the current answer, i.e.*
- `void processAnswer` ()
 

*Adds the given constraint to the backend.*
- `size_t addConstraintsSAT` ()
 

*Removes the given constraints from the backend.*
- `void removeConstraintsSAT` ()
 

*Adds the given constraint to the backend.*
- `void addConstraintsUNSAT` ()
 

*Removes the given constraints from the backend Also removes all stored information about the removed constraints.*
- `std::optional< Answer > doBacktracking` ()
 

*The actual backtracking algorithm, which is called when we have constraints to add and no constraints to remove.*
- `std::optional< Answer > doIncremental` ()
 

*The actual incremental algorithm, which is called when we have constraints to add and no constraints to remove.*
- `std::optional< Answer > doIncrementalAndBacktracking` ()
 

*Algorithms which contains backtracking and incremental checking, its called when we have constraints to add and constraints to remove.*
- `bool inform` (const `FormulaT` &\_constraint)

- **Informs the module about the given constraint.**
- void **deinform** (const **FormulaT** &\_constraint)
 

*The inverse of informing about a constraint.*
- bool **add** (**ModuleInput::const\_iterator** \_subformula)
 

*The module has to take the given sub-formula of the received formula into account.*
- virtual **Answer check** (bool \_final=false, bool \_full=true, carl::Variable \_objective=carl::Variable::NO\_VARIABLE)
 

*Checks the received formula for consistency.*
- virtual void **remove** (**ModuleInput::const\_iterator** \_subformula)
 

*Removes everything related to the given sub-formula of the received formula.*
- virtual void **updateAllModels** ()
 

*Updates all satisfying models, if the solver has detected the consistency of the received formula, beforehand.*
- virtual std::list< std::vector< carl::Variable > > **getModelEqualities** () const
 

*Partition the variables from the current model into equivalence classes according to their assigned value.*
- unsigned **currentlySatisfiedByBackend** (const **FormulaT** &\_formula) const
- virtual unsigned **currentlySatisfied** (const **FormulaT** &) const
- bool **receivedVariable** (carl::Variable::Arg \_var) const
- **Answer solverState** () const
- std::size\_t **setId** (std::size\_t \_id)
 

*Sets this modules unique ID to identify itself.*
- **thread\_priority threadPriority** () const
- void **setThreadPriority** (**thread\_priority** \_threadPriority)
 

*Sets the priority of this module to get a thread for running its check procedure.*
- const **ModuleInput** \* **pReceivedFormula** () const
- const **ModuleInput** & **rReceivedFormula** () const
- const **ModuleInput** \* **pPassedFormula** () const
- const **ModuleInput** & **rPassedFormula** () const
- const **Model** & **model** () const
- const std::vector< **Model** > & **allModels** () const
- const std::vector< **FormulaSetT** > & **infeasibleSubsets** () const
- const std::vector< **Module** \* > & **usedBackends** () const
- const carl::FastSet< **FormulaT** > & **constraintsToInform** () const
- const carl::FastSet< **FormulaT** > & **informedConstraints** () const
- void **addLemma** (const **FormulaT** &\_lemma, const **LemmaType** &\_lt=LemmaType::NORMAL, const **FormulaT** &\_preferredFormula=**FormulaT**(carl::FormulaType::TRUE))
 

*Stores a lemma being a valid formula.*
- bool **hasLemmas** ()
 

*Checks whether this module or any of its backends provides any lemmas.*
- void **clearLemmas** ()
 

*Deletes all yet found lemmas.*
- const std::vector< **Lemma** > & **lemmas** () const
- **ModuleInput::const\_iterator** **firstUncheckedReceivedSubformula** () const
- **ModuleInput::const\_iterator** **firstSubformulaToPass** () const
- void **receivedFormulaChecked** ()
 

*Notifies that the received formulas has been checked.*
- const **smrat::Conditionals** & **answerFound** () const
- bool **isPreprocessor** () const
- virtual std::string **moduleName** () const
- carl::Variable **objective** () const
- bool **is\_minimizing** () const
- void **excludeNotReceivedVariablesFromModel** () const
 

*Excludes all variables from the current model, which do not occur in the received formula.*

- void `updateLemmas ()`  
*Stores all lemmas of any backend of this module in its own lemma vector.*
- void `collectTheoryPropagations ()`
- void `collectOrigins (const FormulaT &_formula, FormulasT &_origins) const`  
*Collects the formulas in the given formula, which are part of the received formula.*
- void `collectOrigins (const FormulaT &_formula, FormulaSetT &_origins) const`
- bool `isValidInfeasibleSubset () const`
- void `checkInfeasibleSubsetForMinimality (std::vector< FormulaSetT >::const_iterator _infssubset, const std::string &_filename="smaller_muses", unsigned _maxSizeDifference=1) const`  
*Checks the given infeasible subset for minimality by storing all subsets of it, which have a smaller size which differs from the size of the infeasible subset not more than the given threshold.*
- virtual std::pair< bool, FormulaT > `getReceivedFormulaSimplified ()`
- void `print (const std::string &_initiation="***") const`  
*Prints everything relevant of the solver.*
- void `printReceivedFormula (const std::string &_initiation="***") const`  
*Prints the vector of the received formula.*
- void `printPassedFormula (const std::string &_initiation="***") const`  
*Prints the vector of passed formula.*
- void `printInfeasibleSubsets (const std::string &_initiation="***") const`  
*Prints the infeasible subsets.*
- void `printModel (std::ostream &_out=std::cout) const`  
*Prints the assignment of this module satisfying its received formula if it satisfiable and this module could find an assignment.*
- void `printAllModels (std::ostream &_out=std::cout)`  
*Prints all assignments of this module satisfying its received formula if it satisfiable and this module could find an assignment.*

### Static Public Member Functions

- static void `freeSplittingVariable (const FormulaT &_splittingVariable)`

### Static Public Attributes

- static size\_t `mNumOfBranchVarsToStore = 5`  
*The number of different variables to consider for a probable infinite loop of branchings.*
- static std::vector< Branching > `mLastBranches = std::vector<Branching>(mNumOfBranchVarsToStore, Branching(typename Poly::PolyType(), 0))`  
*Stores the last branches in a cycle buffer.*
- static size\_t `mFirstPosInLastBranches = 0`  
*The beginning of the cyclic buffer storing the last branches.*
- static std::vector< FormulaT > `mOldSplittingVariables`  
*Reusable splitting variables.*

### Protected Member Functions

- virtual void `deinformCore (const FormulaT &_constraint)`  
*The inverse of informing about a constraint.*
- bool `anAnswerFound () const`  
*Checks for all antecedent modules and those which run in parallel with the same antecedent modules, whether one of them has determined a result.*
- void `clearModel () const`  
*Clears the assignment, if any was found.*
- void `clearModels () const`  
*Clears all assignments, if any was found.*

- void `cleanModel () const`  
*Substitutes variable occurrences by its model value in the model values of other variables.*
- `ModuleInput::iterator passedFormulaBegin ()`
- `ModuleInput::iterator passedFormulaEnd ()`
- void `addOrigin (ModuleInput::iterator _formula, const FormulaT &_origin)`  
*Adds the given set of formulas in the received formula to the origins of the given passed formula.*
- const `FormulaT & getOrigins (ModuleInput::const_iterator _formula) const`  
*Gets the origins of the passed formula at the given position.*
- void `getOrigins (const FormulaT &_formula, FormulasT &_origins) const`
- void `getOrigins (const FormulaT &_formula, FormulaSetT &_origins) const`
- std::pair< `ModuleInput::iterator, bool` > `removeOrigin (ModuleInput::iterator _formula, const FormulaT &_origin)`
- std::pair< `ModuleInput::iterator, bool` > `removeOrigins (ModuleInput::iterator _formula, const std::shared_ptr< std::vector< FormulaT >> &_origins)`
- void `informBackends (const FormulaT &_constraint)`  
*Informs all backends of this module about the given constraint.*
- virtual void `addConstraintToInform (const FormulaT &_constraint)`  
*Adds a constraint to the collection of constraints of this module, which are informed to a freshly generated backend.*
- std::pair< `ModuleInput::iterator, bool` > `addReceivedSubformulaToPassedFormula (ModuleInput::const_iterator _subformula)`  
*Copies the given sub-formula of the received formula to the passed formula.*
- bool `originInReceivedFormula (const FormulaT &_origin) const`
- std::pair< `ModuleInput::iterator, bool` > `addSubformulaToPassedFormula (const FormulaT &_formula)`  
*Adds the given formula to the passed formula with no origin.*
- std::pair< `ModuleInput::iterator, bool` > `addSubformulaToPassedFormula (const FormulaT &_formula, const std::shared_ptr< std::vector< FormulaT >> &_origins)`  
*Adds the given formula to the passed formula.*
- std::pair< `ModuleInput::iterator, bool` > `addSubformulaToPassedFormula (const FormulaT &_formula, const FormulaT &_origin)`  
*Adds the given formula to the passed formula.*
- void `generateTrivialInfeasibleSubset ()`  
*Stores the trivial infeasible subset being the set of received formulas.*
- void `receivedFormulasAsInfeasibleSubset (ModuleInput::const_iterator _subformula)`  
*Stores an infeasible subset consisting only of the given received formula.*
- std::vector< `FormulaT` >::const\_iterator `findBestOrigin (const std::vector< FormulaT > &_origins) const`
- void `getInfeasibleSubsets ()`  
*Copies the infeasible subsets of the passed formula.*
- std::vector< `FormulaSetT` > `getInfeasibleSubsets (const Module &backend) const`  
*Get the infeasible subsets the given backend provides.*
- const `Model & backendsModel () const`  
*Stores the model of a backend which determined satisfiability of the passed formula in the model of this module.*
- void `getBackendsModel () const`
- void `getBackendsAllModels () const`  
*Stores all models of a backend in the list of all models of this module.*
- virtual `Answer runBackends (bool _final, bool _full, carl::Variable _objective)`  
*Runs the backend solvers on the passed formula.*
- virtual `Answer runBackends ()`
- virtual `ModuleInput::iterator eraseSubformulaFromPassedFormula (ModuleInput::iterator _subformula, bool _ignoreOrigins=false)`  
*Removes everything related to the sub-formula to remove from the passed formula in the backends of this module.*
- void `clearPassedFormula ()`
- std::vector< `FormulaT` > `merge (const std::vector< FormulaT > &, const std::vector< FormulaT > &) const`

- `size_t determine_smallest_origin (const std::vector< FormulaT > &origins) const`

*Merges the two vectors of sets into the first one.*
- `bool probablyLooping (const typename Poly::PolyType &_branchingPolynomial, const Rational &_branchingValue) const`

*Checks whether given the current branching value and branching variable/polynomial it is (highly) probable that this branching is part of an infinite loop of branchings.*
- `bool branchAt (const Poly &_polynomial, bool _integral, const Rational &_value, std::vector< FormulaT > &&_premise, bool _leftCaseWeak=true, bool _preferLeftCase=true, bool _useReceivedFormulaAsPremise=false)`

*Adds a lemmas which provoke a branching for the given variable at the given value, if this module returns Unknown and there exists a preceding SATModule.*
- `bool branchAt (const Poly &_polynomial, bool _integral, const Rational &_value, bool _leftCaseWeak=true, bool _preferLeftCase=true, bool _useReceivedFormulaAsPremise=false, const std::vector< FormulaT > &&_premise=std::vector< FormulaT >())`
- `bool branchAt (carl::Variable::Arg _var, const Rational &_value, std::vector< FormulaT > &&_premise, bool _leftCaseWeak=true, bool _preferLeftCase=true, bool _useReceivedFormulaAsPremise=false)`
- `bool branchAt (carl::Variable::Arg _var, const Rational &_value, bool _leftCaseWeak=true, bool _preferLeftCase=true, bool _useReceivedFormulaAsPremise=false, const std::vector< FormulaT > &_premise=std::vector< FormulaT >())`
- `void splitUnequalConstraint (const FormulaT &)`

*Adds the following lemmas for the given constraint p!=0.*
- `unsigned checkModel () const`
- `void addInformationRelevantFormula (const FormulaT &formula)`

*Adds a formula to the InformationRelevantFormula.*
- `const std::set< FormulaT > & getInformationRelevantFormulas ()`

*Gets all InformationRelevantFormulas.*
- `bool isLemmaLevel (LemmaLevel level)`

*Checks if current lemma level is greater or equal to given level.*

## Static Protected Member Functions

- `static bool modelsDisjoint (const Model &_modelA, const Model &_modelB)`

*Checks whether there is no variable assigned by both models.*

## Protected Attributes

- `std::vector< FormulaSetT > mInfeasibleSubsets`

*Stores the infeasible subsets.*
- `Manager *const mpManager`

*A reference to the manager.*
- `Model mModel`

*Stores the assignment of the current satisfiable result, if existent.*
- `std::vector< Model > mAllModels`

*Stores all satisfying assignments.*
- `bool mModelComputed`

*True, if the model has already been computed.*
- `bool mFinalCheck`

*true, if the check procedure should perform a final check which especially means not to postpone splitting decisions*
- `bool mFullCheck`

*false, if this module should avoid too expensive procedures and rather return unknown instead.*
- `carl::Variable mObjectiveVariable`

*Objective variable to be minimized. If set to NO\_VARIABLE, a normal sat check should be performed.*
- `std::vector< TheoryPropagation > mTheoryPropagations`
- `std::atomic< Answer > mSolverState`

- States whether the received formula is known to be satisfiable or unsatisfiable otherwise it is set to unknown.*
- std::atomic\_bool \* mBackendsFoundAnswer  
*This flag is passed to any backend and if it determines an answer to a prior check call, this flag is fired.*
  - Conditionals mFoundAnswer  
*Vector of Booleans: If any of them is true, we have to terminate a running check procedure.*
  - std::vector< Module \* > mUsedBackends  
*The backends of this module which are currently used (conditions to use this module are fulfilled for the passed formula).*
  - std::vector< Module \* > mAllBackends  
*The backends of this module which have been used.*
  - std::vector< Lemma > mLemmas  
*Stores the lemmas being valid formulas this module or its backends made.*
  - ModuleInput::iterator mFirstSubformulaToPass  
*Stores the position of the first sub-formula in the passed formula, which has not yet been considered for a consistency check of the backends.*
  - carl::FastSet< FormulaT > mConstraintsToInform  
*Stores the constraints which the backends must be informed about.*
  - carl::FastSet< FormulaT > mInformedConstraints  
*Stores the position of the first constraint of which no backend has been informed about.*
  - ModuleInput::const\_iterator mFirstUncheckedReceivedSubformula  
*Stores the position of the first (by this module) unchecked sub-formula of the received formula.*
  - unsigned mSmallerMusesCheckCounter  
*Counter used for the generation of the smt2 files to check for smaller muses.*
  - std::vector< std::size\_t > mVariableCounters  
*Maps variables to the number of their occurrences.*

```

---

**0.15.333.3.2 ~NewCoveringModule()** template<typename Settings >  
`smtrat::NewCoveringModule< Settings >::~NewCoveringModule ( )`

#### 0.15.333.4 Member Function Documentation

**0.15.333.4.1 add()** bool smtrat::Module::add (  
`ModuleInput::const_iterator _subformula`) [inherited]

The module has to take the given sub-formula of the received formula into account.

##### Parameters

|                          |                                                    |
|--------------------------|----------------------------------------------------|
| <code>_subformula</code> | The sub-formula to take additionally into account. |
|--------------------------|----------------------------------------------------|

##### Returns

false, if it can be easily decided that this sub-formula causes a conflict with the already considered sub-formulas; true, otherwise.

**0.15.333.4.2 addConstraintsSAT()** template<typename Settings >  
`size_t smtrat::NewCoveringModule< Settings >::addConstraintsSAT ( )`  
 Adds the given constraint to the backend.

##### Returns

the lowest level with an unsatisfied new constraint

##### Note

returns mVariableOrdering.size() + 1 if all new constraints are satisfied

If not all new constraints are satisfied the

**0.15.333.4.3 addConstraintsUNSAT()** template<typename Settings >  
`void smtrat::NewCoveringModule< Settings >::addConstraintsUNSAT ( )`  
 Adds the given constraint to the backend.

**0.15.333.4.4 addConstraintToInform()** void smtrat::Module::addConstraintToInform (  
`const FormulaT & _constraint`) [protected], [virtual], [inherited]

Adds a constraint to the collection of constraints of this module, which are informed to a freshly generated backend.

##### Parameters

|                          |                        |
|--------------------------|------------------------|
| <code>_constraint</code> | The constraint to add. |
|--------------------------|------------------------|

Reimplemented in `smtrat::SATModule< Settings >`.

**0.15.333.4.5 addCore()** template<typename Settings >  
`bool smtrat::NewCoveringModule< Settings >::addCore (`  
`ModuleInput::const_iterator _subformula`) [virtual]

The module has to take the given sub-formula of the received formula into account.

#### Parameters

|                          |                                                    |
|--------------------------|----------------------------------------------------|
| <code>_subformula</code> | The sub-formula to take additionally into account. |
|--------------------------|----------------------------------------------------|

#### Returns

false, if it can be easily decided that this sub-formula causes a conflict with the already considered sub-formulas; true, otherwise.

Reimplemented from [smtrat::Module](#).

**0.15.333.4.6 addInformationRelevantFormula()** `void smtrat::Module::addInformationRelevantFormula (`  
`const FormulaT & formula ) [protected], [inherited]`

Adds a formula to the InformationRelevantFormula.

#### Parameters

|                      |                |
|----------------------|----------------|
| <code>formula</code> | Formula to add |
|----------------------|----------------|

**0.15.333.4.7 addLemma()** `void smtrat::Module::addLemma (`  
`const FormulaT & _lemma,`  
`const LemmaType & _lt = LemmaType::NORMAL,`  
`const FormulaT & _preferredFormula = FormulaT( carl::FormulaType::TRUE ) ) [inline],`  
[inherited]

Stores a lemma being a valid formula.

#### Parameters

|                                |                                                                       |
|--------------------------------|-----------------------------------------------------------------------|
| <code>_lemma</code>            | The eduction/lemma to store.                                          |
| <code>_lt</code>               | The type of the lemma.                                                |
| <code>_preferredFormula</code> | Hint for the next decision, which formula should be assigned to true. |

**0.15.333.4.8 addOrigin()** `void smtrat::Module::addOrigin (`  
`ModuleInput::iterator _formula,`  
`const FormulaT & _origin ) [inline], [protected], [inherited]`

Adds the given set of formulas in the received formula to the origins of the given passed formula.

#### Parameters

|                       |                                                           |
|-----------------------|-----------------------------------------------------------|
| <code>_formula</code> | The passed formula to set the origins for.                |
| <code>_origin</code>  | A set of formulas in the received formula of this module. |

**0.15.333.4.9 addReceivedSubformulaToPassedFormula()** `std::pair<ModuleInput::iterator, bool> smtrat::Module::addReceivedSubformulaToPassedFormula (`  
`ModuleInput::const_iterator _subformula ) [inline], [protected], [inherited]`

Copies the given sub-formula of the received formula to the passed formula.

Note, that there is always a link between sub-formulas of the passed formulas to sub-formulas of the received formulas, which are responsible for its occurrence.

#### Parameters

|                          |                                                  |
|--------------------------|--------------------------------------------------|
| <code>_subformula</code> | The sub-formula of the received formula to copy. |
|--------------------------|--------------------------------------------------|

#### 0.15.333.4.10 `addSubformulaToPassedFormula()` [1/3] `std::pair<ModuleInput::iterator,bool>`

```
smtrat::Module::addSubformulaToPassedFormula (
 const FormulaT & _formula) [inline], [protected], [inherited]
```

Adds the given formula to the passed formula with no origin.

Note that in the next call of this module's `removeSubformula`, all formulas in the passed formula without origins will be removed.

#### Parameters

|                       |                                           |
|-----------------------|-------------------------------------------|
| <code>_formula</code> | The formula to add to the passed formula. |
|-----------------------|-------------------------------------------|

#### Returns

A pair to the position where the formula to add has been inserted (or its first sub-formula which has not yet been in the passed formula, in case the formula to add is a conjunction), and a Boolean stating whether anything has been added to the passed formula.

#### 0.15.333.4.11 `addSubformulaToPassedFormula()` [2/3] `std::pair<ModuleInput::iterator,bool>`

```
smtrat::Module::addSubformulaToPassedFormula (
 const FormulaT & _formula,
 const FormulaT & _origin) [inline], [protected], [inherited]
```

Adds the given formula to the passed formula.

#### Parameters

|                       |                                                                                                                           |
|-----------------------|---------------------------------------------------------------------------------------------------------------------------|
| <code>_formula</code> | The formula to add to the passed formula.                                                                                 |
| <code>_origin</code>  | The sub-formula of the received formula being responsible for the occurrence of the formula to add to the passed formula. |

#### Returns

A pair to the position where the formula to add has been inserted (or its first sub-formula which has not yet been in the passed formula, in case the formula to add is a conjunction), and a Boolean stating whether anything has been added to the passed formula.

#### 0.15.333.4.12 `addSubformulaToPassedFormula()` [3/3] `std::pair<ModuleInput::iterator,bool>`

```
smtrat::Module::addSubformulaToPassedFormula (
 const FormulaT & _formula,
 const std::shared_ptr< std::vector< FormulaT >> & _origins) [inline], [protected],
[inherited]
```

Adds the given formula to the passed formula.

#### Parameters

|                       |                                           |
|-----------------------|-------------------------------------------|
| <code>_formula</code> | The formula to add to the passed formula. |
|-----------------------|-------------------------------------------|

**Parameters**

|                       |                                                                                                                                         |
|-----------------------|-----------------------------------------------------------------------------------------------------------------------------------------|
| <code>_origins</code> | The link of the formula to add to the passed formula to sub-formulas of the received formulas, which are responsible for its occurrence |
|-----------------------|-----------------------------------------------------------------------------------------------------------------------------------------|

**Returns**

A pair to the position where the formula to add has been inserted (or its first sub-formula which has not yet been in the passed formula, in case the formula to add is a conjunction), and a Boolean stating whether anything has been added to the passed formula.

**0.15.333.4.13 `allModels()`** `const std::vector<Model>& smtrat::Module::allModels () const [inline], [inherited]`

**Returns**

All satisfying assignments, if existent.

**0.15.333.4.14 `anAnswerFound()`** `bool smtrat::Module::anAnswerFound () const [inline], [protected], [inherited]`

Checks for all antecedent modules and those which run in parallel with the same antecedent modules, whether one of them has determined a result.

**Returns**

True, if one of them has determined a result.

**0.15.333.4.15 `answerFound()`** `const smtrat::Conditionals& smtrat::Module::answerFound () const [inline], [inherited]`

**Returns**

A vector of Booleans: If any of them is true, we have to terminate a running check procedure.

**0.15.333.4.16 `backendsModel()`** `const Model & smtrat::Module::backendsModel () const [protected], [inherited]`

Stores the model of a backend which determined satisfiability of the passed formula in the model of this module.

**0.15.333.4.17 `branchAt() [1/4]`** `bool smtrat::Module::branchAt ( carl::Variable::Arg _var, const Rational & _value, bool _leftCaseWeak = true, bool _preferLeftCase = true, bool _useReceivedFormulaAsPremise = false, const std::vector< FormulaT > & _premise = std::vector< FormulaT > () ) [inline], [protected], [inherited]`

```
0.15.333.4.18 branchAt() [2/4] bool smtrat::Module::branchAt (
 carl::Variable::Arg _var,
 const Rational & _value,
 std::vector< FormulaT > && _premise,
 bool _leftCaseWeak = true,
 bool _preferLeftCase = true,
 bool _useReceivedFormulaAsPremise = false) [inline], [protected], [inherited]
```

```
0.15.333.4.19 branchAt() [3/4] bool smtrat::Module::branchAt (
 const Poly & _polynomial,
 bool _integral,
 const Rational & _value,
 bool _leftCaseWeak = true,
 bool _preferLeftCase = true,
 bool _useReceivedFormulaAsPremise = false,
 const std::vector< FormulaT > & _premise = std::vector<FormulaT>()) [inline],
[protected], [inherited]
```

```
0.15.333.4.20 branchAt() [4/4] bool smtrat::Module::branchAt (
 const Poly & _polynomial,
 bool _integral,
 const Rational & _value,
 std::vector< FormulaT > && _premise,
 bool _leftCaseWeak = true,
 bool _preferLeftCase = true,
 bool _useReceivedFormulaAsPremise = false) [protected], [inherited]
```

Adds a lemmas which provoke a branching for the given variable at the given value, if this module returns Unknown and there exists a preceding [SATModule](#).

Note that the given value is rounded down and up, if the given variable is integer-valued.

#### Parameters

|                                           |                                                                                                                                                                                                                |
|-------------------------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>_polynomial</code>                  | The variable to branch for.                                                                                                                                                                                    |
| <code>_integral</code>                    | A flag being true, if all variables in the polynomial to branch for are integral.                                                                                                                              |
| <code>_value</code>                       | The value to branch at.                                                                                                                                                                                        |
| <code>_premise</code>                     | The sub-formulas of the received formula from which the branch is followed. Note, that a premise is not necessary, as every branch is a valid formula. But a premise can prevent from branching unnecessarily. |
| <code>_leftCaseWeak</code>                | true, if a branching in the form of (or ( $\leq p b$ ) ( $> p b$ )) is desired. false, if a branching in the form of (or ( $< p b$ ) ( $\geq p b$ )) is desired.                                               |
| <code>_preferLeftCase</code>              | true, if the left case (polynomial less(or equal) 0 shall be chosen first. false, otherwise.                                                                                                                   |
| <code>_useReceivedFormulaAsPremise</code> | true, if the whole received formula should be used as premise                                                                                                                                                  |

```
0.15.333.4.21 check() Answer smtrat::Module::check (
 bool _final = false,
 bool _full = true,
 carl::Variable _objective = carl::Variable::NO_VARIABLE) [virtual], [inherited]
```

Checks the received formula for consistency.

Note, that this is an implementation of the satisfiability check of the conjunction of the so far received formulas, which does actually nothing but passing the problem to its backends. This implementation is only used internally and must be overwritten by any derived module.

**Parameters**

|                         |                                                                                                                                       |
|-------------------------|---------------------------------------------------------------------------------------------------------------------------------------|
| <code>_final</code>     | true, if this satisfiability check will be the last one (for a global sat-check), if its result is SAT                                |
| <code>_full</code>      | false, if this module should avoid too expensive procedures and rather return unknown instead.                                        |
| <code>_objective</code> | if not set to NO_VARIABLE, the module should find an assignment minimizing this objective variable; otherwise any assignment is good. |

**Returns**

True, if the received formula is satisfiable; False, if the received formula is not satisfiable; Unknown, otherwise.

Reimplemented in [smtrat::PModule](#).

**0.15.333.4.22 `checkCore()`** `template<typename Settings >`  
`Answer smtrat::NewCoveringModule< Settings >::checkCore ( ) [virtual]`  
 Checks the received formula for consistency.

**Returns**

True, if the received formula is satisfiable; False, if the received formula is not satisfiable; Unknown, otherwise.

Reimplemented from [smtrat::Module](#).

**0.15.333.4.23 `checkInfSubsetForMinimality()`** `void smtrat::Module::checkInfSubsetForMinimality (`  
`std::vector< FormulaSetT >::const_iterator _infsSubset,`  
`const std::string & _filename = "smaller_muses",`  
`unsigned _maxSizeDifference = 1 ) const [inherited]`

Checks the given infeasible subset for minimality by storing all subsets of it, which have a smaller size which differs from the size of the infeasible subset not more than the given threshold.

**Parameters**

|                                 |                                                                                                        |
|---------------------------------|--------------------------------------------------------------------------------------------------------|
| <code>_infsSubset</code>        | The infeasible subset to check for minimality.                                                         |
| <code>_filename</code>          | The name of the file to store the infeasible subsets in order to be able to check their infeasibility. |
| <code>_maxSizeDifference</code> | The maximal difference between the sizes of the subsets compared to the size of the infeasible subset. |

**0.15.333.4.24 `checkModel()`** `unsigned smtrat::Module::checkModel ( ) const [protected], [inherited]`

**Returns**

false, if the current model of this module does not satisfy the current given formula; true, if it cannot be said whether the model satisfies the given formula.

**0.15.333.4.25 `cleanModel()`** `void smtrat::Module::cleanModel ( ) const [inline], [protected], [inherited]`

Substitutes variable occurrences by its model value in the model values of other variables.

**0.15.333.4.26 `clearLemmas()`** `void smtrat::Module::clearLemmas ( ) [inline], [inherited]`

Deletes all yet found lemmas.

**0.15.333.4.27 `clearModel()`** `void smtrat::Module::clearModel () const [inline], [protected], [inherited]`  
 Clears the assignment, if any was found.

**0.15.333.4.28 `clearModels()`** `void smtrat::Module::clearModels () const [inline], [protected], [inherited]`  
 Clears all assignments, if any was found.

**0.15.333.4.29 `clearPassedFormula()`** `void smtrat::Module::clearPassedFormula () [protected], [inherited]`

**0.15.333.4.30 `collectOrigins() [1/2]`** `void smtrat::Module::collectOrigins (const FormulaT & _formula, FormulaSetT & _origins ) const [inherited]`

**0.15.333.4.31 `collectOrigins() [2/2]`** `void smtrat::Module::collectOrigins (const FormulaT & _formula, FormulasT & _origins ) const [inherited]`

Collects the formulas in the given formula, which are part of the received formula.

If the given formula directly occurs in the received formula, it is inserted into the given set. Otherwise, the given formula must be of type AND and all its sub-formulas part of the received formula. Hence, they will be added to the given set.

#### Parameters

|                       |                                                                                                      |
|-----------------------|------------------------------------------------------------------------------------------------------|
| <code>_formula</code> | The formula from which to collect the formulas being sub-formulas of the received formula (origins). |
| <code>_origins</code> | The set in which to store the origins.                                                               |

**0.15.333.4.32 `collectTheoryPropagations()`** `void smtrat::Module::collectTheoryPropagations () [inherited]`

**0.15.333.4.33 `constraintsToInform()`** `const carl::FastSet<FormulaT>& smtrat::Module::constraintsToInform () const [inline], [inherited]`

#### Returns

The constraints which the backends must be informed about.

**0.15.333.4.34 `currentlySatisfied()`** `virtual unsigned smtrat::Module::currentlySatisfied (const FormulaT & ) const [inline], [virtual], [inherited]`

#### Returns

0, if the given formula is conflicted by the current model; 1, if the given formula is satisfied by the current model; 2, otherwise; 3, if we do not know anything (default)

Reimplemented in `smtrat::LRAModule< Settings >`, `smtrat::LRAModule< LRASettingsICP >`, and `smtrat::LRAModule< LRASettings >`

**0.15.333.4.35 currentlySatisfiedByBackend()** `unsigned smtrat::Module::currentlySatisfiedByBackend ( const FormulaT & _formula ) const [inherited]`

**Returns**

0, if the given formula is conflicted by the current model; 1, if the given formula is satisfied by the current model; 2, otherwise 3, if we do not know anything (default)

**0.15.333.4.36 deinform()** `void smtrat::Module::deinform ( const FormulaT & _constraint ) [inherited]`

The inverse of informing about a constraint.

All data structures which were kept regarding this constraint are going to be removed. Note, that this makes only sense if it is not likely enough that a formula with this constraint must be solved again.

**Parameters**

|                          |                                                         |
|--------------------------|---------------------------------------------------------|
| <code>_constraint</code> | The constraint to remove from internal data structures. |
|--------------------------|---------------------------------------------------------|

**0.15.333.4.37 deinformCore()** `virtual void smtrat::Module::deinformCore ( const FormulaT & _constraint ) [inline], [protected], [virtual], [inherited]`

The inverse of informing about a constraint.

All data structures which were kept regarding this constraint are going to be removed. Note, that this makes only sense if it is not likely enough that a formula with this constraint must be solved again.

**Parameters**

|                          |                                                         |
|--------------------------|---------------------------------------------------------|
| <code>_constraint</code> | The constraint to remove from internal data structures. |
|--------------------------|---------------------------------------------------------|

Reimplemented in [smtrat::LRAModule< Settings >](#), [smtrat::LRAModule< LRASettingsICP >](#), and [smtrat::LRAModule< LRASetting >](#)

**0.15.333.4.38 determine\_smallest\_origin()** `size_t smtrat::Module::determine_smallest_origin ( const std::vector< FormulaT > & origins ) const [protected], [inherited]`

**Parameters**

|                      |                              |
|----------------------|------------------------------|
| <code>origins</code> | A vector of sets of origins. |
|----------------------|------------------------------|

**Returns**

The index of the smallest (regarding the size of the sets) element of origins

**0.15.333.4.39 doBacktracking()** `template<typename Settings >`

`std::optional<Answer> smtrat::NewCoveringModule< Settings >::doBacktracking ( )`

The actual backtracking algorithm, which is called when we have constraints to add and no constraints to remove.

Removes all cells which were created as a rest of the constraints which are to be removed if level 0 is still fully covered after removing the constraints UNSAT is returned Otherwise std::nullopt is returned and level 1 is newly sampled and the algorithm starts again from level 1

**Returns**

`std::optional<Answer>`, which contains the answer if it can be deduced directly

**0.15.333.4.40 doIncremental()** template<typename Settings >  
 std::optional<Answer> smtrat::NewCoveringModule< Settings >::doIncremental ( )  
 The actual incremental algorithm, which is called when we have constraints to add and no constraints to remove.  
 Tests the new constraints with the last satisfying assignment, if the new constraints are also satisfied. If the new constraints are all satisfied SAT is returned accordingly Otherwise std::nullopt is returned and the stored information from the lowest level with an unsatisfied new constraint is removed

**Returns**

std::optional<Answer>, which contains the answer if it can be deduced directly

**0.15.333.4.41 doIncrementalAndBacktracking()** template<typename Settings >  
 std::optional<Answer> smtrat::NewCoveringModule< Settings >::doIncrementalAndBacktracking ( )  
 Algorithms which contains backtracking and incremental checking, its called when we have constraints to add and constraints to remove.

**Returns**

std::optional<Answer>, which contains the answer if it can be deduced directly

**0.15.333.4.42 eraseSubformulaFromPassedFormula()** ModuleInput::iterator smtrat::Module::erase<  
 SubformulaFromPassedFormula (   
     ModuleInput::iterator \_subformula,  
     bool \_ignoreOrigins = false ) [protected], [virtual], [inherited]

Removes everything related to the sub-formula to remove from the passed formula in the backends of this module.  
 Afterwards the sub-formula is removed from the passed formula.

**Parameters**

|                             |                                                                                                              |
|-----------------------------|--------------------------------------------------------------------------------------------------------------|
| <code>_subformula</code>    | The sub-formula to remove from the passed formula.                                                           |
| <code>_ignoreOrigins</code> | True, if the sub-formula shall be removed regardless of its origins (should only be applied with expertise). |

**Returns**

Reimplemented in smtrat::ICPModule< Settings >, smtrat::ICPModule< ICPSettings4 >, and smtrat::ICPModule< ICPSettings1 >.

**0.15.333.4.43 excludeNotReceivedVariablesFromModel()** void smtrat::Module::excludeNotReceived<  
 VariablesFromModel ( ) const [inherited]  
 Excludes all variables from the current model, which do not occur in the received formula.

**0.15.333.4.44 findBestOrigin()** std::vector< FormulaT >::const\_iterator smtrat::Module::find<  
 BestOrigin (   
     const std::vector< FormulaT > & \_origins ) const [protected], [inherited]

**Parameters**

|                       |  |
|-----------------------|--|
| <code>_origins</code> |  |
|-----------------------|--|

Returns

**0.15.333.4.45 firstSubformulaToPass()** `ModuleInput::const_iterator smtrat::Module::firstSubformulaToPass () const [inline], [inherited]`

Returns

The position of the first sub-formula in the passed formula, which has not yet been considered for a consistency check of the backends.

**0.15.333.4.46 firstUncheckedReceivedSubformula()** `ModuleInput::const_iterator smtrat::Module::firstUncheckedReceivedSubformula () const [inline], [inherited]`

Returns

The position of the first (by this module) unchecked sub-formula of the received formula.

**0.15.333.4.47 freeSplittingVariable()** `static void smtrat::Module::freeSplittingVariable (const FormulaT & _splittingVariable ) [inline], [static], [inherited]`

**0.15.333.4.48 generateTrivialInfeasibleSubset()** `void smtrat::Module::generateTrivialInfeasibleSubset () [inline], [protected], [inherited]`

Stores the trivial infeasible subset being the set of received formulas.

**0.15.333.4.49 getBackendsAllModels()** `void smtrat::Module::getBackendsAllModels () const [protected], [inherited]`

Stores all models of a backend in the list of all models of this module.

**0.15.333.4.50 getBackendsModel()** `void smtrat::Module::getBackendsModel () const [protected], [inherited]`

**0.15.333.4.51 getInfeasibleSubsets() [1/2]** `void smtrat::Module::getInfeasibleSubsets () [protected], [inherited]`

Copies the infeasible subsets of the passed formula.

**0.15.333.4.52 getInfeasibleSubsets() [2/2]** `std::vector< FormulaSetT > smtrat::Module::getInfeasibleSubsets (const Module & _backend ) const [protected], [inherited]`

Get the infeasible subsets the given backend provides.

Note, that an infeasible subset in a backend contains sub formulas of the passed formula and an infeasible subset of this module contains sub formulas of the received formula. In this method the LATTER is returned.

Parameters

|                       |                                                          |
|-----------------------|----------------------------------------------------------|
| <code>_backend</code> | The backend from which to obtain the infeasible subsets. |
|-----------------------|----------------------------------------------------------|

**Returns**

The infeasible subsets the given backend provides.

**0.15.333.4.53 `getInformationRelevantFormulas()`** `const std::set< FormulaT > & smtrat::Module::getInformationRelevantFormulas ( ) [protected], [inherited]`  
Gets all InformationRelevantFormulas.

**Returns**

Set of all formulas

**0.15.333.4.54 `getModelEqualities()`** `std::list< std::vector< carl::Variable > > smtrat::Module::getModelEqualities ( ) const [virtual], [inherited]`  
Partition the variables from the current model into equivalence classes according to their assigned value.  
The result is a set of equivalence classes of variables where all variables within one class are assigned the same value. Note that the number of classes may not be minimal, i.e. two classes may actually be equivalent.

**Returns**

Equivalence classes.

**0.15.333.4.55 `getOrigins() [1/3]`** `void smtrat::Module::getOrigins ( const FormulaT & _formula, FormulaSetT & _origins ) const [inline], [protected], [inherited]`

**Parameters**

|                       |  |
|-----------------------|--|
| <code>_formula</code> |  |
| <code>_origins</code> |  |

**0.15.333.4.56 `getOrigins() [2/3]`** `void smtrat::Module::getOrigins ( const FormulaT & _formula, FormulasT & _origins ) const [inline], [protected], [inherited]`

**Parameters**

|                       |  |
|-----------------------|--|
| <code>_formula</code> |  |
| <code>_origins</code> |  |

**0.15.333.4.57 `getOrigins() [3/3]`** `const FormulaT& smtrat::Module::getOrigins ( ModuleInput::const_iterator _formula ) const [inline], [protected], [inherited]`  
Gets the origins of the passed formula at the given position.

**Parameters**

|                       |                                                   |
|-----------------------|---------------------------------------------------|
| <code>_formula</code> | The position of a formula in the passed formulas. |
|-----------------------|---------------------------------------------------|

**Returns**

The origins of the passed formula at the given position.

**0.15.333.4.58 `getReceivedFormulaSimplified()`** `std::pair< bool, FormulaT > smtrat::Module::getReceivedFormulaSimplified( ) [virtual], [inherited]`

**Returns**

A pair of a Boolean and a formula, where the Boolean is true, if the received formula could be simplified to an equisatisfiable formula. The formula is equisatisfiable to this module's received formula, if the Boolean is true.

Reimplemented in [smtrat::PModule](#).

**0.15.333.4.59 `hasLemmas()`** `bool smtrat::Module::hasLemmas( ) [inline], [inherited]`  
Checks whether this module or any of its backends provides any lemmas.

**0.15.333.4.60 `hasValidInfeasibleSubset()`** `bool smtrat::Module::hasValidInfeasibleSubset( ) const [inherited]`

**Returns**

true, if the module has at least one valid infeasible subset, that is all its elements are sub-formulas of the received formula (pointer must be equal).

**0.15.333.4.61 `id()`** `std::size_t smtrat::Module::id( ) const [inline], [inherited]`

**Returns**

A unique ID to identify this module instance.

**0.15.333.4.62 `infeasibleSubsets()`** `const std::vector<FormulaSetT>& smtrat::Module::infeasibleSubsets( ) const [inline], [inherited]`

**Returns**

The infeasible subsets of the set of received formulas (empty, if this module has not detected unsatisfiability of the conjunction of received formulas).

**0.15.333.4.63 `inform()`** `bool smtrat::Module::inform( const FormulaT & _constraint ) [inherited]`

Informs the module about the given constraint.

It should be tried to inform this module about any constraint it could receive eventually before assertSubformula is called (preferably for the first time, but at least before adding a formula containing that constraint).

**Parameters**

|                          |                                 |
|--------------------------|---------------------------------|
| <code>_constraint</code> | The constraint to inform about. |
|--------------------------|---------------------------------|

**Returns**

false, if it can be easily decided whether the given constraint is inconsistent; true, otherwise.

**0.15.333.4.64 informBackends()** `void smrat::Module::informBackends (`

`const FormulaT & _constraint ) [inline], [protected], [inherited]`

Informs all backends of this module about the given constraint.

**Parameters**

|                          |                                 |
|--------------------------|---------------------------------|
| <code>_constraint</code> | The constraint to inform about. |
|--------------------------|---------------------------------|

**0.15.333.4.65 informCore()** `template<typename Settings >`

`bool smrat::NewCoveringModule< Settings >::informCore (`

`const FormulaT & _constraint ) [virtual]`

Informs the module about the given constraint.

It should be tried to inform this module about any constraint it could receive eventually before assertSubformula is called (preferably for the first time, but at least before adding a formula containing that constraint).

**Parameters**

|                          |                                 |
|--------------------------|---------------------------------|
| <code>_constraint</code> | The constraint to inform about. |
|--------------------------|---------------------------------|

**Returns**

false, if it can be easily decided whether the given constraint is inconsistent; true, otherwise.

Reimplemented from [smrat::Module](#).

**0.15.333.4.66 informedConstraints()** `const carl::FastSet<FormulaT>& smrat::Module::informed→`

`Constraints ( ) const [inline], [inherited]`

**Returns**

The position of the first constraint of which no backend has been informed about.

**0.15.333.4.67 init()** `template<typename Settings >`

`void smrat::NewCoveringModule< Settings >::init ( ) [virtual]`

Informs all backends about the so far encountered constraints, which have not yet been communicated.

This method must not and will not be called more than once and only before the first runBackends call.

Reimplemented from [smrat::Module](#).

**0.15.333.4.68 is\_minimizing()** `bool smrat::Module::is_minimizing ( ) const [inline], [inherited]`**0.15.333.4.69 isLemmaLevel()** `bool smrat::Module::isLemmaLevel (`

`LemmaLevel level ) [protected], [inherited]`

Checks if current lemma level is greater or equal to given level.

**Parameters**

|              |                 |
|--------------|-----------------|
| <i>level</i> | Level to check. |
|--------------|-----------------|

**0.15.333.4.70 `isPreprocessor()`** `bool smtrat::Module::isPreprocessor () const [inline], [inherited]`**Returns**

true, if this module is a preprocessor that is a module, which simplifies its received formula to an equisatisfiable formula being passed to its backends. The simplified formula can be obtained with [getReceivedFormulaSimplified\(\)](#).

**0.15.333.4.71 `lemmas()`** `const std::vector<Lemma>& smtrat::Module::lemmas () const [inline], [inherited]`**Returns**

A constant reference to the lemmas being valid formulas this module or its backends made.

**0.15.333.4.72 `merge()`** `std::vector< FormulaT > smtrat::Module::merge (const std::vector< FormulaT > & _vecSetA, const std::vector< FormulaT > & _vecSetB) const [protected], [inherited]`

Merges the two vectors of sets into the first one.

({a,b},{a,c}) and ({b,d},{b}) -> ({a,b,d},{a,b},{a,b,c,d},{a,b,c})

**Parameters**

|                 |                                  |
|-----------------|----------------------------------|
| <i>_vecSetA</i> | A vector of sets of constraints. |
| <i>_vecSetB</i> | A vector of sets of constraints. |

**Returns**

The vector being the two given vectors merged.

**0.15.333.4.73 `model()`** `const Model& smtrat::Module::model () const [inline], [inherited]`**Returns**

The assignment of the current satisfiable result, if existent.

**0.15.333.4.74 `modelsDisjoint()`** `bool smtrat::Module::modelsDisjoint (const Model & _modelA, const Model & _modelB) [static], [protected], [inherited]`

Checks whether there is no variable assigned by both models.

**Parameters**

|                |                                |
|----------------|--------------------------------|
| <i>_modelA</i> | The first model to check for.  |
| <i>_modelB</i> | The second model to check for. |

**Returns**

true, if there is no variable assigned by both models; false, otherwise.

**0.15.333.4.75 `moduleName()`** `virtual std::string smtrat::Module::moduleName ( ) const [inline], [virtual], [inherited]`

**Returns**

The name of the given module type as name.

Reimplemented in `smtrat::VSModule< Settings >`, `smtrat::UnionFindModule< Settings >`, `smtrat::UFCegarModule< Settings >`, `smtrat::STropModule< Settings >`, `smtrat::SplitSOSModule< Settings >`, `smtrat::PBPPModule< Settings >`, `smtrat::PBGaussModule< Settings >`, `smtrat::NRAILModule< Settings >`, `smtrat::NewCADModule< Settings >`, `smtrat::LVEModule< Settings >`, `smtrat::LRAModule< Settings >`, `smtrat::LRAModule< LRASettingsICP >`, `smtrat::LRAModule< LRASettings1 >`, `smtrat::IntEqModule< Settings >`, `smtrat::IntBlastModule< Settings >`, `smtrat::IncWidthModule< Settings >`, `smtrat::ICPModule< Settings >`, `smtrat::ICPModule< ICPSettings4 >`, `smtrat::ICPModule< ICPSettings1 >`, `smtrat::GBModule< Settings >`, `smtrat::FouMoModule< Settings >`, `smtrat::EQPreprocessingModule< Settings >`, `smtrat::EQModule< Settings >`, `smtrat::CurryModule< Settings >`, `smtrat::CubeLIAModule< Settings >`, `smtrat::CSplitModule< Settings >`, `smtrat::BVModule< Settings >`, and `smtrat::BEModule< Settings >`.

**0.15.333.4.76 `objective()`** `carl::Variable smtrat::Module::objective ( ) const [inline], [inherited]`

**0.15.333.4.77 `originInReceivedFormula()`** `bool smtrat::Module::originInReceivedFormula ( const FormulaT & _origin ) const [protected], [inherited]`

**0.15.333.4.78 `passedFormulaBegin()`** `ModuleInput::iterator smtrat::Module::passedFormulaBegin ( ) [inline], [protected], [inherited]`

**Returns**

An iterator to the end of the passed formula. TODO: disable this method

**0.15.333.4.79 `passedFormulaEnd()`** `ModuleInput::iterator smtrat::Module::passedFormulaEnd ( ) [inline], [protected], [inherited]`

**Returns**

An iterator to the end of the passed formula.

**0.15.333.4.80 `pPassedFormula()`** `const ModuleInput* smtrat::Module::pPassedFormula ( ) const [inline], [inherited]`

**Returns**

A pointer to the formula passed to the backends of this module.

**0.15.333.4.81 `pReceivedFormula()`** `const ModuleInput* smtrat::Module::pReceivedFormula ( ) const [inline], [inherited]`

**Returns**

A pointer to the formula passed to this module.

**0.15.333.4.82 print()** void smtrat::Module::print ( const std::string & \_initiation = "\*\*\*" ) const [inherited]  
Prints everything relevant of the solver.

Parameters

|                    |                      |
|--------------------|----------------------|
| <i>_initiation</i> | The line initiation. |
|--------------------|----------------------|

**0.15.333.4.83 printAllModels()** void smtrat::Module::printAllModels ( std::ostream & \_out = std::cout ) [inherited]

Prints all assignments of this module satisfying its received formula if it satisfiable and this module could find an assignment.

Parameters

|             |                                        |
|-------------|----------------------------------------|
| <i>_out</i> | The stream to print the assignment on. |
|-------------|----------------------------------------|

**0.15.333.4.84 printInfeasibleSubsets()** void smtrat::Module::printInfeasibleSubsets ( const std::string & \_initiation = "\*\*\*" ) const [inherited]

Prints the infeasible subsets.

Parameters

|                    |                      |
|--------------------|----------------------|
| <i>_initiation</i> | The line initiation. |
|--------------------|----------------------|

**0.15.333.4.85 printModel()** void smtrat::Module::printModel ( std::ostream & \_out = std::cout ) const [inherited]

Prints the assignment of this module satisfying its received formula if it satisfiable and this module could find an assignment.

Parameters

|             |                                        |
|-------------|----------------------------------------|
| <i>_out</i> | The stream to print the assignment on. |
|-------------|----------------------------------------|

**0.15.333.4.86 printPassedFormula()** void smtrat::Module::printPassedFormula ( const std::string & \_initiation = "\*\*\*" ) const [inherited]

Prints the vector of passed formula.

Parameters

|                    |                      |
|--------------------|----------------------|
| <i>_initiation</i> | The line initiation. |
|--------------------|----------------------|

**0.15.333.4.87 printReceivedFormula()** void smtrat::Module::printReceivedFormula ( const std::string & \_initiation = "\*\*\*" ) const [inherited]

Prints the vector of the received formula.

## Parameters

|                          |                      |
|--------------------------|----------------------|
| <code>_initiation</code> | The line initiation. |
|--------------------------|----------------------|

**0.15.333.4.88 `probablyLooping()`** `bool smtrat::Module::probablyLooping ( const typename Poly::PolyType & _branchingPolynomial, const Rational & _branchingValue ) const [protected], [inherited]`

Checks whether given the current branching value and branching variable/polynomial it is (highly) probable that this branching is part of an infinite loop of branchings.

## Parameters

|                                   |                                                                                     |
|-----------------------------------|-------------------------------------------------------------------------------------|
| <code>_branchingPolynomial</code> | The polynomial to branch at (in most branching strategies this is just a variable). |
| <code>_branchingValue</code>      | The value to branch at.                                                             |

## Returns

true, if this branching is probably part of an infinite loop of branchings; false, otherwise.

**0.15.333.4.89 `processAnswer()`** `template<typename Settings > void smtrat::NewCoveringModule< Settings >::processAnswer ( )`

Processes the current answer, i.e.

computes a model or adds the infeasible subset.

**0.15.333.4.90 `receivedFormulaChecked()`** `void smtrat::Module::receivedFormulaChecked ( ) [inline], [inherited]`

Notifies that the received formulas has been checked.

**0.15.333.4.91 `receivedFormulasAsInfeasibleSubset()`** `void smtrat::Module::receivedFormulasAsInfeasibleSubset ( ModuleInput::const_iterator _subformula ) [inline], [protected], [inherited]`

Stores an infeasible subset consisting only of the given received formula.

**0.15.333.4.92 `receivedVariable()`** `bool smtrat::Module::receivedVariable ( carl::Variable::Arg _var ) const [inline], [inherited]`

**0.15.333.4.93 `remove()`** `void smtrat::Module::remove ( ModuleInput::const_iterator _subformula ) [virtual], [inherited]`

Removes everything related to the given sub-formula of the received formula.

However, it is desired not to lose track of search spaces where no satisfying assignment can be found for the remaining sub-formulas.

## Parameters

|                          |                                                    |
|--------------------------|----------------------------------------------------|
| <code>_subformula</code> | The sub formula of the received formula to remove. |
|--------------------------|----------------------------------------------------|

Reimplemented in [smtrat::PModule](#).

**0.15.333.4.94 removeConstraintsSAT()** template<typename Settings >  
void smtrat::NewCoveringModule< Settings >::removeConstraintsSAT ( )  
Removes the given constraints from the backend.

**Note**

This also removes all stored information about the removed constraints

**0.15.333.4.95 removeConstraintsUNSAT()** template<typename Settings >  
bool smtrat::NewCoveringModule< Settings >::removeConstraintsUNSAT ( )  
Removes the given constraints from the backend Also removes all stored information about the removed constraints.

**Returns**

True: If the model is still unsat after removing the constraints False: If the model might needs recomputation for the higher levels

**0.15.333.4.96 removeCore()** template<typename Settings >  
void smtrat::NewCoveringModule< Settings >::removeCore (   
    ModuleInput::const\_iterator \_subformula ) [virtual]  
Removes the subformula of the received formula at the given position to the considered ones of this module.  
Note that this includes every stored calculation which depended on this subformula, but should keep the other stored calculation, if possible, untouched.

**Parameters**

|                          |                                           |
|--------------------------|-------------------------------------------|
| <code>_subformula</code> | The position of the subformula to remove. |
|--------------------------|-------------------------------------------|

Reimplemented from [smtrat::Module](#).

**0.15.333.4.97 removeOrigin()** std::pair<ModuleInput::iterator,bool> smtrat::Module::remove←  
Origin (   
    ModuleInput::iterator \_formula,  
    const FormulaT & \_origin ) [inline], [protected], [inherited]

**0.15.333.4.98 removeOrigins()** std::pair<ModuleInput::iterator,bool> smtrat::Module::remove←  
Origins (   
    ModuleInput::iterator \_formula,  
    const std::shared\_ptr< std::vector< FormulaT >> & \_origins ) [inline], [protected],  
[inherited]

**0.15.333.4.99 rPassedFormula()** const ModuleInput& smtrat::Module::rPassedFormula ( ) const  
[inline], [inherited]

**Returns**

A reference to the formula passed to the backends of this module.

**0.15.333.4.100 rReceivedFormula()** const ModuleInput& smtrat::Module::rReceivedFormula ( ) const  
[inline], [inherited]

**Returns**

A reference to the formula passed to this module.

**0.15.333.4.101 runBackends() [1/2]** `virtual Answer smtrat::Module::runBackends () [inline], [protected], [virtual], [inherited]`

Reimplemented in [smtrat::PModule](#).

**0.15.333.4.102 runBackends() [2/2]** `Answer smtrat::Module::runBackends (`

```
 bool _final,
 bool _full,
 carl::Variable _objective) [protected], [virtual], [inherited]
```

Runs the backend solvers on the passed formula.

**Parameters**

|                         |                                                                                                                                       |
|-------------------------|---------------------------------------------------------------------------------------------------------------------------------------|
| <code>_final</code>     | true, if this satisfiability check will be the last one (for a global sat-check), if its result is SAT                                |
| <code>_full</code>      | false, if this module should avoid too expensive procedures and rather return unknown instead.                                        |
| <code>_objective</code> | if not set to NO_VARIABLE, the module should find an assignment minimizing this objective variable; otherwise any assignment is good. |

**Returns**

True, if the passed formula is consistent; False, if the passed formula is inconsistent; Unknown, otherwise.

Reimplemented in [smtrat::PModule](#).

**0.15.333.4.103 setId()** `void smtrat::Module::setId (`

```
 std::size_t _id) [inline], [inherited]
```

Sets this modules unique ID to identify itself.

**Parameters**

|                 |                                    |
|-----------------|------------------------------------|
| <code>id</code> | The id to set this module's id to. |
|-----------------|------------------------------------|

**0.15.333.4.104 setThreadPriority()** `void smtrat::Module::setThreadPriority (`

```
 thread_priority _threadPriority) [inline], [inherited]
```

Sets the priority of this module to get a thread for running its check procedure.

**Parameters**

|                              |                                                       |
|------------------------------|-------------------------------------------------------|
| <code>_threadPriority</code> | The priority to set this module's thread priority to. |
|------------------------------|-------------------------------------------------------|

**0.15.333.4.105 solverState()** `Answer smtrat::Module::solverState () const [inline], [inherited]`

**Returns**

True, if this module is in a state, such that it has found a solution for its received formula; False, if this module is in a state, such that it has determined that there is no solution for its received formula; Unknown, otherwise.

**0.15.333.4.106 `splitUnequalConstraint()`** `void smtrat::Module::splitUnequalConstraint (`

`const FormulaT & _unequalConstraint ) [protected], [inherited]`

Adds the following lemmas for the given constraint  $p \neq 0$ .

$(p \neq 0 \leftrightarrow (p < 0 \text{ or } p > 0))$

and  $\neg(p < 0 \text{ and } p > 0)$

**Parameters**

|                                 |                                                           |
|---------------------------------|-----------------------------------------------------------|
| <code>_unequalConstraint</code> | A constraint having the relation symbol <code>!=</code> . |
|---------------------------------|-----------------------------------------------------------|

**0.15.333.4.107 `threadPriority()`** `thread_priority smtrat::Module::threadPriority ( ) const [inline], [inherited]`**Returns**

The priority of this module to get a thread for running its check procedure.

**0.15.333.4.108 `updateAllModels()`** `void smtrat::Module::updateAllModels ( ) [virtual], [inherited]`

Updates all satisfying models, if the solver has detected the consistency of the received formula, beforehand.

Reimplemented in [smtrat::SATModule< Settings >](#).

**0.15.333.4.109 `updateLemmas()`** `void smtrat::Module::updateLemmas ( ) [inherited]`

Stores all lemmas of any backend of this module in its own lemma vector.

**0.15.333.4.110 `updateModel()`** `template<typename Settings >`

`void smtrat::NewCoveringModule< Settings >::updateModel ( ) const [virtual]`

Updates the current assignment into the model.

Note, that this is a unique but possibly symbolic assignment maybe containing newly introduced variables.

Reimplemented from [smtrat::Module](#).

**0.15.333.4.111 `usedBackends()`** `const std::vector<Module*>& smtrat::Module::usedBackends ( )`

`const [inline], [inherited]`

**Returns**

The backends of this module which are currently used (conditions to use this module are fulfilled for the passed formula).

**0.15.333.5 Field Documentation****0.15.333.5.1 `mAllBackends`** `std::vector<Module*> smtrat::Module::mAllBackends [protected], [inherited]`

The backends of this module which have been used.

**0.15.333.5.2 mAllModels** `std::vector<Model>` `smtrat::Module::mAllModels` [mutable], [protected], [inherited]  
Stores all satisfying assignments.

**0.15.333.5.3 mBackendsFoundAnswer** `std::atomic_bool*` `smtrat::Module::mBackendsFoundAnswer` [protected], [inherited]  
This flag is passed to any backend and if it determines an answer to a prior check call, this flag is fired.

**0.15.333.5.4 mConstraintsToInform** `carl::FastSet<FormulaT>` `smtrat::Module::mConstraintsToInform` [protected], [inherited]  
Stores the constraints which the backends must be informed about.

**0.15.333.5.5 mFinalCheck** `bool` `smtrat::Module::mFinalCheck` [protected], [inherited]  
true, if the check procedure should perform a final check which especially means not to postpone splitting decisions

**0.15.333.5.6 mFirstPosInLastBranches** `std::size_t` `smtrat::Module::mFirstPosInLastBranches` = 0 [static], [inherited]  
The beginning of the cyclic buffer storing the last branches.

**0.15.333.5.7 mFirstSubformulaToPass** `ModuleInput::iterator` `smtrat::Module::mFirstSubformulaToPass` [protected], [inherited]  
Stores the position of the first sub-formula in the passed formula, which has not yet been considered for a consistency check of the backends.

**0.15.333.5.8 mFirstUncheckedReceivedSubformula** `ModuleInput::const_iterator` `smtrat::Module::mFirstUncheckedReceivedSubformula` [protected], [inherited]  
Stores the position of the first (by this module) unchecked sub-formula of the received formula.

**0.15.333.5.9 mFoundAnswer** `Conditionals` `smtrat::Module::mFoundAnswer` [protected], [inherited]  
Vector of Booleans: If any of them is true, we have to terminate a running check procedure.

**0.15.333.5.10 mFullCheck** `bool` `smtrat::Module::mFullCheck` [protected], [inherited]  
false, if this module should avoid too expensive procedures and rather return unknown instead.

**0.15.333.5.11 mInfeasibleSubsets** `std::vector<FormulaSetT>` `smtrat::Module::mInfeasibleSubsets` [protected], [inherited]  
Stores the infeasible subsets.

**0.15.333.5.12 mInformedConstraints** `carl::FastSet<FormulaT>` `smtrat::Module::mInformedConstraints` [protected], [inherited]  
Stores the position of the first constraint of which no backend has been informed about.

**0.15.333.5.13 mLastBranches** std::vector< Branching > smtrat::Module::mLastBranches = std::vector<Branching> (mNumOfBranchVarsToStore, Branching(typename Poly::PolyType(), 0)) [static], [inherited]

Stores the last branches in a cycle buffer.

**0.15.333.5.14 mLemmas** std::vector<Lemma> smtrat::Module::mLemmas [protected], [inherited]  
Stores the lemmas being valid formulas this module or its backends made.

**0.15.333.5.15 mModel** Model smtrat::Module::mModel [mutable], [protected], [inherited]  
Stores the assignment of the current satisfiable result, if existent.

**0.15.333.5.16 mModelComputed** bool smtrat::Module::mModelComputed [mutable], [protected], [inherited]  
True, if the model has already been computed.

**0.15.333.5.17 mNumOfBranchVarsToStore** std::size\_t smtrat::Module::mNumOfBranchVarsToStore = 5 [static], [inherited]  
The number of different variables to consider for a probable infinite loop of branchings.

**0.15.333.5.18 mObjectiveVariable** carl::Variable smtrat::Module::mObjectiveVariable [protected], [inherited]  
Objective variable to be minimized. If set to NO\_VARIABLE, a normal sat check should be performed.

**0.15.333.5.19 mOldSplittingVariables** std::vector< FormulaT > smtrat::Module::mOldSplittingVariables [static], [inherited]  
Reusable splitting variables.

**0.15.333.5.20 mpManager** Manager\* const smtrat::Module::mpManager [protected], [inherited]  
A reference to the manager.

**0.15.333.5.21 mSmallerMusesCheckCounter** unsigned smtrat::Module::mSmallerMusesCheckCounter [mutable], [protected], [inherited]  
Counter used for the generation of the smt2 files to check for smaller muses.

**0.15.333.5.22 mSolverState** std::atomic<Answer> smtrat::Module::mSolverState [protected], [inherited]  
States whether the received formula is known to be satisfiable or unsatisfiable otherwise it is set to unknown.

**0.15.333.5.23 mTheoryPropagations** std::vector<TheoryPropagation> smtrat::Module::mTheoryPropagations [protected], [inherited]

**0.15.333.5.24 mUsedBackends** std::vector<[Module](#)\*> smtrat::Module::mUsedBackends [protected], [inherited]

The backends of this module which are currently used (conditions to use this module are fulfilled for the passed formula).

**0.15.333.5.25 mVariableCounters** std::vector<std::size\_t> smtrat::Module::mVariableCounters [protected], [inherited]  
Maps variables to the number of their occurrences.

## 0.15.336 `benchmax::ssh::Node` Struct Reference

Specification of a computation node for the SSH backend.

```
#include <Node.h>
```

### Data Fields

- `std::string hostname`  
*Hostname to connect to.*
- `std::string username`  
*Username.*
- `std::string password`  
*Password (only used if public key authentication fails).*
- `int port`  
*Port (default is 22)*
- `unsigned long cores`  
*Number of cores we use per connection (default is 1)*
- `std::size_t connections`  
*Number of concurrent connections (default is 1)*

### 0.15.336.1 Detailed Description

Specification of a computation node for the SSH backend.

### 0.15.336.2 Field Documentation

**0.15.336.2.1 `connections`** `std::size_t benchmax::ssh::Node::connections`  
Number of concurrent connections (default is 1)

**0.15.336.2.2 `cores`** `unsigned long benchmax::ssh::Node::cores`  
Number of cores we use per connection (default is 1)

**0.15.336.2.3 `hostname`** `std::string benchmax::ssh::Node::hostname`  
Hostname to connect to.

**0.15.336.2.4 `password`** `std::string benchmax::ssh::Node::password`  
Password (only used if public key authentication fails).

**0.15.336.2.5 `port`** `int benchmax::ssh::Node::port`  
Port (default is 22)

**0.15.336.2.6 `username`** std::string benchmax::ssh::Node::username  
Username.

## 0.15.337 `delta::Node` Struct Reference

This class represents a node in a SMTLIB file.

```
#include <Node.h>
```

### Public Member Functions

*Children of the node.*
- `bool brackets`  
*Flag if the node was contained in brackets.*
- `std::size_t size`

### 0.15.337.1 Detailed Description

This class represents a node in a SMTLIB file.

Every syntactical constructor is represented by a node. A node may have a name and may have several children. In a file, this corresponds to (`<name> <child> <child> ...`).

Note that these nodes are constructed by a parser that has no semantic knowledge of the smtlib format. Hence, the data representable by these nodes is only a very rough overapproximation of the actual smtlib format.

### 0.15.337.2 Constructor & Destructor Documentation

**0.15.337.2.1 Node() [1/6]** `delta::Node::Node ()` [inline], [explicit]  
Create an empty node.

**0.15.337.2.2 Node() [2/6]** `delta::Node::Node (`  
    `const std::string & name,`  
    `bool brackets = true )` [inline], [explicit]

Create a node with a name.

#### Parameters

|                       |                                  |
|-----------------------|----------------------------------|
| <code>name</code>     | Name of the node.                |
| <code>brackets</code> | If not is contained in brackets. |

**0.15.337.2.3 Node() [3/6]** `delta::Node::Node (`  
    `const std::tuple< std::string, bool > & data )` [inline], [explicit]  
Create a node with a name.

#### Parameters

|                   |                                                  |
|-------------------|--------------------------------------------------|
| <code>data</code> | Tuple containing the name and the brackets flag. |
|-------------------|--------------------------------------------------|

**0.15.337.2.4 Node() [4/6]** `delta::Node::Node (`  
    `const std::tuple< std::vector< Node >, bool > & data )` [inline], [explicit]  
Create a node with children.

#### Parameters

|                   |                                                      |
|-------------------|------------------------------------------------------|
| <code>data</code> | Tuple containing the children and the brackets flag. |
|-------------------|------------------------------------------------------|

**0.15.337.2.5 Node() [5/6]** `delta::Node::Node (`  
    `const std::tuple< std::string, std::vector< Node >, bool > & data )` [inline],  
[explicit]  
Create a node with a name and children.

#### Parameters

|                   |                                                                |
|-------------------|----------------------------------------------------------------|
| <code>data</code> | Tuple containing the name, the children and the brackets flag. |
|-------------------|----------------------------------------------------------------|

**0.15.337.2.6 Node() [6/6]** `delta::Node::Node (`  
    `const std::string & name,`  
    `const std::initializer_list< Node > & children,`  
    `bool brackets = true )` [inline], [explicit]

### 0.15.337.3 Member Function Documentation

**0.15.337.3.1 clone()** [1/2] `Node delta::Node::clone (`  
    `const Node * from,`  
    `const Node * to ) const [inline]`

Clone this node recursively.

If the node `from` is encountered, replace it with `to`. If `to` is a `nullptr`, remove it instead.

#### Parameters

|                   |                                    |
|-------------------|------------------------------------|
| <code>from</code> | <code>Node</code> to replace.      |
| <code>to</code>   | <code>Node</code> to replace with. |

#### Returns

Cloned node.

**0.15.337.3.2 clone()** [2/2] `Node delta::Node::clone (`  
    `const std::string & from,`  
    `const Node * to ) const [inline]`

Clone this node recursively.

If a node with name `from` without children is encountered, replace it with `to`.

#### Parameters

|                   |                                    |
|-------------------|------------------------------------|
| <code>from</code> | <code>Node</code> name to replace. |
| <code>to</code>   | <code>Node</code> to replace with. |

#### Returns

Cloned node.

**0.15.337.3.3 collectNames()** `void delta::Node::collectNames (`  
    `std::set< std::string > & names ) const [inline]`

**0.15.337.3.4 complexity()** `std::size_t delta::Node::complexity ( ) const [inline]`  
Calculates the number of nodes.

#### Returns

Number of nodes.

**0.15.337.3.5 eliminateDefineFuns()** `void delta::Node::eliminateDefineFuns ( ) [inline]`

**0.15.337.3.6 immutable()** `bool delta::Node::immutable ( ) const [inline]`

Checks if this node is immutable.

This method implements simple checks to prevent unnecessary solver errors if essential parts of the smtlib file are removed, for example the `set-logic` statement.

**Returns**

If node may be removed.

**0.15.337.3.7 recalculateSize()** void delta::Node::recalculateSize ( ) [inline]**0.15.337.3.8 repr()** std::string delta::Node::repr ( bool longRepr = false ) const [inline]

Returns a string representation of this node.

**Returns**

[String](#) of the node.

**0.15.337.4 Field Documentation****0.15.337.4.1 brackets** bool delta::Node::brackets

Flag if the node was contained in brackets.

**0.15.337.4.2 children** std::vector<[Node](#)> delta::Node::children

Children of the node.

**0.15.337.4.3 name** std::string delta::Node::name

Name of the node.

**0.15.337.4.4 size** std::size\_t delta::Node::size**0.15.338 delta::NodePrinter< pretty > Struct Template Reference**

- `bool is_minimizing () const`
- `void excludeNotReceivedVariablesFromModel () const`

*Excludes all variables from the current model, which do not occur in the received formula.*
- `void updateLemmas ()`

*Stores all lemmas of any backend of this module in its own lemma vector.*
- `void collectTheoryPropagations ()`
- `void collectOrigins (const FormulaT &_formula, FormulasT &_origins) const`

*Collects the formulas in the given formula, which are part of the received formula.*
- `void collectOrigins (const FormulaT &_formula, FormulaSetT &_origins) const`
- `bool hasValidInfeasibleSubset () const`
- `void checkInfeasibleSubsetForMinimality (std::vector<FormulaSetT>::const_iterator _insubset, const std::string &filename="smaller_muses", unsigned _maxSizeDifference=1) const`

*Checks the given infeasible subset for minimality by storing all subsets of it, which have a smaller size which differs from the size of the infeasible subset not more than the given threshold.*
- `virtual std::pair< bool, FormulaT > getReceivedFormulaSimplified ()`
- `void print (const std::string &_initiation="***") const`

*Prints everything relevant of the solver.*
- `void printReceivedFormula (const std::string &_initiation="***") const`

*Prints the vector of the received formula.*
- `void printPassedFormula (const std::string &_initiation="***") const`

*Prints the vector of passed formula.*
- `void printInfeasibleSubsets (const std::string &_initiation="***") const`

*Prints the infeasible subsets.*
- `void printModel (std::ostream &_out=std::cout) const`

*Prints the assignment of this module satisfying its received formula if it satisfiable and this module could find an assignment.*
- `void printAllModels (std::ostream &_out=std::cout)`

*Prints all assignments of this module satisfying its received formula if it satisfiable and this module could find an assignment.*

## Static Public Member Functions

- `static void freeSplittingVariable (const FormulaT &_splittingVariable)`

## Static Public Attributes

- `static size_t mNumOfBranchVarsToStore = 5`

*The number of different variables to consider for a probable infinite loop of branchings.*
- `static std::vector< Branching > mLastBranches = std::vector<Branching>(mNumOfBranchVarsToStore, Branching(typename Poly::PolyType(), 0))`

*Stores the last branches in a cycle buffer.*
- `static size_t mFirstPosInLastBranches = 0`

*The beginning of the cyclic buffer storing the last branches.*
- `static std::vector< FormulaT > mOldSplittingVariables`

*Reusable splitting variables.*

### Protected Member Functions

- virtual void `deinformCore` (const `FormulaT` &\_constraint)
 

*The inverse of informing about a constraint.*
- bool `anAnswerFound` () const
 

*Checks for all antecedent modules and those which run in parallel with the same antecedent modules, whether one of them has determined a result.*
- void `clearModel` () const
 

*Clears the assignment, if any was found.*
- void `clearModels` () const
 

*Clears all assignments, if any was found.*
- void `cleanModel` () const
 

*Substitutes variable occurrences by its model value in the model values of other variables.*
- `ModuleInput::iterator passedFormulaBegin` ()
- `ModuleInput::iterator passedFormulaEnd` ()
- void `addOrigin` (`ModuleInput::iterator` \_formula, const `FormulaT` &\_origin)
 

*Adds the given set of formulas in the received formula to the origins of the given passed formula.*
- const `FormulaT` & `getOrigins` (`ModuleInput::const_iterator` \_formula) const
 

*Gets the origins of the passed formula at the given position.*
- void `getOrigins` (const `FormulaT` &\_formula, `FormulasT` &\_origins) const
- void `getOrigins` (const `FormulaT` &\_formula, `FormulaSetT` &\_origins) const
- std::pair< `ModuleInput::iterator`, bool > `removeOrigin` (`ModuleInput::iterator` \_formula, const `FormulaT` &\_origin)
- std::pair< `ModuleInput::iterator`, bool > `removeOrigins` (`ModuleInput::iterator` \_formula, const std::shared\_ptr< std::vector< `FormulaT` >> &\_origins)
- void `informBackends` (const `FormulaT` &\_constraint)
 

*Informs all backends of this module about the given constraint.*
- virtual void `addConstraintToInform` (const `FormulaT` &\_constraint)
 

*Adds a constraint to the collection of constraints of this module, which are informed to a freshly generated backend.*
- std::pair< `ModuleInput::iterator`, bool > `addReceivedSubformulaToPassedFormula` (`ModuleInput::const_iterator` \_subformula)
 

*Copies the given sub-formula of the received formula to the passed formula.*
- bool `originInReceivedFormula` (const `FormulaT` &\_origin) const
- std::pair< `ModuleInput::iterator`, bool > `addSubformulaToPassedFormula` (const `FormulaT` &\_formula)
 

*Adds the given formula to the passed formula with no origin.*
- std::pair< `ModuleInput::iterator`, bool > `addSubformulaToPassedFormula` (const `FormulaT` &\_formula, const std::shared\_ptr< std::vector< `FormulaT` >> &\_origins)
 

*Adds the given formula to the passed formula.*
- std::pair< `ModuleInput::iterator`, bool > `addSubformulaToPassedFormula` (const `FormulaT` &\_formula, const `FormulaT` &\_origin)
 

*Adds the given formula to the passed formula.*
- void `generateTrivialInfeasibleSubset` ()
 

*Stores the trivial infeasible subset being the set of received formulas.*
- void `receivedFormulasAsInfeasibleSubset` (`ModuleInput::const_iterator` \_subformula)
 

*Stores an infeasible subset consisting only of the given received formula.*
- std::vector< `FormulaT` >::const\_iterator `findBestOrigin` (const std::vector< `FormulaT` > &\_origins) const
- void `getInfeasibleSubsets` ()
 

*Copies the infeasible subsets of the passed formula.*
- std::vector< `FormulaSetT` > `getInfeasibleSubsets` (const `Module` &\_backend) const
 

*Get the infeasible subsets the given backend provides.*
- const `Model` & `backendsModel` () const
 

*Stores the model of a backend which determined satisfiability of the passed formula in the model of this module.*
- void `getBackendsModel` () const

- void `getBackendsAllModels () const`  
*Stores all models of a backend in the list of all models of this module.*
- virtual `Answer runBackends (bool _final, bool _full, carl::Variable _objective)`  
*Runs the backend solvers on the passed formula.*
- virtual `Answer runBackends ()`
- virtual `ModuleInput::iterator eraseSubformulaFromPassedFormula (ModuleInput::iterator _subformula, bool _ignoreOrigins=false)`  
*Removes everything related to the sub-formula to remove from the passed formula in the backends of this module.*
- void `clearPassedFormula ()`
- std::vector< `FormulaT` > `merge (const std::vector< FormulaT > &, const std::vector< FormulaT > &)` const  
*Merges the two vectors of sets into the first one.*
- size\_t `determine_smallest_origin (const std::vector< FormulaT > &origins) const`
- bool `probablyLooping (const typename Poly::PolyType &_branchingPolynomial, const Rational &_branchingValue) const`  
*Checks whether given the current branching value and branching variable/polynomial it is (highly) probable that this branching is part of an infinite loop of branchings.*
- bool `branchAt (const Poly &_polynomial, bool _integral, const Rational &_value, std::vector< FormulaT > &&_premise, bool _leftCaseWeak=true, bool _preferLeftCase=true, bool _useReceivedFormulaAsPremise=false)`  
*Adds a lemmas which provoke a branching for the given variable at the given value, if this module returns Unknown and there exists a preceding SATModule.*
- bool `branchAt (const Poly &_polynomial, bool _integral, const Rational &_value, bool _leftCaseWeak=true, bool _preferLeftCase=true, bool _useReceivedFormulaAsPremise=false, const std::vector< FormulaT > &&_premise=std::vector< FormulaT >())`
- bool `branchAt (carl::Variable::Arg _var, const Rational &_value, std::vector< FormulaT > &&_premise, bool _leftCaseWeak=true, bool _preferLeftCase=true, bool _useReceivedFormulaAsPremise=false)`
- bool `branchAt (carl::Variable::Arg _var, const Rational &_value, bool _leftCaseWeak=true, bool _preferLeftCase=true, bool _useReceivedFormulaAsPremise=false, const std::vector< FormulaT > &_premise=std::vector< FormulaT >())`
- void `splitUnequalConstraint (const FormulaT &)`  
*Adds the following lemmas for the given constraint  $p \neq 0$ .*
- unsigned `checkModel () const`
- void `addInformationRelevantFormula (const FormulaT &formula)`  
*Adds a formula to the InformationRelevantFormula.*
- const std::set< `FormulaT` > & `getInformationRelevantFormulas ()`  
*Gets all InformationRelevantFormulas.*
- bool `isLemmaLevel (LemmaLevel level)`  
*Checks if current lemma level is greater or equal to given level.*

## Static Protected Member Functions

- static bool `modelsDisjoint (const Model &_modelA, const Model &_modelB)`  
*Checks whether there is no variable assigned by both models.*

## Protected Attributes

- std::vector< `FormulaSetT` > `mInfeasibleSubsets`  
*Stores the infeasible subsets.*
- `Manager *const mpManager`  
*A reference to the manager.*
- `Model mModel`  
*Stores the assignment of the current satisfiable result, if existent.*
- std::vector< `Model` > `mAllModels`  
*Stores all satisfying assignments.*

- bool `mModelComputed`  
*True, if the model has already been computed.*
- bool `mFinalCheck`  
*true, if the check procedure should perform a final check which especially means not to postpone splitting decisions*
- bool `mFullCheck`  
*false, if this module should avoid too expensive procedures and rather return unknown instead.*
- carl::Variable `mObjectiveVariable`  
*Objective variable to be minimized. If set to NO\_VARIABLE, a normal sat check should be performed.*
- std::vector< `TheoryPropagation` > `mTheoryPropagations`
- std::atomic< `Answer` > `mSolverState`  
*States whether the received formula is known to be satisfiable or unsatisfiable otherwise it is set to unknown.*
- std::atomic\_bool \* `mBackendsFoundAnswer`  
*This flag is passed to any backend and if it determines an answer to a prior check call, this flag is fired.*
- Conditionals `mFoundAnswer`  
*Vector of Booleans: If any of them is true, we have to terminate a running check procedure.*
- std::vector< `Module` \* > `mUsedBackends`  
*The backends of this module which are currently used (conditions to use this module are fulfilled for the passed formula).*
- std::vector< `Module` \* > `mAllBackends`  
*The backends of this module which have been used.*
- std::vector< `Lemma` > `mLemmas`  
*Stores the lemmas being valid formulas this module or its backends made.*
- ModuleInput::iterator `mFirstSubformulaToPass`  
*Stores the position of the first sub-formula in the passed formula, which has not yet been considered for a consistency check of the backends.*
- carl::FastSet< `FormulaT` > `mConstraintsToInform`  
*Stores the constraints which the backends must be informed about.*
- carl::FastSet< `FormulaT` > `mInformedConstraints`  
*Stores the position of the first constraint of which no backend has been informed about.*
- ModuleInput::const\_iterator `mFirstUncheckedReceivedSubformula`  
*Stores the position of the first (by this module) unchecked sub-formula of the received formula.*
- unsigned `mSmallerMusesCheckCounter`  
*Counter used for the generation of the smt2 files to check for smaller muses.*
- std::vector< std::size\_t > `mVariableCounters`  
*Maps variables to the number of their occurrences.*

### 0.15.340.3 Constructor & Destructor Documentation

**0.15.340.3.1 `NRAILModule()`** template<typename Settings >  
smtrat::NRAILModule< Settings >::NRAILModule ( const ModuleInput \* \_formula, Conditionals & \_conditionals, Manager \* \_manager = nullptr )

**0.15.340.3.2 `~NRAILModule()`** template<typename Settings >  
smtrat::NRAILModule< Settings >::~NRAILModule ( )

### 0.15.340.4 Member Function Documentation

**0.15.340.4.1 `add()`** bool smtrat::Module::add ( ModuleInput::const\_iterator \_subformula ) [inherited]

The module has to take the given sub-formula of the received formula into account.

#### Parameters

|             |                                                    |
|-------------|----------------------------------------------------|
| _subformula | The sub-formula to take additionally into account. |
|-------------|----------------------------------------------------|

#### Returns

false, if it can be easily decided that this sub-formula causes a conflict with the already considered sub-formulas; true, otherwise.

**0.15.340.4.2 `addConstraintToInform()`** void smtrat::Module::addConstraintToInform ( const FormulaT & \_constraint ) [protected], [virtual], [inherited]

Adds a constraint to the collection of constraints of this module, which are informed to a freshly generated backend.

#### Parameters

|             |                        |
|-------------|------------------------|
| _constraint | The constraint to add. |
|-------------|------------------------|

Reimplemented in [smtrat::SATModule< Settings >](#).

**0.15.340.4.3 `addCore()`** template<typename Settings >  
bool smtrat::NRAILModule< Settings >::addCore (

ModuleInput::const\_iterator \_subformula ) [virtual]

The module has to take the given sub-formula of the received formula into account.

#### Parameters

|             |                                                    |
|-------------|----------------------------------------------------|
| _subformula | The sub-formula to take additionally into account. |
|-------------|----------------------------------------------------|

#### Returns

false, if it can be easily decided that this sub-formula causes a conflict with the already considered sub-formulas; true, otherwise.

Reimplemented from [smtrat::Module](#).

```
0.15.340.4.4 addInformationRelevantFormula() void smtrat::Module::addInformationRelevantFormula (
 const FormulaT & formula) [protected], [inherited]
```

Adds a formula to the InformationRelevantFormula.

#### Parameters

|                |                |
|----------------|----------------|
| <i>formula</i> | Formula to add |
|----------------|----------------|

```
0.15.340.4.5 addLemma() void smtrat::Module::addLemma (
 const FormulaT & _lemma,
 const LemmaType & _lt = LemmaType::NORMAL,
 const FormulaT & _preferredFormula = FormulaT(carl::FormulaType::TRUE)) [inline],
[inherited]
```

Stores a lemma being a valid formula.

#### Parameters

|                          |                                                                       |
|--------------------------|-----------------------------------------------------------------------|
| <i>_lemma</i>            | The eduction/lemma to store.                                          |
| <i>_lt</i>               | The type of the lemma.                                                |
| <i>_preferredFormula</i> | Hint for the next decision, which formula should be assigned to true. |

```
0.15.340.4.6 addOrigin() void smtrat::Module::addOrigin (
 ModuleInput::iterator _formula,
 const FormulaT & _origin) [inline], [protected], [inherited]
```

Adds the given set of formulas in the received formula to the origins of the given passed formula.

#### Parameters

|                 |                                                           |
|-----------------|-----------------------------------------------------------|
| <i>_formula</i> | The passed formula to set the origins for.                |
| <i>_origin</i>  | A set of formulas in the received formula of this module. |

```
0.15.340.4.7 addReceivedSubformulaToPassedFormula() std::pair<ModuleInput::iterator,bool>
smtrat::Module::addReceivedSubformulaToPassedFormula (
 ModuleInput::const_iterator _subformula) [inline], [protected], [inherited]
```

Copies the given sub-formula of the received formula to the passed formula.

Note, that there is always a link between sub-formulas of the passed formulas to sub-formulas of the received formulas, which are responsible for its occurrence.

#### Parameters

|                    |                                                  |
|--------------------|--------------------------------------------------|
| <i>_subformula</i> | The sub-formula of the received formula to copy. |
|--------------------|--------------------------------------------------|

```
0.15.340.4.8 addSubformulaToPassedFormula() [1/3] std::pair<ModuleInput::iterator,bool> smtrat->
```

---

```
::Module::addSubformulaToPassedFormula (
 const FormulaT & _formula) [inline], [protected], [inherited]
Adds the given formula to the passed formula with no origin.
Note that in the next call of this module's removeSubformula, all formulas in the passed formula without origins will
be removed.
```

**Parameters**

|                       |                                           |
|-----------------------|-------------------------------------------|
| <code>_formula</code> | The formula to add to the passed formula. |
|-----------------------|-------------------------------------------|

**Returns**

A pair to the position where the formula to add has been inserted (or its first sub-formula which has not yet been in the passed formula, in case the formula to add is a conjunction), and a Boolean stating whether anything has been added to the passed formula.

**0.15.340.4.9 `addSubformulaToPassedFormula()` [2/3]** `std::pair<ModuleInput::iterator,bool> smrat->`

```
::Module::addSubformulaToPassedFormula (
 const FormulaT & _formula,
 const FormulaT & _origin) [inline], [protected], [inherited]
Adds the given formula to the passed formula.
```

**Parameters**

|                       |                                                                                                                           |
|-----------------------|---------------------------------------------------------------------------------------------------------------------------|
| <code>_formula</code> | The formula to add to the passed formula.                                                                                 |
| <code>_origin</code>  | The sub-formula of the received formula being responsible for the occurrence of the formula to add to the passed formula. |

**Returns**

A pair to the position where the formula to add has been inserted (or its first sub-formula which has not yet been in the passed formula, in case the formula to add is a conjunction), and a Boolean stating whether anything has been added to the passed formula.

**0.15.340.4.10 `addSubformulaToPassedFormula()` [3/3]** `std::pair<ModuleInput::iterator,bool> smrat->`

```
smrat::Module::addSubformulaToPassedFormula (
 const FormulaT & _formula,
 const std::shared_ptr< std::vector< FormulaT >> & _origins) [inline], [protected],
[inherited]
Adds the given formula to the passed formula.
```

**Parameters**

|                       |                                                                                                                                         |
|-----------------------|-----------------------------------------------------------------------------------------------------------------------------------------|
| <code>_formula</code> | The formula to add to the passed formula.                                                                                               |
| <code>_origins</code> | The link of the formula to add to the passed formula to sub-formulas of the received formulas, which are responsible for its occurrence |

**Returns**

A pair to the position where the formula to add has been inserted (or its first sub-formula which has not yet been in the passed formula, in case the formula to add is a conjunction), and a Boolean stating whether anything has been added to the passed formula.

**0.15.340.4.11 allModels()** const std::vector<[Model](#)>& smtrat::Module::allModels () const [inline], [inherited]

**Returns**

All satisfying assignments, if existent.

**0.15.340.4.12 anAnswerFound()** bool smtrat::Module::anAnswerFound () const [inline], [protected], [inherited]

Checks for all antecedent modules and those which run in parallel with the same antecedent modules, whether one of them has determined a result.

**Returns**

True, if one of them has determined a result.

**0.15.340.4.13 answerFound()** const [smtrat::Conditionals](#)& smtrat::Module::answerFound () const [inline], [inherited]

**Returns**

A vector of Booleans: If any of them is true, we have to terminate a running check procedure.

**0.15.340.4.14 backendsModel()** const [Model](#) & smtrat::Module::backendsModel () const [protected], [inherited]

Stores the model of a backend which determined satisfiability of the passed formula in the model of this module.

**0.15.340.4.15 branchAt() [1/4]** bool smtrat::Module::branchAt ( carl::Variable::Arg \_var, const [Rational](#) & \_value, bool \_leftCaseWeak = true, bool \_preferLeftCase = true, bool \_useReceivedFormulaAsPremise = false, const std::vector< [FormulaT](#) > & \_premise = std::vector<[FormulaT](#)>() ) [inline], [protected], [inherited]

**0.15.340.4.16 branchAt() [2/4]** bool smtrat::Module::branchAt ( carl::Variable::Arg \_var, const [Rational](#) & \_value, std::vector< [FormulaT](#) > && \_premise, bool \_leftCaseWeak = true, bool \_preferLeftCase = true, bool \_useReceivedFormulaAsPremise = false ) [inline], [protected], [inherited]

**0.15.340.4.17 branchAt() [3/4]** bool smtrat::Module::branchAt ( const [Poly](#) & \_polynomial, bool \_integral, const [Rational](#) & \_value, bool \_leftCaseWeak = true, bool \_preferLeftCase = true, bool \_useReceivedFormulaAsPremise = false, const std::vector< [FormulaT](#) > & \_premise = std::vector<[FormulaT](#)>() ) [inline], [protected], [inherited]

---

**0.15.340.4.18 branchAt() [4/4]** `bool smtrat::Module::branchAt (`

```

const Poly & _polynomial,
bool _integral,
const Rational & _value,
std::vector< FormulaT > && _premise,
bool _leftCaseWeak = true,
bool _preferLeftCase = true,
bool _useReceivedFormulaAsPremise = false) [protected], [inherited]

```

Adds a lemmas which provoke a branching for the given variable at the given value, if this module returns Unknown and there exists a preceding [SATModule](#).

Note that the given value is rounded down and up, if the given variable is integer-valued.

#### Parameters

|                                           |                                                                                                                                                                                                                |
|-------------------------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>_polynomial</code>                  | The variable to branch for.                                                                                                                                                                                    |
| <code>_integral</code>                    | A flag being true, if all variables in the polynomial to branch for are integral.                                                                                                                              |
| <code>_value</code>                       | The value to branch at.                                                                                                                                                                                        |
| <code>_premise</code>                     | The sub-formulas of the received formula from which the branch is followed. Note, that a premise is not necessary, as every branch is a valid formula. But a premise can prevent from branching unnecessarily. |
| <code>_leftCaseWeak</code>                | true, if a branching in the form of (or ( $\leq p b$ ) ( $> p b$ )) is desired. false, if a branching in the form of (or ( $< p b$ ) ( $\geq p b$ )) is desired.                                               |
| <code>_preferLeftCase</code>              | true, if the left case (polynomial less(or equal) 0 shall be chosen first. false, otherwise.                                                                                                                   |
| <code>_useReceivedFormulaAsPremise</code> | true, if the whole received formula should be used as premise                                                                                                                                                  |

**0.15.340.4.19 check()** [Answer](#) `smtrat::Module::check (`

```

bool _final = false,
bool _full = true,
carl::Variable _objective = carl::Variable::NO_VARIABLE) [virtual], [inherited]

```

Checks the received formula for consistency.

Note, that this is an implementation of the satisfiability check of the conjunction of the so far received formulas, which does actually nothing but passing the problem to its backends. This implementation is only used internally and must be overwritten by any derived module.

#### Parameters

|                         |                                                                                                                                       |
|-------------------------|---------------------------------------------------------------------------------------------------------------------------------------|
| <code>_final</code>     | true, if this satisfiability check will be the last one (for a global sat-check), if its result is SAT                                |
| <code>_full</code>      | false, if this module should avoid too expensive procedures and rather return unknown instead.                                        |
| <code>_objective</code> | if not set to NO_VARIABLE, the module should find an assignment minimizing this objective variable; otherwise any assignment is good. |

#### Returns

True, if the received formula is satisfiable; False, if the received formula is not satisfiable; Unknown, otherwise.

Reimplemented in [smtrat::PModule](#).

**0.15.340.4.20 checkCore()** `template<typename Settings >`

```
Answer smtrat::NRAILModule< Settings >::checkCore () [virtual]
```

Checks the received formula for consistency.

**Returns**

True, if the received formula is satisfiable; False, if the received formula is not satisfiable; Unknown, otherwise.

Reimplemented from [smrat::Module](#).

**0.15.340.4.21 `checkInfSubsetForMinimality()`** `void smrat::Module::checkInfSubsetForMinimality ( std::vector< FormulaSetT >::const_iterator _infssubset,`  
`const std::string & _filename = "smaller_muses",`  
`unsigned _maxSizeDifference = 1 ) const [inherited]`

Checks the given infeasible subset for minimality by storing all subsets of it, which have a smaller size which differs from the size of the infeasible subset not more than the given threshold.

**Parameters**

|                                 |                                                                                                        |
|---------------------------------|--------------------------------------------------------------------------------------------------------|
| <code>_infssubset</code>        | The infeasible subset to check for minimality.                                                         |
| <code>_filename</code>          | The name of the file to store the infeasible subsets in order to be able to check their infeasibility. |
| <code>_maxSizeDifference</code> | The maximal difference between the sizes of the subsets compared to the size of the infeasible subset. |

**0.15.340.4.22 `checkModel()`** `unsigned smrat::Module::checkModel ( ) const [protected], [inherited]`

**Returns**

false, if the current model of this module does not satisfy the current given formula; true, if it cannot be said whether the model satisfies the given formula.

**0.15.340.4.23 `cleanModel()`** `void smrat::Module::cleanModel ( ) const [inline], [protected], [inherited]`

Substitutes variable occurrences by its model value in the model values of other variables.

**0.15.340.4.24 `clearLemmas()`** `void smrat::Module::clearLemmas ( ) [inline], [inherited]`  
Deletes all yet found lemmas.

**0.15.340.4.25 `clearModel()`** `void smrat::Module::clearModel ( ) const [inline], [protected], [inherited]`

Clears the assignment, if any was found.

**0.15.340.4.26 `clearModels()`** `void smrat::Module::clearModels ( ) const [inline], [protected], [inherited]`

Clears all assignments, if any was found.

**0.15.340.4.27 `clearPassedFormula()`** `void smrat::Module::clearPassedFormula ( ) [protected], [inherited]`

---

**0.15.340.4.28 collectOrigins() [1/2]** void smtrat::Module::collectOrigins ( const FormulaT & \_formula, FormulaSetT & \_origins ) const [inherited]

**0.15.340.4.29 collectOrigins() [2/2]** void smtrat::Module::collectOrigins ( const FormulaT & \_formula, FormulasT & \_origins ) const [inherited]

Collects the formulas in the given formula, which are part of the received formula.

If the given formula directly occurs in the received formula, it is inserted into the given set. Otherwise, the given formula must be of type AND and all its sub-formulas part of the received formula. Hence, they will be added to the given set.

#### Parameters

|                       |                                                                                                      |
|-----------------------|------------------------------------------------------------------------------------------------------|
| <code>_formula</code> | The formula from which to collect the formulas being sub-formulas of the received formula (origins). |
| <code>_origins</code> | The set in which to store the origins.                                                               |

**0.15.340.4.30 collectTheoryPropagations()** void smtrat::Module::collectTheoryPropagations ( ) [inherited]

**0.15.340.4.31 constraintsToInform()** const carl::FastSet<FormulaT>& smtrat::Module::constraintsToInform ( ) const [inline], [inherited]

#### Returns

The constraints which the backends must be informed about.

**0.15.340.4.32 currentlySatisfied()** virtual unsigned smtrat::Module::currentlySatisfied ( const FormulaT & ) const [inline], [virtual], [inherited]

#### Returns

0, if the given formula is conflicted by the current model; 1, if the given formula is satisfied by the current model; 2, otherwise; 3, if we do not know anything (default)

Reimplemented in [smtrat::LRAbstractModule< Settings >](#), [smtrat::LRAbstractModule< LRASettingsICP >](#), and [smtrat::LRAbstractModule< LRASettings >](#)

**0.15.340.4.33 currentlySatisfiedByBackend()** unsigned smtrat::Module::currentlySatisfiedByBackend ( const FormulaT & \_formula ) const [inherited]

#### Returns

0, if the given formula is conflicted by the current model; 1, if the given formula is satisfied by the current model; 2, otherwise 3, if we do not know anything (default)

**0.15.340.4.34 deinform()** void smtrat::Module::deinform ( const FormulaT & \_constraint ) [inherited]

The inverse of informing about a constraint.

All data structures which were kept regarding this constraint are going to be removed. Note, that this makes only sense if it is not likely enough that a formula with this constraint must be solved again.

## Parameters

|                          |                                                         |
|--------------------------|---------------------------------------------------------|
| <code>_constraint</code> | The constraint to remove from internal data structures. |
|--------------------------|---------------------------------------------------------|

**0.15.340.4.35 `deinformCore()`** `virtual void smtrat::Module::deinformCore (``const FormulaT & _constraint ) [inline], [protected], [virtual], [inherited]`

The inverse of informing about a constraint.

All data structures which were kept regarding this constraint are going to be removed. Note, that this makes only sense if it is not likely enough that a formula with this constraint must be solved again.

## Parameters

|                          |                                                         |
|--------------------------|---------------------------------------------------------|
| <code>_constraint</code> | The constraint to remove from internal data structures. |
|--------------------------|---------------------------------------------------------|

Reimplemented in [smtrat::LRAModule< Settings >](#), [smtrat::LRAModule< LRASettingsICP >](#), and [smtrat::LRAModule< LRASettings1 >](#).

**0.15.340.4.36 `determine_smallest_origin()`** `size_t smtrat::Module::determine_smallest_origin (``const std::vector< FormulaT > & origins ) const [protected], [inherited]`

## Parameters

|                      |                              |
|----------------------|------------------------------|
| <code>origins</code> | A vector of sets of origins. |
|----------------------|------------------------------|

## Returns

The index of the smallest (regarding the size of the sets) element of origins

**0.15.340.4.37 `eraseSubformulaFromPassedFormula()`** `ModuleInput::iterator smtrat::Module::eraseSubformulaFromPassedFormula (``ModuleInput::iterator _subformula,``bool _ignoreOrigins = false ) [protected], [virtual], [inherited]`

Removes everything related to the sub-formula to remove from the passed formula in the backends of this module. Afterwards the sub-formula is removed from the passed formula.

## Parameters

|                             |                                                                                                              |
|-----------------------------|--------------------------------------------------------------------------------------------------------------|
| <code>_subformula</code>    | The sub-formula to remove from the passed formula.                                                           |
| <code>_ignoreOrigins</code> | True, if the sub-formula shall be removed regardless of its origins (should only be applied with expertise). |

## Returns

Reimplemented in [smtrat::ICPModule< Settings >](#), [smtrat::ICPModule< ICPSettings4 >](#), and [smtrat::ICPModule< ICPSettings1 >](#).

**0.15.340.4.38 `excludeNotReceivedVariablesFromModel()`** `void smtrat::Module::excludeNotReceivedVariablesFromModel ( ) const [inherited]`

Excludes all variables from the current model, which do not occur in the received formula.

**0.15.340.4.39 `findBestOrigin()`** `std::vector< FormulaT >::const_iterator smrat::Module::findBestOrigin (`  
`const std::vector< FormulaT > & _origins ) const [protected], [inherited]`

**Returns**

|                       |  |
|-----------------------|--|
| <code>_origins</code> |  |
|-----------------------|--|

**Returns**

**0.15.340.4.40 `firstSubformulaToPass()`** `ModuleInput::const_iterator smrat::Module::firstSubformulaToPass ( ) const [inline], [inherited]`

**Returns**

The position of the first sub-formula in the passed formula, which has not yet been considered for a consistency check of the backends.

**0.15.340.4.41 `firstUncheckedReceivedSubformula()`** `ModuleInput::const_iterator smrat::Module::firstUncheckedReceivedSubformula ( ) const [inline], [inherited]`

**Returns**

The position of the first (by this module) unchecked sub-formula of the received formula.

**0.15.340.4.42 `freeSplittingVariable()`** `static void smrat::Module::freeSplittingVariable (`  
`const FormulaT & _splittingVariable ) [inline], [static], [inherited]`

**0.15.340.4.43 `generateTrivialInfeasibleSubset()`** `void smrat::Module::generateTrivialInfeasibleSubset ( ) [inline], [protected], [inherited]`

Stores the trivial infeasible subset being the set of received formulas.

**0.15.340.4.44 `getBackendsAllModels()`** `void smrat::Module::getBackendsAllModels ( ) const [protected], [inherited]`

Stores all models of a backend in the list of all models of this module.

**0.15.340.4.45 `getBackendsModel()`** `void smrat::Module::getBackendsModel ( ) const [protected], [inherited]`

**0.15.340.4.46 `getInfeasibleSubsets()` [1/2]** `void smrat::Module::getInfeasibleSubsets ( ) [protected], [inherited]`

Copies the infeasible subsets of the passed formula.

**0.15.340.4.47 getInfeasibleSubsets()** [2/2] std::vector< `FormulaSetT` > smtrat::Module::getInfeasibleSubsets (

    const `Module` & `_backend` ) const [protected], [inherited]

Get the infeasible subsets the given backend provides.

Note, that an infeasible subset in a backend contains sub formulas of the passed formula and an infeasible subset of this module contains sub formulas of the received formula. In this method the LATTER is returned.

**Parameters**

|                       |                                                          |
|-----------------------|----------------------------------------------------------|
| <code>_backend</code> | The backend from which to obtain the infeasible subsets. |
|-----------------------|----------------------------------------------------------|

**Returns**

The infeasible subsets the given backend provides.

**0.15.340.4.48 `getInformationRelevantFormulas()`** `const std::set< FormulaT > & smtrat::Module::getInformationRelevantFormulas ( ) [protected], [inherited]`  
Gets all InformationRelevantFormulas.

**Returns**

Set of all formulas

**0.15.340.4.49 `getModelEqualities()`** `std::list< std::vector< carl::Variable > > smtrat::Module::getModelEqualities ( ) const [virtual], [inherited]`  
Partition the variables from the current model into equivalence classes according to their assigned value.  
The result is a set of equivalence classes of variables where all variables within one class are assigned the same value. Note that the number of classes may not be minimal, i.e. two classes may actually be equivalent.

**Returns**

Equivalence classes.

**0.15.340.4.50 `getOrigins()` [1/3]** `void smtrat::Module::getOrigins ( const FormulaT & _formula, FormulaSetT & _origins ) const [inline], [protected], [inherited]`

**Parameters**

|                       |  |
|-----------------------|--|
| <code>_formula</code> |  |
| <code>_origins</code> |  |

**0.15.340.4.51 `getOrigins()` [2/3]** `void smtrat::Module::getOrigins ( const FormulaT & _formula, FormulasT & _origins ) const [inline], [protected], [inherited]`

**Parameters**

|                       |  |
|-----------------------|--|
| <code>_formula</code> |  |
| <code>_origins</code> |  |

**0.15.340.4.52 `getOrigins()` [3/3]** `const FormulaT& smtrat::Module::getOrigins ( ModuleInput::const_iterator _formula ) const [inline], [protected], [inherited]`  
Gets the origins of the passed formula at the given position.

**Parameters**

|                 |                                                   |
|-----------------|---------------------------------------------------|
| <i>_formula</i> | The position of a formula in the passed formulas. |
|-----------------|---------------------------------------------------|

**Returns**

The origins of the passed formula at the given position.

**0.15.340.4.53 `getReceivedFormulaSimplified()`** `std::pair< bool, FormulaT > smtrat::Module::getReceivedFormulaSimplified( ) [virtual], [inherited]`

**Returns**

A pair of a Boolean and a formula, where the Boolean is true, if the received formula could be simplified to an equisatisfiable formula. The formula is equisatisfiable to this module's received formula, if the Boolean is true.

Reimplemented in [smtrat::PModule](#).

**0.15.340.4.54 `hasLemmas()`** `bool smtrat::Module::hasLemmas( ) [inline], [inherited]`

Checks whether this module or any of its backends provides any lemmas.

**0.15.340.4.55 `hasValidInfeasibleSubset()`** `bool smtrat::Module::hasValidInfeasibleSubset( ) const [inherited]`

**Returns**

true, if the module has at least one valid infeasible subset, that is all its elements are sub-formulas of the received formula (pointer must be equal).

**0.15.340.4.56 `id()`** `std::size_t smtrat::Module::id( ) const [inline], [inherited]`

**Returns**

A unique ID to identify this module instance.

**0.15.340.4.57 `infeasibleSubsets()`** `const std::vector<FormulaSetT>& smtrat::Module::infeasibleSubsets( ) const [inline], [inherited]`

**Returns**

The infeasible subsets of the set of received formulas (empty, if this module has not detected unsatisfiability of the conjunction of received formulas).

**0.15.340.4.58 `inform()`** `bool smtrat::Module::inform( const FormulaT & _constraint ) [inherited]`

Informs the module about the given constraint.

It should be tried to inform this module about any constraint it could receive eventually before assertSubformula is called (preferably for the first time, but at least before adding a formula containing that constraint).

**Parameters**

|                    |                                 |
|--------------------|---------------------------------|
| <i>_constraint</i> | The constraint to inform about. |
|--------------------|---------------------------------|

**Returns**

false, if it can be easily decided whether the given constraint is inconsistent; true, otherwise.

**0.15.340.4.59 informBackends()** `void smrat::Module::informBackends (`

```
 const FormulaT & _constraint) [inline], [protected], [inherited]
```

Informs all backends of this module about the given constraint.

**Parameters**

|                          |                                 |
|--------------------------|---------------------------------|
| <code>_constraint</code> | The constraint to inform about. |
|--------------------------|---------------------------------|

**0.15.340.4.60 informCore()** `template<typename Settings >`

```
bool smrat::NRAILModule< Settings >::informCore (
```

  

```
 const FormulaT & _constraint) [virtual]
```

Informs the module about the given constraint.

It should be tried to inform this module about any constraint it could receive eventually before assertSubformula is called (preferably for the first time, but at least before adding a formula containing that constraint).

**Parameters**

|                          |                                 |
|--------------------------|---------------------------------|
| <code>_constraint</code> | The constraint to inform about. |
|--------------------------|---------------------------------|

**Returns**

false, if it can be easily decided whether the given constraint is inconsistent; true, otherwise.

Reimplemented from [smrat::Module](#).

**0.15.340.4.61 informedConstraints()** `const carl::FastSet<FormulaT>& smrat::Module::informed→`

```
Constraints () const [inline], [inherited]
```

**Returns**

The position of the first constraint of which no backend has been informed about.

**0.15.340.4.62 init()** `template<typename Settings >`

```
void smrat::NRAILModule< Settings >::init () [virtual]
```

Informs all backends about the so far encountered constraints, which have not yet been communicated.

This method must not and will not be called more than once and only before the first runBackends call.

Reimplemented from [smrat::Module](#).

**0.15.340.4.63 is\_minimizing()** `bool smrat::Module::is_minimizing ( ) const [inline], [inherited]`**0.15.340.4.64 isLemmaLevel()** `bool smrat::Module::isLemmaLevel (`

```
 LemmaLevel level) [protected], [inherited]
```

Checks if current lemma level is greater or equal to given level.

**Parameters**

|              |                 |
|--------------|-----------------|
| <i>level</i> | Level to check. |
|--------------|-----------------|

**0.15.340.4.65 `isPreprocessor()`** `bool smtrat::Module::isPreprocessor () const [inline], [inherited]`**Returns**

true, if this module is a preprocessor that is a module, which simplifies its received formula to an equisatisfiable formula being passed to its backends. The simplified formula can be obtained with [getReceivedFormulaSimplified\(\)](#).

**0.15.340.4.66 `lemmas()`** `const std::vector<Lemma>& smtrat::Module::lemmas () const [inline], [inherited]`**Returns**

A constant reference to the lemmas being valid formulas this module or its backends made.

**0.15.340.4.67 `merge()`** `std::vector< FormulaT > smtrat::Module::merge (const std::vector< FormulaT > & _vecSetA, const std::vector< FormulaT > & _vecSetB) const [protected], [inherited]`

Merges the two vectors of sets into the first one.

({a,b},{a,c}) and ({b,d},{b}) -> ({a,b,d},{a,b},{a,b,c,d},{a,b,c})

**Parameters**

|                 |                                  |
|-----------------|----------------------------------|
| <i>_vecSetA</i> | A vector of sets of constraints. |
| <i>_vecSetB</i> | A vector of sets of constraints. |

**Returns**

The vector being the two given vectors merged.

**0.15.340.4.68 `model()`** `const Model& smtrat::Module::model () const [inline], [inherited]`**Returns**

The assignment of the current satisfiable result, if existent.

**0.15.340.4.69 `modelsDisjoint()`** `bool smtrat::Module::modelsDisjoint (const Model & _modelA, const Model & _modelB) [static], [protected], [inherited]`

Checks whether there is no variable assigned by both models.

**Parameters**

|                |                                |
|----------------|--------------------------------|
| <i>_modelA</i> | The first model to check for.  |
| <i>_modelB</i> | The second model to check for. |

**Returns**

true, if there is no variable assigned by both models; false, otherwise.

**0.15.340.4.70 `moduleName()`** template<typename Settings >  
std::string smrat::NRAILModule< Settings >::moduleName ( ) const [inline], [virtual]

**Returns**

The name of the given module type as name.

Reimplemented from [smrat::Module](#).

**0.15.340.4.71 `objective()`** carl::Variable smrat::Module::objective ( ) const [inline], [inherited]

**0.15.340.4.72 `originInReceivedFormula()`** bool smrat::Module::originInReceivedFormula (const FormulaT & \_origin ) const [protected], [inherited]

**0.15.340.4.73 `passedFormulaBegin()`** ModuleInput::iterator smrat::Module::passedFormulaBegin ( ) [inline], [protected], [inherited]

**Returns**

An iterator to the end of the passed formula. TODO: disable this method

**0.15.340.4.74 `passedFormulaEnd()`** ModuleInput::iterator smrat::Module::passedFormulaEnd ( ) [inline], [protected], [inherited]

**Returns**

An iterator to the end of the passed formula.

**0.15.340.4.75 `pPassedFormula()`** const ModuleInput\* smrat::Module::pPassedFormula ( ) const [inline], [inherited]

**Returns**

A pointer to the formula passed to the backends of this module.

**0.15.340.4.76 `pReceivedFormula()`** const ModuleInput\* smrat::Module::pReceivedFormula ( ) const [inline], [inherited]

**Returns**

A pointer to the formula passed to this module.

**0.15.340.4.77 `print()`** void smrat::Module::print (const std::string & \_initiation = "\*\*\*" ) const [inherited]

Prints everything relevant of the solver.

**Parameters**

|                    |                      |
|--------------------|----------------------|
| <i>_initiation</i> | The line initiation. |
|--------------------|----------------------|

**0.15.340.4.78 printAllModels()** void smtrat::Module::printAllModels ( std::ostream & *\_out* = std::cout ) [inherited]

Prints all assignments of this module satisfying its received formula if it satisfiable and this module could find an assignment.

**Parameters**

|             |                                        |
|-------------|----------------------------------------|
| <i>_out</i> | The stream to print the assignment on. |
|-------------|----------------------------------------|

**0.15.340.4.79 printInfeasibleSubsets()** void smtrat::Module::printInfeasibleSubsets ( const std::string & *\_initiation* = "\*\*\*" ) const [inherited]

Prints the infeasible subsets.

**Parameters**

|                    |                      |
|--------------------|----------------------|
| <i>_initiation</i> | The line initiation. |
|--------------------|----------------------|

**0.15.340.4.80 printModel()** void smtrat::Module::printModel ( std::ostream & *\_out* = std::cout ) const [inherited]

Prints the assignment of this module satisfying its received formula if it satisfiable and this module could find an assignment.

**Parameters**

|             |                                        |
|-------------|----------------------------------------|
| <i>_out</i> | The stream to print the assignment on. |
|-------------|----------------------------------------|

**0.15.340.4.81 printPassedFormula()** void smtrat::Module::printPassedFormula ( const std::string & *\_initiation* = "\*\*\*" ) const [inherited]

Prints the vector of passed formula.

**Parameters**

|                    |                      |
|--------------------|----------------------|
| <i>_initiation</i> | The line initiation. |
|--------------------|----------------------|

**0.15.340.4.82 printReceivedFormula()** void smtrat::Module::printReceivedFormula ( const std::string & *\_initiation* = "\*\*\*" ) const [inherited]

Prints the vector of the received formula.

**Parameters**

|                    |                      |
|--------------------|----------------------|
| <i>_initiation</i> | The line initiation. |
|--------------------|----------------------|

**0.15.340.4.83 probablyLooping()** `bool smtrat::Module::probablyLooping (`

```
const typename Poly::PolyType & _branchingPolynomial,
const Rational & _branchingValue) const [protected], [inherited]
```

Checks whether given the current branching value and branching variable/polynomial it is (highly) probable that this branching is part of an infinite loop of branchings.

**Parameters**

|                                   |                                                                                     |
|-----------------------------------|-------------------------------------------------------------------------------------|
| <code>_branchingPolynomial</code> | The polynomial to branch at (in most branching strategies this is just a variable). |
| <code>_branchingValue</code>      | The value to branch at.                                                             |

**Returns**

true, if this branching is probably part of an infinite loop of branchings; false, otherwise.

**0.15.340.4.84 receivedFormulaChecked()** `void smtrat::Module::receivedFormulaChecked ( ) [inline], [inherited]`

Notifies that the received formulas has been checked.

**0.15.340.4.85 receivedFormulasAsInfeasibleSubset()** `void smtrat::Module::receivedFormulasAsInfeasibleSubset (`

```
ModuleInput::const_iterator _subformula) [inline], [protected], [inherited]
```

Stores an infeasible subset consisting only of the given received formula.

**0.15.340.4.86 receivedVariable()** `bool smtrat::Module::receivedVariable (`

```
carl::Variable::Arg _var) const [inline], [inherited]
```

**0.15.340.4.87 remove()** `void smtrat::Module::remove (`

```
ModuleInput::const_iterator _subformula) [virtual], [inherited]
```

Removes everything related to the given sub-formula of the received formula.

However, it is desired not to lose track of search spaces where no satisfying assignment can be found for the remaining sub-formulas.

**Parameters**

|                          |                                                    |
|--------------------------|----------------------------------------------------|
| <code>_subformula</code> | The sub formula of the received formula to remove. |
|--------------------------|----------------------------------------------------|

Reimplemented in [smtrat::PModule](#).

**0.15.340.4.88 removeCore()** `template<typename Settings >`

```
void smtrat::NRailModule< Settings >::removeCore (
 ModuleInput::const_iterator _subformula) [virtual]
```

Removes the subformula of the received formula at the given position to the considered ones of this module.

Note that this includes every stored calculation which depended on this subformula, but should keep the other stored calculation, if possible, untouched.

**Parameters**

|                          |                                           |
|--------------------------|-------------------------------------------|
| <code>_subformula</code> | The position of the subformula to remove. |
|--------------------------|-------------------------------------------|

Reimplemented from [smtrat::Module](#).

**0.15.340.4.89 `removeOrigin()`** `std::pair<ModuleInput::iterator, bool> smtrat::Module::removeOrigin (`

```
 ModuleInput::iterator _formula,
 const FormulaT & _origin) [inline], [protected], [inherited]
```

**0.15.340.4.90 `removeOrigins()`** `std::pair<ModuleInput::iterator, bool> smtrat::Module::removeOrigins (`

```
 ModuleInput::iterator _formula,
 const std::shared_ptr< std::vector< FormulaT >> & _origins) [inline], [protected],
 [inherited]
```

**0.15.340.4.91 `rPassedFormula()`** `const ModuleInput& smtrat::Module::rPassedFormula ( ) const`

`[inline], [inherited]`

#### Returns

A reference to the formula passed to the backends of this module.

**0.15.340.4.92 `rReceivedFormula()`** `const ModuleInput& smtrat::Module::rReceivedFormula ( ) const`

`[inline], [inherited]`

#### Returns

A reference to the formula passed to this module.

**0.15.340.4.93 `runBackends() [1/2]`** `virtual Answer smtrat::Module::runBackends ( ) [inline],`

`[protected], [virtual], [inherited]`

Reimplemented in [smtrat::PModule](#).

**0.15.340.4.94 `runBackends() [2/2]`** `Answer smtrat::Module::runBackends (`

```
 bool _final,
 bool _full,
 carl::Variable _objective) [protected], [virtual], [inherited]
```

Runs the backend solvers on the passed formula.

#### Parameters

|                         |                                                                                                                                       |
|-------------------------|---------------------------------------------------------------------------------------------------------------------------------------|
| <code>_final</code>     | true, if this satisfiability check will be the last one (for a global sat-check), if its result is SAT                                |
| <code>_full</code>      | false, if this module should avoid too expensive procedures and rather return unknown instead.                                        |
| <code>_objective</code> | if not set to NO_VARIABLE, the module should find an assignment minimizing this objective variable; otherwise any assignment is good. |

#### Returns

True, if the passed formula is consistent; False, if the passed formula is inconsistent; Unknown, otherwise.

Reimplemented in [smtrat::PModule](#).

**0.15.340.4.95 setId()** void smtrat::Module::setId ( std::size\_t \_id ) [inline], [inherited]  
Sets this modules unique ID to identify itself.

Parameters

|                             |                                    |
|-----------------------------|------------------------------------|
| $\leftrightarrow$<br>$\_id$ | The id to set this module's id to. |
|-----------------------------|------------------------------------|

**0.15.340.4.96 setThreadPriority()** void smtrat::Module::setThreadPriority ( thread\_priority \_threadPriority ) [inline], [inherited]  
Sets the priority of this module to get a thread for running its check procedure.

Parameters

|                    |                                                       |
|--------------------|-------------------------------------------------------|
| $\_threadPriority$ | The priority to set this module's thread priority to. |
|--------------------|-------------------------------------------------------|

**0.15.340.4.97 solverState()** Answer smtrat::Module::solverState ( ) const [inline], [inherited]

Returns

True, if this module is in a state, such that it has found a solution for its received formula; False, if this module is in a state, such that it has determined that there is no solution for its received formula; Unknown, otherwise.

**0.15.340.4.98 splitUnequalConstraint()** void smtrat::Module::splitUnequalConstraint ( const FormulaT & \_unequalConstraint ) [protected], [inherited]  
Adds the following lemmas for the given constraint  $p \neq 0$ .

$(p \neq 0 \leftrightarrow (p < 0 \text{ or } p > 0))$

and  $\neg(p < 0 \text{ and } p > 0)$

Parameters

|                       |                                                  |
|-----------------------|--------------------------------------------------|
| $\_unequalConstraint$ | A constraint having the relation symbol $\neq$ . |
|-----------------------|--------------------------------------------------|

**0.15.340.4.99 threadPriority()** thread\_priority smtrat::Module::threadPriority ( ) const [inline], [inherited]

Returns

The priority of this module to get a thread for running its check procedure.

**0.15.340.4.100 updateAllModels()** void smtrat::Module::updateAllModels ( ) [virtual], [inherited]  
Updates all satisfying models, if the solver has detected the consistency of the received formula, beforehand.  
Reimplemented in [smtrat::SATModule< Settings >](#).

**0.15.340.4.101 updateLemmas()** void smtrat::Module::updateLemmas () [inherited]  
Stores all lemmas of any backend of this module in its own lemma vector.

**0.15.340.4.102 updateModel()** template<typename Settings >  
void smtrat::NRAILModule< Settings >::updateModel () const [virtual]

Updates the current assignment into the model.

Note, that this is a unique but possibly symbolic assignment maybe containing newly introduced variables.  
Reimplemented from [smtrat::Module](#).

**0.15.340.4.103 usedBackends()** const std::vector<[Module](#)\*>& smtrat::Module::usedBackends ()  
const [inline], [inherited]

#### Returns

The backends of this module which are currently used (conditions to use this module are fulfilled for the passed formula).

### 0.15.340.5 Field Documentation

**0.15.340.5.1 mAllBackends** std::vector<[Module](#)\*> smtrat::Module::mAllBackends [protected],  
[inherited]

The backends of this module which have been used.

**0.15.340.5.2 mAllModels** std::vector<[Model](#)> smtrat::Module::mAllModels [mutable], [protected],  
[inherited]

Stores all satisfying assignments.

**0.15.340.5.3 mBackendsFoundAnswer** std::atomic\_bool\* smtrat::Module::mBackendsFoundAnswer  
[protected], [inherited]

This flag is passed to any backend and if it determines an answer to a prior check call, this flag is fired.

**0.15.340.5.4 mConstraintsToInform** carl::FastSet<[FormulaT](#)> smtrat::Module::mConstraintsToInform  
[protected], [inherited]

Stores the constraints which the backends must be informed about.

**0.15.340.5.5 mFinalCheck** bool smtrat::Module::mFinalCheck [protected], [inherited]  
true, if the check procedure should perform a final check which especially means not to postpone splitting decisions

**0.15.340.5.6 mFirstPosInLastBranches** std::size\_t smtrat::Module::mFirstPosInLastBranches = 0  
[static], [inherited]

The beginning of the cyclic buffer storing the last branches.

**0.15.340.5.7 mFirstSubformulaToPass** [ModuleInput](#)::iterator smtrat::Module::mFirstSubformulaTo←  
Pass [protected], [inherited]

Stores the position of the first sub-formula in the passed formula, which has not yet been considered for a consistency check of the backends.

**0.15.340.5.8 mFirstUncheckedReceivedSubformula** `ModuleInput::const_iterator smtrat::Module::mFirstUncheckedReceivedSubformula [protected], [inherited]`  
Stores the position of the first (by this module) unchecked sub-formula of the received formula.

**0.15.340.5.9 mFoundAnswer** `Conditionals smtrat::Module::mFoundAnswer [protected], [inherited]`  
Vector of Booleans: If any of them is true, we have to terminate a running check procedure.

**0.15.340.5.10 mFullCheck** `bool smtrat::Module::mFullCheck [protected], [inherited]`  
false, if this module should avoid too expensive procedures and rather return unknown instead.

**0.15.340.5.11 mInfeasibleSubsets** `std::vector<FormulaSetT> smtrat::Module::mInfeasibleSubsets [protected], [inherited]`  
Stores the infeasible subsets.

**0.15.340.5.12 mInformedConstraints** `carl::FastSet<FormulaT> smtrat::Module::mInformedConstraints [protected], [inherited]`  
Stores the position of the first constraint of which no backend has been informed about.

**0.15.340.5.13 mLastBranches** `std::vector<Branching> smtrat::Module::mLastBranches = std::vector<Branching>(mNumOfBranchVarsToStore, Branching(typename Poly::PolyType(), 0)) [static], [inherited]`  
Stores the last branches in a cycle buffer.

**0.15.340.5.14 mLemmas** `std::vector<Lemma> smtrat::Module::mLemmas [protected], [inherited]`  
Stores the lemmas being valid formulas this module or its backends made.

**0.15.340.5.15 mModel** `Model smtrat::Module::mModel [mutable], [protected], [inherited]`  
Stores the assignment of the current satisfiable result, if existent.

**0.15.340.5.16 mModelComputed** `bool smtrat::Module::mModelComputed [mutable], [protected], [inherited]`  
True, if the model has already been computed.

**0.15.340.5.17 mNumOfBranchVarsToStore** `std::size_t smtrat::Module::mNumOfBranchVarsToStore = 5 [static], [inherited]`  
The number of different variables to consider for a probable infinite loop of branchings.

**0.15.340.5.18 mObjectiveVariable** `carl::Variable smtrat::Module::mObjectiveVariable [protected], [inherited]`  
Objective variable to be minimized. If set to NO\_VARIABLE, a normal sat check should be performed.

**0.15.340.5.19 mOldSplittingVariables** `std::vector<FormulaT> smtrat::Module::mOldSplittingVariables [static], [inherited]`  
Reusable splitting variables.

**0.15.340.5.20 mpManager** `Manager* const smtrat::Module::mpManager` [protected], [inherited]  
A reference to the manager.

**0.15.340.5.21 mSmallerMusesCheckCounter** `unsigned smtrat::Module::mSmallerMusesCheckCounter`  
[mutable], [protected], [inherited]  
Counter used for the generation of the smt2 files to check for smaller muses.

**0.15.340.5.22 mSolverState** `std::atomic<Answer> smtrat::Module::mSolverState` [protected],  
[inherited]  
States whether the received formula is known to be satisfiable or unsatisfiable otherwise it is set to unknown.

**0.15.340.5.23 mTheoryPropagations** `std::vector<TheoryPropagation> smtrat::Module::mTheory->`  
Propagations [protected], [inherited]

**0.15.340.5.24 mUsedBackends** `std::vector<Module*> smtrat::Module::mUsedBackends` [protected],  
[inherited]  
The backends of this module which are currently used (conditions to use this module are fulfilled for the passed formula).

**0.15.340.5.25 mVariableCounters** `std::vector<std::size_t> smtrat::Module::mVariableCounters`  
[protected], [inherited]  
Maps variables to the number of their occurrences.

#### 0.15.342.1 Constructor & Destructor Documentation

**0.15.342.1.1 `Numeric()` [1/8]** smtrat::lra::Numeric::Numeric ( )  
Default constructor.

**0.15.342.1.2 `Numeric()` [2/8]** smtrat::lra::Numeric::Numeric (   
  `const Rational & _value` )  
Constructing from a Rational.

**Parameters**

|            |           |
|------------|-----------|
| <i>The</i> | Rational. |
|------------|-----------|

**0.15.342.1.3 Numeric() [3/8]** smtrat::lra::Numeric::Numeric ( int \_value )

Constructing from an integer.

**Parameters**

|               |              |
|---------------|--------------|
| <i>_value</i> | The integer. |
|---------------|--------------|

**0.15.342.1.4 Numeric() [4/8]** smtrat::lra::Numeric::Numeric ( unsigned int \_value )

Constructing from an unsigned integer.

**Parameters**

|               |                      |
|---------------|----------------------|
| <i>_value</i> | The unsigned integer |
|---------------|----------------------|

**0.15.342.1.5 Numeric() [5/8]** smtrat::lra::Numeric::Numeric ( long \_value )

Constructing from a long integer.

**Parameters**

|               |                            |
|---------------|----------------------------|
| <i>_value</i> | The unsigned long integer. |
|---------------|----------------------------|

**0.15.342.1.6 Numeric() [6/8]** smtrat::lra::Numeric::Numeric ( unsigned long \_value )

Constructing from an unsigned long integer.

**Parameters**

|               |                            |
|---------------|----------------------------|
| <i>_value</i> | The unsigned long integer. |
|---------------|----------------------------|

**0.15.342.1.7 Numeric() [7/8]** smtrat::lra::Numeric::Numeric ( const char \* \_value )

Constructing from a char array.

**Parameters**

|               |                 |
|---------------|-----------------|
| <i>_value</i> | The char array. |
|---------------|-----------------|

**0.15.342.1.8 Numeric() [8/8]** smtrat::lra::Numeric::Numeric (

const Numeric &amp; \_value )

Copy constructor.

## Parameters

|        |                      |
|--------|----------------------|
| _value | The Numeric to copy. |
|--------|----------------------|

**0.15.342.1.9 ~Numeric()** smtrat::lra::Numeric::~Numeric ( )**0.15.342.2 Member Function Documentation****0.15.342.2.1 content()** const Rational& smtrat::lra::Numeric::content ( ) const [inline]**0.15.342.2.2 denom()** Numeric smtrat::lra::Numeric::denom ( ) const

## Returns

The denominator of this Numeric.

**0.15.342.2.3 floor()** Numeric smtrat::lra::Numeric::floor ( ) const

## Returns

The next smaller integer to this Numeric.

**0.15.342.2.4 is\_integer()** bool smtrat::lra::Numeric::is\_integer ( ) const

## Returns

true, if this Numeric is integer; false, otherwise.

**0.15.342.2.5 is\_negative()** bool smtrat::lra::Numeric::is\_negative ( ) const

## Returns

true, if this Numeric corresponds to a positive rational number; false, otherwise.

**0.15.342.2.6 is\_positive()** bool smtrat::lra::Numeric::is\_positive ( ) const

Checks whether this Numeric corresponds to a positive rational number.

## Returns

True, if this Numeric corresponds to a positive rational number; False, otherwise.

**0.15.342.2.7 `is_zero()`** `bool smtrat::lra::Numeric::is_zero ( ) const`**Returns**

true, if this [Numeric](#) corresponds to zero; false, otherwise.

**0.15.342.2.8 `numer()`** `Numeric smtrat::lra::Numeric::numer ( ) const`**Returns**

The enumerator of this [Numeric](#).

**0.15.342.2.9 `operator"!="()`** `bool smtrat::lra::Numeric::operator!= ( const Numeric & _value ) const`

Compares whether this [Numeric](#) and the given one are not equal.

**Parameters**

|                     |                                              |
|---------------------|----------------------------------------------|
| <code>_value</code> | The <a href="#">Numeric</a> to compare with. |
|---------------------|----------------------------------------------|

**Returns**

True, if the two Numerics are not equal; False, otherwise.

**0.15.342.2.10 `operator<()`** `bool smtrat::lra::Numeric::operator< ( const Numeric & _value ) const`

Compares whether this [Numeric](#) is less than the given one.

**Parameters**

|                     |                                              |
|---------------------|----------------------------------------------|
| <code>_value</code> | The <a href="#">Numeric</a> to compare with. |
|---------------------|----------------------------------------------|

**Returns**

True, if this [Numeric](#) is less than the given one; False, otherwise.

**0.15.342.2.11 `operator<=()`** `bool smtrat::lra::Numeric::operator<= ( const Numeric & _value ) const`

Compares whether this [Numeric](#) is less or equal than the given one.

**Parameters**

|                     |                                              |
|---------------------|----------------------------------------------|
| <code>_value</code> | The <a href="#">Numeric</a> to compare with. |
|---------------------|----------------------------------------------|

**Returns**

True, if this [Numeric](#) is less or equal than the given one; False, otherwise.

**0.15.342.2.12 `operator=()` [1/6]** `Numeric & smtrat::lra::Numeric::operator= ( const char * _value )`

Cast from a char array.

**Parameters**

|                     |                 |
|---------------------|-----------------|
| <code>_value</code> | The char array. |
|---------------------|-----------------|

**Returns**

The corresponding [Numeric](#).

**0.15.342.2.13 operator=()** [2/6] `Numeric & smtrat::lra::Numeric::operator= ( const Numeric & _value )`

Cast from a char array.

**Parameters**

|                     |                 |
|---------------------|-----------------|
| <code>_value</code> | The char array. |
|---------------------|-----------------|

**Returns**

The corresponding [Numeric](#).

**0.15.342.2.14 operator=()** [3/6] `Numeric & smtrat::lra::Numeric::operator= ( int _value )`

Cast from an integer.

**Parameters**

|                     |              |
|---------------------|--------------|
| <code>_value</code> | The integer. |
|---------------------|--------------|

**Returns**

The corresponding [Numeric](#).

**0.15.342.2.15 operator=()** [4/6] `Numeric & smtrat::lra::Numeric::operator= ( long _value )`

Cast from a long integer.

**Parameters**

|                     |                   |
|---------------------|-------------------|
| <code>_value</code> | The long integer. |
|---------------------|-------------------|

**Returns**

The corresponding [Numeric](#).

**0.15.342.2.16 operator=()** [5/6] `Numeric & smtrat::lra::Numeric::operator= ( unsigned int _value )`

Cast from an unsigned integer.

**Parameters**

|                     |                       |
|---------------------|-----------------------|
| <code>_value</code> | The unsigned integer. |
|---------------------|-----------------------|

**Returns**

The corresponding [Numeric](#).

**0.15.342.2.17 operator=()** [6/6] `Numeric & smtrat::lra::Numeric::operator= (`  
`unsigned long _value )`

Cast from an unsigned long integer.

**Parameters**

|                     |                            |
|---------------------|----------------------------|
| <code>_value</code> | The unsigned long integer. |
|---------------------|----------------------------|

**Returns**

The corresponding [Numeric](#).

**0.15.342.2.18 operator==( )** `bool smtrat::lra::Numeric::operator== (`  
`const Numeric & _value ) const`

Compares whether this [Numeric](#) and the given one are equal.

**Parameters**

|                     |                                              |
|---------------------|----------------------------------------------|
| <code>_value</code> | The <a href="#">Numeric</a> to compare with. |
|---------------------|----------------------------------------------|

**Returns**

True, if the two Numerics are equal; False, otherwise.

**0.15.342.2.19 operator>()** `bool smtrat::lra::Numeric::operator> (`  
`const Numeric & _value ) const`

Compares whether this [Numeric](#) is greater than the given one.

**Parameters**

|                     |                                              |
|---------------------|----------------------------------------------|
| <code>_value</code> | The <a href="#">Numeric</a> to compare with. |
|---------------------|----------------------------------------------|

**Returns**

True, if this [Numeric](#) is greater than the given one; False, otherwise.

**0.15.342.2.20 operator>=( )** `bool smtrat::lra::Numeric::operator>= (`  
`const Numeric & _value ) const`

Compares whether this [Numeric](#) is greater or equal than the given one.

**Parameters**

|                     |                                              |
|---------------------|----------------------------------------------|
| <code>_value</code> | The <a href="#">Numeric</a> to compare with. |
|---------------------|----------------------------------------------|

**Returns**

True, if this [Numeric](#) is greater or equal than the given one; False, otherwise.

**0.15.342.2.21 `rContent()`** `Rational& smtrat::lra::Numeric::rContent ()` [inline]

### 0.15.352.1 Detailed Description

This class represents one or more origins of some object.

An origin is a single id or a pair of ids (where a single id is represented as a pair of the same id).

As an object can have multiple origins, this class stores a list of such pairs. This class makes sure that the pairs are unique.

## 0.15.354 smtrat::OrPathShortener Struct Reference

A rewriter that checks every (X)OR that only contains ANDs and UEQs as children for equalities that hold for every alternative, and adds such equalities explicitly.

```
#include <OrPathShortener.h>
```

### Public Member Functions

- **OrPathShortener** (ModuleWrapper< EQModule< EQSettingsForPreprocessing >> &facts)
- **FormulaT rewrite\_or** (const FormulaT &formula, FormulaSetT &&subformulas)
- **FormulaT rewrite\_xor** (const FormulaT &formula, FormulasMultiT &&subformulas)
- **void enter\_default** (const FormulaT &formula)
- **FormulaT rewrite\_default** (const FormulaT &formula, const FormulaT &default\_result)

### 0.15.354.1 Detailed Description

A rewriter that checks every (X)OR that only contains ANDs and UEQs as children for equalities that hold for every alternative, and adds such equalities explicitly.

This should run after NNF transformation (but clearly before CNF transformation). This defeats eq\_diamond examples (and also more general cases where the paths are longer or irregular).

### 0.15.354.2 Constructor & Destructor Documentation

## 0.15.360 delta::Parser Class Reference

This class parses a whole smtlib file into a hierarchy of [Node](#) objects.

```
#include <Parser.h>
```

### Public Member Functions

- [Parser \(\)](#)  
*Constructs the parsing rules.*
- [bool parseFile \(const std::string &filename, Node &node\)](#)  
*Parses a file into a node.*

### Static Public Member Functions

- [static bool parse \(const std::string &filename, Node &node\)](#)  
*Parses a file into a node.*

#### 0.15.360.1 Detailed Description

This class parses a whole smtlib file into a hierarchy of [Node](#) objects.

#### 0.15.360.2 Constructor & Destructor Documentation

**0.15.360.2.1 Parser()** `delta::Parser::Parser () [inline]`  
Constructs the parsing rules.

#### 0.15.360.3 Member Function Documentation

**0.15.360.3.1 parse()** `static bool delta::Parser::parse (`  
    `const std::string & filename,`  
    `Node & node ) [inline], [static]`  
Parses a file into a node.

##### Parameters

|                       |                             |
|-----------------------|-----------------------------|
| <code>filename</code> | Filename of the input file. |
|-----------------------|-----------------------------|

##### Returns

[Node](#) object produced by the parser.

**0.15.360.3.2 parseFile()** `bool delta::Parser::parseFile (`  
    `const std::string & filename,`  
    `Node & node ) [inline]`

Parses a file into a node.

**Parameters**

|                       |                             |
|-----------------------|-----------------------------|
| <code>filename</code> | Filename of the input file. |
|-----------------------|-----------------------------|

**Returns**

`Node` object produced by the parser.

**0.15.361 smtrat::parser::ParserSettings Struct Reference**

```
#include <ParserSettings.h>
```

- std::pair< `ModuleInput::iterator`, bool > `removeOrigins` (`ModuleInput::iterator` `_formula`, const std::shared\_ptr< std::vector< `FormulaT` >> &`_origins`)
- void `informBackends` (const `FormulaT` &`_constraint`)  
*Informs all backends of this module about the given constraint.*
- virtual void `addConstraintToInform` (const `FormulaT` &`_constraint`)  
*Adds a constraint to the collection of constraints of this module, which are informed to a freshly generated backend.*
- std::pair< `ModuleInput::iterator`, bool > `addReceivedSubformulaToPassedFormula` (`ModuleInput::const_iterator` `_subformula`)  
*Copies the given sub-formula of the received formula to the passed formula.*
- bool `originInReceivedFormula` (const `FormulaT` &`_origin`) const
- std::pair< `ModuleInput::iterator`, bool > `addSubformulaToPassedFormula` (const `FormulaT` &`_formula`)

- Adds the given formula to the passed formula with no origin.*

  - std::pair< [ModuleInput::iterator](#), bool > [addSubformulaToPassedFormula](#) (const [FormulaT](#) &\_formula, const std::shared\_ptr< std::vector< [FormulaT](#) >> &\_origins)

*Adds the given formula to the passed formula.*

  - std::pair< [ModuleInput::iterator](#), bool > [addSubformulaToPassedFormula](#) (const [FormulaT](#) &\_formula, const [FormulaT](#) &\_origin)

*Adds the given formula to the passed formula.*

  - void [generateTrivialInfeasibleSubset](#) ()

*Stores the trivial infeasible subset being the set of received formulas.*

  - void [receivedFormulasAsInfeasibleSubset](#) ([ModuleInput::const\\_iterator](#) \_subformula)

*Stores an infeasible subset consisting only of the given received formula.*

  - std::vector< [FormulaT](#) >::const\_iterator [findBestOrigin](#) (const std::vector< [FormulaT](#) > &\_origins) const
  - void [getInfeasibleSubsets](#) ()

*Copies the infeasible subsets of the passed formula.*

  - std::vector< [FormulaSetT](#) > [getInfeasibleSubsets](#) (const [Module](#) &\_backend) const

*Get the infeasible subsets the given backend provides.*

  - const [Model & backendsModel](#) () const

*Stores the model of a backend which determined satisfiability of the passed formula in the model of this module.*

  - void [getBackendsModel](#) () const
  - void [getBackendsAllModels](#) () const

*Stores all models of a backend in the list of all models of this module.*

  - virtual [Answer runBackends](#) (bool \_final, bool \_full, carl::Variable \_objective)

*Runs the backend solvers on the passed formula.*

  - virtual [Answer runBackends](#) ()
  - virtual [ModuleInput::iterator eraseSubformulaFromPassedFormula](#) ([ModuleInput::iterator](#) \_subformula, bool \_ignoreOrigins=false)

*Removes everything related to the sub-formula to remove from the passed formula in the backends of this module.*

  - void [clearPassedFormula](#) ()
  - std::vector< [FormulaT](#) > [merge](#) (const std::vector< [FormulaT](#) > &, const std::vector< [FormulaT](#) > &) const

*Merges the two vectors of sets into the first one.*

  - size\_t [determine\\_smallest\\_origin](#) (const std::vector< [FormulaT](#) > &origins) const
  - bool [probablyLooping](#) (const typename Poly::PolyType &\_branchingPolynomial, const [Rational](#) &← branchingValue) const

*Checks whether given the current branching value and branching variable/polynomial it is (highly) probable that this branching is part of an infinite loop of branchings.*

  - bool [branchAt](#) (const [Poly](#) &\_polynomial, bool \_integral, const [Rational](#) &\_value, std::vector< [FormulaT](#) > &&\_premise, bool \_leftCaseWeak=true, bool \_preferLeftCase=true, bool \_useReceivedFormulaAsPremise=false)

*Adds a lemmas which provoke a branching for the given variable at the given value, if this module returns Unknown and there exists a preceding SATModule.*

  - bool [branchAt](#) (const [Poly](#) &\_polynomial, bool \_integral, const [Rational](#) &\_value, bool \_leftCaseWeak=true, bool \_preferLeftCase=true, bool \_useReceivedFormulaAsPremise=false, const std::vector< [FormulaT](#) > &← \_premise=std::vector< [FormulaT](#) >())
  - bool [branchAt](#) (carl::Variable::Arg \_var, const [Rational](#) &\_value, std::vector< [FormulaT](#) > &&\_premise, bool \_leftCaseWeak=true, bool \_preferLeftCase=true, bool \_useReceivedFormulaAsPremise=false)
  - bool [branchAt](#) (carl::Variable::Arg \_var, const [Rational](#) &\_value, bool \_leftCaseWeak=true, bool \_preferLeftCase=true, bool \_useReceivedFormulaAsPremise=false, const std::vector< [FormulaT](#) > &\_premise=std::vector< [FormulaT](#) >())
  - void [splitUnequalConstraint](#) (const [FormulaT](#) &)

*Adds the following lemmas for the given constraint  $p \neq 0$ .*

  - unsigned [checkModel](#) () const
  - void [addInformationRelevantFormula](#) (const [FormulaT](#) &formula)

*Adds a formula to the InformationRelevantFormula.*

- const std::set< [FormulaT](#) > & [getInformationRelevantFormulas](#) ()
 

*Gets all InformationRelevantFormulas.*
- bool [isLemmaLevel](#) ([LemmaLevel](#) level)
 

*Checks if current lemma level is greater or equal to given level.*

### Static Protected Member Functions

- static bool [modelsDisjoint](#) (const [Model](#) &\_modelA, const [Model](#) &\_modelB)
 

*Checks whether there is no variable assigned by both models.*

### Protected Attributes

- std::vector< [FormulaSetT](#) > [mInfeasibleSubsets](#)

*Stores the infeasible subsets.*
- [Manager](#) \*const [mpManager](#)

*A reference to the manager.*
- [Model](#) [mModel](#)

*Stores the assignment of the current satisfiable result, if existent.*
- std::vector< [Model](#) > [mAllModels](#)

*Stores all satisfying assignments.*
- bool [mModelComputed](#)

*True, if the model has already been computed.*
- bool [mFinalCheck](#)

*true, if the check procedure should perform a final check which especially means not to postpone splitting decisions*
- bool [mFullCheck](#)

*false, if this module should avoid too expensive procedures and rather return unknown instead.*
- carl::Variable [mObjectiveVariable](#)

*Objective variable to be minimized. If set to NO\_VARIABLE, a normal sat check should be performed.*
- std::vector< [TheoryPropagation](#) > [mTheoryPropagations](#)
- std::atomic< [Answer](#) > [mSolverState](#)

*States whether the received formula is known to be satisfiable or unsatisfiable otherwise it is set to unknown.*
- std::atomic\_bool \* [mBackendsFoundAnswer](#)

*This flag is passed to any backend and if it determines an answer to a prior check call, this flag is fired.*
- [Conditionals](#) [mFoundAnswer](#)

*Vector of Booleans: If any of them is true, we have to terminate a running check procedure.*
- std::vector< [Module](#) \* > [mUsedBackends](#)

*The backends of this module which are currently used (conditions to use this module are fulfilled for the passed formula).*
- std::vector< [Module](#) \* > [mAllBackends](#)

*The backends of this module which have been used.*
- std::vector< [Lemma](#) > [mLemmas](#)

*Stores the lemmas being valid formulas this module or its backends made.*
- [ModuleInput](#)::iterator [mFirstSubformulaToPass](#)

*Stores the position of the first sub-formula in the passed formula, which has not yet been considered for a consistency check of the backends.*
- carl::FastSet< [FormulaT](#) > [mConstraintsToInform](#)

*Stores the constraints which the backends must be informed about.*
- carl::FastSet< [FormulaT](#) > [mInformedConstraints](#)

*Stores the position of the first constraint of which no backend has been informed about.*
- [ModuleInput](#)::const\_iterator [mFirstUncheckedReceivedSubformula](#)

*Stores the position of the first (by this module) unchecked sub-formula of the received formula.*
- unsigned [mSmallerMusesCheckCounter](#)

*Counter used for the generation of the smt2 files to check for smaller muses.*
- std::vector< std::size\_t > [mVariableCounters](#)

*Maps variables to the number of their occurrences.*

 using smtrat::PBGaussModule< Settings >::VectorT = Eigen::Matrix< Rational, Eigen::Dynamic, 1>

### 0.15.363.2 Member Enumeration Documentation

**0.15.363.2.1 LemmaType** enum smtrat::Module::LemmaType : unsigned [strong], [inherited]

Enumerator

|           |  |
|-----------|--|
| NORMAL    |  |
| PERMANENT |  |

### 0.15.363.3 Constructor & Destructor Documentation

**0.15.363.3.1 PBGaussModule()** template<typename Settings >  
 smtrat::PBGaussModule< Settings >::PBGaussModule ( const ModuleInput \* \_formula, Conditionals & \_conditionals, Manager \* \_manager = nullptr )

**0.15.363.3.2 ~PBGaussModule()** template<typename Settings >  
 smtrat::PBGaussModule< Settings >::~PBGaussModule ( )

### 0.15.363.4 Member Function Documentation

**0.15.363.4.1 add()** bool smtrat::Module::add ( ModuleInput::const\_iterator \_subformula ) [inherited]

The module has to take the given sub-formula of the received formula into account.

Parameters

|             |                                                    |
|-------------|----------------------------------------------------|
| _subformula | The sub-formula to take additionally into account. |
|-------------|----------------------------------------------------|

**Returns**

false, if it can be easily decided that this sub-formula causes a conflict with the already considered sub-formulas; true, otherwise.

**0.15.363.4.2 addConstraintToInform()** `void smtrat::Module::addConstraintToInform (`

```
const FormulaT & _constraint) [protected], [virtual], [inherited]
```

Adds a constraint to the collection of constraints of this module, which are informed to a freshly generated backend.

**Parameters**

|                          |                        |
|--------------------------|------------------------|
| <code>_constraint</code> | The constraint to add. |
|--------------------------|------------------------|

Reimplemented in [smtrat::SATModule< Settings >](#).

**0.15.363.4.3 addCore()** `template<typename Settings >`

```
bool smtrat::PBGaussModule< Settings >::addCore (
 ModuleInput::const_iterator _subformula) [virtual]
```

The module has to take the given sub-formula of the received formula into account.

**Parameters**

|                          |                                                    |
|--------------------------|----------------------------------------------------|
| <code>_subformula</code> | The sub-formula to take additionally into account. |
|--------------------------|----------------------------------------------------|

**Returns**

false, if it can be easily decided that this sub-formula causes a conflict with the already considered sub-formulas; true, otherwise.

Reimplemented from [smtrat::Module](#).

**0.15.363.4.4 addInformationRelevantFormula()** `void smtrat::Module::addInformationRelevantFormula`

```
(
```

```
const FormulaT & formula) [protected], [inherited]
```

Adds a formula to the InformationRelevantFormula.

**Parameters**

|                      |                |
|----------------------|----------------|
| <code>formula</code> | Formula to add |
|----------------------|----------------|

**0.15.363.4.5 addLemma()** `void smtrat::Module::addLemma (`

```
const FormulaT & _lemma,
```

```
const LemmaType & _lt = LemmaType::NORMAL,
```

```
const FormulaT & _preferredFormula = FormulaT(carl::FormulaType::TRUE)) [inline],
```

```
[inherited]
```

Stores a lemma being a valid formula.

**Parameters**

|                                |                                                                       |
|--------------------------------|-----------------------------------------------------------------------|
| <code>_lemma</code>            | The eduction/lemma to store.                                          |
| <code>_lt</code>               | The type of the lemma.                                                |
| <code>_preferredFormula</code> | Hint for the next decision, which formula should be assigned to true. |

**0.15.363.4.6 addOrigin()** `void smtrat::Module::addOrigin (`

```
 ModuleInput::iterator _formula,
 const FormulaT & _origin) [inline], [protected], [inherited]
```

Adds the given set of formulas in the received formula to the origins of the given passed formula.

**Parameters**

|                       |                                                           |
|-----------------------|-----------------------------------------------------------|
| <code>_formula</code> | The passed formula to set the origins for.                |
| <code>_origin</code>  | A set of formulas in the received formula of this module. |

**0.15.363.4.7 addReceivedSubformulaToPassedFormula()** `std::pair<ModuleInput::iterator, bool>`

```
smtrat::Module::addReceivedSubformulaToPassedFormula (
```

```
 ModuleInput::const_iterator _subformula) [inline], [protected], [inherited]
```

Copies the given sub-formula of the received formula to the passed formula.

Note, that there is always a link between sub-formulas of the passed formulas to sub-formulas of the received formulas, which are responsible for its occurrence.

**Parameters**

|                          |                                                  |
|--------------------------|--------------------------------------------------|
| <code>_subformula</code> | The sub-formula of the received formula to copy. |
|--------------------------|--------------------------------------------------|

**0.15.363.4.8 addSubformulaToPassedFormula() [1/3]** `std::pair<ModuleInput::iterator, bool>`

```
smtrat::Module::addSubformulaToPassedFormula (
```

```
 const FormulaT & _formula) [inline], [protected], [inherited]
```

Adds the given formula to the passed formula with no origin.

Note that in the next call of this module's removeSubformula, all formulas in the passed formula without origins will be removed.

**Parameters**

|                       |                                           |
|-----------------------|-------------------------------------------|
| <code>_formula</code> | The formula to add to the passed formula. |
|-----------------------|-------------------------------------------|

**Returns**

A pair to the position where the formula to add has been inserted (or its first sub-formula which has not yet been in the passed formula, in case the formula to add is a conjunction), and a Boolean stating whether anything has been added to the passed formula.

**0.15.363.4.9 addSubformulaToPassedFormula() [2/3]** `std::pair<ModuleInput::iterator, bool>`

```
smtrat::Module::addSubformulaToPassedFormula (
```

```
 const FormulaT & _formula,
```

```
 const FormulaT & _origin) [inline], [protected], [inherited]
```

Adds the given formula to the passed formula.

**Parameters**

|                       |                                                                                                                           |
|-----------------------|---------------------------------------------------------------------------------------------------------------------------|
| <code>_formula</code> | The formula to add to the passed formula.                                                                                 |
| <code>_origin</code>  | The sub-formula of the received formula being responsible for the occurrence of the formula to add to the passed formula. |

**Returns**

A pair to the position where the formula to add has been inserted (or its first sub-formula which has not yet been in the passed formula, in case the formula to add is a conjunction), and a Boolean stating whether anything has been added to the passed formula.

**0.15.363.4.10 addSubformulaToPassedFormula() [3/3] std::pair<ModuleInput::iterator,bool>**

```
smtrat::Module::addSubformulaToPassedFormula (
 const FormulaT & _formula,
 const std::shared_ptr< std::vector< FormulaT >> & _origins) [inline], [protected],
[inherited]
```

Adds the given formula to the passed formula.

**Parameters**

|                       |                                                                                                                                         |
|-----------------------|-----------------------------------------------------------------------------------------------------------------------------------------|
| <code>_formula</code> | The formula to add to the passed formula.                                                                                               |
| <code>_origins</code> | The link of the formula to add to the passed formula to sub-formulas of the received formulas, which are responsible for its occurrence |

**Returns**

A pair to the position where the formula to add has been inserted (or its first sub-formula which has not yet been in the passed formula, in case the formula to add is a conjunction), and a Boolean stating whether anything has been added to the passed formula.

**0.15.363.4.11 allModels() const std::vector<Model>& smtrat::Module::allModels () const [inline], [inherited]****Returns**

All satisfying assignments, if existent.

**0.15.363.4.12 anAnswerFound() bool smtrat::Module::anAnswerFound () const [inline], [protected], [inherited]**

Checks for all antecedent modules and those which run in parallel with the same antecedent modules, whether one of them has determined a result.

**Returns**

True, if one of them has determined a result.

**0.15.363.4.13 answerFound() const smtrat::Conditionals& smtrat::Module::answerFound () const [inline], [inherited]****Returns**

A vector of Booleans: If any of them is true, we have to terminate a running check procedure.

**0.15.363.4.14 backendsModel() const Model & smtrat::Module::backendsModel () const [protected], [inherited]**

Stores the model of a backend which determined satisfiability of the passed formula in the model of this module.

---

**0.15.363.4.15** **branchAt()** [1/4] `bool smrat::Module::branchAt (`

```
carl::Variable::Arg _var,
const Rational & _value,
bool _leftCaseWeak = true,
bool _preferLeftCase = true,
bool _useReceivedFormulaAsPremise = false,
const std::vector< FormulaT > & _premise = std::vector<FormulaT>()) [inline],
[protected], [inherited]
```

**0.15.363.4.16** **branchAt()** [2/4] `bool smrat::Module::branchAt (`

```
carl::Variable::Arg _var,
const Rational & _value,
std::vector< FormulaT > && _premise,
bool _leftCaseWeak = true,
bool _preferLeftCase = true,
bool _useReceivedFormulaAsPremise = false) [inline], [protected], [inherited]
```

**0.15.363.4.17** **branchAt()** [3/4] `bool smrat::Module::branchAt (`

```
const Poly & _polynomial,
bool _integral,
const Rational & _value,
bool _leftCaseWeak = true,
bool _preferLeftCase = true,
bool _useReceivedFormulaAsPremise = false,
const std::vector< FormulaT > & _premise = std::vector<FormulaT>()) [inline],
[protected], [inherited]
```

**0.15.363.4.18** **branchAt()** [4/4] `bool smrat::Module::branchAt (`

```
const Poly & _polynomial,
bool _integral,
const Rational & _value,
std::vector< FormulaT > && _premise,
bool _leftCaseWeak = true,
bool _preferLeftCase = true,
bool _useReceivedFormulaAsPremise = false) [protected], [inherited]
```

Adds a lemmas which provoke a branching for the given variable at the given value, if this module returns Unknown and there exists a preceding [SATModule](#).

Note that the given value is rounded down and up, if the given variable is integer-valued.

#### Parameters

|                                           |                                                                                                                                                                                                                |
|-------------------------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>_polynomial</code>                  | The variable to branch for.                                                                                                                                                                                    |
| <code>_integral</code>                    | A flag being true, if all variables in the polynomial to branch for are integral.                                                                                                                              |
| <code>_value</code>                       | The value to branch at.                                                                                                                                                                                        |
| <code>_premise</code>                     | The sub-formulas of the received formula from which the branch is followed. Note, that a premise is not necessary, as every branch is a valid formula. But a premise can prevent from branching unnecessarily. |
| <code>_leftCaseWeak</code>                | true, if a branching in the form of (or ( $\leq p b$ ) ( $> p b$ )) is desired. false, if a branching in the form of (or ( $< p b$ ) ( $\geq p b$ )) is desired.                                               |
| <code>_preferLeftCase</code>              | true, if the left case (polynomial less(or equal) 0 shall be chosen first. false, otherwise.                                                                                                                   |
| <code>_useReceivedFormulaAsPremise</code> | true, if the whole received formula should be used as premise                                                                                                                                                  |

```
0.15.363.4.19 check() Answer smrat::Module::check (
 bool _final = false,
 bool _full = true,
 carl::Variable _objective = carl::Variable::NO_VARIABLE) [virtual], [inherited]
```

Checks the received formula for consistency.

Note, that this is an implementation of the satisfiability check of the conjunction of the so far received formulas, which does actually nothing but passing the problem to its backends. This implementation is only used internally and must be overwritten by any derived module.

#### Parameters

|                   |                                                                                                                                       |
|-------------------|---------------------------------------------------------------------------------------------------------------------------------------|
| <i>_final</i>     | true, if this satisfiability check will be the last one (for a global sat-check), if its result is SAT                                |
| <i>_full</i>      | false, if this module should avoid too expensive procedures and rather return unknown instead.                                        |
| <i>_objective</i> | if not set to NO_VARIABLE, the module should find an assignment minimizing this objective variable; otherwise any assignment is good. |

#### Returns

True, if the received formula is satisfiable; False, if the received formula is not satisfiable; Unknown, otherwise.

Reimplemented in [smrat::PModule](#).

```
0.15.363.4.20 checkCore() template<typename Settings >
Answer smrat::PBGaussModule< Settings >::checkCore () [virtual]
```

Checks the received formula for consistency.

#### Returns

True, if the received formula is satisfiable; False, if the received formula is not satisfiable; Unknown, otherwise.

Reimplemented from [smrat::Module](#).

```
0.15.363.4.21 checkInfSubsetForMinimality() void smrat::Module::checkInfSubsetForMinimality (
 std::vector< FormulaSetT >::const_iterator _infssubset,
 const std::string & _filename = "smaller_muses",
 unsigned _maxSizeDifference = 1) const [inherited]
```

Checks the given infeasible subset for minimality by storing all subsets of it, which have a smaller size which differs from the size of the infeasible subset not more than the given threshold.

#### Parameters

|                           |                                                                                                        |
|---------------------------|--------------------------------------------------------------------------------------------------------|
| <i>_infssubset</i>        | The infeasible subset to check for minimality.                                                         |
| <i>_filename</i>          | The name of the file to store the infeasible subsets in order to be able to check their infeasibility. |
| <i>_maxSizeDifference</i> | The maximal difference between the sizes of the subsets compared to the size of the infeasible subset. |

```
0.15.363.4.22 checkModel() unsigned smrat::Module::checkModel () const [protected], [inherited]
```

**Returns**

false, if the current model of this module does not satisfy the current given formula; true, if it cannot be said whether the model satisfies the given formula.

**0.15.363.4.23 cleanModel()** void smtrat::Module::cleanModel ( ) const [inline], [protected], [inherited]

Substitutes variable occurrences by its model value in the model values of other variables.

**0.15.363.4.24 clearLemmas()** void smtrat::Module::clearLemmas ( ) [inline], [inherited]

Deletes all yet found lemmas.

**0.15.363.4.25 clearModel()** void smtrat::Module::clearModel ( ) const [inline], [protected], [inherited]

Clears the assignment, if any was found.

**0.15.363.4.26 clearModels()** void smtrat::Module::clearModels ( ) const [inline], [protected], [inherited]

Clears all assignments, if any was found.

**0.15.363.4.27 clearPassedFormula()** void smtrat::Module::clearPassedFormula ( ) [protected], [inherited]

**0.15.363.4.28 collectOrigins() [1/2]** void smtrat::Module::collectOrigins ( const **FormulaT** & \_formula, **FormulaSetT** & \_origins ) const [inherited]

**0.15.363.4.29 collectOrigins() [2/2]** void smtrat::Module::collectOrigins ( const **FormulaT** & \_formula, **FormulasT** & \_origins ) const [inherited]

Collects the formulas in the given formula, which are part of the received formula.

If the given formula directly occurs in the received formula, it is inserted into the given set. Otherwise, the given formula must be of type AND and all its sub-formulas part of the received formula. Hence, they will be added to the given set.

**Parameters**

|                 |                                                                                                      |
|-----------------|------------------------------------------------------------------------------------------------------|
| <b>_formula</b> | The formula from which to collect the formulas being sub-formulas of the received formula (origins). |
| <b>_origins</b> | The set in which to store the origins.                                                               |

**0.15.363.4.30 collectTheoryPropagations()** void smtrat::Module::collectTheoryPropagations ( ) [inherited]

**0.15.363.4.31 conservativeResize() [1/2]** template<typename Settings >  
static void smtrat::PBGaussModule< Settings >::conservativeResize (

```
MatrixT & m,
long newRows,
long newCols) [inline], [static]
```

Convenience wrapper for Eigen::conservativeResizeLike with a zero matrix.

**0.15.363.4.32 conservativeResize() [2/2]** template<typename Settings>
static void smtrat::PBGaussModule<Settings>::conservativeResize(
 VectorT & v,
 long newSize) [inline], [static]

Convenience wrapper for Eigen::conservativeResizeLike with a zero vector.

**0.15.363.4.33 constraintsToInform()** const carl::FastSet<FormulaT>& smtrat::Module::constraints←
ToInform () const [inline], [inherited]

#### Returns

The constraints which the backends must be informed about.

**0.15.363.4.34 currentlySatisfied()** virtual unsigned smtrat::Module::currentlySatisfied (
 const FormulaT & ) const [inline], [virtual], [inherited]

#### Returns

0, if the given formula is conflicted by the current model; 1, if the given formula is satisfied by the current model; 2, otherwise; 3, if we do not know anything (default)

Reimplemented in [smtrat::LRAbstractModule<Settings>](#), [smtrat::LRAbstractModule<LRASettingsICP>](#), and [smtrat::LRAbstractModule<LRASettings>](#).

**0.15.363.4.35 currentlySatisfiedByBackend()** unsigned smtrat::Module::currentlySatisfiedByBackend (
 const FormulaT & \_formula) const [inherited]

#### Returns

0, if the given formula is conflicted by the current model; 1, if the given formula is satisfied by the current model; 2, otherwise 3, if we do not know anything (default)

**0.15.363.4.36 deinform()** void smtrat::Module::deinform (
 const FormulaT & \_constraint) [inherited]

The inverse of informing about a constraint.

All data structures which were kept regarding this constraint are going to be removed. Note, that this makes only sense if it is not likely enough that a formula with this constraint must be solved again.

#### Parameters

|                          |                                                         |
|--------------------------|---------------------------------------------------------|
| <code>_constraint</code> | The constraint to remove from internal data structures. |
|--------------------------|---------------------------------------------------------|

**0.15.363.4.37 deinformCore()** virtual void smtrat::Module::deinformCore (
 const FormulaT & \_constraint) [inline], [protected], [virtual], [inherited]

The inverse of informing about a constraint.

All data structures which were kept regarding this constraint are going to be removed. Note, that this makes only

sense if it is not likely enough that a formula with this constraint must be solved again.

#### Parameters

|                          |                                                         |
|--------------------------|---------------------------------------------------------|
| <code>_constraint</code> | The constraint to remove from internal data structures. |
|--------------------------|---------------------------------------------------------|

Reimplemented in [smtrat::LRAModule< Settings >](#), [smtrat::LRAModule< LRASettingsICP >](#), and [smtrat::LRAModule< LRASettings4 >](#).

**0.15.363.4.38 `determine_smallest_origin()`** `size_t smtrat::Module::determine_smallest_origin ( const std::vector< FormulaT > & origins ) const` [protected], [inherited]

#### Parameters

|                      |                              |
|----------------------|------------------------------|
| <code>origins</code> | A vector of sets of origins. |
|----------------------|------------------------------|

#### Returns

The index of the smallest (regarding the size of the sets) element of `origins`

**0.15.363.4.39 `eraseSubformulaFromPassedFormula()`** `ModuleInput::iterator smtrat::Module::eraseSubformulaFromPassedFormula ( ModuleInput::iterator _subformula, bool _ignoreOrigins = false )` [protected], [virtual], [inherited]

Removes everything related to the sub-formula to remove from the passed formula in the backends of this module. Afterwards the sub-formula is removed from the passed formula.

#### Parameters

|                             |                                                                                                              |
|-----------------------------|--------------------------------------------------------------------------------------------------------------|
| <code>_subformula</code>    | The sub-formula to remove from the passed formula.                                                           |
| <code>_ignoreOrigins</code> | True, if the sub-formula shall be removed regardless of its origins (should only be applied with expertise). |

#### Returns

Reimplemented in [smtrat::ICPModule< Settings >](#), [smtrat::ICPModule< ICPSettings4 >](#), and [smtrat::ICPModule< ICPSettings1 >](#).

**0.15.363.4.40 `excludeNotReceivedVariablesFromModel()`** `void smtrat::Module::excludeNotReceivedVariablesFromModel ( ) const` [inherited]

Excludes all variables from the current model, which do not occur in the received formula.

**0.15.363.4.41 `findBestOrigin()`** `std::vector< FormulaT >::const_iterator smtrat::Module::findBestOrigin ( const std::vector< FormulaT > & _origins ) const` [protected], [inherited]

#### Parameters

|                       |  |
|-----------------------|--|
| <code>_origins</code> |  |
|-----------------------|--|

Returns

**0.15.363.4.42 firstSubformulaToPass()** `ModuleInput::const_iterator smtrat::Module::firstSubformulaToPass () const [inline], [inherited]`

Returns

The position of the first sub-formula in the passed formula, which has not yet been considered for a consistency check of the backends.

**0.15.363.4.43 firstUncheckedReceivedSubformula()** `ModuleInput::const_iterator smtrat::Module::firstUncheckedReceivedSubformula () const [inline], [inherited]`

Returns

The position of the first (by this module) unchecked sub-formula of the received formula.

**0.15.363.4.44 freeSplittingVariable()** `static void smtrat::Module::freeSplittingVariable (const FormulaT & _splittingVariable ) [inline], [static], [inherited]`

**0.15.363.4.45 gaussAlgorithm()** `template<typename Settings > FormulaT smtrat::PBGaussModule< Settings >::gaussAlgorithm ()`

**0.15.363.4.46 generateTrivialInfeasibleSubset()** `void smtrat::Module::generateTrivialInfeasibleSubset () [inline], [protected], [inherited]`

Stores the trivial infeasible subset being the set of received formulas.

**0.15.363.4.47 getBackendsAllModels()** `void smtrat::Module::getBackendsAllModels () const [protected], [inherited]`

Stores all models of a backend in the list of all models of this module.

**0.15.363.4.48 getBackendsModel()** `void smtrat::Module::getBackendsModel () const [protected], [inherited]`

**0.15.363.4.49 getInfeasibleSubsets() [1/2]** `void smtrat::Module::getInfeasibleSubsets () [protected], [inherited]`

Copies the infeasible subsets of the passed formula.

**0.15.363.4.50 getInfeasibleSubsets() [2/2]** `std::vector< FormulaSetT > smtrat::Module::getInfeasibleSubsets (const Module & _backend ) const [protected], [inherited]`

Get the infeasible subsets the given backend provides.

Note, that an infeasible subset in a backend contains sub formulas of the passed formula and an infeasible subset of this module contains sub formulas of the received formula. In this method the LATTER is returned.

**Parameters**

|                       |                                                          |
|-----------------------|----------------------------------------------------------|
| <code>_backend</code> | The backend from which to obtain the infeasible subsets. |
|-----------------------|----------------------------------------------------------|

**Returns**

The infeasible subsets the given backend provides.

**0.15.363.4.51 `getInformationRelevantFormulas()`** `const std::set< FormulaT > & smtrat::Module::getInformationRelevantFormulas ( ) [protected], [inherited]`  
Gets all InformationRelevantFormulas.

**Returns**

Set of all formulas

**0.15.363.4.52 `getModelEqualities()`** `std::list< std::vector< carl::Variable > > smtrat::Module::getModelEqualities ( ) const [virtual], [inherited]`  
Partition the variables from the current model into equivalence classes according to their assigned value.  
The result is a set of equivalence classes of variables where all variables within one class are assigned the same value. Note that the number of classes may not be minimal, i.e. two classes may actually be equivalent.

**Returns**

Equivalence classes.

**0.15.363.4.53 `getOrigins()` [1/3]** `void smtrat::Module::getOrigins ( const FormulaT & _formula, FormulaSetT & _origins ) const [inline], [protected], [inherited]`

**Parameters**

|                       |  |
|-----------------------|--|
| <code>_formula</code> |  |
| <code>_origins</code> |  |

**0.15.363.4.54 `getOrigins()` [2/3]** `void smtrat::Module::getOrigins ( const FormulaT & _formula, FormulasT & _origins ) const [inline], [protected], [inherited]`

**Parameters**

|                       |  |
|-----------------------|--|
| <code>_formula</code> |  |
| <code>_origins</code> |  |

**0.15.363.4.55 `getOrigins()` [3/3]** `const FormulaT& smtrat::Module::getOrigins ( ModuleInput::const_iterator _formula ) const [inline], [protected], [inherited]`  
Gets the origins of the passed formula at the given position.

**Parameters**

|                       |                                                   |
|-----------------------|---------------------------------------------------|
| <code>_formula</code> | The position of a formula in the passed formulas. |
|-----------------------|---------------------------------------------------|

**Returns**

The origins of the passed formula at the given position.

**0.15.363.4.56 `getReceivedFormulaSimplified()`** `std::pair< bool, FormulaT >` `smtrat::Module::getReceivedFormulaSimplified( )` [virtual], [inherited]

**Returns**

A pair of a Boolean and a formula, where the Boolean is true, if the received formula could be simplified to an equisatisfiable formula. The formula is equisatisfiable to this module's received formula, if the Boolean is true.

Reimplemented in [smtrat::PModule](#).

**0.15.363.4.57 `hasLemmas()`** `bool smtrat::Module::hasLemmas( )` [inline], [inherited]

Checks whether this module or any of its backends provides any lemmas.

**0.15.363.4.58 `hasValidInfeasibleSubset()`** `bool smtrat::Module::hasValidInfeasibleSubset( ) const` [inherited]

**Returns**

true, if the module has at least one valid infeasible subset, that is all its elements are sub-formulas of the received formula (pointer must be equal).

**0.15.363.4.59 `id()`** `std::size_t smtrat::Module::id( ) const` [inline], [inherited]

**Returns**

A unique ID to identify this module instance.

**0.15.363.4.60 `infeasibleSubsets()`** `const std::vector<FormulaSetT>& smtrat::Module::infeasibleSubsets( ) const` [inline], [inherited]

**Returns**

The infeasible subsets of the set of received formulas (empty, if this module has not detected unsatisfiability of the conjunction of received formulas).

**0.15.363.4.61 `inform()`** `bool smtrat::Module::inform( const FormulaT & _constraint )` [inherited]

Informs the module about the given constraint.

It should be tried to inform this module about any constraint it could receive eventually before assertSubformula is called (preferably for the first time, but at least before adding a formula containing that constraint).

**Parameters**

|                          |                                 |
|--------------------------|---------------------------------|
| <code>_constraint</code> | The constraint to inform about. |
|--------------------------|---------------------------------|

**Returns**

false, if it can be easily decided whether the given constraint is inconsistent; true, otherwise.

**0.15.363.4.62 informBackends()** `void smrat::Module::informBackends (`

```
 const FormulaT & _constraint) [inline], [protected], [inherited]
```

Informs all backends of this module about the given constraint.

**Parameters**

|                          |                                 |
|--------------------------|---------------------------------|
| <code>_constraint</code> | The constraint to inform about. |
|--------------------------|---------------------------------|

**0.15.363.4.63 informCore()** `template<typename Settings >`

```
bool smrat::PBGaussModule< Settings >::informCore (
```

```
 const FormulaT & _constraint) [virtual]
```

Informs the module about the given constraint.

It should be tried to inform this module about any constraint it could receive eventually before assertSubformula is called (preferably for the first time, but at least before adding a formula containing that constraint).

**Parameters**

|                          |                                 |
|--------------------------|---------------------------------|
| <code>_constraint</code> | The constraint to inform about. |
|--------------------------|---------------------------------|

**Returns**

false, if it can be easily decided whether the given constraint is inconsistent; true, otherwise.

Reimplemented from [smrat::Module](#).

**0.15.363.4.64 informedConstraints()** `const carl::FastSet<FormulaT>& smrat::Module::informed→`

```
Constraints () const [inline], [inherited]
```

**Returns**

The position of the first constraint of which no backend has been informed about.

**0.15.363.4.65 init()** `template<typename Settings >`

```
void smrat::PBGaussModule< Settings >::init () [virtual]
```

Informs all backends about the so far encountered constraints, which have not yet been communicated.

This method must not and will not be called more than once and only before the first runBackends call.

Reimplemented from [smrat::Module](#).

**0.15.363.4.66 is\_minimizing()** `bool smrat::Module::is_minimizing ( ) const [inline], [inherited]`**0.15.363.4.67 isLemmaLevel()** `bool smrat::Module::isLemmaLevel (`

```
 LemmaLevel level) [protected], [inherited]
```

Checks if current lemma level is greater or equal to given level.

## Parameters

|              |                 |
|--------------|-----------------|
| <i>level</i> | Level to check. |
|--------------|-----------------|

**0.15.363.4.68 isPreprocessor()** `bool smtrat::Module::isPreprocessor () const [inline], [inherited]`

## Returns

true, if this module is a preprocessor that is a module, which simplifies its received formula to an equisatisfiable formula being passed to its backends. The simplified formula can be obtained with [getReceivedFormulaSimplified\(\)](#).

**0.15.363.4.69 lemmas()** `const std::vector<Lemma>& smtrat::Module::lemmas () const [inline], [inherited]`

## Returns

A constant reference to the lemmas being valid formulas this module or its backends made.

**0.15.363.4.70 lookForReductionRow()** `template<typename Settings >  
std::vector<Rational> smtrat::PBGaussModule< Settings >::lookForReductionRow (  
 const MatrixT & uMatrix,  
 const VectorT & ineqRow,  
 long column )`**0.15.363.4.71 merge()** `std::vector< FormulaT > smtrat::Module::merge (`  
 `const std::vector< FormulaT > & _vecSetA,`  
 `const std::vector< FormulaT > & _vecSetB ) const [protected], [inherited]`

Merges the two vectors of sets into the first one.

({a,b},{a,c}) and ({b,d},{b}) -> ({a,b,d},{a,b},{a,b,c,d},{a,b,c})

## Parameters

|                 |                                  |
|-----------------|----------------------------------|
| <i>_vecSetA</i> | A vector of sets of constraints. |
| <i>_vecSetB</i> | A vector of sets of constraints. |

## Returns

The vector being the two given vectors merged.

**0.15.363.4.72 model()** `const Model& smtrat::Module::model () const [inline], [inherited]`

## Returns

The assignment of the current satisfiable result, if existent.

**0.15.363.4.73 modelsDisjoint()** `bool smtrat::Module::modelsDisjoint (`  
 `const Model & _modelA,`  
 `const Model & _modelB ) [static], [protected], [inherited]`

Checks whether there is no variable assigned by both models.

**Parameters**

|                      |                                |
|----------------------|--------------------------------|
| <code>_modelA</code> | The first model to check for.  |
| <code>_modelB</code> | The second model to check for. |

**Returns**

true, if there is no variable assigned by both models; false, otherwise.

**0.15.363.4.74 `moduleName()`** `template<typename Settings >`  
`std::string smtrat::PBGaussModule< Settings >::moduleName ( ) const [inline], [virtual]`

**Returns**

The name of the given module type as name.

Reimplemented from [smtrat::Module](#).

**0.15.363.4.75 `objective()`** `carl::Variable smtrat::Module::objective ( ) const [inline], [inherited]`

**0.15.363.4.76 `originInReceivedFormula()`** `bool smtrat::Module::originInReceivedFormula (`  
`const FormulaT & _origin ) const [protected], [inherited]`

**0.15.363.4.77 `passedFormulaBegin()`** `ModuleInput::iterator smtrat::Module::passedFormulaBegin (`  
`) [inline], [protected], [inherited]`

**Returns**

An iterator to the end of the passed formula. TODO: disable this method

**0.15.363.4.78 `passedFormulaEnd()`** `ModuleInput::iterator smtrat::Module::passedFormulaEnd ( )`  
`[inline], [protected], [inherited]`

**Returns**

An iterator to the end of the passed formula.

**0.15.363.4.79 `pPassedFormula()`** `const ModuleInput* smtrat::Module::pPassedFormula ( ) const`  
`[inline], [inherited]`

**Returns**

A pointer to the formula passed to the backends of this module.

**0.15.363.4.80 `pReceivedFormula()`** `const ModuleInput* smtrat::Module::pReceivedFormula ( ) const`  
`[inline], [inherited]`

**Returns**

A pointer to the formula passed to this module.

**0.15.363.4.81 `print()`** `void smtrat::Module::print (`  
`const std::string & _initiation = "***" ) const [inherited]`

Prints everything relevant of the solver.

**Parameters**

|                    |                      |
|--------------------|----------------------|
| <i>_initiation</i> | The line initiation. |
|--------------------|----------------------|

**0.15.363.4.82 printAllModels()** void smtrat::Module::printAllModels ( std::ostream & *\_out* = std::cout ) [inherited]

Prints all assignments of this module satisfying its received formula if it satisfiable and this module could find an assignment.

**Parameters**

|             |                                        |
|-------------|----------------------------------------|
| <i>_out</i> | The stream to print the assignment on. |
|-------------|----------------------------------------|

**0.15.363.4.83 printInfeasibleSubsets()** void smtrat::Module::printInfeasibleSubsets ( const std::string & *\_initiation* = "\*\*\*" ) const [inherited]

Prints the infeasible subsets.

**Parameters**

|                    |                      |
|--------------------|----------------------|
| <i>_initiation</i> | The line initiation. |
|--------------------|----------------------|

**0.15.363.4.84 printModel()** void smtrat::Module::printModel ( std::ostream & *\_out* = std::cout ) const [inherited]

Prints the assignment of this module satisfying its received formula if it satisfiable and this module could find an assignment.

**Parameters**

|             |                                        |
|-------------|----------------------------------------|
| <i>_out</i> | The stream to print the assignment on. |
|-------------|----------------------------------------|

**0.15.363.4.85 printPassedFormula()** void smtrat::Module::printPassedFormula ( const std::string & *\_initiation* = "\*\*\*" ) const [inherited]

Prints the vector of passed formula.

**Parameters**

|                    |                      |
|--------------------|----------------------|
| <i>_initiation</i> | The line initiation. |
|--------------------|----------------------|

**0.15.363.4.86 printReceivedFormula()** void smtrat::Module::printReceivedFormula ( const std::string & *\_initiation* = "\*\*\*" ) const [inherited]

Prints the vector of the received formula.

**Parameters**

|                    |                      |
|--------------------|----------------------|
| <i>_initiation</i> | The line initiation. |
|--------------------|----------------------|

---

**0.15.363.4.87 `probablyLooping()`** `bool smtrat::Module::probablyLooping (`  
 `const typename Poly::PolyType & _branchingPolynomial,`  
 `const Rational & _branchingValue ) const [protected], [inherited]`

Checks whether given the current branching value and branching variable/polynomial it is (highly) probable that this branching is part of an infinite loop of branchings.

#### Parameters

|                                   |                                                                                     |
|-----------------------------------|-------------------------------------------------------------------------------------|
| <code>_branchingPolynomial</code> | The polynomial to branch at (in most branching strategies this is just a variable). |
| <code>_branchingValue</code>      | The value to branch at.                                                             |

#### Returns

`true`, if this branching is probably part of an infinite loop of branchings; `false`, otherwise.

**0.15.363.4.88 `receivedFormulaChecked()`** `void smtrat::Module::receivedFormulaChecked ( ) [inline], [inherited]`

Notifies that the received formulas has been checked.

**0.15.363.4.89 `receivedFormulasAsInfeasibleSubset()`** `void smtrat::Module::receivedFormulasAsInfeasibleSubset (`  
 `ModuleInput::const_iterator _subformula ) [inline], [protected], [inherited]`

Stores an infeasible subset consisting only of the given received formula.

**0.15.363.4.90 `receivedVariable()`** `bool smtrat::Module::receivedVariable (`  
 `carl::Variable::Arg _var ) const [inline], [inherited]`

**0.15.363.4.91 `reconstructEqSystem()`** `template<typename Settings >`  
`FormulaT smtrat::PBGaussModule< Settings >::reconstructEqSystem (`  
 `const MatrixT & m,`  
 `const VectorT & b,`  
 `const carl::Variables & vars,`  
 `const std::vector< carl::Relation > & rels )`

**0.15.363.4.92 `reduce()`** `template<typename Settings >`  
`FormulaT smtrat::PBGaussModule< Settings >::reduce (`  
 `const MatrixT & u,`  
 `const VectorT & b,`  
 `const carl::Variables vars )`

**0.15.363.4.93 `remove()`** `void smtrat::Module::remove (`  
 `ModuleInput::const_iterator _subformula ) [virtual], [inherited]`

Removes everything related to the given sub-formula of the received formula.

However, it is desired not to lose track of search spaces where no satisfying assignment can be found for the remaining sub-formulas.

**Parameters**

|                          |                                                    |
|--------------------------|----------------------------------------------------|
| <code>_subformula</code> | The sub formula of the received formula to remove. |
|--------------------------|----------------------------------------------------|

Reimplemented in [smrat::PModule](#).

**0.15.363.4.94 `removeCore()`** template<typename Settings >

```
void smrat::PBGaussModule< Settings >::removeCore (
 ModuleInput::const_iterator _subformula) [virtual]
```

Removes the subformula of the received formula at the given position to the considered ones of this module.

Note that this includes every stored calculation which depended on this subformula, but should keep the other stored calculation, if possible, untouched.

**Parameters**

|                          |                                           |
|--------------------------|-------------------------------------------|
| <code>_subformula</code> | The position of the subformula to remove. |
|--------------------------|-------------------------------------------|

Reimplemented from [smrat::Module](#).

**0.15.363.4.95 `removeOrigin()`** std::pair<ModuleInput::iterator, bool> smrat::Module::remove←

Origin (

```
 ModuleInput::iterator _formula,
 const FormulaT & _origin) [inline], [protected], [inherited]
```

**0.15.363.4.96 `removeOrigins()`** std::pair<ModuleInput::iterator, bool> smrat::Module::remove←

Origins (

```
 ModuleInput::iterator _formula,
 const std::shared_ptr< std::vector< FormulaT >> & _origins) [inline], [protected],
[inherited]
```

**0.15.363.4.97 `rPassedFormula()`** const ModuleInput& smrat::Module::rPassedFormula ( ) const

[inline], [inherited]

**Returns**

A reference to the formula passed to the backends of this module.

**0.15.363.4.98 `rReceivedFormula()`** const ModuleInput& smrat::Module::rReceivedFormula ( ) const

[inline], [inherited]

**Returns**

A reference to the formula passed to this module.

**0.15.363.4.99 `runBackends()` [1/2]** virtual Answer smrat::Module::runBackends ( ) [inline], [protected], [virtual], [inherited]

Reimplemented in [smrat::PModule](#).

---

**0.15.363.4.100 runBackends()** [2/2] [Answer](#) smtrat::Module::runBackends (

```
 bool _final,
 bool _full,
 carl::Variable _objective) [protected], [virtual], [inherited]
```

Runs the backend solvers on the passed formula.

**Parameters**

|                         |                                                                                                                                       |
|-------------------------|---------------------------------------------------------------------------------------------------------------------------------------|
| <code>_final</code>     | true, if this satisfiability check will be the last one (for a global sat-check), if its result is SAT                                |
| <code>_full</code>      | false, if this module should avoid too expensive procedures and rather return unknown instead.                                        |
| <code>_objective</code> | if not set to NO_VARIABLE, the module should find an assignment minimizing this objective variable; otherwise any assignment is good. |

**Returns**

True, if the passed formula is consistent; False, if the passed formula is inconsistent; Unknown, otherwise.

Reimplemented in [smtrat::PModule](#).

**0.15.363.4.101 setId()** void smtrat::Module::setId (

```
 std::size_t _id) [inline], [inherited]
```

Sets this modules unique ID to identify itself.

**Parameters**

|                 |                                    |
|-----------------|------------------------------------|
| <code>id</code> | The id to set this module's id to. |
|-----------------|------------------------------------|

**0.15.363.4.102 setThreadPriority()** void smtrat::Module::setThreadPriority (

```
 thread_priority _threadPriority) [inline], [inherited]
```

Sets the priority of this module to get a thread for running its check procedure.

**Parameters**

|                              |                                                       |
|------------------------------|-------------------------------------------------------|
| <code>_threadPriority</code> | The priority to set this module's thread priority to. |
|------------------------------|-------------------------------------------------------|

**0.15.363.4.103 solverState()** [Answer](#) smtrat::Module::solverState ( ) const [inline], [inherited]

**Returns**

True, if this module is in a state, such that it has found a solution for its received formula; False, if this module is in a state, such that it has determined that there is no solution for its received formula; Unknown, otherwise.

**0.15.363.4.104 splitUnequalConstraint()** void smtrat::Module::splitUnequalConstraint (

```
 const FormulaT & _unequalConstraint) [protected], [inherited]
```

Adds the following lemmas for the given constraint p!=0.

$(p \neq 0 \Leftrightarrow (p < 0 \text{ or } p > 0))$

and  $\neg(p < 0 \text{ and } p > 0)$

**Parameters**

|                                 |                                             |
|---------------------------------|---------------------------------------------|
| <code>_unequalConstraint</code> | A constraint having the relation symbol !=. |
|---------------------------------|---------------------------------------------|

**0.15.363.4.105 `threadPriority()`** `thread_priority` `smtrat::Module::threadPriority () const [inline], [inherited]`

**Returns**

The priority of this module to get a thread for running its check procedure.

**0.15.363.4.106 `updateAllModels()`** `void smtrat::Module::updateAllModels () [virtual], [inherited]`

Updates all satisfying models, if the solver has detected the consistency of the received formula, beforehand.  
Reimplemented in `smtrat::SATModule< Settings >`.

**0.15.363.4.107 `updateLemmas()`** `void smtrat::Module::updateLemmas () [inherited]`

Stores all lemmas of any backend of this module in its own lemma vector.

**0.15.363.4.108 `updateModel()`** `template<typename Settings > void smtrat::PBGaussModule< Settings >::updateModel () const [virtual]`

Updates the current assignment into the model.

Note, that this is a unique but possibly symbolic assignment maybe containing newly introduced variables.

Reimplemented from `smtrat::Module`.

**0.15.363.4.109 `usedBackends()`** `const std::vector<Module*>& smtrat::Module::usedBackends () const [inline], [inherited]`

**Returns**

The backends of this module which are currently used (conditions to use this module are fulfilled for the passed formula).

## 0.15.363.5 Field Documentation

**0.15.363.5.1 `mAllBackends`** `std::vector<Module*> smtrat::Module::mAllBackends [protected], [inherited]`

The backends of this module which have been used.

**0.15.363.5.2 `mAllModels`** `std::vector<Model> smtrat::Module::mAllModels [mutable], [protected], [inherited]`

Stores all satisfying assignments.

**0.15.363.5.3 `mBackendsFoundAnswer`** `std::atomic_bool* smtrat::Module::mBackendsFoundAnswer [protected], [inherited]`

This flag is passed to any backend and if it determines an answer to a prior check call, this flag is fired.

**0.15.363.5.4 mConstraintsToInform** `carl::FastSet<FormulaT> smrat::Module::mConstraintsToInform` [protected], [inherited]  
Stores the constraints which the backends must be informed about.

**0.15.363.5.5 mFinalCheck** `bool smrat::Module::mFinalCheck` [protected], [inherited]  
true, if the check procedure should perform a final check which especially means not to postpone splitting decisions

**0.15.363.5.6 mFirstPosInLastBranches** `std::size_t smrat::Module::mFirstPosInLastBranches = 0` [static], [inherited]  
The beginning of the cyclic buffer storing the last branches.

**0.15.363.5.7 mFirstSubformulaToPass** `ModuleInput::iterator smrat::Module::mFirstSubformulaToPass` [protected], [inherited]  
Stores the position of the first sub-formula in the passed formula, which has not yet been considered for a consistency check of the backends.

**0.15.363.5.8 mFirstUncheckedReceivedSubformula** `ModuleInput::const_iterator smrat::Module::mFirstUncheckedReceivedSubformula` [protected], [inherited]  
Stores the position of the first (by this module) unchecked sub-formula of the received formula.

**0.15.363.5.9 mFoundAnswer** `Conditionals smrat::Module::mFoundAnswer` [protected], [inherited]  
Vector of Booleans: If any of them is true, we have to terminate a running check procedure.

**0.15.363.5.10 mFullCheck** `bool smrat::Module::mFullCheck` [protected], [inherited]  
false, if this module should avoid too expensive procedures and rather return unknown instead.

**0.15.363.5.11 mInfeasibleSubsets** `std::vector<FormulaSet> smrat::Module::mInfeasibleSubsets` [protected], [inherited]  
Stores the infeasible subsets.

**0.15.363.5.12 mInformedConstraints** `carl::FastSet<FormulaT> smrat::Module::mInformedConstraints` [protected], [inherited]  
Stores the position of the first constraint of which no backend has been informed about.

**0.15.363.5.13 mLastBranches** `std::vector<Branching> smrat::Module::mLastBranches = std::vector<Branching>(mNumOfBranchVarsToStore, Branching(typename Poly::PolyType(), 0))` [static], [inherited]  
Stores the last branches in a cycle buffer.

**0.15.363.5.14 mLemmas** `std::vector<Lemma> smrat::Module::mLemmas` [protected], [inherited]  
Stores the lemmas being valid formulas this module or its backends made.

**0.15.363.5.15 mModel** `Model smrat::Module::mModel` [mutable], [protected], [inherited]  
Stores the assignment of the current satisfiable result, if existent.

**0.15.363.5.16 mModelComputed** `bool smtrat::Module::mModelComputed` [mutable], [protected], [inherited]  
True, if the model has already been computed.

**0.15.363.5.17 mNumOfBranchVarsToStore** `std::size_t smtrat::Module::mNumOfBranchVarsToStore = 5` [static], [inherited]  
The number of different variables to consider for a probable infinite loop of branchings.

**0.15.363.5.18 mObjectiveVariable** `carl::Variable smtrat::Module::mObjectiveVariable` [protected], [inherited]  
Objective variable to be minimized. If set to NO\_VARIABLE, a normal sat check should be performed.

**0.15.363.5.19 mOldSplittingVariables** `std::vector<FormulaT> smtrat::Module::mOldSplittingVariables` [static], [inherited]  
Reusable splitting variables.

**0.15.363.5.20 mpManager** `Manager* const smtrat::Module::mpManager` [protected], [inherited]  
A reference to the manager.

**0.15.363.5.21 mSmallerMusesCheckCounter** `unsigned smtrat::Module::mSmallerMusesCheckCounter` [mutable], [protected], [inherited]  
Counter used for the generation of the smt2 files to check for smaller muses.

**0.15.363.5.22 mSolverState** `std::atomic<Answer> smtrat::Module::mSolverState` [protected], [inherited]  
States whether the received formula is known to be satisfiable or unsatisfiable otherwise it is set to unknown.

**0.15.363.5.23 mTheoryPropagations** `std::vector<TheoryPropagation> smtrat::Module::mTheoryPropagations` [protected], [inherited]

**0.15.363.5.24 mUsedBackends** `std::vector<Module*> smtrat::Module::mUsedBackends` [protected], [inherited]  
The backends of this module which are currently used (conditions to use this module are fulfilled for the passed formula).

**0.15.363.5.25 mVariableCounters** `std::vector<std::size_t> smtrat::Module::mVariableCounters` [protected], [inherited]  
Maps variables to the number of their occurrences.

## 0.15.364 smtrat::PBPPModule< Settings > Class Template Reference

```
#include <PBPPModule.h>
```

### Public Types

- `typedef Settings SettingsType`
- `enum class LemmaType : unsigned { NORMAL = 0, PERMANENT = 1 }`

## Public Member Functions

- std::string `moduleName () const`
- PBPPModule (const ModuleInput \*\_formula, Conditionals &\_conditionals, Manager \*\_manager=nullptr)
- ~PBPPModule ()
- bool `informCore (const FormulaT &_constraint)`  
*Informs the module about the given constraint.*
- void `init ()`  
*Informs all backends about the so far encountered constraints, which have not yet been communicated.*
- bool `addCore (ModuleInput::const_iterator _subformula)`  
*The module has to take the given sub-formula of the received formula into account.*
- void `removeCore (ModuleInput::const_iterator _subformula)`  
*Removes the subformula of the received formula at the given position to the considered ones of this module.*
- void `updateModel () const`  
*Updates the current assignment into the model.*
- Answer `checkCore ()`  
*Checks the received formula for consistency.*
- bool `inform (const FormulaT &_constraint)`  
*Informs the module about the given constraint.*
- void `deinform (const FormulaT &_constraint)`  
*The inverse of informing about a constraint.*
- bool `add (ModuleInput::const_iterator _subformula)`  
*The module has to take the given sub-formula of the received formula into account.*
- virtual Answer `check (bool _final=false, bool _full=true, carl::Variable _objective=carl::Variable::NO_VARIABLE)`  
*Checks the received formula for consistency.*
- virtual void `remove (ModuleInput::const_iterator _subformula)`  
*Removes everything related to the given sub-formula of the received formula.*
- virtual void `updateAllModels ()`  
*Updates all satisfying models, if the solver has detected the consistency of the received formula, beforehand.*
- virtual std::list< std::vector< carl::Variable > > `getModelEqualities () const`  
*Partition the variables from the current model into equivalence classes according to their assigned value.*
- unsigned `currentlySatisfiedByBackend (const FormulaT &_formula) const`
- virtual unsigned `currentlySatisfied (const FormulaT &) const`
- bool `receivedVariable (carl::Variable::Arg _var) const`
- Answer `solverState () const`
- std::size\_t `id () const`

*ptr< std::vector< FormulaT >> &\_origins)*
- std::pair< ModuleInput::iterator, bool > `removeOrigins` (ModuleInput::iterator \_formula, const std::shared\_ptr< std::vector< FormulaT >> &\_origins)
- void `informBackends` (const FormulaT &\_constraint)  
*Informs all backends of this module about the given constraint.*
- virtual void `addConstraintToInform` (const FormulaT &\_constraint)  
*Adds a constraint to the collection of constraints of this module, which are informed to a freshly generated backend.*
- std::pair< ModuleInput::iterator, bool > `addReceivedSubformulaToPassedFormula` (ModuleInput::const\_iterator \_subformula)  
*Copies the given sub-formula of the received formula to the passed formula.*
- bool `originInReceivedFormula` (const FormulaT &\_origin) const
- std::pair< ModuleInput::iterator, bool > `addSubformulaToPassedFormula` (const FormulaT &\_formula)  
*Adds the given formula to the passed formula with no origin.*
- std::pair< ModuleInput::iterator, bool > `addSubformulaToPassedFormula` (const FormulaT &\_formula, const std::shared\_ptr< std::vector< FormulaT >> &\_origins)  
*Adds the given formula to the passed formula.*
- std::pair< ModuleInput::iterator, bool > `addSubformulaToPassedFormula` (const FormulaT &\_formula, const FormulaT &\_origin)  
*Adds the given formula to the passed formula.*

- void `generateTrivialInfeasibleSubset ()`  
*Stores the trivial infeasible subset being the set of received formulas.*
- void `receivedFormulasAsInfeasibleSubset (ModuleInput::const_iterator _subformula)`  
*Stores an infeasible subset consisting only of the given received formula.*
- std::vector< `FormulaT` >::const\_iterator `findBestOrigin (const std::vector< FormulaT > &_origins) const`
- void `getInfeasibleSubsets ()`  
*Copies the infeasible subsets of the passed formula.*
- std::vector< `FormulaSetT` > `getInfeasibleSubsets (const Module &backend) const`  
*Get the infeasible subsets the given backend provides.*
- const `Model & backendsModel () const`  
*Stores the model of a backend which determined satisfiability of the passed formula in the model of this module.*
- void `getBackendsModel () const`
- void `getBackendsAllModels () const`  
*Stores all models of a backend in the list of all models of this module.*
- virtual `Answer runBackends (bool _final, bool _full, carl::Variable _objective)`  
*Runs the backend solvers on the passed formula.*
- virtual `Answer runBackends ()`
- virtual `ModuleInput::iterator eraseSubformulaFromPassedFormula (ModuleInput::iterator _subformula, bool _ignoreOrigins=false)`  
*Removes everything related to the sub-formula to remove from the passed formula in the backends of this module.*
- void `clearPassedFormula ()`
- std::vector< `FormulaT` > `merge (const std::vector< FormulaT > &, const std::vector< FormulaT > &) const`  
*Merges the two vectors of sets into the first one.*
- size\_t `determine_smallest_origin (const std::vector< FormulaT > &origins) const`
- bool `probablyLooping (const typename Poly::PolyType &_branchingPolynomial, const Rational &_branchingValue) const`  
*Checks whether given the current branching value and branching variable/polynomial it is (highly) probable that this branching is part of an infinite loop of branchings.*
- bool `branchAt (const Poly &_polynomial, bool _integral, const Rational &_value, std::vector< FormulaT > &&_premise, bool _leftCaseWeak=true, bool _preferLeftCase=true, bool _useReceivedFormulaAsPremise=false)`  
*Adds a lemmas which provoke a branching for the given variable at the given value, if this module returns Unknown and there exists a preceding SATModule.*
- bool `branchAt (const Poly &_polynomial, bool _integral, const Rational &_value, bool _leftCaseWeak=true, bool _preferLeftCase=true, bool _useReceivedFormulaAsPremise=false, const std::vector< FormulaT > &&_premise=std::vector< FormulaT >())`
- bool `branchAt (carl::Variable::Arg _var, const Rational &_value, std::vector< FormulaT > &&_premise, bool _leftCaseWeak=true, bool _preferLeftCase=true, bool _useReceivedFormulaAsPremise=false)`
- bool `branchAt (carl::Variable::Arg _var, const Rational &_value, bool _leftCaseWeak=true, bool _preferLeftCase=true, bool _useReceivedFormulaAsPremise=false, const std::vector< FormulaT > &_premise=std::vector< FormulaT >())`
- void `splitUnequalConstraint (const FormulaT &)`  
*Adds the following lemmas for the given constraint  $p \neq 0$ .*
- unsigned `checkModel () const`
- void `addInformationRelevantFormula (const FormulaT &formula)`  
*Adds a formula to the InformationRelevantFormula.*
- const std::set< `FormulaT` > & `getInformationRelevantFormulas ()`  
*Gets all InformationRelevantFormulas.*
- bool `isLemmaLevel (LemmaLevel level)`  
*Checks if current lemma level is greater or equal to given level.*

## Static Protected Member Functions

- static bool `modelsDisjoint` (const `Model` &\_modelA, const `Model` &\_modelB)

*Checks whether there is no variable assigned by both models.*

## Protected Attributes

- `std::vector<FormulaSetT> mInfeasibleSubsets`

*Stores the infeasible subsets.*

- `Manager *const mpManager`

*A reference to the manager.*

- `Model mModel`

*Stores the assignment of the current satisfiable result, if existent.*

- `std::vector<Model> mAllModels`

*Stores all satisfying assignments.*

- `bool mModelComputed`

*True, if the model has already been computed.*

- `bool mFinalCheck`

*true, if the check procedure should perform a final check which especially means not to postpone splitting decisions*

- `bool mFullCheck`

*false, if this module should avoid too expensive procedures and rather return unknown instead.*

- `carl::Variable mObjectiveVariable`

*Objective variable to be minimized. If set to NO\_VARIABLE, a normal sat check should be performed.*

- `std::vector<TheoryPropagation> mTheoryPropagations`

- `std::atomic<Answer> mSolverState`

*States whether the received formula is known to be satisfiable or unsatisfiable otherwise it is set to unknown.*

- `std::atomic_bool * mBackendsFoundAnswer`

*This flag is passed to any backend and if it determines an answer to a prior check call, this flag is fired.*

- `Conditionals mFoundAnswer`

*Vector of Booleans: If any of them is true, we have to terminate a running check procedure.*

- `std::vector<Module*> mUsedBackends`

*The backends of this module which are currently used (conditions to use this module are fulfilled for the passed formula).*

- `std::vector<Module*> mAllBackends`

*The backends of this module which have been used.*

- `std::vector<Lemma> mLemmas`

*Stores the lemmas being valid formulas this module or its backends made.*

- `ModuleInput::iterator mFirstSubformulaToPass`

*Stores the position of the first sub-formula in the passed formula, which has not yet been considered for a consistency check of the backends.*

- `carl::FastSet<FormulaT> mConstraintsToInform`

*Stores the constraints which the backends must be informed about.*

- `carl::FastSet<FormulaT> mInformedConstraints`

*Stores the position of the first constraint of which no backend has been informed about.*

- `ModuleInput::const_iterator mFirstUncheckedReceivedSubformula`

*Stores the position of the first (by this module) unchecked sub-formula of the received formula.*

- `unsigned mSmallerMusesCheckCounter`

*Counter used for the generation of the smt2 files to check for smaller muses.*

- `std::vector<std::size_t> mVariableCounters`

*Maps variables to the number of their occurrences.*

| NORMAL    |  |
| PERMANENT |  |

### 0.15.364.3 Constructor & Destructor Documentation

**0.15.364.3.1 PBPPModule()** template<typename Settings >  
`smrat::PBPPModule< Settings >::PBPPModule` (  
   const `ModuleInput` \* `_formula`,  
   `Conditionals` & `_conditionals`,  
   `Manager` \* `_manager` = `nullptr` )

**0.15.364.3.2 ~PBPPModule()** template<typename Settings >  
`smrat::PBPPModule< Settings >::~PBPPModule` ( )

### 0.15.364.4 Member Function Documentation

**0.15.364.4.1 add()** bool `smrat::Module::add` (  
   `ModuleInput::const_iterator` `_subformula` ) [inherited]

The module has to take the given sub-formula of the received formula into account.

Parameters

|                          |                                                    |
|--------------------------|----------------------------------------------------|
| <code>_subformula</code> | The sub-formula to take additionally into account. |
|--------------------------|----------------------------------------------------|

Returns

false, if it can be easily decided that this sub-formula causes a conflict with the already considered sub-formulas; true, otherwise.

**0.15.364.4.2 addConstraintToInform()** void `smrat::Module::addConstraintToInform` (  
   const `FormulaT` & `_constraint` ) [protected], [virtual], [inherited]

Adds a constraint to the collection of constraints of this module, which are informed to a freshly generated backend.

**Parameters**

|                    |                        |
|--------------------|------------------------|
| <i>_constraint</i> | The constraint to add. |
|--------------------|------------------------|

Reimplemented in [smtrat::SATModule< Settings >](#).

**0.15.364.4.3 addCore()** `template<typename Settings >`

```
bool smtrat::PBPPModule< Settings >::addCore (
 ModuleInput::const_iterator _subformula) [virtual]
```

The module has to take the given sub-formula of the received formula into account.

**Parameters**

|                    |                                                    |
|--------------------|----------------------------------------------------|
| <i>_subformula</i> | The sub-formula to take additionally into account. |
|--------------------|----------------------------------------------------|

**Returns**

false, if it can be easily decided that this sub-formula causes a conflict with the already considered sub-formulas; true, otherwise.

Reimplemented from [smtrat::Module](#).

**0.15.364.4.4 addInformationRelevantFormula()** `void smtrat::Module::addInformationRelevantFormula (`

```
 const FormulaT & formula) [protected], [inherited]
```

Adds a formula to the InformationRelevantFormula.

**Parameters**

|                |                |
|----------------|----------------|
| <i>formula</i> | Formula to add |
|----------------|----------------|

**0.15.364.4.5 addLemma()** `void smtrat::Module::addLemma (`

```
 const FormulaT & _lemma,
```

```
 const LemmaType & _lt = LemmaType::NORMAL,
```

```
 const FormulaT & _preferredFormula = FormulaT(carl::FormulaType::TRUE)) [inline],
```

[inherited]

Stores a lemma being a valid formula.

**Parameters**

|                          |                                                                       |
|--------------------------|-----------------------------------------------------------------------|
| <i>_lemma</i>            | The eduction/lemma to store.                                          |
| <i>_lt</i>               | The type of the lemma.                                                |
| <i>_preferredFormula</i> | Hint for the next decision, which formula should be assigned to true. |

**0.15.364.4.6 addOrigin()** `void smtrat::Module::addOrigin (`

```
 ModuleInput::iterator _formula,
```

```
 const FormulaT & _origin) [inline], [protected], [inherited]
```

Adds the given set of formulas in the received formula to the origins of the given passed formula.

**Parameters**

|                       |                                                           |
|-----------------------|-----------------------------------------------------------|
| <code>_formula</code> | The passed formula to set the origins for.                |
| <code>_origin</code>  | A set of formulas in the received formula of this module. |

**0.15.364.4.7 addReceivedSubformulaToPassedFormula()** `std::pair<ModuleInput::iterator,bool>`

```
smrat::Module::addReceivedSubformulaToPassedFormula (
 ModuleInput::const_iterator _subformula) [inline], [protected], [inherited]
```

Copies the given sub-formula of the received formula to the passed formula.

Note, that there is always a link between sub-formulas of the passed formulas to sub-formulas of the received formulas, which are responsible for its occurrence.

**Parameters**

|                          |                                                  |
|--------------------------|--------------------------------------------------|
| <code>_subformula</code> | The sub-formula of the received formula to copy. |
|--------------------------|--------------------------------------------------|

**0.15.364.4.8 addSubformulaToPassedFormula() [1/3]** `std::pair<ModuleInput::iterator,bool>`

```
smrat::Module::addSubformulaToPassedFormula (
 const FormulaT & _formula) [inline], [protected], [inherited]
```

Adds the given formula to the passed formula with no origin.

Note that in the next call of this module's removeSubformula, all formulas in the passed formula without origins will be removed.

**Parameters**

|                       |                                           |
|-----------------------|-------------------------------------------|
| <code>_formula</code> | The formula to add to the passed formula. |
|-----------------------|-------------------------------------------|

**Returns**

A pair to the position where the formula to add has been inserted (or its first sub-formula which has not yet been in the passed formula, in case the formula to add is a conjunction), and a Boolean stating whether anything has been added to the passed formula.

**0.15.364.4.9 addSubformulaToPassedFormula() [2/3]** `std::pair<ModuleInput::iterator,bool>`

```
smrat::Module::addSubformulaToPassedFormula (
 const FormulaT & _formula,
 const FormulaT & _origin) [inline], [protected], [inherited]
```

Adds the given formula to the passed formula.

**Parameters**

|                       |                                                                                                                           |
|-----------------------|---------------------------------------------------------------------------------------------------------------------------|
| <code>_formula</code> | The formula to add to the passed formula.                                                                                 |
| <code>_origin</code>  | The sub-formula of the received formula being responsible for the occurrence of the formula to add to the passed formula. |

**Returns**

A pair to the position where the formula to add has been inserted (or its first sub-formula which has not yet been in the passed formula, in case the formula to add is a conjunction), and a Boolean stating whether anything has been added to the passed formula.

```
0.15.364.4.10 addSubformulaToPassedFormula() [3/3] std::pair<ModuleInput::iterator,bool>
smrat::Module::addSubformulaToPassedFormula (
 const FormulaT & _formula,
 const std::shared_ptr< std::vector< FormulaT >> & _origins) [inline], [protected],
[inherited]
```

Adds the given formula to the passed formula.

#### Parameters

|                       |                                                                                                                                         |
|-----------------------|-----------------------------------------------------------------------------------------------------------------------------------------|
| <code>_formula</code> | The formula to add to the passed formula.                                                                                               |
| <code>_origins</code> | The link of the formula to add to the passed formula to sub-formulas of the received formulas, which are responsible for its occurrence |

#### Returns

A pair to the position where the formula to add has been inserted (or its first sub-formula which has not yet been in the passed formula, in case the formula to add is a conjunction), and a Boolean stating whether anything has been added to the passed formula.

```
0.15.364.4.11 allModels() const std::vector<Model>& smrat::Module::allModels () const [inline],
[inherited]
```

#### Returns

All satisfying assignments, if existent.

```
0.15.364.4.12 anAnswerFound() bool smrat::Module::anAnswerFound () const [inline], [protected],
[inherited]
```

Checks for all antecedent modules and those which run in parallel with the same antecedent modules, whether one of them has determined a result.

#### Returns

True, if one of them has determined a result.

```
0.15.364.4.13 answerFound() const smrat::Conditionals& smrat::Module::answerFound () const
[inline], [inherited]
```

#### Returns

A vector of Booleans: If any of them is true, we have to terminate a running check procedure.

```
0.15.364.4.14 backendsModel() const Model & smrat::Module::backendsModel () const [protected],
[inherited]
```

Stores the model of a backend which determined satisfiability of the passed formula in the model of this module.

```
0.15.364.4.15 branchAt() [1/4] bool smtrat::Module::branchAt (
 carl::Variable::Arg _var,
 const Rational & _value,
 bool _leftCaseWeak = true,
 bool _preferLeftCase = true,
 bool _useReceivedFormulaAsPremise = false,
 const std::vector< FormulaT > & _premise = std::vector<FormulaT>()) [inline],
[protected], [inherited]
```

```
0.15.364.4.16 branchAt() [2/4] bool smtrat::Module::branchAt (
 carl::Variable::Arg _var,
 const Rational & _value,
 std::vector< FormulaT > && _premise,
 bool _leftCaseWeak = true,
 bool _preferLeftCase = true,
 bool _useReceivedFormulaAsPremise = false) [inline], [protected], [inherited]
```

```
0.15.364.4.17 branchAt() [3/4] bool smtrat::Module::branchAt (
 const Poly & _polynomial,
 bool _integral,
 const Rational & _value,
 bool _leftCaseWeak = true,
 bool _preferLeftCase = true,
 bool _useReceivedFormulaAsPremise = false,
 const std::vector< FormulaT > & _premise = std::vector<FormulaT>()) [inline],
[protected], [inherited]
```

```
0.15.364.4.18 branchAt() [4/4] bool smtrat::Module::branchAt (
 const Poly & _polynomial,
 bool _integral,
 const Rational & _value,
 std::vector< FormulaT > && _premise,
 bool _leftCaseWeak = true,
 bool _preferLeftCase = true,
 bool _useReceivedFormulaAsPremise = false) [protected], [inherited]
```

Adds a lemmas which provoke a branching for the given variable at the given value, if this module returns Unknown and there exists a preceding [SATModule](#).

Note that the given value is rounded down and up, if the given variable is integer-valued.

#### Parameters

|                                           |                                                                                                                                                                                                                |
|-------------------------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>_polynomial</code>                  | The variable to branch for.                                                                                                                                                                                    |
| <code>_integral</code>                    | A flag being true, if all variables in the polynomial to branch for are integral.                                                                                                                              |
| <code>_value</code>                       | The value to branch at.                                                                                                                                                                                        |
| <code>_premise</code>                     | The sub-formulas of the received formula from which the branch is followed. Note, that a premise is not necessary, as every branch is a valid formula. But a premise can prevent from branching unnecessarily. |
| <code>_leftCaseWeak</code>                | true, if a branching in the form of (or ( $\leq p b$ ) ( $> p b$ )) is desired. false, if a branching in the form of (or ( $< p b$ ) ( $\geq p b$ )) is desired.                                               |
| <code>_preferLeftCase</code>              | true, if the left case (polynomial less(or equal) 0 shall be chosen first. false, otherwise.                                                                                                                   |
| <code>_useReceivedFormulaAsPremise</code> | true, if the whole received formula should be used as premise                                                                                                                                                  |

---

**0.15.364.4.19 check()** *Answer* smrat::Module::check (

```
 bool _final = false,
 bool _full = true,
 carl::Variable _objective = carl::Variable::NO_VARIABLE) [virtual], [inherited]
```

Checks the received formula for consistency.

Note, that this is an implementation of the satisfiability check of the conjunction of the so far received formulas, which does actually nothing but passing the problem to its backends. This implementation is only used internally and must be overwritten by any derived module.

#### Parameters

|                   |                                                                                                                                       |
|-------------------|---------------------------------------------------------------------------------------------------------------------------------------|
| <i>_final</i>     | true, if this satisfiability check will be the last one (for a global sat-check), if its result is SAT                                |
| <i>_full</i>      | false, if this module should avoid too expensive procedures and rather return unknown instead.                                        |
| <i>_objective</i> | if not set to NO_VARIABLE, the module should find an assignment minimizing this objective variable; otherwise any assignment is good. |

#### Returns

True, if the received formula is satisfiable; False, if the received formula is not satisfiable; Unknown, otherwise.

Reimplemented in [smrat::PModule](#).

**0.15.364.4.20 checkCore()** *template<typename Settings >*  
*Answer* smrat::PBPModule< Settings >::checkCore ( ) [virtual]

Checks the received formula for consistency.

#### Returns

True, if the received formula is satisfiable; False, if the received formula is not satisfiable; Unknown, otherwise.

Reimplemented from [smrat::Module](#).

**0.15.364.4.21 checkInfSubsetForMinimality()** *void* smrat::Module::checkInfSubsetForMinimality (

```
 std::vector< FormulaSetT >::const_iterator _infssubset,
 const std::string & _filename = "smaller_muses",
 unsigned _maxSizeDifference = 1) const [inherited]
```

Checks the given infeasible subset for minimality by storing all subsets of it, which have a smaller size which differs from the size of the infeasible subset not more than the given threshold.

#### Parameters

|                           |                                                                                                        |
|---------------------------|--------------------------------------------------------------------------------------------------------|
| <i>_infssubset</i>        | The infeasible subset to check for minimality.                                                         |
| <i>_filename</i>          | The name of the file to store the infeasible subsets in order to be able to check their infeasibility. |
| <i>_maxSizeDifference</i> | The maximal difference between the sizes of the subsets compared to the size of the infeasible subset. |

**0.15.364.4.22 checkModel()** *unsigned* smrat::Module::checkModel ( ) const [protected], [inherited]

**Returns**

false, if the current model of this module does not satisfy the current given formula; true, if it cannot be said whether the model satisfies the given formula.

**0.15.364.4.23 cleanModel()** void smtrat::Module::cleanModel ( ) const [inline], [protected], [inherited]

Substitutes variable occurrences by its model value in the model values of other variables.

**0.15.364.4.24 clearLemmas()** void smtrat::Module::clearLemmas ( ) [inline], [inherited]

Deletes all yet found lemmas.

**0.15.364.4.25 clearModel()** void smtrat::Module::clearModel ( ) const [inline], [protected], [inherited]

Clears the assignment, if any was found.

**0.15.364.4.26 clearModels()** void smtrat::Module::clearModels ( ) const [inline], [protected], [inherited]

Clears all assignments, if any was found.

**0.15.364.4.27 clearPassedFormula()** void smtrat::Module::clearPassedFormula ( ) [protected], [inherited]

**0.15.364.4.28 collectOrigins() [1/2]** void smtrat::Module::collectOrigins ( const `FormulaT` & `_formula`, `FormulaSetT` & `_origins` ) const [inherited]

**0.15.364.4.29 collectOrigins() [2/2]** void smtrat::Module::collectOrigins ( const `FormulaT` & `_formula`, `FormulasT` & `_origins` ) const [inherited]

Collects the formulas in the given formula, which are part of the received formula.

If the given formula directly occurs in the received formula, it is inserted into the given set. Otherwise, the given formula must be of type AND and all its sub-formulas part of the received formula. Hence, they will be added to the given set.

**Parameters**

|                       |                                                                                                      |
|-----------------------|------------------------------------------------------------------------------------------------------|
| <code>_formula</code> | The formula from which to collect the formulas being sub-formulas of the received formula (origins). |
| <code>_origins</code> | The set in which to store the origins.                                                               |

**0.15.364.4.30 collectTheoryPropagations()** void smtrat::Module::collectTheoryPropagations ( ) [inherited]

**0.15.364.4.31 constraintsToInform()** const carl::FastSet<`FormulaT`>& smtrat::Module::constraintsToInform ( ) const [inline], [inherited]

**Returns**

The constraints which the backends must be informed about.

**0.15.364.4.32 currentlySatisfied()** `virtual unsigned smtrat::Module::currentlySatisfied ( const FormulaT & ) const [inline], [virtual], [inherited]`

**Returns**

0, if the given formula is conflicted by the current model; 1, if the given formula is satisfied by the current model; 2, otherwise; 3, if we do not know anything (default)

Reimplemented in [smtrat::LRAModule< Settings >](#), [smtrat::LRAModule< LRASettingsICP >](#), and [smtrat::LRAModule< LRASettings >](#)

**0.15.364.4.33 currentlySatisfiedByBackend()** `unsigned smtrat::Module::currentlySatisfiedByBackend ( const FormulaT & _formula ) const [inherited]`

**Returns**

0, if the given formula is conflicted by the current model; 1, if the given formula is satisfied by the current model; 2, otherwise 3, if we do not know anything (default)

**0.15.364.4.34 deinform()** `void smtrat::Module::deinform ( const FormulaT & _constraint ) [inherited]`

The inverse of informing about a constraint.

All data structures which were kept regarding this constraint are going to be removed. Note, that this makes only sense if it is not likely enough that a formula with this constraint must be solved again.

**Parameters**

|                          |                                                         |
|--------------------------|---------------------------------------------------------|
| <code>_constraint</code> | The constraint to remove from internal data structures. |
|--------------------------|---------------------------------------------------------|

**0.15.364.4.35 deinformCore()** `virtual void smtrat::Module::deinformCore ( const FormulaT & _constraint ) [inline], [protected], [virtual], [inherited]`

The inverse of informing about a constraint.

All data structures which were kept regarding this constraint are going to be removed. Note, that this makes only sense if it is not likely enough that a formula with this constraint must be solved again.

**Parameters**

|                          |                                                         |
|--------------------------|---------------------------------------------------------|
| <code>_constraint</code> | The constraint to remove from internal data structures. |
|--------------------------|---------------------------------------------------------|

Reimplemented in [smtrat::LRAModule< Settings >](#), [smtrat::LRAModule< LRASettingsICP >](#), and [smtrat::LRAModule< LRASettings >](#)

**0.15.364.4.36 determine\_smallest\_origin()** `size_t smtrat::Module::determine_smallest_origin ( const std::vector< FormulaT > & origins ) const [protected], [inherited]`

**Parameters**

|                      |                              |
|----------------------|------------------------------|
| <code>origins</code> | A vector of sets of origins. |
|----------------------|------------------------------|

**Returns**

The index of the smallest (regarding the size of the sets) element of origins

**0.15.364.4.37 `eraseSubformulaFromPassedFormula()`** `ModuleInput::iterator smtrat::Module::eraseSubformulaFromPassedFormula (`

```
 ModuleInput::iterator _subformula,
 bool _ignoreOrigins = false) [protected], [virtual], [inherited]
```

Removes everything related to the sub-formula to remove from the passed formula in the backends of this module. Afterwards the sub-formula is removed from the passed formula.

**Parameters**

|                             |                                                                                                              |
|-----------------------------|--------------------------------------------------------------------------------------------------------------|
| <code>_subformula</code>    | The sub-formula to remove from the passed formula.                                                           |
| <code>_ignoreOrigins</code> | True, if the sub-formula shall be removed regardless of its origins (should only be applied with expertise). |

**Returns**

Reimplemented in `smtrat::ICPModule< Settings >`, `smtrat::ICPModule< ICPSettings4 >`, and `smtrat::ICPModule< ICPSettings1 >`.

**0.15.364.4.38 `excludeNotReceivedVariablesFromModel()`** `void smtrat::Module::excludeNotReceivedVariablesFromModel ( ) const [inherited]`

Excludes all variables from the current model, which do not occur in the received formula.

**0.15.364.4.39 `findBestOrigin()`** `std::vector< FormulaT >::const_iterator smtrat::Module::findBestOrigin (`

```
 const std::vector< FormulaT > & _origins) const [protected], [inherited]
```

**Parameters**

|                       |  |
|-----------------------|--|
| <code>_origins</code> |  |
|-----------------------|--|

**Returns****0.15.364.4.40 `firstSubformulaToPass()`** `ModuleInput::const_iterator smtrat::Module::firstSubformulaToPass ( ) const [inline], [inherited]`**Returns**

The position of the first sub-formula in the passed formula, which has not yet been considered for a consistency check of the backends.

**0.15.364.4.41 `firstUncheckedReceivedSubformula()`** `ModuleInput::const_iterator smtrat::Module::firstUncheckedReceivedSubformula ( ) const [inline], [inherited]`**Returns**

The position of the first (by this module) unchecked sub-formula of the received formula.

**0.15.364.4.42 freeSplittingVariable()** static void smtrat::Module::freeSplittingVariable ( const `FormulaT` & `_splittingVariable` ) [inline], [static], [inherited]

**0.15.364.4.43 generateTrivialInfeasibleSubset()** void smtrat::Module::generateTrivialInfeasibleSubset ( ) [inline], [protected], [inherited]  
Stores the trivial infeasible subset being the set of received formulas.

**0.15.364.4.44 getBackendsAllModels()** void smtrat::Module::getBackendsAllModels ( ) const [protected], [inherited]  
Stores all models of a backend in the list of all models of this module.

**0.15.364.4.45 getBackendsModel()** void smtrat::Module::getBackendsModel ( ) const [protected], [inherited]

**0.15.364.4.46 getInfeasibleSubsets() [1/2]** void smtrat::Module::getInfeasibleSubsets ( ) [protected], [inherited]  
Copies the infeasible subsets of the passed formula.

**0.15.364.4.47 getInfeasibleSubsets() [2/2]** std::vector< `FormulaSetT` > smtrat::Module::getInfeasibleSubsets ( const `Module` & `_backend` ) const [protected], [inherited]

Get the infeasible subsets the given backend provides.  
Note, that an infeasible subset in a backend contains sub formulas of the passed formula and an infeasible subset of this module contains sub formulas of the received formula. In this method the LATTER is returned.

#### Parameters

|                       |                                                          |
|-----------------------|----------------------------------------------------------|
| <code>_backend</code> | The backend from which to obtain the infeasible subsets. |
|-----------------------|----------------------------------------------------------|

#### Returns

The infeasible subsets the given backend provides.

**0.15.364.4.48 getInformationRelevantFormulas()** const std::set< `FormulaT` > & smtrat::Module::getInformationRelevantFormulas ( ) [protected], [inherited]  
Gets all InformationRelevantFormulas.

#### Returns

Set of all formulas

**0.15.364.4.49 getModelEqualities()** std::list< std::vector< `carl::Variable` > > smtrat::Module::getModelEqualities ( ) const [virtual], [inherited]

Partition the variables from the current model into equivalence classes according to their assigned value.  
The result is a set of equivalence classes of variables where all variables within one class are assigned the same value. Note that the number of classes may not be minimal, i.e. two classes may actually be equivalent.

#### Returns

Equivalence classes.

**0.15.364.4.50 getOrigins() [1/3]** void smtrat::Module::getOrigins ( const FormulaT & \_formula, FormulaSetT & \_origins ) const [inline], [protected], [inherited]

#### Parameters

|          |  |
|----------|--|
| _formula |  |
| _origins |  |

**0.15.364.4.51 getOrigins() [2/3]** void smtrat::Module::getOrigins ( const FormulaT & \_formula, FormulasT & \_origins ) const [inline], [protected], [inherited]

#### Parameters

|          |  |
|----------|--|
| _formula |  |
| _origins |  |

**0.15.364.4.52 getOrigins() [3/3]** const FormulaT& smtrat::Module::getOrigins ( ModuleInput::const\_iterator \_formula ) const [inline], [protected], [inherited]  
Gets the origins of the passed formula at the given position.

#### Parameters

|          |                                                   |
|----------|---------------------------------------------------|
| _formula | The position of a formula in the passed formulas. |
|----------|---------------------------------------------------|

#### Returns

The origins of the passed formula at the given position.

**0.15.364.4.53 getReceivedFormulaSimplified()** std::pair< bool, FormulaT > smtrat::Module::getReceivedFormulaSimplified ( ) [virtual], [inherited]

#### Returns

A pair of a Boolean and a formula, where the Boolean is true, if the received formula could be simplified to an equisatisfiable formula. The formula is equisatisfiable to this module's received formula, if the Boolean is true.

Reimplemented in [smtrat::PModule](#).

**0.15.364.4.54 hasLemmas()** bool smtrat::Module::hasLemmas ( ) [inline], [inherited]  
Checks whether this module or any of its backends provides any lemmas.

**0.15.364.4.55 hasValidInfeasibleSubset()** bool smtrat::Module::hasValidInfeasibleSubset ( ) const [inherited]

#### Returns

true, if the module has at least one valid infeasible subset, that is all its elements are sub-formulas of the received formula (pointer must be equal).

**0.15.364.4.56 `id()`** `std::size_t smtrat::Module::id () const [inline], [inherited]`

**Returns**

A unique ID to identify this module instance.

**0.15.364.4.57 `infeasibleSubsets()`** `const std::vector<FormulaSetT>& smtrat::Module::infeasibleSubsets () const [inline], [inherited]`

**Returns**

The infeasible subsets of the set of received formulas (empty, if this module has not detected unsatisfiability of the conjunction of received formulas).

**0.15.364.4.58 `inform()`** `bool smtrat::Module::inform (const FormulaT & _constraint) [inherited]`

Informs the module about the given constraint.

It should be tried to inform this module about any constraint it could receive eventually before assertSubformula is called (preferably for the first time, but at least before adding a formula containing that constraint).

**Parameters**

|                          |                                 |
|--------------------------|---------------------------------|
| <code>_constraint</code> | The constraint to inform about. |
|--------------------------|---------------------------------|

**Returns**

false, if it can be easily decided whether the given constraint is inconsistent; true, otherwise.

**0.15.364.4.59 `informBackends()`** `void smtrat::Module::informBackends (const FormulaT & _constraint) [inline], [protected], [inherited]`

Informs all backends of this module about the given constraint.

**Parameters**

|                          |                                 |
|--------------------------|---------------------------------|
| <code>_constraint</code> | The constraint to inform about. |
|--------------------------|---------------------------------|

**0.15.364.4.60 `informCore()`** `template<typename Settings > bool smtrat::PBPPModule< Settings >::informCore (const FormulaT & _constraint) [virtual]`

Informs the module about the given constraint.

It should be tried to inform this module about any constraint it could receive eventually before assertSubformula is called (preferably for the first time, but at least before adding a formula containing that constraint).

**Parameters**

|                          |                                 |
|--------------------------|---------------------------------|
| <code>_constraint</code> | The constraint to inform about. |
|--------------------------|---------------------------------|

**Returns**

false, if it can be easily decided whether the given constraint is inconsistent; true, otherwise.

Reimplemented from [smtrat::Module](#).

**0.15.364.4.61 informedConstraints()** const carl::FastSet<[FormulaT](#)>& smtrat::Module::informedConstraints ( ) const [inline], [inherited]

**Returns**

The position of the first constraint of which no backend has been informed about.

**0.15.364.4.62 init()** template<typename Settings >  
void smtrat::PBPModule< Settings >::init ( ) [virtual]

Informs all backends about the so far encountered constraints, which have not yet been communicated.  
This method must not and will not be called more than once and only before the first runBackends call.  
Reimplemented from [smtrat::Module](#).

**0.15.364.4.63 is\_minimizing()** bool smtrat::Module::is\_minimizing ( ) const [inline], [inherited]

**0.15.364.4.64 isLemmaLevel()** bool smtrat::Module::isLemmaLevel ( [LemmaLevel](#) level ) [protected], [inherited]

Checks if current lemma level is greater or equal to given level.

**Parameters**

|              |                 |
|--------------|-----------------|
| <i>level</i> | Level to check. |
|--------------|-----------------|

**0.15.364.4.65 isPreprocessor()** bool smtrat::Module::isPreprocessor ( ) const [inline], [inherited]

**Returns**

true, if this module is a preprocessor that is a module, which simplifies its received formula to an equisatisfiable formula being passed to its backends. The simplified formula can be obtained with [getReceivedFormulaSimplified\(\)](#).

**0.15.364.4.66 lemmas()** const std::vector<[Lemma](#)>& smtrat::Module::lemmas ( ) const [inline], [inherited]

**Returns**

A constant reference to the lemmas being valid formulas this module or its backends made.

**0.15.364.4.67 merge()** std::vector< [FormulaT](#) > smtrat::Module::merge ( const std::vector< [FormulaT](#) > & \_vecSetA, const std::vector< [FormulaT](#) > & \_vecSetB ) const [protected], [inherited]

Merges the two vectors of sets into the first one.

({a,b},{a,c}) and ({b,d},{b}) -> ({a,b,d},{a,b},{a,b,c,d},{a,b,c})

**Parameters**

|                       |                                  |
|-----------------------|----------------------------------|
| <code>_vecSetA</code> | A vector of sets of constraints. |
| <code>_vecSetB</code> | A vector of sets of constraints. |

**Returns**

The vector being the two given vectors merged.

**0.15.364.4.68 `model()`** `const Model& smtrat::Module::model () const [inline], [inherited]`**Returns**

The assignment of the current satisfiable result, if existent.

**0.15.364.4.69 `modelsDisjoint()`** `bool smtrat::Module::modelsDisjoint (const Model & _modelA, const Model & _modelB ) [static], [protected], [inherited]`

Checks whether there is no variable assigned by both models.

**Parameters**

|                      |                                |
|----------------------|--------------------------------|
| <code>_modelA</code> | The first model to check for.  |
| <code>_modelB</code> | The second model to check for. |

**Returns**

true, if there is no variable assigned by both models; false, otherwise.

**0.15.364.4.70 `moduleName()`** `template<typename Settings > std::string smtrat::PBPPModule< Settings >::moduleName () const [inline], [virtual]`**Returns**

The name of the given module type as name.

Reimplemented from [smtrat::Module](#).

**0.15.364.4.71 `objective()`** `carl::Variable smtrat::Module::objective () const [inline], [inherited]`**0.15.364.4.72 `originInReceivedFormula()`** `bool smtrat::Module::originInReceivedFormula (const FormulaT & _origin ) const [protected], [inherited]`**0.15.364.4.73 `passedFormulaBegin()`** `ModuleInput::iterator smtrat::Module::passedFormulaBegin () [inline], [protected], [inherited]`**Returns**

An iterator to the end of the passed formula. TODO: disable this method

**0.15.364.4.74 passedFormulaEnd()** `ModuleInput::iterator smrat::Module::passedFormulaEnd () [inline], [protected], [inherited]`

**Returns**

An iterator to the end of the passed formula.

**0.15.364.4.75 pPassedFormula()** `const ModuleInput* smrat::Module::pPassedFormula () const [inline], [inherited]`

**Returns**

A pointer to the formula passed to the backends of this module.

**0.15.364.4.76 pReceivedFormula()** `const ModuleInput* smrat::Module::pReceivedFormula () const [inline], [inherited]`

**Returns**

A pointer to the formula passed to this module.

**0.15.364.4.77 print()** `void smrat::Module::print ( const std::string & _initiation = "***" ) const [inherited]`

Prints everything relevant of the solver.

**Parameters**

|                          |                      |
|--------------------------|----------------------|
| <code>_initiation</code> | The line initiation. |
|--------------------------|----------------------|

**0.15.364.4.78 printAllModels()** `void smrat::Module::printAllModels ( std::ostream & _out = std::cout ) [inherited]`

Prints all assignments of this module satisfying its received formula if it satisfiable and this module could find an assignment.

**Parameters**

|                   |                                        |
|-------------------|----------------------------------------|
| <code>_out</code> | The stream to print the assignment on. |
|-------------------|----------------------------------------|

**0.15.364.4.79 printInfeasibleSubsets()** `void smrat::Module::printInfeasibleSubsets ( const std::string & _initiation = "***" ) const [inherited]`

Prints the infeasible subsets.

**Parameters**

|                          |                      |
|--------------------------|----------------------|
| <code>_initiation</code> | The line initiation. |
|--------------------------|----------------------|

**0.15.364.4.80 printModel()** `void smrat::Module::printModel ( std::ostream & _out = std::cout ) const [inherited]`

Prints the assignment of this module satisfying its received formula if it satisfiable and this module could find an assignment.

Parameters

|                   |                                        |
|-------------------|----------------------------------------|
| <code>_out</code> | The stream to print the assignment on. |
|-------------------|----------------------------------------|

**0.15.364.4.81 `printPassedFormula()`** `void smtrat::Module::printPassedFormula ( const std::string & _initiation = "***" ) const [inherited]`

Prints the vector of passed formula.

Parameters

|                          |                      |
|--------------------------|----------------------|
| <code>_initiation</code> | The line initiation. |
|--------------------------|----------------------|

**0.15.364.4.82 `printReceivedFormula()`** `void smtrat::Module::printReceivedFormula ( const std::string & _initiation = "***" ) const [inherited]`

Prints the vector of the received formula.

Parameters

|                          |                      |
|--------------------------|----------------------|
| <code>_initiation</code> | The line initiation. |
|--------------------------|----------------------|

**0.15.364.4.83 `probablyLooping()`** `bool smtrat::Module::probablyLooping ( const typename Poly::PolyType & _branchingPolynomial, const Rational & _branchingValue ) const [protected], [inherited]`

Checks whether given the current branching value and branching variable/polynomial it is (highly) probable that this branching is part of an infinite loop of branchings.

Parameters

|                                   |                                                                                     |
|-----------------------------------|-------------------------------------------------------------------------------------|
| <code>_branchingPolynomial</code> | The polynomial to branch at (in most branching strategies this is just a variable). |
| <code>_branchingValue</code>      | The value to branch at.                                                             |

Returns

true, if this branching is probably part of an infinite loop of branchings; false, otherwise.

**0.15.364.4.84 `receivedFormulaChecked()`** `void smtrat::Module::receivedFormulaChecked ( ) [inline], [inherited]`

Notifies that the received formulas has been checked.

**0.15.364.4.85 `receivedFormulasAsInfeasibleSubset()`** `void smtrat::Module::receivedFormulasAsInfeasibleSubset ( ModuleInput::const_iterator _subformula ) [inline], [protected], [inherited]`

Stores an infeasible subset consisting only of the given received formula.

**0.15.364.4.86 receivedVariable()** `bool smrat::Module::receivedVariable ( carl::Variable::Arg _var ) const [inline], [inherited]`

**0.15.364.4.87 remove()** `void smrat::Module::remove ( ModuleInput::const_iterator _subformula ) [virtual], [inherited]`

Removes everything related to the given sub-formula of the received formula.

However, it is desired not to lose track of search spaces where no satisfying assignment can be found for the remaining sub-formulas.

#### Parameters

|                          |                                                    |
|--------------------------|----------------------------------------------------|
| <code>_subformula</code> | The sub formula of the received formula to remove. |
|--------------------------|----------------------------------------------------|

Reimplemented in [smrat::PModule](#).

**0.15.364.4.88 removeCore()** `template<typename Settings > void smrat::PBPPModule< Settings >::removeCore ( ModuleInput::const_iterator _subformula ) [virtual]`

Removes the subformula of the received formula at the given position to the considered ones of this module.

Note that this includes every stored calculation which depended on this subformula, but should keep the other stored calculation, if possible, untouched.

#### Parameters

|                          |                                           |
|--------------------------|-------------------------------------------|
| <code>_subformula</code> | The position of the subformula to remove. |
|--------------------------|-------------------------------------------|

Reimplemented from [smrat::Module](#).

**0.15.364.4.89 removeOrigin()** `std::pair<ModuleInput::iterator,bool> smrat::Module::removeOrigin ( ModuleInput::iterator _formula, const FormulaT & _origin ) [inline], [protected], [inherited]`

**0.15.364.4.90 removeOrigins()** `std::pair<ModuleInput::iterator,bool> smrat::Module::removeOrigins ( ModuleInput::iterator _formula, const std::shared_ptr< std::vector< FormulaT >> & _origins ) [inline], [protected], [inherited]`

**0.15.364.4.91 rPassedFormula()** `const ModuleInput& smrat::Module::rPassedFormula ( ) const [inline], [inherited]`

#### Returns

A reference to the formula passed to the backends of this module.

**0.15.364.4.92 rReceivedFormula()** `const ModuleInput& smrat::Module::rReceivedFormula ( ) const [inline], [inherited]`

**Returns**

A reference to the formula passed to this module.

**0.15.364.4.93 runBackends() [1/2]** `virtual Answer smtrat::Module::runBackends () [inline], [protected], [virtual], [inherited]`

Reimplemented in [smtrat::PModule](#).

**0.15.364.4.94 runBackends() [2/2]** `Answer smtrat::Module::runBackends (`

```
 bool _final,
 bool _full,
 carl::Variable _objective) [protected], [virtual], [inherited]
```

Runs the backend solvers on the passed formula.

**Parameters**

|                         |                                                                                                                                       |
|-------------------------|---------------------------------------------------------------------------------------------------------------------------------------|
| <code>_final</code>     | true, if this satisfiability check will be the last one (for a global sat-check), if its result is SAT                                |
| <code>_full</code>      | false, if this module should avoid too expensive procedures and rather return unknown instead.                                        |
| <code>_objective</code> | if not set to NO_VARIABLE, the module should find an assignment minimizing this objective variable; otherwise any assignment is good. |

**Returns**

True, if the passed formula is consistent; False, if the passed formula is inconsistent; Unknown, otherwise.

Reimplemented in [smtrat::PModule](#).

**0.15.364.4.95 setId()** `void smtrat::Module::setId (`

```
 std::size_t _id) [inline], [inherited]
```

Sets this modules unique ID to identify itself.

**Parameters**

|                   |                                    |
|-------------------|------------------------------------|
| <code>↔ id</code> | The id to set this module's id to. |
|-------------------|------------------------------------|

**0.15.364.4.96 setThreadPriority()** `void smtrat::Module::setThreadPriority (`

```
 thread_priority _threadPriority) [inline], [inherited]
```

Sets the priority of this module to get a thread for running its check procedure.

**Parameters**

|                              |                                                       |
|------------------------------|-------------------------------------------------------|
| <code>_threadPriority</code> | The priority to set this module's thread priority to. |
|------------------------------|-------------------------------------------------------|

**0.15.364.4.97 solverState()** `Answer smtrat::Module::solverState () const [inline], [inherited]`

**Returns**

True, if this module is in a state, such that it has found a solution for its received formula; False, if this module is in a state, such that it has determined that there is no solution for its received formula; Unknown, otherwise.

**0.15.364.4.98 splitUnequalConstraint()** `void smtrat::Module::splitUnequalConstraint (`

`const FormulaT & _unequalConstraint ) [protected], [inherited]`

Adds the following lemmas for the given constraint  $p \neq 0$ .

$(p \neq 0 \leftrightarrow (p < 0 \text{ or } p > 0))$

and  $\neg(p < 0 \text{ and } p > 0)$

**Parameters**

|                                 |                                                  |
|---------------------------------|--------------------------------------------------|
| <code>_unequalConstraint</code> | A constraint having the relation symbol $\neq$ . |
|---------------------------------|--------------------------------------------------|

**0.15.364.4.99 threadPriority()** `thread_priority smtrat::Module::threadPriority ( ) const [inline], [inherited]`**Returns**

The priority of this module to get a thread for running its check procedure.

**0.15.364.4.100 updateAllModels()** `void smtrat::Module::updateAllModels ( ) [virtual], [inherited]`

Updates all satisfying models, if the solver has detected the consistency of the received formula, beforehand.

Reimplemented in [smtrat::SATModule< Settings >](#).

**0.15.364.4.101 updateLemmas()** `void smtrat::Module::updateLemmas ( ) [inherited]`

Stores all lemmas of any backend of this module in its own lemma vector.

**0.15.364.4.102 updateModel()** `template<typename Settings >`

`void smtrat::PBPPModule< Settings >::updateModel ( ) const [virtual]`

Updates the current assignment into the model.

Note, that this is a unique but possibly symbolic assignment maybe containing newly introduced variables.

Reimplemented from [smtrat::Module](#).

**0.15.364.4.103 usedBackends()** `const std::vector<Module*>& smtrat::Module::usedBackends ( )`

`const [inline], [inherited]`

**Returns**

The backends of this module which are currently used (conditions to use this module are fulfilled for the passed formula).

**0.15.364.5 Field Documentation****0.15.364.5.1 mAllBackends** `std::vector<Module*> smtrat::Module::mAllBackends [protected], [inherited]`

The backends of this module which have been used.

**0.15.364.5.2 mAllModels** `std::vector<Model>` `smtrat::Module::mAllModels` [mutable], [protected], [inherited]  
Stores all satisfying assignments.

**0.15.364.5.3 mBackendsFoundAnswer** `std::atomic_bool*` `smtrat::Module::mBackendsFoundAnswer` [protected], [inherited]  
This flag is passed to any backend and if it determines an answer to a prior check call, this flag is fired.

**0.15.364.5.4 mConstraintsToInform** `carl::FastSet<FormulaT>` `smtrat::Module::mConstraintsToInform` [protected], [inherited]  
Stores the constraints which the backends must be informed about.

**0.15.364.5.5 mFinalCheck** `bool` `smtrat::Module::mFinalCheck` [protected], [inherited]  
true, if the check procedure should perform a final check which especially means not to postpone splitting decisions

**0.15.364.5.6 mFirstPosInLastBranches** `std::size_t` `smtrat::Module::mFirstPosInLastBranches` = 0 [static], [inherited]  
The beginning of the cyclic buffer storing the last branches.

**0.15.364.5.7 mFirstSubformulaToPass** `ModuleInput::iterator` `smtrat::Module::mFirstSubformulaToPass` [protected], [inherited]  
Stores the position of the first sub-formula in the passed formula, which has not yet been considered for a consistency check of the backends.

**0.15.364.5.8 mFirstUncheckedReceivedSubformula** `ModuleInput::const_iterator` `smtrat::Module::mFirstUncheckedReceivedSubformula` [protected], [inherited]  
Stores the position of the first (by this module) unchecked sub-formula of the received formula.

**0.15.364.5.9 mFoundAnswer** `Conditionals` `smtrat::Module::mFoundAnswer` [protected], [inherited]  
Vector of Booleans: If any of them is true, we have to terminate a running check procedure.

**0.15.364.5.10 mFullCheck** `bool` `smtrat::Module::mFullCheck` [protected], [inherited]  
false, if this module should avoid too expensive procedures and rather return unknown instead.

**0.15.364.5.11 mInfeasibleSubsets** `std::vector<FormulaSetT>` `smtrat::Module::mInfeasibleSubsets` [protected], [inherited]  
Stores the infeasible subsets.

**0.15.364.5.12 mInformedConstraints** `carl::FastSet<FormulaT>` `smtrat::Module::mInformedConstraints` [protected], [inherited]  
Stores the position of the first constraint of which no backend has been informed about.

**0.15.364.5.13 mLastBranches** std::vector< Branching > smtrat::Module::mLastBranches = std::vector<Branching> (mNumOfBranchVarsToStore, Branching(typename Poly::PolyType(), 0)) [static], [inherited]

Stores the last branches in a cycle buffer.

**0.15.364.5.14 mLemmas** std::vector<Lemma> smtrat::Module::mLemmas [protected], [inherited]

Stores the lemmas being valid formulas this module or its backends made.

**0.15.364.5.15 mModel** Model smtrat::Module::mModel [mutable], [protected], [inherited]

Stores the assignment of the current satisfiable result, if existent.

**0.15.364.5.16 mModelComputed** bool smtrat::Module::mModelComputed [mutable], [protected], [inherited]

True, if the model has already been computed.

**0.15.364.5.17 mNumOfBranchVarsToStore** std::size\_t smtrat::Module::mNumOfBranchVarsToStore =

5 [static], [inherited]

The number of different variables to consider for a probable infinite loop of branchings.

**0.15.364.5.18 mObjectiveVariable** carl::Variable smtrat::Module::mObjectiveVariable [protected], [inherited]

Objective variable to be minimized. If set to NO\_VARIABLE, a normal sat check should be performed.

**0.15.364.5.19 mOldSplittingVariables** std::vector< FormulaT > smtrat::Module::mOldSplittingVariables [static], [inherited]

Reusable splitting variables.

**0.15.364.5.20 mpManager** Manager\* const smtrat::Module::mpManager [protected], [inherited]

A reference to the manager.

**0.15.364.5.21 mSmallerMusesCheckCounter** unsigned smtrat::Module::mSmallerMusesCheckCounter [mutable], [protected], [inherited]

Counter used for the generation of the smt2 files to check for smaller muses.

**0.15.364.5.22 mSolverState** std::atomic<Answer> smtrat::Module::mSolverState [protected], [inherited]

States whether the received formula is known to be satisfiable or unsatisfiable otherwise it is set to unknown.

**0.15.364.5.23 mTheoryPropagations** std::vector<TheoryPropagation> smtrat::Module::mTheoryPropagations [protected], [inherited]

**0.15.364.5.24 mUsedBackends** std::vector<[Module](#)\*> smtrat::Module::mUsedBackends [protected], [inherited]

The backends of this module which are currently used (conditions to use this module are fulfilled for the passed formula).

**0.15.364.5.25 mVariableCounters** std::vector<std::size\_t> smtrat::Module::mVariableCounters [protected], [inherited]

Maps variables to the number of their occurrences.

- void [clearPassedFormula](#) ()
 

*Clears the passed formula.*
- std::vector< [FormulaT](#) > [merge](#) (const std::vector< [FormulaT](#) > &, const std::vector< [FormulaT](#) > &) const
 

*Merges the two vectors of sets into the first one.*
- size\_t [determine\\_smallest\\_origin](#) (const std::vector< [FormulaT](#) > &\_origins) const
- bool [probablyLooping](#) (const typename Poly::PolyType &\_branchingPolynomial, const Rational &\_branchingValue) const
 

*Checks whether given the current branching value and branching variable/polynomial it is (highly) probable that this branching is part of an infinite loop of branchings.*
- bool [branchAt](#) (const Poly &\_polynomial, bool \_integral, const Rational &\_value, std::vector< [FormulaT](#) > &&\_premise, bool \_leftCaseWeak=true, bool \_preferLeftCase=true, bool \_useReceivedFormulaAsPremise=false)
 

*Adds a lemmas which provoke a branching for the given variable at the given value, if this module returns Unknown and there exists a preceding SATModule.*
- bool [branchAt](#) (const Poly &\_polynomial, bool \_integral, const Rational &\_value, bool \_leftCaseWeak=true, bool \_preferLeftCase=true, bool \_useReceivedFormulaAsPremise=false, const std::vector< [FormulaT](#) > &\_premise=std::vector< [FormulaT](#) >())
 

*Adds a lemmas which provoke a branching for the given variable at the given value, if this module returns Unknown and there exists a preceding SATModule.*
- bool [branchAt](#) (carl::Variable::Arg \_var, const Rational &\_value, std::vector< [FormulaT](#) > &&\_premise, bool \_leftCaseWeak=true, bool \_preferLeftCase=true, bool \_useReceivedFormulaAsPremise=false)
 

*Adds a lemmas which provoke a branching for the given variable at the given value, if this module returns Unknown and there exists a preceding SATModule.*
- bool [branchAt](#) (carl::Variable::Arg \_var, const Rational &\_value, bool \_leftCaseWeak=true, bool \_preferLeftCase=true, bool \_useReceivedFormulaAsPremise=false, const std::vector< [FormulaT](#) > &\_premise=std::vector< [FormulaT](#) >())
 

*Adds a lemmas which provoke a branching for the given variable at the given value, if this module returns Unknown and there exists a preceding SATModule.*
- void [splitUnequalConstraint](#) (const [FormulaT](#) &)
 

*Adds the following lemmas for the given constraint p!=0.*
- unsigned [checkModel](#) () const

- void `addInformationRelevantFormula` (const `FormulaT` &formula)  
*Adds a formula to the InformationRelevantFormula.*
- const std::set< `FormulaT` > & `getInformationRelevantFormulas` ()  
*Gets all InformationRelevantFormulas.*
- bool `isLemmaLevel` (`LemmaLevel` level)  
*Checks if current lemma level is greater or equal to given level.*

## Static Protected Member Functions

- static bool `modelsDisjoint` (const `Model` &\_modelA, const `Model` &\_modelB)  
*Checks whether there is no variable assigned by both models.*

## Protected Attributes

- std::vector< `FormulaSetT` > `mInfeasibleSubsets`  
*Stores the infeasible subsets.*
- `Manager` \*const `mpManager`  
*A reference to the manager.*
- `Model` `mModel`  
*Stores the assignment of the current satisfiable result, if existent.*
- std::vector< `Model` > `mAllModels`  
*Stores all satisfying assignments.*
- bool `mModelComputed`  
*True, if the model has already been computed.*
- bool `mFinalCheck`  
*true, if the check procedure should perform a final check which especially means not to postpone splitting decisions*
- bool `mFullCheck`  
*false, if this module should avoid too expensive procedures and rather return unknown instead.*
- carl::Variable `mObjectiveVariable`  
*Objective variable to be minimized. If set to NO\_VARIABLE, a normal sat check should be performed.*
- std::vector< `TheoryPropagation` > `mTheoryPropagations`
- std::atomic< `Answer` > `mSolverState`  
*States whether the received formula is known to be satisfiable or unsatisfiable otherwise it is set to unknown.*
- std::atomic\_bool \* `mBackendsFoundAnswer`  
*This flag is passed to any backend and if it determines an answer to a prior check call, this flag is fired.*
- `Conditionals` `mFoundAnswer`  
*Vector of Booleans: If any of them is true, we have to terminate a running check procedure.*
- std::vector< `Module` \* > `mUsedBackends`  
*The backends of this module which are currently used (conditions to use this module are fulfilled for the passed formula).*
- std::vector< `Module` \* > `mAllBackends`  
*The backends of this module which have been used.*
- std::vector< `Lemma` > `mLemmas`  
*Stores the lemmas being valid formulas this module or its backends made.*
- `ModuleInput::iterator` `mFirstSubformulaToPass`  
*Stores the position of the first sub-formula in the passed formula, which has not yet been considered for a consistency check of the backends.*
- carl::FastSet< `FormulaT` > `mConstraintsToInform`  
*Stores the constraints which the backends must be informed about.*
- carl::FastSet< `FormulaT` > `mInformedConstraints`  
*Stores the position of the first constraint of which no backend has been informed about.*
- `ModuleInput::const_iterator` `mFirstUncheckedReceivedSubformula`

- **unsigned mSmallerMusesCheckCounter**  
*Counter used for the generation of the smt2 files to check for smaller muses.*
- **std::vector< std::size\_t > mVariableCounters**  
*Maps variables to the number of their occurrences.*

### 0.15.366.3 Constructor & Destructor Documentation

**0.15.366.3.1 PFEModule()** template<typename Settings >  
smrat::PFEModule< Settings >::PFEModule ( const ModuleInput \* \_formula, Conditionals & \_conditionals, Manager \* \_manager = NULL )

**0.15.366.3.2 ~PFEModule()** template<typename Settings >  
smrat::PFEModule< Settings >::~PFEModule ( )

### 0.15.366.4 Member Function Documentation

**0.15.366.4.1 add()** bool smrat::PModule::add ( ModuleInput::const\_iterator \_subformula ) [inherited]  
The module has to take the given sub-formula of the received formula into account.

Parameters

|             |                                                    |
|-------------|----------------------------------------------------|
| _subformula | The sub-formula to take additionally into account. |
|-------------|----------------------------------------------------|

Returns

false, if it can be easily decided that this sub-formula causes a conflict with the already considered sub-formulas; true, otherwise.

**0.15.366.4.2 addConstraintToInform()** void smtrat::Module::addConstraintToInform ( const FormulaT & \_constraint ) [protected], [virtual], [inherited]  
Adds a constraint to the collection of constraints of this module, which are informed to a freshly generated backend.

Parameters

|             |                        |
|-------------|------------------------|
| _constraint | The constraint to add. |
|-------------|------------------------|

Reimplemented in [smtrat::SATModule< Settings >](#).

**0.15.366.4.3 addCore()** template<typename Settings >

bool smtrat::PFEModule< Settings >::addCore ( ModuleInput::const\_iterator formula ) [virtual]

The module has to take the given sub-formula of the received formula into account.

Parameters

|         |                                                    |
|---------|----------------------------------------------------|
| formula | The sub-formula to take additionally into account. |
|---------|----------------------------------------------------|

Returns

false, if it can be easily decided that this sub-formula causes a conflict with the already considered sub-formulas; true, otherwise.

Reimplemented from [smtrat::Module](#).

**0.15.366.4.4 addInformationRelevantFormula()** void smtrat::Module::addInformationRelevantFormula

(

const FormulaT & formula ) [protected], [inherited]

Adds a formula to the InformationRelevantFormula.

Parameters

|         |                |
|---------|----------------|
| formula | Formula to add |
|---------|----------------|

**0.15.366.4.5 addLemma()** void smtrat::Module::addLemma (

const FormulaT & \_lemma,

const LemmaType & \_lt = LemmaType::NORMAL,

const FormulaT & \_preferredFormula = FormulaT( carl::FormulaType::TRUE ) ) [inline],

[inherited]

Stores a lemma being a valid formula.

Parameters

|                   |                                                                       |
|-------------------|-----------------------------------------------------------------------|
| _lemma            | The eduction/lemma to store.                                          |
| _lt               | The type of the lemma.                                                |
| _preferredFormula | Hint for the next decision, which formula should be assigned to true. |

**0.15.366.4.6 addOrigin()** void smtrat::Module::addOrigin (

ModuleInput::iterator \_formula,

```
const FormulaT & _origin) [inline], [protected], [inherited]
Adds the given set of formulas in the received formula to the origins of the given passed formula.
```

#### Parameters

|                       |                                                           |
|-----------------------|-----------------------------------------------------------|
| <code>_formula</code> | The passed formula to set the origins for.                |
| <code>_origin</code>  | A set of formulas in the received formula of this module. |

**0.15.366.4.7 addReceivedSubformulaToPassedFormula()** std::pair<[ModuleInput::iterator](#),bool>  
`smtrat::Module::addReceivedSubformulaToPassedFormula (`

```
 ModuleInput::const_iterator _subformula) [inline], [protected], [inherited]
```

Copies the given sub-formula of the received formula to the passed formula.

Note, that there is always a link between sub-formulas of the passed formulas to sub-formulas of the received formulas, which are responsible for its occurrence.

#### Parameters

|                          |                                                  |
|--------------------------|--------------------------------------------------|
| <code>_subformula</code> | The sub-formula of the received formula to copy. |
|--------------------------|--------------------------------------------------|

**0.15.366.4.8 addSubformulaToPassedFormula() [1/3]** std::pair<[ModuleInput::iterator](#),bool> smtrat<->  
`::Module::addSubformulaToPassedFormula (`

```
 const FormulaT & _formula) [inline], [protected], [inherited]
```

Adds the given formula to the passed formula with no origin.

Note that in the next call of this module's removeSubformula, all formulas in the passed formula without origins will be removed.

#### Parameters

|                       |                                           |
|-----------------------|-------------------------------------------|
| <code>_formula</code> | The formula to add to the passed formula. |
|-----------------------|-------------------------------------------|

#### Returns

A pair to the position where the formula to add has been inserted (or its first sub-formula which has not yet been in the passed formula, in case the formula to add is a conjunction), and a Boolean stating whether anything has been added to the passed formula.

**0.15.366.4.9 addSubformulaToPassedFormula() [2/3]** std::pair<[ModuleInput::iterator](#),bool> smtrat<->  
`::Module::addSubformulaToPassedFormula (`

```
 const FormulaT & _formula,
```

```
 const FormulaT & _origin) [inline], [protected], [inherited]
```

Adds the given formula to the passed formula.

#### Parameters

|                       |                                                                                                                           |
|-----------------------|---------------------------------------------------------------------------------------------------------------------------|
| <code>_formula</code> | The formula to add to the passed formula.                                                                                 |
| <code>_origin</code>  | The sub-formula of the received formula being responsible for the occurrence of the formula to add to the passed formula. |

**Returns**

A pair to the position where the formula to add has been inserted (or its first sub-formula which has not yet been in the passed formula, in case the formula to add is a conjunction), and a Boolean stating whether anything has been added to the passed formula.

**0.15.366.4.10 addSubformulaToPassedFormula() [3/3] std::pair<ModuleInput::iterator,bool>**

```
smrat::Module::addSubformulaToPassedFormula (
 const FormulaT & _formula,
 const std::shared_ptr< std::vector< FormulaT >> & _origins) [inline], [protected],
[inherited]
```

Adds the given formula to the passed formula.

**Parameters**

|                       |                                                                                                                                         |
|-----------------------|-----------------------------------------------------------------------------------------------------------------------------------------|
| <code>_formula</code> | The formula to add to the passed formula.                                                                                               |
| <code>_origins</code> | The link of the formula to add to the passed formula to sub-formulas of the received formulas, which are responsible for its occurrence |

**Returns**

A pair to the position where the formula to add has been inserted (or its first sub-formula which has not yet been in the passed formula, in case the formula to add is a conjunction), and a Boolean stating whether anything has been added to the passed formula.

**0.15.366.4.11 allModels() const std::vector<Model>& smrat::Module::allModels () const [inline], [inherited]****Returns**

All satisfying assignments, if existent.

**0.15.366.4.12 anAnswerFound() bool smrat::Module::anAnswerFound () const [inline], [protected], [inherited]**

Checks for all antecedent modules and those which run in parallel with the same antecedent modules, whether one of them has determined a result.

**Returns**

True, if one of them has determined a result.

**0.15.366.4.13 answerFound() const smrat::Conditionals& smrat::Module::answerFound () const [inline], [inherited]****Returns**

A vector of Booleans: If any of them is true, we have to terminate a running check procedure.

**0.15.366.4.14 appliedPreprocessing() bool smrat::PModule::appliedPreprocessing () const [inline], [inherited]****Returns**

true, if the current received formula has been simplified and the result of this simplification is stored in the passed formula.

**0.15.366.4.15 `backendsModel()`** const `Model` & smtrat::Module::backendsModel () const [protected], [inherited]

Stores the model of a backend which determined satisfiability of the passed formula in the model of this module.

**0.15.366.4.16 `branchAt() [1/4]`** bool smtrat::Module::branchAt ( carl::Variable::Arg \_var, const Rational & \_value, bool \_leftCaseWeak = true, bool \_preferLeftCase = true, bool \_useReceivedFormulaAsPremise = false, const std::vector< `FormulaT` > & \_premise = std::vector<`FormulaT`>() ) [inline], [protected], [inherited]

**0.15.366.4.17 `branchAt() [2/4]`** bool smtrat::Module::branchAt ( carl::Variable::Arg \_var, const Rational & \_value, std::vector< `FormulaT` > && \_premise, bool \_leftCaseWeak = true, bool \_preferLeftCase = true, bool \_useReceivedFormulaAsPremise = false ) [inline], [protected], [inherited]

**0.15.366.4.18 `branchAt() [3/4]`** bool smtrat::Module::branchAt ( const Poly & \_polynomial, bool \_integral, const Rational & \_value, bool \_leftCaseWeak = true, bool \_preferLeftCase = true, bool \_useReceivedFormulaAsPremise = false, const std::vector< `FormulaT` > & \_premise = std::vector<`FormulaT`>() ) [inline], [protected], [inherited]

**0.15.366.4.19 `branchAt() [4/4]`** bool smtrat::Module::branchAt ( const Poly & \_polynomial, bool \_integral, const Rational & \_value, std::vector< `FormulaT` > && \_premise, bool \_leftCaseWeak = true, bool \_preferLeftCase = true, bool \_useReceivedFormulaAsPremise = false ) [protected], [inherited]

Adds a lemmas which provoke a branching for the given variable at the given value, if this module returns Unknown and there exists a preceding `SATModule`.

Note that the given value is rounded down and up, if the given variable is integer-valued.

#### Parameters

|                            |                                                                                                                                                                                                                |
|----------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>_polynomial</code>   | The variable to branch for.                                                                                                                                                                                    |
| <code>_integral</code>     | A flag being true, if all variables in the polynomial to branch for are integral.                                                                                                                              |
| <code>_value</code>        | The value to branch at.                                                                                                                                                                                        |
| <code>_premise</code>      | The sub-formulas of the received formula from which the branch is followed. Note, that a premise is not necessary, as every branch is a valid formula. But a premise can prevent from branching unnecessarily. |
| <code>_leftCaseWeak</code> | true, if a branching in the form of (or ( $\leq p b$ ) ( $> p b$ )) is desired. false, if a branching in the form of (or ( $< p b$ ) ( $\geq p b$ )) is desired.                                               |

**Parameters**

|                                           |                                                                                              |
|-------------------------------------------|----------------------------------------------------------------------------------------------|
| <code>_preferLeftCase</code>              | true, if the left case (polynomial less(or equal) 0 shall be chosen first. false, otherwise. |
| <code>_useReceivedFormulaAsPremise</code> | true, if the whole received formula should be used as premise                                |

**0.15.366.4.20 `check()`** `Answer smtrat::PModule::check (`

```
 bool _final = false,
 bool _full = true,
 carl::Variable _objective = carl::Variable::NO_VARIABLE) [virtual], [inherited]
```

Checks the received formula for consistency.

Note, that this is an implementation of the satisfiability check of the conjunction of the so far received formulas, which does actually nothing but passing the problem to its backends. This implementation is only used internally and must be overwritten by any derived module.

**Parameters**

|                         |                                                                                                                                       |
|-------------------------|---------------------------------------------------------------------------------------------------------------------------------------|
| <code>_final</code>     | true, if this satisfiability check will be the last one (for a global sat-check), if its result is SAT                                |
| <code>_full</code>      | false, if this module should avoid too expensive procedures and rather return unknown instead.                                        |
| <code>_objective</code> | if not set to NO_VARIABLE, the module should find an assignment minimizing this objective variable; otherwise any assignment is good. |

**Returns**

True, if the received formula is satisfiable; False, if the received formula is not satisfiable; Unknown, otherwise.

Reimplemented from [smtrat::Module](#).

**0.15.366.4.21 `checkCore()`** `template<typename Settings >`

```
Answer smtrat::PFEModule< Settings >::checkCore () [virtual]
```

Checks the received formula for consistency.

**Returns**

SAT, if the received formula is satisfiable; UNSAT, if the received formula is not satisfiable; Unknown, otherwise.

Reimplemented from [smtrat::Module](#).

**0.15.366.4.22 `checkInfeasibleSubsetForMinimality()`** `void smtrat::Module::checkInfeasibleSubsetForMinimality (`

```
 std::vector< FormulaSet >::const_iterator _infssubset,
 const std::string & _filename = "smaller_muses",
 unsigned _maxSizeDifference = 1) const [inherited]
```

Checks the given infeasible subset for minimality by storing all subsets of it, which have a smaller size which differs from the size of the infeasible subset not more than the given threshold.

**Parameters**

|                                 |                                                                                                        |
|---------------------------------|--------------------------------------------------------------------------------------------------------|
| <code>_infssubset</code>        | The infeasible subset to check for minimality.                                                         |
| <code>_filename</code>          | The name of the file to store the infeasible subsets in order to be able to check their infeasibility. |
| <code>_maxSizeDifference</code> | The maximal difference between the sizes of the subsets compared to the size of the infeasible subset. |

**0.15.366.4.23 `checkModel()`** `unsigned smtrat::Module::checkModel ( ) const [protected], [inherited]`

**Returns**

false, if the current model of this module does not satisfy the current given formula; true, if it cannot be said whether the model satisfies the given formula.

**0.15.366.4.24 `cleanModel()`** `void smtrat::Module::cleanModel ( ) const [inline], [protected], [inherited]`

Substitutes variable occurrences by its model value in the model values of other variables.

**0.15.366.4.25 `clearLemmas()`** `void smtrat::Module::clearLemmas ( ) [inline], [inherited]`  
Deletes all yet found lemmas.

**0.15.366.4.26 `clearModel()`** `void smtrat::Module::clearModel ( ) const [inline], [protected], [inherited]`

Clears the assignment, if any was found.

**0.15.366.4.27 `clearModels()`** `void smtrat::Module::clearModels ( ) const [inline], [protected], [inherited]`

Clears all assignments, if any was found.

**0.15.366.4.28 `clearPassedFormula()`** `void smtrat::Module::clearPassedFormula ( ) [protected], [inherited]`

**0.15.366.4.29 `collectOrigins() [1/2]`** `void smtrat::Module::collectOrigins ( const FormulaT & _formula, FormulaSetT & _origins ) const [inherited]`

**0.15.366.4.30 `collectOrigins() [2/2]`** `void smtrat::Module::collectOrigins ( const FormulaT & _formula, FormulasT & _origins ) const [inherited]`

Collects the formulas in the given formula, which are part of the received formula.

If the given formula directly occurs in the received formula, it is inserted into the given set. Otherwise, the given formula must be of type AND and all its sub-formulas part of the received formula. Hence, they will be added to the given set.

**Parameters**

|                       |                                                                                                      |
|-----------------------|------------------------------------------------------------------------------------------------------|
| <code>_formula</code> | The formula from which to collect the formulas being sub-formulas of the received formula (origins). |
| <code>_origins</code> | The set in which to store the origins.                                                               |

**0.15.366.4.31 `collectTheoryPropagations()`** `void smtrat::Module::collectTheoryPropagations ( ) [inherited]`

**0.15.366.4.32 constraintsToInform()** const carl::FastSet<[FormulaT](#)>& smrat::Module::constraintsToInform( ) const [inline], [inherited]

**Returns**

The constraints which the backends must be informed about.

**0.15.366.4.33 currentlySatisfied()** virtual unsigned smrat::Module::currentlySatisfied( const [FormulaT](#) & ) const [inline], [virtual], [inherited]

**Returns**

0, if the given formula is conflicted by the current model; 1, if the given formula is satisfied by the current model; 2, otherwise; 3, if we do not know anything (default)

Reimplemented in [smrat::LRAbstractModule< Settings >](#), [smrat::LRAbstractModule< LRASettingsICP >](#), and [smrat::LRAbstractModule< LRASettings >](#)

**0.15.366.4.34 currentlySatisfiedByBackend()** unsigned smrat::Module::currentlySatisfiedByBackend( const [FormulaT](#) & \_formula ) const [inherited]

**Returns**

0, if the given formula is conflicted by the current model; 1, if the given formula is satisfied by the current model; 2, otherwise 3, if we do not know anything (default)

**0.15.366.4.35 deinform()** void smrat::Module::deinform( const [FormulaT](#) & \_constraint ) [inherited]

The inverse of informing about a constraint.

All data structures which were kept regarding this constraint are going to be removed. Note, that this makes only sense if it is not likely enough that a formula with this constraint must be solved again.

**Parameters**

|                          |                                                         |
|--------------------------|---------------------------------------------------------|
| <code>_constraint</code> | The constraint to remove from internal data structures. |
|--------------------------|---------------------------------------------------------|

**0.15.366.4.36 deinformCore()** virtual void smrat::Module::deinformCore( const [FormulaT](#) & \_constraint ) [inline], [protected], [virtual], [inherited]

The inverse of informing about a constraint.

All data structures which were kept regarding this constraint are going to be removed. Note, that this makes only sense if it is not likely enough that a formula with this constraint must be solved again.

**Parameters**

|                          |                                                         |
|--------------------------|---------------------------------------------------------|
| <code>_constraint</code> | The constraint to remove from internal data structures. |
|--------------------------|---------------------------------------------------------|

Reimplemented in [smrat::LRAbstractModule< Settings >](#), [smrat::LRAbstractModule< LRASettingsICP >](#), and [smrat::LRAbstractModule< LRASettings >](#)

**0.15.366.4.37 determine\_smallest\_origin()** size\_t smrat::Module::determine\_smallest\_origin( const std::vector< [FormulaT](#) > & origins ) const [protected], [inherited]

## Parameters

|                       |                              |
|-----------------------|------------------------------|
| <code>_origins</code> | A vector of sets of origins. |
|-----------------------|------------------------------|

## Returns

The index of the smallest (regarding the size of the sets) element of origins

**0.15.366.4.38 `eraseSubformulaFromPassedFormula()`** `ModuleInput::iterator smtrat::Module::eraseSubformulaFromPassedFormula (`

```
ModuleInput::iterator _subformula,
bool _ignoreOrigins = false) [protected], [virtual], [inherited]
```

Removes everything related to the sub-formula to remove from the passed formula in the backends of this module. Afterwards the sub-formula is removed from the passed formula.

## Parameters

|                             |                                                                                                              |
|-----------------------------|--------------------------------------------------------------------------------------------------------------|
| <code>_subformula</code>    | The sub-formula to remove from the passed formula.                                                           |
| <code>_ignoreOrigins</code> | True, if the sub-formula shall be removed regardless of its origins (should only be applied with expertise). |

## Returns

Reimplemented in `smtrat::ICPModule< Settings >`, `smtrat::ICPModule< ICPSettings4 >`, and `smtrat::ICPModule< ICPSettings1 >`.

**0.15.366.4.39 `excludeNotReceivedVariablesFromModel()`** `void smtrat::Module::excludeNotReceivedVariablesFromModel ( ) const [inherited]`

Excludes all variables from the current model, which do not occur in the received formula.

**0.15.366.4.40 `findBestOrigin()`** `std::vector< FormulaT >::const_iterator smtrat::Module::findBestOrigin (`

```
const std::vector< FormulaT > & _origins) const [protected], [inherited]
```

## Parameters

|                       |  |
|-----------------------|--|
| <code>_origins</code> |  |
|-----------------------|--|

## Returns

**0.15.366.4.41 `firstSubformulaToPass()`** `ModuleInput::const_iterator smtrat::Module::firstSubformulaToPass ( ) const [inline], [inherited]`

## Returns

The position of the first sub-formula in the passed formula, which has not yet been considered for a consistency check of the backends.

**0.15.366.4.42 firstUncheckedReceivedSubformula()** `ModuleInput::const_iterator smtrat::Module::firstUncheckedReceivedSubformula ( ) const [inline], [inherited]`

**Returns**

The position of the first (by this module) unchecked sub-formula of the received formula.

**0.15.366.4.43 freeSplittingVariable()** `static void smtrat::Module::freeSplittingVariable ( const FormulaT & _splittingVariable ) [inline], [static], [inherited]`

**0.15.366.4.44 generateTrivialInfeasibleSubset()** `void smtrat::Module::generateTrivialInfeasibleSubset ( ) [inline], [protected], [inherited]`

Stores the trivial infeasible subset being the set of received formulas.

**0.15.366.4.45 getBackendsAllModels()** `void smtrat::Module::getBackendsAllModels ( ) const [protected], [inherited]`

Stores all models of a backend in the list of all models of this module.

**0.15.366.4.46 getBackendsModel()** `void smtrat::Module::getBackendsModel ( ) const [protected], [inherited]`

**0.15.366.4.47 getInfeasibleSubsets() [1/2]** `void smtrat::Module::getInfeasibleSubsets ( ) [protected], [inherited]`

Copies the infeasible subsets of the passed formula.

**0.15.366.4.48 getInfeasibleSubsets() [2/2]** `std::vector< FormulaSetT > smtrat::Module::getInfeasibleSubsets (`

`const Module & _backend ) const [protected], [inherited]`

Get the infeasible subsets the given backend provides.

Note, that an infeasible subset in a backend contains sub formulas of the passed formula and an infeasible subset of this module contains sub formulas of the received formula. In this method the LATTER is returned.

**Parameters**

|                       |                                                          |
|-----------------------|----------------------------------------------------------|
| <code>_backend</code> | The backend from which to obtain the infeasible subsets. |
|-----------------------|----------------------------------------------------------|

**Returns**

The infeasible subsets the given backend provides.

**0.15.366.4.49 getInformationRelevantFormulas()** `const std::set< FormulaT > & smtrat::Module::getInformationRelevantFormulas ( ) [protected], [inherited]`

Gets all InformationRelevantFormulas.

**Returns**

Set of all formulas

**0.15.366.4.50 `getModelEqualities()`** `std::list< std::vector< carl::Variable > > smtrat::Module::getModelEqualities ( ) const [virtual], [inherited]`

Partition the variables from the current model into equivalence classes according to their assigned value.

The result is a set of equivalence classes of variables where all variables within one class are assigned the same value. Note that the number of classes may not be minimal, i.e. two classes may actually be equivalent.

#### Returns

Equivalence classes.

**0.15.366.4.51 `getOrigins() [1/3]`** `void smtrat::Module::getOrigins (`

```
const FormulaT & _formula,
FormulaSetT & _origins) const [inline], [protected], [inherited]
```

#### Parameters

|                       |  |
|-----------------------|--|
| <code>_formula</code> |  |
| <code>_origins</code> |  |

**0.15.366.4.52 `getOrigins() [2/3]`** `void smtrat::Module::getOrigins (`

```
const FormulaT & _formula,
FormulasT & _origins) const [inline], [protected], [inherited]
```

#### Parameters

|                       |  |
|-----------------------|--|
| <code>_formula</code> |  |
| <code>_origins</code> |  |

**0.15.366.4.53 `getOrigins() [3/3]`** `const FormulaT& smtrat::Module::getOrigins (`

```
ModuleInput::const_iterator _formula) const [inline], [protected], [inherited]
```

Gets the origins of the passed formula at the given position.

#### Parameters

|                       |                                                   |
|-----------------------|---------------------------------------------------|
| <code>_formula</code> | The position of a formula in the passed formulas. |
|-----------------------|---------------------------------------------------|

#### Returns

The origins of the passed formula at the given position.

**0.15.366.4.54 `getReceivedFormulaSimplified()`** `std::pair< bool, FormulaT > smtrat::PModule::getReceivedFormulaSimplified ( ) [virtual], [inherited]`

#### Returns

A pair of a Boolean and a formula, where the Boolean is true, if the received formula could be simplified to an equisatisfiable formula. The formula is equisatisfiable to this module's received formula, if the Boolean is true.

Reimplemented from [smtrat::Module](#).

**0.15.366.4.55 hasLemmas()** `bool smrat::Module::hasLemmas () [inline], [inherited]`  
Checks whether this module or any of its backends provides any lemmas.

**0.15.366.4.56 hasValidInfeasibleSubset()** `bool smrat::Module::hasValidInfeasibleSubset () const [inherited]`

**Returns**

true, if the module has at least one valid infeasible subset, that is all its elements are sub-formulas of the received formula (pointer must be equal).

**0.15.366.4.57 id()** `std::size_t smrat::Module::id () const [inline], [inherited]`

**Returns**

A unique ID to identify this module instance.

**0.15.366.4.58 infeasibleSubsets()** `const std::vector<FormulaSetT>& smrat::Module::infeasibleSubsets () const [inline], [inherited]`

**Returns**

The infeasible subsets of the set of received formulas (empty, if this module has not detected unsatisfiability of the conjunction of received formulas).

**0.15.366.4.59 inform()** `bool smrat::Module::inform (const FormulaT & _constraint) [inherited]`

Informs the module about the given constraint.

It should be tried to inform this module about any constraint it could receive eventually before assertSubformula is called (preferably for the first time, but at least before adding a formula containing that constraint).

**Parameters**

|                          |                                 |
|--------------------------|---------------------------------|
| <code>_constraint</code> | The constraint to inform about. |
|--------------------------|---------------------------------|

**Returns**

false, if it can be easily decided whether the given constraint is inconsistent; true, otherwise.

**0.15.366.4.60 informBackends()** `void smrat::Module::informBackends (const FormulaT & _constraint) [inline], [protected], [inherited]`

Informs all backends of this module about the given constraint.

**Parameters**

|                          |                                 |
|--------------------------|---------------------------------|
| <code>_constraint</code> | The constraint to inform about. |
|--------------------------|---------------------------------|

**0.15.366.4.61 informCore()** `virtual bool smrat::Module::informCore (const FormulaT & _constraint) [inline], [protected], [virtual], [inherited]`

Informs the module about the given constraint.

It should be tried to inform this module about any constraint it could receive eventually before assertSubformula is called (preferably for the first time, but at least before adding a formula containing that constraint).

#### Parameters

|                          |                                 |
|--------------------------|---------------------------------|
| <code>_constraint</code> | The constraint to inform about. |
|--------------------------|---------------------------------|

#### Returns

`false`, if it can be easily decided whether the given constraint is inconsistent; `true`, otherwise.

Reimplemented in [smrat::UnionFindModule< Settings >](#), [smrat::PBPPModule< Settings >](#), [smrat::PBGaussModule< Settings >](#), [smrat::NRAILModule< Settings >](#), [smrat::NewCoveringModule< Settings >](#), [smrat::NewCADModule< Settings >](#), [smrat::LRAModule< Settings >](#), [smrat::LRAModule< LRASettingsICP >](#), [smrat::LRAModule< LRASettings1 >](#), [smrat::IntBlastModule< Settings >](#), [smrat::FPPModule< Settings >](#), [smrat::EQModule< Settings >](#), [smrat::CurryModule< Settings >](#), [smrat::BVMModule< Settings >](#), [smrat::ICPModule< Settings >](#), [smrat::ICPModule< ICPSettings4 >](#), and [smrat::ICPModule< ICPSettings1 >](#).

#### 0.15.366.4.62 informedConstraints()

```
const carl::FastSet<FormulaT>& smrat::Module::informed<→
Constraints () const [inline], [inherited]
```

#### Returns

The position of the first constraint of which no backend has been informed about.

#### 0.15.366.4.63 init()

```
void smrat::Module::init () [virtual], [inherited]
```

Informs all backends about the so far encountered constraints, which have not yet been communicated.

This method must not be called twice and only before the first runBackends call.

Reimplemented in [smrat::PBPPModule< Settings >](#), [smrat::PBGaussModule< Settings >](#), [smrat::NRAILModule< Settings >](#), [smrat::NewCoveringModule< Settings >](#), [smrat::NewCADModule< Settings >](#), [smrat::LRAModule< Settings >](#), [smrat::LRAModule< LRASettingsICP >](#), [smrat::LRAModule< LRASettings1 >](#), [smrat::IntBlastModule< Settings >](#), [smrat::FPPModule< Settings >](#), [smrat::EQModule< Settings >](#), [smrat::CurryModule< Settings >](#), and [smrat::BVMModule< Settings >](#).

#### 0.15.366.4.64 is\_minimizing()

```
bool smrat::Module::is_minimizing () const [inline], [inherited]
```

#### 0.15.366.4.65 isLemmaLevel()

```
bool smrat::Module::isLemmaLevel (
 LemmaLevel level) [protected], [inherited]
```

Checks if current lemma level is greater or equal to given level.

#### Parameters

|                    |                 |
|--------------------|-----------------|
| <code>level</code> | Level to check. |
|--------------------|-----------------|

#### 0.15.366.4.66 isPreprocessor()

```
bool smrat::PModule::isPreprocessor () const [inline], [inherited]
```

#### Returns

`true`, if this module is a preprocessor that is a module, which simplifies its received formula to an equisatisfiable formula being passed to its backends. The simplified formula can be obtained with [getReceivedFormulaSimplified\(\)](#).

**0.15.366.4.67 lemmas()** const std::vector<[Lemma](#)>& smtrat::Module::lemmas ( ) const [inline], [inherited]

**Returns**

A constant reference to the lemmas being valid formulas this module or its backends made.

**0.15.366.4.68 merge()** std::vector< [FormulaT](#) > smtrat::Module::merge ( const std::vector< [FormulaT](#) > & [\\_vecSetA](#), const std::vector< [FormulaT](#) > & [\\_vecSetB](#) ) const [protected], [inherited]

Merges the two vectors of sets into the first one.

({a,b},{a,c}) and ({b,d},{b}) -> ({a,b,d},{a,b},{a,b,c,d},{a,b,c})

**Parameters**

|                          |                                  |
|--------------------------|----------------------------------|
| <a href="#">_vecSetA</a> | A vector of sets of constraints. |
| <a href="#">_vecSetB</a> | A vector of sets of constraints. |

**Returns**

The vector being the two given vectors merged.

**0.15.366.4.69 model()** const [Model](#)& smtrat::Module::model ( ) const [inline], [inherited]

**Returns**

The assignment of the current satisfiable result, if existent.

**0.15.366.4.70 modelsDisjoint()** bool smtrat::Module::modelsDisjoint ( const [Model](#) & [\\_modelA](#), const [Model](#) & [\\_modelB](#) ) [static], [protected], [inherited]

Checks whether there is no variable assigned by both models.

**Parameters**

|                         |                                |
|-------------------------|--------------------------------|
| <a href="#">_modelA</a> | The first model to check for.  |
| <a href="#">_modelB</a> | The second model to check for. |

**Returns**

true, if there is no variable assigned by both models; false, otherwise.

**0.15.366.4.71 moduleName()** virtual std::string smtrat::Module::moduleName ( ) const [inline], [virtual], [inherited]

**Returns**

The name of the given module type as name.

Reimplemented in `smrat::VSModule< Settings >`, `smrat::UnionFindModule< Settings >`, `smrat::UFCegarModule< Settings >`, `smrat::STropModule< Settings >`, `smrat::SplitSOSModule< Settings >`, `smrat::PBPPModule< Settings >`, `smrat::PBGaussModule< Settings >`, `smrat::NRAILModule< Settings >`, `smrat::NewCADModule< Settings >`, `smrat::LVEModule< Settings >`, `smrat::LRAModule< Settings >`, `smrat::LRAModule< LRASettingsICP >`, `smrat::LRAModule< LRASettings1 >`, `smrat::IntEqModule< Settings >`, `smrat::IntBlastModule< Settings >`, `smrat::IncWidthModule< Settings >`, `smrat::ICPModule< Settings >`, `smrat::ICPModule< ICPSettings4 >`, `smrat::ICPModule< ICPSettings1 >`, `smrat::GBModule< Settings >`, `smrat::FouMoModule< Settings >`, `smrat::EQPreprocessingModule< Settings >`, `smrat::EQModule< Settings >`, `smrat::CurryModule< Settings >`, `smrat::CubeLIAModule< Settings >`, `smrat::CSplitModule< Settings >`, `smrat::BVMModule< Settings >`, and `smrat::BEModule< Settings >`.

**0.15.366.4.72 `objective()`** `carl::Variable smrat::Module::objective ( ) const [inline], [inherited]`**0.15.366.4.73 `originInReceivedFormula()`** `bool smrat::Module::originInReceivedFormula ( const FormulaT & _origin ) const [protected], [inherited]`**0.15.366.4.74 `passedFormulaBegin()`** `ModuleInput::iterator smrat::Module::passedFormulaBegin ( ) [inline], [protected], [inherited]`**Returns**

An iterator to the end of the passed formula. TODO: disable this method

**0.15.366.4.75 `passedFormulaEnd()`** `ModuleInput::iterator smrat::Module::passedFormulaEnd ( ) [inline], [protected], [inherited]`**Returns**

An iterator to the end of the passed formula.

**0.15.366.4.76 `pPassedFormula()`** `const ModuleInput* smrat::Module::pPassedFormula ( ) const [inline], [inherited]`**Returns**

A pointer to the formula passed to the backends of this module.

**0.15.366.4.77 `pReceivedFormula()`** `const ModuleInput* smrat::Module::pReceivedFormula ( ) const [inline], [inherited]`**Returns**

A pointer to the formula passed to this module.

**0.15.366.4.78 `print()`** `void smrat::Module::print ( const std::string & _initiation = "***" ) const [inherited]`

Prints everything relevant of the solver.

**Parameters**

|                    |                      |
|--------------------|----------------------|
| <i>_initiation</i> | The line initiation. |
|--------------------|----------------------|

**0.15.366.4.79 printAllModels()** void smtrat::Module::printAllModels ( std::ostream & *\_out* = std::cout ) [inherited]

Prints all assignments of this module satisfying its received formula if it satisfiable and this module could find an assignment.

**Parameters**

|             |                                        |
|-------------|----------------------------------------|
| <i>_out</i> | The stream to print the assignment on. |
|-------------|----------------------------------------|

**0.15.366.4.80 printInfeasibleSubsets()** void smtrat::Module::printInfeasibleSubsets ( const std::string & *\_initiation* = "\*\*\*" ) const [inherited]

Prints the infeasible subsets.

**Parameters**

|                    |                      |
|--------------------|----------------------|
| <i>_initiation</i> | The line initiation. |
|--------------------|----------------------|

**0.15.366.4.81 printModel()** void smtrat::Module::printModel ( std::ostream & *\_out* = std::cout ) const [inherited]

Prints the assignment of this module satisfying its received formula if it satisfiable and this module could find an assignment.

**Parameters**

|             |                                        |
|-------------|----------------------------------------|
| <i>_out</i> | The stream to print the assignment on. |
|-------------|----------------------------------------|

**0.15.366.4.82 printPassedFormula()** void smtrat::Module::printPassedFormula ( const std::string & *\_initiation* = "\*\*\*" ) const [inherited]

Prints the vector of passed formula.

**Parameters**

|                    |                      |
|--------------------|----------------------|
| <i>_initiation</i> | The line initiation. |
|--------------------|----------------------|

**0.15.366.4.83 printReceivedFormula()** void smtrat::Module::printReceivedFormula ( const std::string & *\_initiation* = "\*\*\*" ) const [inherited]

Prints the vector of the received formula.

**Parameters**

|                    |                      |
|--------------------|----------------------|
| <i>_initiation</i> | The line initiation. |
|--------------------|----------------------|

```
0.15.366.4.84 probablyLooping() bool smtrat::Module::probablyLooping (
 const typename Poly::PolyType & _branchingPolynomial,
 const Rational & _branchingValue) const [protected], [inherited]
```

Checks whether given the current branching value and branching variable/polynomial it is (highly) probable that this branching is part of an infinite loop of branchings.

#### Parameters

|                             |                                                                                     |
|-----------------------------|-------------------------------------------------------------------------------------|
| <i>_branchingPolynomial</i> | The polynomial to branch at (in most branching strategies this is just a variable). |
| <i>_branchingValue</i>      | The value to branch at.                                                             |

#### Returns

true, if this branching is probably part of an infinite loop of branchings; false, otherwise.

```
0.15.366.4.85 receivedFormulaChecked() void smtrat::Module::receivedFormulaChecked () [inline], [inherited]
```

Notifies that the received formulas has been checked.

```
0.15.366.4.86 receivedFormulasAsInfeasibleSubset() void smtrat::Module::receivedFormulasAs<= InfeasibleSubset (
```

```
 ModuleInput::const_iterator _subformula) [inline], [protected], [inherited]
```

Stores an infeasible subset consisting only of the given received formula.

```
0.15.366.4.87 receivedVariable() bool smtrat::Module::receivedVariable (
 carl::Variable::Arg _var) const [inline], [inherited]
```

```
0.15.366.4.88 remove() void smtrat::PModule::remove (
```

```
 ModuleInput::const_iterator _subformula) [virtual], [inherited]
```

Removes everything related to the given sub-formula of the received formula.

However, it is desired not to lose track of search spaces where no satisfying assignment can be found for the remaining sub-formulas.

#### Parameters

|                    |                                                    |
|--------------------|----------------------------------------------------|
| <i>_subformula</i> | The sub formula of the received formula to remove. |
|--------------------|----------------------------------------------------|

Reimplemented from [smtrat::Module](#).

```
0.15.366.4.89 removeCore() template<typename Settings >
void smtrat::PFEModule< Settings >::removeCore (
 ModuleInput::const_iterator formula) [virtual]
```

Removes everything related to the given sub-formula of the received formula.

However, it is desired not to lose track of search spaces where no satisfying assignment can be found for the remaining sub-formulas.

#### Parameters

|                |                                                    |
|----------------|----------------------------------------------------|
| <i>formula</i> | The sub formula of the received formula to remove. |
|----------------|----------------------------------------------------|

Reimplemented from [smrat::Module](#).

**0.15.366.4.90 removeOrigin()** `std::pair<ModuleInput::iterator, bool> smrat::Module::removeOrigin (`

```
 ModuleInput::iterator _formula,
 const FormulaT & _origin) [inline], [protected], [inherited]
```

**0.15.366.4.91 removeOrigins()** `std::pair<ModuleInput::iterator, bool> smrat::Module::removeOrigins (`

```
 ModuleInput::iterator _formula,
 const std::shared_ptr< std::vector< FormulaT >> & _origins) [inline], [protected],
[inherited]
```

**0.15.366.4.92 rPassedFormula()** `const ModuleInput& smrat::Module::rPassedFormula ( ) const`  
`[inline], [inherited]`

#### Returns

A reference to the formula passed to the backends of this module.

**0.15.366.4.93 rReceivedFormula()** `const ModuleInput& smrat::Module::rReceivedFormula ( ) const`  
`[inline], [inherited]`

#### Returns

A reference to the formula passed to this module.

**0.15.366.4.94 runBackends() [1/2]** `virtual Answer smrat::PModule::runBackends ( ) [inline],`  
`[virtual], [inherited]`

Reimplemented from [smrat::Module](#).

**0.15.366.4.95 runBackends() [2/2]** `Answer smrat::PModule::runBackends (`

|                                                                 |                                                                                                                                       |
|-----------------------------------------------------------------|---------------------------------------------------------------------------------------------------------------------------------------|
| <code>bool _final,</code>                                       | true, if this satisfiability check will be the last one (for a global sat-check), if its result is SAT.                               |
| <code>bool _full,</code>                                        | false, if this module should avoid too expensive procedures and rather return unknown instead.                                        |
| <code>carl::Variable _objective ) [virtual], [inherited]</code> | if not set to NO_VARIABLE, the module should find an assignment minimizing this objective variable; otherwise any assignment is good. |

Runs the backend solvers on the passed formula.

#### Parameters

|                         |                                                                                                                                       |
|-------------------------|---------------------------------------------------------------------------------------------------------------------------------------|
| <code>_final</code>     | true, if this satisfiability check will be the last one (for a global sat-check), if its result is SAT.                               |
| <code>_full</code>      | false, if this module should avoid too expensive procedures and rather return unknown instead.                                        |
| <code>_objective</code> | if not set to NO_VARIABLE, the module should find an assignment minimizing this objective variable; otherwise any assignment is good. |

#### Returns

True, if the passed formula is consistent; False, if the passed formula is inconsistent; Unknown, otherwise.

Reimplemented from [smrat::Module](#).

**0.15.366.4.96 setId()** void smtrat::Module::setId ( std::size\_t \_id ) [inline], [inherited]  
 Sets this modules unique ID to identify itself.

#### Parameters

|                                                 |                                    |
|-------------------------------------------------|------------------------------------|
| $\leftarrow$<br>$\overline{\leftarrow}$<br>$id$ | The id to set this module's id to. |
|-------------------------------------------------|------------------------------------|

**0.15.366.4.97 setThreadPriority()** void smtrat::Module::setThreadPriority ( thread\_priority \_threadPriority ) [inline], [inherited]  
 Sets the priority of this module to get a thread for running its check procedure.

#### Parameters

|                   |                                                       |
|-------------------|-------------------------------------------------------|
| $_threadPriority$ | The priority to set this module's thread priority to. |
|-------------------|-------------------------------------------------------|

**0.15.366.4.98 solverState()** Answer smtrat::Module::solverState ( ) const [inline], [inherited]

#### Returns

True, if this module is in a state, such that it has found a solution for its received formula; False, if this module is in a state, such that it has determined that there is no solution for its received formula; Unknown, otherwise.

**0.15.366.4.99 splitUnequalConstraint()** void smtrat::Module::splitUnequalConstraint ( const FormulaT & \_unequalConstraint ) [protected], [inherited]  
 Adds the following lemmas for the given constraint  $p \neq 0$ .

$(p \neq 0 \leftrightarrow (p < 0 \text{ or } p > 0))$

and  $\neg(p < 0 \text{ and } p > 0)$

#### Parameters

|                      |                                                  |
|----------------------|--------------------------------------------------|
| $_unequalConstraint$ | A constraint having the relation symbol $\neq$ . |
|----------------------|--------------------------------------------------|

**0.15.366.4.100 threadPriority()** thread\_priority smtrat::Module::threadPriority ( ) const [inline], [inherited]

#### Returns

The priority of this module to get a thread for running its check procedure.

**0.15.366.4.101 updateAllModels()** void smtrat::Module::updateAllModels ( ) [virtual], [inherited]  
 Updates all satisfying models, if the solver has detected the consistency of the received formula, beforehand.  
 Reimplemented in [smtrat::SATModule< Settings >](#).

**0.15.366.4.102 updateLemmas()** void smtrat::Module::updateLemmas ( ) [inherited]  
Stores all lemmas of any backend of this module in its own lemma vector.

**0.15.366.4.103 updateModel()** void smtrat::PModule::updateModel ( ) const [virtual], [inherited]  
Updates the current assignment into the model.

Note, that this is a unique but possibly symbolic assignment maybe containing newly introduced variables.  
Reimplemented from [smtrat::Module](#).

**0.15.366.4.104 usedBackends()** const std::vector<[Module](#)\*>& smtrat::Module::usedBackends ( )  
const [inline], [inherited]

**Returns**

The backends of this module which are currently used (conditions to use this module are fulfilled for the passed formula).

## 0.15.366.5 Field Documentation

**0.15.366.5.1 mAllBackends** std::vector<[Module](#)\*> smtrat::Module::mAllBackends [protected], [inherited]

The backends of this module which have been used.

**0.15.366.5.2 mAllModels** std::vector<[Model](#)> smtrat::Module::mAllModels [mutable], [protected], [inherited]

Stores all satisfying assignments.

**0.15.366.5.3 mBackendsFoundAnswer** std::atomic\_bool\* smtrat::Module::mBackendsFoundAnswer [protected], [inherited]

This flag is passed to any backend and if it determines an answer to a prior check call, this flag is fired.

**0.15.366.5.4 mConstraintsToInform** carl::FastSet<[FormulaT](#)> smtrat::Module::mConstraintsToInform [protected], [inherited]

Stores the constraints which the backends must be informed about.

**0.15.366.5.5 mFinalCheck** bool smtrat::Module::mFinalCheck [protected], [inherited]

true, if the check procedure should perform a final check which especially means not to postpone splitting decisions

**0.15.366.5.6 mFirstPosInLastBranches** std::size\_t smtrat::Module::mFirstPosInLastBranches = 0 [static], [inherited]

The beginning of the cyclic buffer storing the last branches.

**0.15.366.5.7 mFirstSubformulaToPass** [ModuleInput](#)::iterator smtrat::Module::mFirstSubformulaToPass [protected], [inherited]

Stores the position of the first sub-formula in the passed formula, which has not yet been considered for a consistency check of the backends.

**0.15.366.5.8 mFirstUncheckedReceivedSubformula** `ModuleInput::const_iterator smtrat::Module::mFirstUncheckedReceivedSubformula [protected], [inherited]`  
Stores the position of the first (by this module) unchecked sub-formula of the received formula.

**0.15.366.5.9 mFoundAnswer** `Conditionals smtrat::Module::mFoundAnswer [protected], [inherited]`  
Vector of Booleans: If any of them is true, we have to terminate a running check procedure.

**0.15.366.5.10 mFullCheck** `bool smtrat::Module::mFullCheck [protected], [inherited]`  
false, if this module should avoid too expensive procedures and rather return unknown instead.

**0.15.366.5.11 mInfeasibleSubsets** `std::vector<FormulaSetT> smtrat::Module::mInfeasibleSubsets [protected], [inherited]`  
Stores the infeasible subsets.

**0.15.366.5.12 mInformedConstraints** `carl::FastSet<FormulaT> smtrat::Module::mInformedConstraints [protected], [inherited]`  
Stores the position of the first constraint of which no backend has been informed about.

**0.15.366.5.13 mLastBranches** `std::vector<Branching> smtrat::Module::mLastBranches = std::vector<Branching>(mNumOfBranchVarsToStore, Branching(typename Poly::PolyType(), 0)) [static], [inherited]`  
Stores the last branches in a cycle buffer.

**0.15.366.5.14 mLemmas** `std::vector<Lemma> smtrat::Module::mLemmas [protected], [inherited]`  
Stores the lemmas being valid formulas this module or its backends made.

**0.15.366.5.15 mModel** `Model smtrat::Module::mModel [mutable], [protected], [inherited]`  
Stores the assignment of the current satisfiable result, if existent.

**0.15.366.5.16 mModelComputed** `bool smtrat::Module::mModelComputed [mutable], [protected], [inherited]`  
True, if the model has already been computed.

**0.15.366.5.17 mNumOfBranchVarsToStore** `std::size_t smtrat::Module::mNumOfBranchVarsToStore = 5 [static], [inherited]`  
The number of different variables to consider for a probable infinite loop of branchings.

**0.15.366.5.18 mObjectiveVariable** `carl::Variable smtrat::Module::mObjectiveVariable [protected], [inherited]`  
Objective variable to be minimized. If set to NO\_VARIABLE, a normal sat check should be performed.

**0.15.366.5.19 mOldSplittingVariables** `std::vector<FormulaT> smtrat::Module::mOldSplittingVariables [static], [inherited]`  
Reusable splitting variables.

**0.15.366.5.20 mpManager** `Manager* const smrat::Module::mpManager [protected], [inherited]`  
A reference to the manager.

**0.15.366.5.21 mSmallerMusesCheckCounter** `unsigned smrat::Module::mSmallerMusesCheckCounter [mutable], [protected], [inherited]`  
Counter used for the generation of the smt2 files to check for smaller muses.

**0.15.366.5.22 mSolverState** `std::atomic<Answer> smrat::Module::mSolverState [protected], [inherited]`  
States whether the received formula is known to be satisfiable or unsatisfiable otherwise it is set to unknown.

**0.15.366.5.23 mTheoryPropagations** `std::vector<TheoryPropagation> smrat::Module::mTheoryPropagations [protected], [inherited]`

**0.15.366.5.24 mUsedBackends** `std::vector<Module*> smrat::Module::mUsedBackends [protected], [inherited]`  
The backends of this module which are currently used (conditions to use this module are fulfilled for the passed formula).

**0.15.366.5.25 mVariableCounters** `std::vector<std::size_t> smrat::Module::mVariableCounters [protected], [inherited]`  
Maps variables to the number of their occurrences.

## 0.15.367 smrat::PModule Class Reference

```
#include <PModule.h>
```

### Public Types

- enum class `LemmaType` : unsigned { `NORMAL` = 0 , `PERMANENT` = 1 }

### Public Member Functions

- `PModule` (const `ModuleInput` \*`_formula`, `Conditionals` &`_foundAnswer`, `Manager` \*`_manager=nullptr`, std::string `module_name="PModule"`)
- `bool isPreprocessor () const`
- `bool appliedPreprocessing () const`
- `bool add (ModuleInput::const_iterator _subformula)`  
*The module has to take the given sub-formula of the received formula into account.*
- `void remove (ModuleInput::const_iterator _subformula)`  
*Removes everything related to the given sub-formula of the received formula.*
- `Answer check (bool _final=false, bool _full=true, carl::Variable _objective=carl::Variable::NO_VARIABLE)`  
*Checks the received formula for consistency.*
- `Answer runBackends (bool _final, bool _full, carl::Variable _objective)`  
*Runs the backend solvers on the passed formula.*
- `virtual Answer runBackends ()`
- `std::pair< bool, FormulaT > getReceivedFormulaSimplified ()`
- `void updateModel () const`  
*Updates the current assignment into the model.*
- `bool inform (const FormulaT &_constraint)`

- **Informs the module about the given constraint.**
- void **deinform** (const **FormulaT** &\_constraint)
  - The inverse of informing about a constraint.*
- virtual void **init** ()
  - Informs all backends about the so far encountered constraints, which have not yet been communicated.*
- virtual void **updateAllModels** ()
  - Updates all satisfying models, if the solver has detected the consistency of the received formula, beforehand.*
- virtual std::list< std::vector< carl::Variable > > **getModelEqualities** () const
  - Partition the variables from the current model into equivalence classes according to their assigned value.*
- unsigned **currentlySatisfiedByBackend** (const **FormulaT** &\_formula) const
- virtual unsigned **currentlySatisfied** (const **FormulaT** &) const
- bool **receivedVariable** (carl::Variable::Arg \_var) const
- **Answer solverState** () const
- std::size\_t **id** () const
- void **setId** (std::size\_t \_id)
  - Sets this modules unique ID to identify itself.*
- **thread\_priority threadPriority** () const
- void **setThreadPriority** (**thread\_priority** \_threadPriority)
  - Sets the priority of this module to get a thread for running its check procedure.*
- const **ModuleInput** \* **pReceivedFormula** () const
- const **ModuleInput** & **rReceivedFormula** () const
- const **ModuleInput** \* **pPassedFormula** () const
- const **ModuleInput** & **rPassedFormula** () const
- const **Model** & **model** () const
- const std::vector< **Model** > & **allModels** () const
- const std::vector< **FormulaSetT** > & **infeasibleSubsets** () const
- const std::vector< **Module** \* > & **usedBackends** () const
- const carl::FastSet< **FormulaT** > & **constraintsToInform** () const
- const carl::FastSet< **FormulaT** > & **informedConstraints** () const
- void **addLemma** (const **FormulaT** &\_lemma, const **LemmaType** &\_lt= **LemmaType**::NORMAL, const **FormulaT** &\_preferredFormula= **FormulaT**(carl::FormulaType::TRUE))
  - Stores a lemma being a valid formula.*
- bool **hasLemmas** ()
  - Checks whether this module or any of its backends provides any lemmas.*
- void **clearLemmas** ()
  - Deletes all yet found lemmas.*
- const std::vector< **Lemma** > & **lemmas** () const
- **ModuleInput**::const\_iterator **firstUncheckedReceivedSubformula** () const
- **ModuleInput**::const\_iterator **firstSubformulaToPass** () const
- void **receivedFormulaChecked** ()
  - Notifies that the received formulas has been checked.*
- const **smrat::Conditionals** & **answerFound** () const
- virtual std::string **moduleName** () const
- carl::Variable **objective** () const
- bool **is\_minimizing** () const
- void **excludeNotReceivedVariablesFromModel** () const
  - Excludes all variables from the current model, which do not occur in the received formula.*
- void **updateLemmas** ()
  - Stores all lemmas of any backend of this module in its own lemma vector.*
- void **collectTheoryPropagations** ()
- void **collectOrigins** (const **FormulaT** &\_formula, **FormulasT** &\_origins) const
  - Collects the formulas in the given formula, which are part of the received formula.*
- void **collectOrigins** (const **FormulaT** &\_formula, **FormulaSetT** &\_origins) const

- bool `isValidInfeasibleSubset () const`
- void `checkInfSubsetForMinimality (std::vector< FormulaSetT >::const_iterator _insubset, const std::string &_filename="smaller_muses", unsigned _maxSizeDifference=1) const`  
*Checks the given infeasible subset for minimality by storing all subsets of it, which have a smaller size which differs from the size of the infeasible subset not more than the given threshold.*
- void `print (const std::string &_initiation="***") const`  
*Prints everything relevant of the solver.*
- void `printReceivedFormula (const std::string &_initiation="***") const`  
*Prints the vector of the received formula.*
- void `printPassedFormula (const std::string &_initiation="***") const`  
*Prints the vector of passed formula.*
- void `printInfeasibleSubsets (const std::string &_initiation="***") const`  
*Prints the infeasible subsets.*
- void `printModel (std::ostream &_out=std::cout) const`  
*Prints the assignment of this module satisfying its received formula if it satisfiable and this module could find an assignment.*
- void `printAllModels (std::ostream &_out=std::cout)`  
*Prints all assignments of this module satisfying its received formula if it satisfiable and this module could find an assignment.*

### Static Public Member Functions

- static void `freeSplittingVariable (const FormulaT &_splittingVariable)`

### Static Public Attributes

- static size\_t `mNumOfBranchVarsToStore = 5`  
*The number of different variables to consider for a probable infinite loop of branchings.*
- static std::vector< Branching > `mLastBranches = std::vector<Branching>(mNumOfBranchVarsToStore, Branching(typename Poly::PolyType(), 0))`  
*Stores the last branches in a cycle buffer.*
- static size\_t `mFirstPosInLastBranches = 0`  
*The beginning of the cyclic buffer storing the last branches.*
- static std::vector< FormulaT > `mOldSplittingVariables`  
*Reusable splitting variables.*

### Protected Member Functions

- virtual bool `informCore (const FormulaT &_constraint)`  
*Informs the module about the given constraint.*
- virtual void `deinformCore (const FormulaT &_constraint)`  
*The inverse of informing about a constraint.*
- virtual bool `addCore (ModuleInput::const_iterator formula)`  
*The module has to take the given sub-formula of the received formula into account.*
- virtual `Answer checkCore ()`  
*Checks the received formula for consistency.*
- virtual void `removeCore (ModuleInput::const_iterator formula)`  
*Removes everything related to the given sub-formula of the received formula.*
- bool `anAnswerFound () const`  
*Checks for all antecedent modules and those which run in parallel with the same antecedent modules, whether one of them has determined a result.*
- void `clearModel () const`  
*Clears the assignment, if any was found.*
- void `clearModels () const`

- **void cleanModel () const**

*Clears all assignments, if any was found.*
- **ModuleInput::iterator passedFormulaBegin ()**

*Substitutes variable occurrences by its model value in the model values of other variables.*
- **ModuleInput::iterator passedFormulaEnd ()**
- **void addOrigin (ModuleInput::iterator \_formula, const FormulaT &\_origin)**

*Adds the given set of formulas in the received formula to the origins of the given passed formula.*
- **const FormulaT & getOrigins (ModuleInput::const\_iterator \_formula) const**

*Gets the origins of the passed formula at the given position.*
- **void getOrigins (const FormulaT &\_formula, FormulasT &\_origins) const**
- **void getOrigins (const FormulaT &\_formula, FormulaSetT &\_origins) const**
- **std::pair< ModuleInput::iterator, bool > removeOrigin (ModuleInput::iterator \_formula, const FormulaT &\_origin)**
- **std::pair< ModuleInput::iterator, bool > removeOrigins (ModuleInput::iterator \_formula, const std::shared\_ptr< std::vector< FormulaT >> &\_origins)**
- **void informBackends (const FormulaT &\_constraint)**

*Informs all backends of this module about the given constraint.*
- **virtual void addConstraintToInform (const FormulaT &\_constraint)**

*Adds a constraint to the collection of constraints of this module, which are informed to a freshly generated backend.*
- **std::pair< ModuleInput::iterator, bool > addReceivedSubformulaToPassedFormula (ModuleInput::const\_iterator \_subformula)**

*Copies the given sub-formula of the received formula to the passed formula.*
- **bool originInReceivedFormula (const FormulaT &\_origin) const**
- **std::pair< ModuleInput::iterator, bool > addSubformulaToPassedFormula (const FormulaT &\_formula)**

*Adds the given formula to the passed formula with no origin.*
- **std::pair< ModuleInput::iterator, bool > addSubformulaToPassedFormula (const FormulaT &\_formula, const std::shared\_ptr< std::vector< FormulaT >> &\_origins)**

*Adds the given formula to the passed formula.*
- **std::pair< ModuleInput::iterator, bool > addSubformulaToPassedFormula (const FormulaT &\_formula, const FormulaT &\_origin)**

*Adds the given formula to the passed formula.*
- **void generateTrivialInfeasibleSubset ()**

*Stores the trivial infeasible subset being the set of received formulas.*
- **void receivedFormulasAsInfeasibleSubset (ModuleInput::const\_iterator \_subformula)**

*Stores an infeasible subset consisting only of the given received formula.*
- **std::vector< FormulaT >::const\_iterator findBestOrigin (const std::vector< FormulaT > &\_origins) const**
- **void getInfeasibleSubsets ()**

*Copies the infeasible subsets of the passed formula.*
- **std::vector< FormulaSetT > getInfeasibleSubsets (const Module &\_backend) const**

*Get the infeasible subsets the given backend provides.*
- **const Model & backendsModel () const**

*Stores the model of a backend which determined satisfiability of the passed formula in the model of this module.*
- **void getBackendsModel () const**
- **void getBackendsAllModels () const**

*Stores all models of a backend in the list of all models of this module.*
- **virtual ModuleInput::iterator eraseSubformulaFromPassedFormula (ModuleInput::iterator \_subformula, bool \_ignoreOrigins=false)**

*Removes everything related to the sub-formula to remove from the passed formula in the backends of this module.*
- **void clearPassedFormula ()**
- **std::vector< FormulaT > merge (const std::vector< FormulaT > &, const std::vector< FormulaT > &) const**

*Merges the two vectors of sets into the first one.*
- **size\_t determine\_smallest\_origin (const std::vector< FormulaT > &origins) const**

- bool `probablyLooping` (const typename Poly::PolyType &\_branchingPolynomial, const Rational &\_branchingValue) const  
*Checks whether given the current branching value and branching variable/polynomial it is (highly) probable that this branching is part of an infinite loop of branchings.*
- bool `branchAt` (const Poly &\_polynomial, bool \_integral, const Rational &\_value, std::vector< FormulaT > &&\_premise, bool \_leftCaseWeak=true, bool \_preferLeftCase=true, bool \_useReceivedFormulaAsPremise=false)  
*Adds a lemmas which provoke a branching for the given variable at the given value, if this module returns Unknown and there exists a preceding SATModule.*
- bool `branchAt` (const Poly &\_polynomial, bool \_integral, const Rational &\_value, bool \_leftCaseWeak=true, bool \_preferLeftCase=true, bool \_useReceivedFormulaAsPremise=false, const std::vector< FormulaT > &&\_premise=std::vector< FormulaT >())
- bool `branchAt` (carl::Variable::Arg \_var, const Rational &\_value, std::vector< FormulaT > &&\_premise, bool \_leftCaseWeak=true, bool \_preferLeftCase=true, bool \_useReceivedFormulaAsPremise=false)
- bool `branchAt` (carl::Variable::Arg \_var, const Rational &\_value, bool \_leftCaseWeak=true, bool \_preferLeftCase=true, bool \_useReceivedFormulaAsPremise=false, const std::vector< FormulaT > &\_premise=std::vector< FormulaT >())
- void `splitUnequalConstraint` (const FormulaT &)  
*Adds the following lemmas for the given constraint  $p \neq 0$ .*
- unsigned `checkModel` () const
- void `addInformationRelevantFormula` (const FormulaT &formula)  
*Adds a formula to the InformationRelevantFormula.*
- const std::set< FormulaT > & `getInformationRelevantFormulas` ()  
*Gets all InformationRelevantFormulas.*
- bool `isLemmaLevel` (LemmaLevel level)  
*Checks if current lemma level is greater or equal to given level.*

## Static Protected Member Functions

- static bool `modelsDisjoint` (const Model &\_modelA, const Model &\_modelB)  
*Checks whether there is no variable assigned by both models.*

## Protected Attributes

- std::vector< FormulaSetT > `mInfeasibleSubsets`  
*Stores the infeasible subsets.*
- Manager \*const `mpManager`  
*A reference to the manager.*
- Model `mModel`  
*Stores the assignment of the current satisfiable result, if existent.*
- std::vector< Model > `mAllModels`  
*Stores all satisfying assignments.*
- bool `mModelComputed`  
*True, if the model has already been computed.*
- bool `mFinalCheck`  
*true, if the check procedure should perform a final check which especially means not to postpone splitting decisions*
- bool `mFullCheck`  
*false, if this module should avoid too expensive procedures and rather return unknown instead.*
- carl::Variable `mObjectiveVariable`  
*Objective variable to be minimized. If set to NO\_VARIABLE, a normal sat check should be performed.*
- std::vector< TheoryPropagation > `mTheoryPropagations`
- std::atomic< Answer > `mSolverState`  
*States whether the received formula is known to be satisfiable or unsatisfiable otherwise it is set to unknown.*
- std::atomic\_bool \* `mBackendsFoundAnswer`

*This flag is passed to any backend and if it determines an answer to a prior check call, this flag is fired.*

- **Conditionals mFoundAnswer**

*Vector of Booleans: If any of them is true, we have to terminate a running check procedure.*

- std::vector< [Module \\*](#) > mUsedBackends

*The backends of this module which are currently used (conditions to use this module are fulfilled for the passed formula).*

- std::vector< [Module \\*](#) > mAllBackends

*The backends of this module which have been used.*

- std::vector< [Lemma](#) > mLemmas

*Stores the lemmas being valid formulas this module or its backends made.*

- [ModuleInput::iterator](#) mFirstSubformulaToPass

*Stores the position of the first sub-formula in the passed formula, which has not yet been considered for a consistency check of the backends.*

- carl::FastSet< [FormulaT](#) > mConstraintsToInform

*Stores the constraints which the backends must be informed about.*

- carl::FastSet< [FormulaT](#) > mInformedConstraints

*Stores the position of the first constraint of which no backend has been informed about.*

- [ModuleInput::const\\_iterator](#) mFirstUncheckedReceivedSubformula

*Stores the position of the first (by this module) unchecked sub-formula of the received formula.*

- unsigned mSmallerMusesCheckCounter

*Counter used for the generation of the smt2 files to check for smaller muses.*

- std::vector< std::size\_t > mVariableCounters

*Maps variables to the number of their occurrences.*

### 0.15.367.1 Member Enumeration Documentation

#### 0.15.367.1.1 LemmaType [enum smtrat::Module::LemmaType : unsigned \[strong\], \[inherited\]](#)

Enumerator

|           |  |
|-----------|--|
| NORMAL    |  |
| PERMANENT |  |

### 0.15.367.2 Constructor & Destructor Documentation

#### 0.15.367.2.1 PModule() [smtrat::PModule::PModule \(](#)

```
 const ModuleInput * _formula,
 Conditionals & _foundAnswer,
 Manager * _manager = nullptr,
 std::string module_name = "PModule")
```

### 0.15.367.3 Member Function Documentation

#### 0.15.367.3.1 add() [bool smtrat::PModule::add \(](#)

```
 ModuleInput::const_iterator _subformula)
```

The module has to take the given sub-formula of the received formula into account.

**Parameters**

|                          |                                                    |
|--------------------------|----------------------------------------------------|
| <code>_subformula</code> | The sub-formula to take additionally into account. |
|--------------------------|----------------------------------------------------|

**Returns**

false, if it can be easily decided that this sub-formula causes a conflict with the already considered sub-formulas; true, otherwise.

**0.15.367.3.2 `addConstraintToInform()`** `void smtrat::Module::addConstraintToInform ( const FormulaT & _constraint )` [protected], [virtual], [inherited]

Adds a constraint to the collection of constraints of this module, which are informed to a freshly generated backend.

**Parameters**

|                          |                        |
|--------------------------|------------------------|
| <code>_constraint</code> | The constraint to add. |
|--------------------------|------------------------|

Reimplemented in [smtrat::SATModule< Settings >](#).

**0.15.367.3.3 `addCore()`** `virtual bool smtrat::Module::addCore ( ModuleInput::const_iterator formula )` [inline], [protected], [virtual], [inherited]

The module has to take the given sub-formula of the received formula into account.

**Parameters**

|                      |                                                    |
|----------------------|----------------------------------------------------|
| <code>formula</code> | The sub-formula to take additionally into account. |
|----------------------|----------------------------------------------------|

**Returns**

false, if it can be easily decided that this sub-formula causes a conflict with the already considered sub-formulas; true, otherwise.

Reimplemented in [smtrat::VSModule< Settings >](#), [smtrat::SATModule< Settings >](#), [smtrat::PFEModule< Settings >](#), [smtrat::ICPModule< Settings >](#), [smtrat::ICPModule< ICPSettings4 >](#), [smtrat::ICPModule< ICPSettings1 >](#), [smtrat::UnionFindModule< Settings >](#), [smtrat::UFCegarModule< Settings >](#), [smtrat::STropModule< Settings >](#), [smtrat::PBPPModule< Settings >](#), [smtrat::PBGaussModule< Settings >](#), [smtrat::NRAILModule< Settings >](#), [smtrat::NewCoveringModule< Settings >](#), [smtrat::NewCADModule< Settings >](#), [smtrat::LRAModule< Settings >](#), [smtrat::LRAModule< LRASettingsICP >](#), [smtrat::LRAModule< LRASettings1 >](#), [smtrat::IntEqModule< Settings >](#), [smtrat::IntBlastModule< Settings >](#), [smtrat::IncWidthModule< Settings >](#), [smtrat::ICEModule< Settings >](#), [smtrat::FPPModule< Settings >](#), [smtrat::FouMoModule< Settings >](#), [smtrat::EQModule< Settings >](#), [smtrat::CurryModule< Settings >](#), [smtrat::CubeLIAModule< Settings >](#), [smtrat::CSplitModule< Settings >](#), [smtrat::BVMModule< Settings >](#), and [smtrat::GBModule< Settings >](#).

**0.15.367.3.4 `addInformationRelevantFormula()`** `void smtrat::Module::addInformationRelevantFormula ( const FormulaT & formula )` [protected], [inherited]

Adds a formula to the InformationRelevantFormula.

**Parameters**

|                      |                |
|----------------------|----------------|
| <code>formula</code> | Formula to add |
|----------------------|----------------|

```
0.15.367.3.5 addLemma() void smtrat::Module::addLemma (
 const FormulaT & _lemma,
 const LemmaType & _lt = LemmaType::NORMAL,
 const FormulaT & _preferredFormula = FormulaT(carl::FormulaType::TRUE)) [inline],
[inherited]
```

Stores a lemma being a valid formula.

#### Parameters

|                   |                                                                       |
|-------------------|-----------------------------------------------------------------------|
| _lemma            | The eduction/lemma to store.                                          |
| _lt               | The type of the lemma.                                                |
| _preferredFormula | Hint for the next decision, which formula should be assigned to true. |

```
0.15.367.3.6 addOrigin() void smtrat::Module::addOrigin (
 ModuleInput::iterator _formula,
 const FormulaT & _origin) [inline], [protected], [inherited]
```

Adds the given set of formulas in the received formula to the origins of the given passed formula.

#### Parameters

|          |                                                           |
|----------|-----------------------------------------------------------|
| _formula | The passed formula to set the origins for.                |
| _origin  | A set of formulas in the received formula of this module. |

```
0.15.367.3.7 addReceivedSubformulaToPassedFormula() std::pair<ModuleInput::iterator,bool>
smtrat::Module::addReceivedSubformulaToPassedFormula (
```

```
 ModuleInput::const_iterator _subformula) [inline], [protected], [inherited]
```

Copies the given sub-formula of the received formula to the passed formula.

Note, that there is always a link between sub-formulas of the passed formulas to sub-formulas of the received formulas, which are responsible for its occurrence.

#### Parameters

|             |                                                  |
|-------------|--------------------------------------------------|
| _subformula | The sub-formula of the received formula to copy. |
|-------------|--------------------------------------------------|

```
0.15.367.3.8 addSubformulaToPassedFormula() [1/3] std::pair<ModuleInput::iterator,bool> smtrat<-
::Module::addSubformulaToPassedFormula (
```

```
 const FormulaT & _formula) [inline], [protected], [inherited]
```

Adds the given formula to the passed formula with no origin.

Note that in the next call of this module's removeSubformula, all formulas in the passed formula without origins will be removed.

#### Parameters

|          |                                           |
|----------|-------------------------------------------|
| _formula | The formula to add to the passed formula. |
|----------|-------------------------------------------|

#### Returns

A pair to the position where the formula to add has been inserted (or its first sub-formula which has not yet been in the passed formula, in case the formula to add is a conjunction), and a Boolean stating whether anything has been added to the passed formula.

---

**0.15.367.3.9 addSubformulaToPassedFormula()** [2/3] std::pair<ModuleInput::iterator,bool> smrat→  
::Module::addSubformulaToPassedFormula ( const FormulaT & \_formula,  
const FormulaT & \_origin ) [inline], [protected], [inherited]

Adds the given formula to the passed formula.

#### Parameters

|          |                                                                                                                           |
|----------|---------------------------------------------------------------------------------------------------------------------------|
| _formula | The formula to add to the passed formula.                                                                                 |
| _origin  | The sub-formula of the received formula being responsible for the occurrence of the formula to add to the passed formula. |

#### Returns

A pair to the position where the formula to add has been inserted (or its first sub-formula which has not yet been in the passed formula, in case the formula to add is a conjunction), and a Boolean stating whether anything has been added to the passed formula.

**0.15.367.3.10 addSubformulaToPassedFormula()** [3/3] std::pair<ModuleInput::iterator,bool>  
smrat::Module::addSubformulaToPassedFormula ( const FormulaT & \_formula,  
const std::shared\_ptr<std::vector<FormulaT>> & \_origins ) [inline], [protected],  
[inherited]

Adds the given formula to the passed formula.

#### Parameters

|          |                                                                                                                                         |
|----------|-----------------------------------------------------------------------------------------------------------------------------------------|
| _formula | The formula to add to the passed formula.                                                                                               |
| _origins | The link of the formula to add to the passed formula to sub-formulas of the received formulas, which are responsible for its occurrence |

#### Returns

A pair to the position where the formula to add has been inserted (or its first sub-formula which has not yet been in the passed formula, in case the formula to add is a conjunction), and a Boolean stating whether anything has been added to the passed formula.

**0.15.367.3.11 allModels()** const std::vector<Model>& smrat::Module::allModels () const [inline],  
[inherited]

#### Returns

All satisfying assignments, if existent.

**0.15.367.3.12 anAnswerFound()** bool smrat::Module::anAnswerFound () const [inline], [protected],  
[inherited]

Checks for all antecedent modules and those which run in parallel with the same antecedent modules, whether one of them has determined a result.

#### Returns

True, if one of them has determined a result.

**0.15.367.3.13 answerFound()** const smtrat::Conditionals& smtrat::Module::answerFound ( ) const [inline], [inherited]

**Returns**

A vector of Booleans: If any of them is true, we have to terminate a running check procedure.

**0.15.367.3.14 appliedPreprocessing()** bool smtrat::PModule::appliedPreprocessing ( ) const [inline]

**Returns**

true, if the current received formula has been simplified and the result of this simplification is stored in the passed formula.

**0.15.367.3.15 backendsModel()** const Model & smtrat::Module::backendsModel ( ) const [protected], [inherited]

Stores the model of a backend which determined satisfiability of the passed formula in the model of this module.

**0.15.367.3.16 branchAt() [1/4]** bool smtrat::Module::branchAt ( carl::Variable::Arg \_var, const Rational & \_value, bool \_leftCaseWeak = true, bool \_preferLeftCase = true, bool \_useReceivedFormulaAsPremise = false, const std::vector< FormulaT > & \_premise = std::vector<FormulaT>() ) [inline], [protected], [inherited]

**0.15.367.3.17 branchAt() [2/4]** bool smtrat::Module::branchAt ( carl::Variable::Arg \_var, const Rational & \_value, std::vector< FormulaT > && \_premise, bool \_leftCaseWeak = true, bool \_preferLeftCase = true, bool \_useReceivedFormulaAsPremise = false ) [inline], [protected], [inherited]

**0.15.367.3.18 branchAt() [3/4]** bool smtrat::Module::branchAt ( const Poly & \_polynomial, bool \_integral, const Rational & \_value, bool \_leftCaseWeak = true, bool \_preferLeftCase = true, bool \_useReceivedFormulaAsPremise = false, const std::vector< FormulaT > & \_premise = std::vector<FormulaT>() ) [inline], [protected], [inherited]

**0.15.367.3.19 branchAt() [4/4]** bool smtrat::Module::branchAt ( const Poly & \_polynomial, bool \_integral, const Rational & \_value, std::vector< FormulaT > && \_premise, bool \_leftCaseWeak = true,

```
 bool _preferLeftCase = true,
 bool _useReceivedFormulaAsPremise = false) [protected], [inherited]
```

Adds a lemmas which provoke a branching for the given variable at the given value, if this module returns Unknown and there exists a preceding [SATModule](#).

Note that the given value is rounded down and up, if the given variable is integer-valued.

#### Parameters

|                                           |                                                                                                                                                                                                                |
|-------------------------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>_polynomial</code>                  | The variable to branch for.                                                                                                                                                                                    |
| <code>_integral</code>                    | A flag being true, if all variables in the polynomial to branch for are integral.                                                                                                                              |
| <code>_value</code>                       | The value to branch at.                                                                                                                                                                                        |
| <code>_premise</code>                     | The sub-formulas of the received formula from which the branch is followed. Note, that a premise is not necessary, as every branch is a valid formula. But a premise can prevent from branching unnecessarily. |
| <code>_leftCaseWeak</code>                | true, if a branching in the form of (or ( $\leq p b$ ) ( $> p b$ )) is desired. false, if a branching in the form of (or ( $< p b$ ) ( $\geq p b$ )) is desired.                                               |
| <code>_preferLeftCase</code>              | true, if the left case (polynomial less(or equal) 0 shall be chosen first. false, otherwise.                                                                                                                   |
| <code>_useReceivedFormulaAsPremise</code> | true, if the whole received formula should be used as premise                                                                                                                                                  |

#### 0.15.367.3.20 `check()` [Answer](#) `smtrat::PModule::check(`

```
 bool _final = false,
 bool _full = true,
 carl::Variable _objective = carl::Variable::NO_VARIABLE) [virtual]
```

Checks the received formula for consistency.

Note, that this is an implementation of the satisfiability check of the conjunction of the so far received formulas, which does actually nothing but passing the problem to its backends. This implementation is only used internally and must be overwritten by any derived module.

#### Parameters

|                         |                                                                                                                                       |
|-------------------------|---------------------------------------------------------------------------------------------------------------------------------------|
| <code>_final</code>     | true, if this satisfiability check will be the last one (for a global sat-check), if its result is SAT                                |
| <code>_full</code>      | false, if this module should avoid too expensive procedures and rather return unknown instead.                                        |
| <code>_objective</code> | if not set to NO_VARIABLE, the module should find an assignment minimizing this objective variable; otherwise any assignment is good. |

#### Returns

True, if the received formula is satisfiable; False, if the received formula is not satisfiable; Unknown, otherwise.

Reimplemented from [smtrat::Module](#).

#### 0.15.367.3.21 `checkCore()` [Answer](#) `smtrat::Module::checkCore( )` [protected], [inherited]

Checks the received formula for consistency.

Note, that this is an implementation of the satisfiability check of the conjunction of the so far received formulas, which does actually nothing but passing the problem to its backends. This implementation is only used internally and must be overwritten by any derived module.

#### Returns

True, if the received formula is satisfiable; False, if the received formula is not satisfiable; Unknown, otherwise.

Reimplemented in [smtrat::VSModule< Settings >](#), [smtrat::UnionFindModule< Settings >](#), [smtrat::UFCegarModule< Settings >](#), [smtrat::SymmetryModule< Settings >](#), [smtrat::STropModule< Settings >](#), [smtrat::SplitSOSModule< Settings >](#),

`smrat::SATModule< Settings >, smrat::PFEModule< Settings >, smrat::PBPPModule< Settings >, smrat::PBGaussModule< Settings >, smrat::NRAILModule< Settings >, smrat::NewCoveringModule< Settings >, smrat::NewCADModule< Settings >, smrat::MCBModule< Settings >, smrat::LVEModule< Settings >, smrat::LRAModule< Settings >, smrat::LRAModule< LRASettings1 >, smrat::IntEqModule< Settings >, smrat::IntBlastModule< Settings >, smrat::IncWidthModule< Settings >, smrat::ICPModule< Settings >, smrat::ICPModule< ICPSettings4 >, smrat::ICPModule< ICPSettings1 >, smrat::ICEModule< Settings >, smrat::GBPPModule< Settings >, smrat::GBModule< Settings >, smrat::FPPModule< Settings >, smrat::FouMoModule< Settings >, smrat::ESModule< Settings >, smrat::EQPreprocessingModule< Settings >, smrat::EQModule< Settings >, smrat::EMModule< Settings >, smrat::CurryModule< Settings >, smrat::CubeLIAModule< Settings >, smrat::CSplitModule< Settings >, smrat::CNFerModule, smrat::BVMODULE< Settings >, and smrat::BEModule< Settings >.`

#### 0.15.367.3.22 **checkInfSubsetForMinimality()** `void smrat::Module::checkInfSubsetForMinimality (`

```
 std::vector< FormulaSet >::const_iterator _infsSubset,
 const std::string & _filename = "smaller_muses",
 unsigned _maxSizeDifference = 1) const [inherited]
```

Checks the given infeasible subset for minimality by storing all subsets of it, which have a smaller size which differs from the size of the infeasible subset not more than the given threshold.

##### Parameters

|                                 |                                                                                                        |
|---------------------------------|--------------------------------------------------------------------------------------------------------|
| <code>_infsSubset</code>        | The infeasible subset to check for minimality.                                                         |
| <code>_filename</code>          | The name of the file to store the infeasible subsets in order to be able to check their infeasibility. |
| <code>_maxSizeDifference</code> | The maximal difference between the sizes of the subsets compared to the size of the infeasible subset. |

#### 0.15.367.3.23 **checkModel()** `unsigned smrat::Module::checkModel ( ) const [protected], [inherited]`

##### Returns

false, if the current model of this module does not satisfy the current given formula; true, if it cannot be said whether the model satisfies the given formula.

#### 0.15.367.3.24 **cleanModel()** `void smrat::Module::cleanModel ( ) const [inline], [protected], [inherited]`

Substitutes variable occurrences by its model value in the model values of other variables.

#### 0.15.367.3.25 **clearLemmas()** `void smrat::Module::clearLemmas ( ) [inline], [inherited]`

Deletes all yet found lemmas.

#### 0.15.367.3.26 **clearModel()** `void smrat::Module::clearModel ( ) const [inline], [protected], [inherited]`

Clears the assignment, if any was found.

#### 0.15.367.3.27 **clearModels()** `void smrat::Module::clearModels ( ) const [inline], [protected], [inherited]`

Clears all assignments, if any was found.

**0.15.367.3.28 clearPassedFormula()** void smtrat::Module::clearPassedFormula () [protected],  
[inherited]

**0.15.367.3.29 collectOrigins() [1/2]** void smtrat::Module::collectOrigins (  
const FormulaT & \_formula,  
FormulaSetT & \_origins ) const [inherited]

**0.15.367.3.30 collectOrigins() [2/2]** void smtrat::Module::collectOrigins (  
const FormulaT & \_formula,  
FormulasT & \_origins ) const [inherited]

Collects the formulas in the given formula, which are part of the received formula.

If the given formula directly occurs in the received formula, it is inserted into the given set. Otherwise, the given formula must be of type AND and all its sub-formulas part of the received formula. Hence, they will be added to the given set.

#### Parameters

|          |                                                                                                      |
|----------|------------------------------------------------------------------------------------------------------|
| _formula | The formula from which to collect the formulas being sub-formulas of the received formula (origins). |
| _origins | The set in which to store the origins.                                                               |

**0.15.367.3.31 collectTheoryPropagations()** void smtrat::Module::collectTheoryPropagations ()  
[inherited]

**0.15.367.3.32 constraintsToInform()** const carl::FastSet<FormulaT>& smtrat::Module::constraintsToInform () const [inline], [inherited]

#### Returns

The constraints which the backends must be informed about.

**0.15.367.3.33 currentlySatisfied()** virtual unsigned smtrat::Module::currentlySatisfied (  
const FormulaT & ) const [inline], [virtual], [inherited]

#### Returns

0, if the given formula is conflicted by the current model; 1, if the given formula is satisfied by the current model; 2, otherwise; 3, if we do not know anything (default)

Reimplemented in [smtrat::LRAModule< Settings >](#), [smtrat::LRAModule< LRASettingsICP >](#), and [smtrat::LRAModule< LRASettings >](#)

**0.15.367.3.34 currentlySatisfiedByBackend()** unsigned smtrat::Module::currentlySatisfiedByBackend (  
const FormulaT & \_formula ) const [inherited]

#### Returns

0, if the given formula is conflicted by the current model; 1, if the given formula is satisfied by the current model; 2, otherwise 3, if we do not know anything (default)

```
0.15.367.3.35 deinform() void smtrat::Module::deinform (
 const FormulaT & _constraint) [inherited]
```

The inverse of informing about a constraint.

All data structures which were kept regarding this constraint are going to be removed. Note, that this makes only sense if it is not likely enough that a formula with this constraint must be solved again.

#### Parameters

|                          |                                                         |
|--------------------------|---------------------------------------------------------|
| <code>_constraint</code> | The constraint to remove from internal data structures. |
|--------------------------|---------------------------------------------------------|

```
0.15.367.3.36 deinformCore() virtual void smtrat::Module::deinformCore (
 const FormulaT & _constraint) [inline], [protected], [virtual], [inherited]
```

The inverse of informing about a constraint.

All data structures which were kept regarding this constraint are going to be removed. Note, that this makes only sense if it is not likely enough that a formula with this constraint must be solved again.

#### Parameters

|                          |                                                         |
|--------------------------|---------------------------------------------------------|
| <code>_constraint</code> | The constraint to remove from internal data structures. |
|--------------------------|---------------------------------------------------------|

Reimplemented in [smtrat::LRAModule< Settings >](#), [smtrat::LRAModule< LRASettingsICP >](#), and [smtrat::LRAModule< LRASettings1 >](#).

```
0.15.367.3.37 determine_smallest_origin() size_t smtrat::Module::determine_smallest_origin (
 const std::vector< FormulaT > & origins) const [protected], [inherited]
```

#### Parameters

|                      |                              |
|----------------------|------------------------------|
| <code>origins</code> | A vector of sets of origins. |
|----------------------|------------------------------|

#### Returns

The index of the smallest (regarding the size of the sets) element of origins

```
0.15.367.3.38 eraseSubformulaFromPassedFormula() ModuleInput::iterator smtrat::Module::eraseSubformulaFromPassedFormula (
 ModuleInput::iterator _subformula,
 bool _ignoreOrigins = false) [protected], [virtual], [inherited]
```

Removes everything related to the sub-formula to remove from the passed formula in the backends of this module. Afterwards the sub-formula is removed from the passed formula.

#### Parameters

|                             |                                                                                                              |
|-----------------------------|--------------------------------------------------------------------------------------------------------------|
| <code>_subformula</code>    | The sub-formula to remove from the passed formula.                                                           |
| <code>_ignoreOrigins</code> | True, if the sub-formula shall be removed regardless of its origins (should only be applied with expertise). |

#### Returns

Reimplemented in [smtrat::ICPModule< Settings >](#), [smtrat::ICPModule< ICPSettings4 >](#), and [smtrat::ICPModule< ICPSettings1 >](#).

**0.15.367.3.39 excludeNotReceivedVariablesFromModel()** void smtrat::Module::excludeNotReceivedVariablesFromModel ( ) const [inherited]  
Excludes all variables from the current model, which do not occur in the received formula.

**0.15.367.3.40 findBestOrigin()** std::vector< [FormulaT](#) >::const\_iterator smtrat::Module::findBestOrigin ( const std::vector< [FormulaT](#) > & *\_origins* ) const [protected], [inherited]

**Parameters**

|                 |  |
|-----------------|--|
| <i>_origins</i> |  |
|-----------------|--|

**Returns**

**0.15.367.3.41 firstSubformulaToPass()** [ModuleInput](#)::const\_iterator smtrat::Module::firstSubformulaToPass ( ) const [inline], [inherited]

**Returns**

The position of the first sub-formula in the passed formula, which has not yet been considered for a consistency check of the backends.

**0.15.367.3.42 firstUncheckedReceivedSubformula()** [ModuleInput](#)::const\_iterator smtrat::Module::firstUncheckedReceivedSubformula ( ) const [inline], [inherited]

**Returns**

The position of the first (by this module) unchecked sub-formula of the received formula.

**0.15.367.3.43 freeSplittingVariable()** static void smtrat::Module::freeSplittingVariable ( const [FormulaT](#) & *\_splittingVariable* ) [inline], [static], [inherited]

**0.15.367.3.44 generateTrivialInfeasibleSubset()** void smtrat::Module::generateTrivialInfeasibleSubset ( ) [inline], [protected], [inherited]  
Stores the trivial infeasible subset being the set of received formulas.

**0.15.367.3.45 getBackendsAllModels()** void smtrat::Module::getBackendsAllModels ( ) const [protected], [inherited]

Stores all models of a backend in the list of all models of this module.

**0.15.367.3.46 getBackendsModel()** void smtrat::Module::getBackendsModel ( ) const [protected], [inherited]

**0.15.367.3.47 getInfeasibleSubsets() [1/2]** void smtrat::Module::getInfeasibleSubsets ( ) [protected], [inherited]  
Copies the infeasible subsets of the passed formula.

**0.15.367.3.48 getInfeasibleSubsets()** [2/2] `std::vector< FormulaSetT > smtrat::Module::getInfeasibleSubsets ( const Module & _backend ) const [protected], [inherited]`  
Get the infeasible subsets the given backend provides.  
Note, that an infeasible subset in a backend contains sub formulas of the passed formula and an infeasible subset of this module contains sub formulas of the received formula. In this method the LATTER is returned.

**Parameters**

|                       |                                                          |
|-----------------------|----------------------------------------------------------|
| <code>_backend</code> | The backend from which to obtain the infeasible subsets. |
|-----------------------|----------------------------------------------------------|

**Returns**

The infeasible subsets the given backend provides.

**0.15.367.3.49 getInformationRelevantFormulas()** `const std::set< FormulaT > & smtrat::Module::getInformationRelevantFormulas ( ) [protected], [inherited]`  
Gets all InformationRelevantFormulas.

**Returns**

Set of all formulas

**0.15.367.3.50 getModelEqualities()** `std::list< std::vector< carl::Variable > > smtrat::Module::getModelEqualities ( ) const [virtual], [inherited]`  
Partition the variables from the current model into equivalence classes according to their assigned value.  
The result is a set of equivalence classes of variables where all variables within one class are assigned the same value. Note that the number of classes may not be minimal, i.e. two classes may actually be equivalent.

**Returns**

Equivalence classes.

**0.15.367.3.51 getOrigins()** [1/3] `void smtrat::Module::getOrigins ( const FormulaT & _formula, FormulaSetT & _origins ) const [inline], [protected], [inherited]`

**Parameters**

|                       |  |
|-----------------------|--|
| <code>_formula</code> |  |
| <code>_origins</code> |  |

**0.15.367.3.52 getOrigins()** [2/3] `void smtrat::Module::getOrigins ( const FormulaT & _formula, FormulasT & _origins ) const [inline], [protected], [inherited]`

**Parameters**

|                       |  |
|-----------------------|--|
| <code>_formula</code> |  |
| <code>_origins</code> |  |

**0.15.367.3.53 getOrigins()** [3/3] `const FormulaT& smrat::Module::getOrigins (`  
`ModuleInput::const_iterator _formula ) const` [inline], [protected], [inherited]  
Gets the origins of the passed formula at the given position.

**Parameters**

|                       |                                                   |
|-----------------------|---------------------------------------------------|
| <code>_formula</code> | The position of a formula in the passed formulas. |
|-----------------------|---------------------------------------------------|

**Returns**

The origins of the passed formula at the given position.

**0.15.367.3.54 getReceivedFormulaSimplified()** `std::pair< bool, FormulaT > smrat::PModule::get<`  
`ReceivedFormulaSimplified ( ) [virtual]`

**Returns**

A pair of a Boolean and a formula, where the Boolean is true, if the received formula could be simplified to an equisatisfiable formula. The formula is equisatisfiable to this module's received formula, if the Boolean is true.

Reimplemented from [smrat::Module](#).

**0.15.367.3.55 hasLemmas()** `bool smrat::Module::hasLemmas ( ) [inline], [inherited]`  
Checks whether this module or any of its backends provides any lemmas.

**0.15.367.3.56 hasValidInfeasibleSubset()** `bool smrat::Module::hasValidInfeasibleSubset ( ) const`  
[inherited]

**Returns**

true, if the module has at least one valid infeasible subset, that is all its elements are sub-formulas of the received formula (pointer must be equal).

**0.15.367.3.57 id()** `std::size_t smrat::Module::id ( ) const [inline], [inherited]`

**Returns**

A unique ID to identify this module instance.

**0.15.367.3.58 infeasibleSubsets()** `const std::vector<FormulaSetT>& smrat::Module::infeasible<`  
`Subsets ( ) const [inline], [inherited]`

**Returns**

The infeasible subsets of the set of received formulas (empty, if this module has not detected unsatisfiability of the conjunction of received formulas).

**0.15.367.3.59 inform()** `bool smrat::Module::inform (`  
`const FormulaT & _constraint ) [inherited]`

Informs the module about the given constraint.

It should be tried to inform this module about any constraint it could receive eventually before assertSubformula is called (preferably for the first time, but at least before adding a formula containing that constraint).

**Parameters**

|                          |                                 |
|--------------------------|---------------------------------|
| <code>_constraint</code> | The constraint to inform about. |
|--------------------------|---------------------------------|

**Returns**

false, if it can be easily decided whether the given constraint is inconsistent; true, otherwise.

**0.15.367.3.60 `informBackends()`** `void smrat::Module::informBackends ( const FormulaT & _constraint ) [inline], [protected], [inherited]`  
Informs all backends of this module about the given constraint.

**Parameters**

|                          |                                 |
|--------------------------|---------------------------------|
| <code>_constraint</code> | The constraint to inform about. |
|--------------------------|---------------------------------|

**0.15.367.3.61 `informCore()`** `virtual bool smrat::Module::informCore ( const FormulaT & _constraint ) [inline], [protected], [virtual], [inherited]`  
Informs the module about the given constraint.

It should be tried to inform this module about any constraint it could receive eventually before assertSubformula is called (preferably for the first time, but at least before adding a formula containing that constraint).

**Parameters**

|                          |                                 |
|--------------------------|---------------------------------|
| <code>_constraint</code> | The constraint to inform about. |
|--------------------------|---------------------------------|

**Returns**

false, if it can be easily decided whether the given constraint is inconsistent; true, otherwise.

Reimplemented in `smrat::UnionFindModule< Settings >`, `smrat::PBPPModule< Settings >`, `smrat::PBGaussModule< Settings >`, `smrat::NRAILModule< Settings >`, `smrat::NewCoveringModule< Settings >`, `smrat::NewCADModule< Settings >`, `smrat::LRAModule< Settings >`, `smrat::LRAModule< LRASettingsICP >`, `smrat::LRAModule< LRASettings1 >`, `smrat::IntBlastModule< Settings >`, `smrat::FPPModule< Settings >`, `smrat::EQModule< Settings >`, `smrat::CurryModule< Settings >`, `smrat::BVMModule< Settings >`, `smrat::ICPModule< Settings >`, `smrat::ICPModule< ICPSettings4 >`, and `smrat::ICPModule< ICPSettings1 >`.

**0.15.367.3.62 `informedConstraints()`** `const carl::FastSet<FormulaT>& smrat::Module::informedConstraints ( ) const [inline], [inherited]`

**Returns**

The position of the first constraint of which no backend has been informed about.

**0.15.367.3.63 `init()`** `void smrat::Module::init ( ) [virtual], [inherited]`

Informs all backends about the so far encountered constraints, which have not yet been communicated.

This method must not be called twice and only before the first runBackends call.

Reimplemented in `smrat::PBPPModule< Settings >`, `smrat::PBGaussModule< Settings >`, `smrat::NRAILModule< Settings >`, `smrat::NewCoveringModule< Settings >`, `smrat::NewCADModule< Settings >`, `smrat::LRAModule< Settings >`, `smrat::LRAModule< LRASettingsICP >`, `smrat::LRAModule< LRASettings1 >`, `smrat::IntBlastModule< Settings >`, `smrat::FPPModule< Settings >`, `smrat::EQModule< Settings >`, `smrat::CurryModule< Settings >`, and `smrat::BVMModule< Settings >`.

**0.15.367.3.64 `is_minimizing()`** `bool smtrat::Module::is_minimizing () const [inline], [inherited]`

**0.15.367.3.65 `isLemmaLevel()`** `bool smtrat::Module::isLemmaLevel (`

`LemmaLevel level ) [protected], [inherited]`

Checks if current lemma level is greater or equal to given level.

Parameters

|                    |                 |
|--------------------|-----------------|
| <code>level</code> | Level to check. |
|--------------------|-----------------|

**0.15.367.3.66 `isPreprocessor()`** `bool smtrat::PModule::isPreprocessor () const [inline]`

Returns

true, if this module is a preprocessor that is a module, which simplifies its received formula to an equisatisfiable formula being passed to its backends. The simplified formula can be obtained with [getReceivedFormulaSimplified\(\)](#).

**0.15.367.3.67 `lemmas()`** `const std::vector<Lemma>& smtrat::Module::lemmas () const [inline], [inherited]`

Returns

A constant reference to the lemmas being valid formulas this module or its backends made.

**0.15.367.3.68 `merge()`** `std::vector< FormulaT > smtrat::Module::merge (`

`const std::vector< FormulaT > & _vecSetA,`

`const std::vector< FormulaT > & _vecSetB ) const [protected], [inherited]`

Merges the two vectors of sets into the first one.

({a,b},{a,c}) and ({b,d},{b}) -> ({a,b,d},{a,b},{a,b,c,d},{a,b,c})

Parameters

|                       |                                  |
|-----------------------|----------------------------------|
| <code>_vecSetA</code> | A vector of sets of constraints. |
| <code>_vecSetB</code> | A vector of sets of constraints. |

Returns

The vector being the two given vectors merged.

**0.15.367.3.69 `model()`** `const Model& smtrat::Module::model () const [inline], [inherited]`

Returns

The assignment of the current satisfiable result, if existent.

**0.15.367.3.70 `modelsDisjoint()`** `bool smtrat::Module::modelsDisjoint (`

`const Model & _modelA,`

`const Model & _modelB ) [static], [protected], [inherited]`

Checks whether there is no variable assigned by both models.

**Parameters**

|                      |                                |
|----------------------|--------------------------------|
| <code>_modelA</code> | The first model to check for.  |
| <code>_modelB</code> | The second model to check for. |

**Returns**

true, if there is no variable assigned by both models; false, otherwise.

**0.15.367.3.71 `moduleName()`** `virtual std::string smtrat::Module::moduleName( ) const [inline], [virtual], [inherited]`

**Returns**

The name of the given module type as name.

Reimplemented in `smtrat::VSModule< Settings >`, `smtrat::UnionFindModule< Settings >`, `smtrat::UFCegarModule< Settings >`, `smtrat::STropModule< Settings >`, `smtrat::SplitSOSModule< Settings >`, `smtrat::PBPPModule< Settings >`, `smtrat::PBGaussModule< Settings >`, `smtrat::NRAILModule< Settings >`, `smtrat::NewCADModule< Settings >`, `smtrat::LVEModule< Settings >`, `smtrat::LRAModule< Settings >`, `smtrat::LRAModule< LRASettingsICP >`, `smtrat::LRAModule< LRASettings1 >`, `smtrat::IntEqModule< Settings >`, `smtrat::IntBlastModule< Settings >`, `smtrat::IncWidthModule< Settings >`, `smtrat::ICPModule< Settings >`, `smtrat::ICPModule< ICPSettings4 >`, `smtrat::ICPModule< ICPSettings1 >`, `smtrat::GBModule< Settings >`, `smtrat::FouMoModule< Settings >`, `smtrat::EQPreprocessingModule< Settings >`, `smtrat::EQModule< Settings >`, `smtrat::CurryModule< Settings >`, `smtrat::CubeLIAModule< Settings >`, `smtrat::CSplitModule< Settings >`, `smtrat::BVMModule< Settings >`, and `smtrat::BEModule< Settings >`.

**0.15.367.3.72 `objective()`** `carl::Variable smtrat::Module::objective( ) const [inline], [inherited]`

**0.15.367.3.73 `originInReceivedFormula()`** `bool smtrat::Module::originInReceivedFormula( const FormulaT & _origin ) const [protected], [inherited]`

**0.15.367.3.74 `passedFormulaBegin()`** `ModuleInput::iterator smtrat::Module::passedFormulaBegin( ) [inline], [protected], [inherited]`

**Returns**

An iterator to the end of the passed formula. TODO: disable this method

**0.15.367.3.75 `passedFormulaEnd()`** `ModuleInput::iterator smtrat::Module::passedFormulaEnd( ) [inline], [protected], [inherited]`

**Returns**

An iterator to the end of the passed formula.

**0.15.367.3.76 `pPassedFormula()`** `const ModuleInput* smtrat::Module::pPassedFormula( ) const [inline], [inherited]`

**Returns**

A pointer to the formula passed to the backends of this module.

**0.15.367.3.77 pReceivedFormula()** const `ModuleInput*` smtrat::Module::pReceivedFormula ( ) const [inline], [inherited]

**Returns**

A pointer to the formula passed to this module.

**0.15.367.3.78 print()** void smtrat::Module::print ( const std::string & `_initiation` = "\*\*\*" ) const [inherited]  
Prints everything relevant of the solver.

**Parameters**

|                          |                      |
|--------------------------|----------------------|
| <code>_initiation</code> | The line initiation. |
|--------------------------|----------------------|

**0.15.367.3.79 printAllModels()** void smtrat::Module::printAllModels ( std::ostream & `_out` = `std::cout` ) [inherited]

Prints all assignments of this module satisfying its received formula if it satisfiable and this module could find an assignment.

**Parameters**

|                   |                                        |
|-------------------|----------------------------------------|
| <code>_out</code> | The stream to print the assignment on. |
|-------------------|----------------------------------------|

**0.15.367.3.80 printInfeasibleSubsets()** void smtrat::Module::printInfeasibleSubsets ( const std::string & `_initiation` = "\*\*\*" ) const [inherited]

Prints the infeasible subsets.

**Parameters**

|                          |                      |
|--------------------------|----------------------|
| <code>_initiation</code> | The line initiation. |
|--------------------------|----------------------|

**0.15.367.3.81 printModel()** void smtrat::Module::printModel ( std::ostream & `_out` = `std::cout` ) const [inherited]

Prints the assignment of this module satisfying its received formula if it satisfiable and this module could find an assignment.

**Parameters**

|                   |                                        |
|-------------------|----------------------------------------|
| <code>_out</code> | The stream to print the assignment on. |
|-------------------|----------------------------------------|

**0.15.367.3.82 printPassedFormula()** void smtrat::Module::printPassedFormula ( const std::string & `_initiation` = "\*\*\*" ) const [inherited]

Prints the vector of passed formula.

**Parameters**

|                          |                      |
|--------------------------|----------------------|
| <code>_initiation</code> | The line initiation. |
|--------------------------|----------------------|

**0.15.367.3.83 printReceivedFormula()** void smtrat::Module::printReceivedFormula ( const std::string & *\_initiation* = "\*\*\*" ) const [inherited]  
 Prints the vector of the received formula.

#### Parameters

|                    |                      |
|--------------------|----------------------|
| <i>_initiation</i> | The line initiation. |
|--------------------|----------------------|

**0.15.367.3.84 probablyLooping()** bool smtrat::Module::probablyLooping ( const typename Poly::PolyType & *\_branchingPolynomial*, const Rational & *\_branchingValue* ) const [protected], [inherited]

Checks whether given the current branching value and branching variable/polynomial it is (highly) probable that this branching is part of an infinite loop of branchings.

#### Parameters

|                             |                                                                                     |
|-----------------------------|-------------------------------------------------------------------------------------|
| <i>_branchingPolynomial</i> | The polynomial to branch at (in most branching strategies this is just a variable). |
| <i>_branchingValue</i>      | The value to branch at.                                                             |

#### Returns

true, if this branching is probably part of an infinite loop of branchings; false, otherwise.

**0.15.367.3.85 receivedFormulaChecked()** void smtrat::Module::receivedFormulaChecked ( ) [inline], [inherited]

Notifies that the received formulas has been checked.

**0.15.367.3.86 receivedFormulasAsInfeasibleSubset()** void smtrat::Module::receivedFormulasAsInfeasibleSubset ( ModuleInput::const\_iterator *\_subformula* ) [inline], [protected], [inherited]

Stores an infeasible subset consisting only of the given received formula.

**0.15.367.3.87 receivedVariable()** bool smtrat::Module::receivedVariable ( carl::Variable::Arg *\_var* ) const [inline], [inherited]

**0.15.367.3.88 remove()** void smtrat::PModule::remove ( ModuleInput::const\_iterator *\_subformula* ) [virtual]

Removes everything related to the given sub-formula of the received formula.

However, it is desired not to lose track of search spaces where no satisfying assignment can be found for the remaining sub-formulas.

#### Parameters

|                    |                                                    |
|--------------------|----------------------------------------------------|
| <i>_subformula</i> | The sub formula of the received formula to remove. |
|--------------------|----------------------------------------------------|

Reimplemented from [smtrat::Module](#).

**0.15.367.3.89 removeCore()** virtual void smrat::Module::removeCore (  
    ModuleInput::const\_iterator formula ) [inline], [protected], [virtual], [inherited]

Removes everything related to the given sub-formula of the received formula.

However, it is desired not to lose track of search spaces where no satisfying assignment can be found for the remaining sub-formulas.

#### Parameters

|                |                                                    |
|----------------|----------------------------------------------------|
| <i>formula</i> | The sub formula of the received formula to remove. |
|----------------|----------------------------------------------------|

Reimplemented in [smrat::VSModule< Settings >](#), [smrat::SATModule< Settings >](#), [smrat::PFEModule< Settings >](#), [smrat::ICPModule< Settings >](#), [smrat::ICPModule< ICPSettings4 >](#), [smrat::ICPModule< ICPSettings1 >](#), [smrat::UnionFindModule< Settings >](#), [smrat::UFCegarModule< Settings >](#), [smrat::STropModule< Settings >](#), [smrat::PBPPModule< Settings >](#), [smrat::PBGaussModule< Settings >](#), [smrat::NRAILModule< Settings >](#), [smrat::NewCoveringModule< Settings >](#), [smrat::NewCADModule< Settings >](#), [smrat::LRAModule< Settings >](#), [smrat::LRAModule< LRASettingsICP >](#), [smrat::LRAModule< LRASettings1 >](#), [smrat::IntEqModule< Settings >](#), [smrat::IntBlastModule< Settings >](#), [smrat::IncWidthModule< Settings >](#), [smrat::ICEModule< Settings >](#), [smrat::FPPModule< Settings >](#), [smrat::FouMoModule< Settings >](#), [smrat::EQModule< Settings >](#), [smrat::CurryModule< Settings >](#), [smrat::CubeLIAModule< Settings >](#), [smrat::CSplitModule< Settings >](#), [smrat::BVModule< Settings >](#), and [smrat::GBModule< Settings >](#).

**0.15.367.3.90 removeOrigin()** std::pair<ModuleInput::iterator,bool> smrat::Module::removeOrigin (   
    ModuleInput::iterator \_formula,  
    const FormulaT & \_origin ) [inline], [protected], [inherited]

**0.15.367.3.91 removeOrigins()** std::pair<ModuleInput::iterator,bool> smrat::Module::removeOrigins (   
    ModuleInput::iterator \_formula,  
    const std::shared\_ptr< std::vector< FormulaT >> & \_origins ) [inline], [protected], [inherited]

**0.15.367.3.92 rPassedFormula()** const ModuleInput& smrat::Module::rPassedFormula ( ) const  
[inline], [inherited]

#### Returns

A reference to the formula passed to the backends of this module.

**0.15.367.3.93 rReceivedFormula()** const ModuleInput& smrat::Module::rReceivedFormula ( ) const  
[inline], [inherited]

#### Returns

A reference to the formula passed to this module.

**0.15.367.3.94 runBackends() [1/2]** virtual Answer smrat::PModule::runBackends ( ) [inline], [virtual]

Reimplemented from [smrat::Module](#).

**0.15.367.3.95 runBackends()** [2/2] [Answer](#) smtrat::PModule::runBackends (

```
 bool _final,
 bool _full,
 carl::Variable _objective) [virtual]
```

Runs the backend solvers on the passed formula.

#### Parameters

|                         |                                                                                                                                       |
|-------------------------|---------------------------------------------------------------------------------------------------------------------------------------|
| <code>_final</code>     | true, if this satisfiability check will be the last one (for a global sat-check), if its result is SAT.                               |
| <code>_full</code>      | false, if this module should avoid too expensive procedures and rather return unknown instead.                                        |
| <code>_objective</code> | if not set to NO_VARIABLE, the module should find an assignment minimizing this objective variable; otherwise any assignment is good. |

#### Returns

True, if the passed formula is consistent; False, if the passed formula is inconsistent; Unknown, otherwise.

Reimplemented from [smtrat::Module](#).

**0.15.367.3.96 setId()** void smtrat::Module::setId (

```
 std::size_t _id) [inline], [inherited]
```

Sets this modules unique ID to identify itself.

#### Parameters

|                 |                                    |
|-----------------|------------------------------------|
| <code>id</code> | The id to set this module's id to. |
|-----------------|------------------------------------|

**0.15.367.3.97 setThreadPriority()** void smtrat::Module::setThreadPriority (

```
 thread_priority _threadPriority) [inline], [inherited]
```

Sets the priority of this module to get a thread for running its check procedure.

#### Parameters

|                              |                                                       |
|------------------------------|-------------------------------------------------------|
| <code>_threadPriority</code> | The priority to set this module's thread priority to. |
|------------------------------|-------------------------------------------------------|

**0.15.367.3.98 solverState()** [Answer](#) smtrat::Module::solverState ( ) const [inline], [inherited]

#### Returns

True, if this module is in a state, such that it has found a solution for its received formula; False, if this module is in a state, such that it has determined that there is no solution for its received formula; Unknown, otherwise.

**0.15.367.3.99 splitUnequalConstraint()** void smtrat::Module::splitUnequalConstraint (

```
 const FormulaT & _unequalConstraint) [protected], [inherited]
```

Adds the following lemmas for the given constraint p!=0.

$(p \neq 0 \leftrightarrow (p < 0 \text{ or } p > 0))$

and  $\neg(p < 0 \text{ and } p > 0)$

**Parameters**

|                                 |                                             |
|---------------------------------|---------------------------------------------|
| <code>_unequalConstraint</code> | A constraint having the relation symbol !=. |
|---------------------------------|---------------------------------------------|

**0.15.367.3.100 `threadPriority()`** `thread_priority` `smtrat::Module::threadPriority () const [inline], [inherited]`

**Returns**

The priority of this module to get a thread for running its check procedure.

**0.15.367.3.101 `updateAllModels()`** `void smtrat::Module::updateAllModels () [virtual], [inherited]`

Updates all satisfying models, if the solver has detected the consistency of the received formula, beforehand.  
Reimplemented in `smtrat::SATModule< Settings >`.

**0.15.367.3.102 `updateLemmas()`** `void smtrat::Module::updateLemmas () [inherited]`

Stores all lemmas of any backend of this module in its own lemma vector.

**0.15.367.3.103 `updateModel()`** `void smtrat::PModule::updateModel () const [virtual]`

Updates the current assignment into the model.

Note, that this is a unique but possibly symbolic assignment maybe containing newly introduced variables.  
Reimplemented from `smtrat::Module`.

**0.15.367.3.104 `usedBackends()`** `const std::vector<Module*>& smtrat::Module::usedBackends () const [inline], [inherited]`

**Returns**

The backends of this module which are currently used (conditions to use this module are fulfilled for the passed formula).

## 0.15.367.4 Field Documentation

**0.15.367.4.1 `mAllBackends`** `std::vector<Module*> smtrat::Module::mAllBackends [protected], [inherited]`

The backends of this module which have been used.

**0.15.367.4.2 `mAllModels`** `std::vector<Model> smtrat::Module::mAllModels [mutable], [protected], [inherited]`

Stores all satisfying assignments.

**0.15.367.4.3 `mBackendsFoundAnswer`** `std::atomic_bool* smtrat::Module::mBackendsFoundAnswer [protected], [inherited]`

This flag is passed to any backend and if it determines an answer to a prior check call, this flag is fired.

**0.15.367.4.4 mConstraintsToInform** `carl::FastSet<FormulaT> smrat::Module::mConstraintsToInform` [protected], [inherited]  
Stores the constraints which the backends must be informed about.

**0.15.367.4.5 mFinalCheck** `bool smrat::Module::mFinalCheck` [protected], [inherited]  
true, if the check procedure should perform a final check which especially means not to postpone splitting decisions

**0.15.367.4.6 mFirstPosInLastBranches** `std::size_t smrat::Module::mFirstPosInLastBranches = 0` [static], [inherited]  
The beginning of the cyclic buffer storing the last branches.

**0.15.367.4.7 mFirstSubformulaToPass** `ModuleInput::iterator smrat::Module::mFirstSubformulaToPass` [protected], [inherited]  
Stores the position of the first sub-formula in the passed formula, which has not yet been considered for a consistency check of the backends.

**0.15.367.4.8 mFirstUncheckedReceivedSubformula** `ModuleInput::const_iterator smrat::Module::mFirstUncheckedReceivedSubformula` [protected], [inherited]  
Stores the position of the first (by this module) unchecked sub-formula of the received formula.

**0.15.367.4.9 mFoundAnswer** `Conditionals smrat::Module::mFoundAnswer` [protected], [inherited]  
Vector of Booleans: If any of them is true, we have to terminate a running check procedure.

**0.15.367.4.10 mFullCheck** `bool smrat::Module::mFullCheck` [protected], [inherited]  
false, if this module should avoid too expensive procedures and rather return unknown instead.

**0.15.367.4.11 mInfeasibleSubsets** `std::vector<FormulaSet> smrat::Module::mInfeasibleSubsets` [protected], [inherited]  
Stores the infeasible subsets.

**0.15.367.4.12 mInformedConstraints** `carl::FastSet<FormulaT> smrat::Module::mInformedConstraints` [protected], [inherited]  
Stores the position of the first constraint of which no backend has been informed about.

**0.15.367.4.13 mLastBranches** `std::vector<Branching> smrat::Module::mLastBranches = std::vector<Branching>(mNumOfBranchVarsToStore, Branching(typename Poly::PolyType(), 0))` [static], [inherited]  
Stores the last branches in a cycle buffer.

**0.15.367.4.14 mLemmas** `std::vector<Lemma> smrat::Module::mLemmas` [protected], [inherited]  
Stores the lemmas being valid formulas this module or its backends made.

**0.15.367.4.15 mModel** `Model smrat::Module::mModel` [mutable], [protected], [inherited]  
Stores the assignment of the current satisfiable result, if existent.

**0.15.367.4.16 mModelComputed** bool smtrat::Module::mModelComputed [mutable], [protected], [inherited]  
True, if the model has already been computed.

**0.15.367.4.17 mNumOfBranchVarsToStore** std::size\_t smtrat::Module::mNumOfBranchVarsToStore = 5 [static], [inherited]  
The number of different variables to consider for a probable infinite loop of branchings.

**0.15.367.4.18 mObjectiveVariable** carl::Variable smtrat::Module::mObjectiveVariable [protected], [inherited]  
Objective variable to be minimized. If set to NO\_VARIABLE, a normal sat check should be performed.

**0.15.367.4.19 mOldSplittingVariables** std::vector< FormulaT > smtrat::Module::mOldSplittingVariables [static], [inherited]  
Reusable splitting variables.

**0.15.367.4.20 mpManager** Manager\* const smtrat::Module::mpManager [protected], [inherited]  
A reference to the manager.

**0.15.367.4.21 mSmallerMusesCheckCounter** unsigned smtrat::Module::mSmallerMusesCheckCounter [mutable], [protected], [inherited]  
Counter used for the generation of the smt2 files to check for smaller muses.

**0.15.367.4.22 mSolverState** std::atomic<Answer> smtrat::Module::mSolverState [protected], [inherited]  
States whether the received formula is known to be satisfiable or unsatisfiable otherwise it is set to unknown.

**0.15.367.4.23 mTheoryPropagations** std::vector<TheoryPropagation> smtrat::Module::mTheoryPropagations [protected], [inherited]

**0.15.367.4.24 mUsedBackends** std::vector<Module\*> smtrat::Module::mUsedBackends [protected], [inherited]  
The backends of this module which are currently used (conditions to use this module are fulfilled for the passed formula).

**0.15.367.4.25 mVariableCounters** std::vector<std::size\_t> smtrat::Module::mVariableCounters [protected], [inherited]  
Maps variables to the number of their occurrences.

### Friends

- std::ostream & **operator<<** (std::ostream &os, const **PolyPool &data**)

### 0.15.381.1 Detailed Description

A pool for polynomials.

The polynomials are stored in a table, that is, a list of lists of polynomials of a given level.

### 0.15.381.2 Constructor & Destructor Documentation

```
0.15.381.2.1 PolyPool() smtrat::cadcells::datastructures::PolyPool::PolyPool (
 const Polynomial::ContextType & context) [inline]
```

Constructs a polynomial pool with respect to a variable ordering.

#### Parameters

|                  |                                                      |
|------------------|------------------------------------------------------|
| <i>var_order</i> | The variable ordering determining polynomial levels. |
|------------------|------------------------------------------------------|

### 0.15.381.3 Member Function Documentation

**0.15.381.3.1 `clear_levels()`** void smtrat::cadcells::datastructures::PolyPool::clear\_levels ( size\_t level ) [inline]

## 0.15.383 smtrat::cadcells::datastructures::PolyRef Struct Reference

Refers to a polynomial.

```
#include <polynomials.h>
```

### Data Fields

- size\_t **level**  
*The level of the polynomial.*
- size\_t **id**  
*The id of the polynomial with respect to its level.*

### 0.15.383.1 Detailed Description

Refers to a polynomial.

### 0.15.383.2 Field Documentation

**0.15.383.2.1 id** size\_t smtrat::cadcells::datastructures::PolyRef::id  
The id of the polynomial with respect to its level.

**0.15.383.2.2 level** size\_t smtrat::cadcells::datastructures::PolyRef::level  
The level of the polynomial.

## 0.15.391 delta::Producer Class Reference

This class iteratively applies the operators to a smtlib file until no further simplifications can be performed.  
`#include <Producer.h>`

### Public Member Functions

- `Producer` (const `Checker` &checker, const `Settings` &settings)  
*Create a new manager that uses the given checker.*
- `void interrupt () const`
- `std::size_t operator() (Node &root)`  
*Apply simplifications to the given node.*

### 0.15.391.1 Detailed Description

This class iteratively applies the operators to a smtlib file until no further simplifications can be performed.

### 0.15.391.2 Constructor & Destructor Documentation

```
0.15.391.2.1 Producer() delta::Producer::Producer (
 const Checker & checker,
 const Settings & settings) [inline]
```

Create a new manager that uses the given checker.

#### Parameters

|                       |                                             |
|-----------------------|---------------------------------------------|
| <code>checker</code>  | <a href="#">Checker</a> to call the solver. |
| <code>settings</code> | <a href="#">Settings</a> object.            |

### 0.15.391.3 Member Function Documentation

```
0.15.391.3.1 interrupt() void delta::Producer::interrupt () const [inline]
```

```
0.15.391.3.2 operator() std::size_t delta::Producer::operator() (
 Node & root) [inline]
```

Apply simplifications to the given node.

#### Parameters

|                   |                                   |
|-------------------|-----------------------------------|
| <code>root</code> | <a href="#">Node</a> to simplify. |
|-------------------|-----------------------------------|

## 0.15.392 delta::ProgressBar Class Reference

This class provides a simple way to show progress bars on the command line.

```
#include <utils.h>
```

### Public Member Functions

- `void operator() ()`  
*Increase progress by one and show progress bar.*
- `void operator() (std::size_t steps)`  
*Increase progress by number of steps and show progress bar.*
- `void operator() (const std::pair< std::size_t, std::size_t > &p)`  
*Print a progress bar for a progress of progress / total.*
- `void operator() (std::size_t progress, std::size_t total)`  
*Print a progress bar for a progress of progress / total.*

### 0.15.392.1 Detailed Description

This class provides a simple way to show progress bars on the command line.

### 0.15.392.2 Member Function Documentation

**0.15.392.2.1 operator() [1/4]** void delta::ProgressBar::operator() () [inline]  
Increase progress by one and show progress bar.

**0.15.392.2.2 operator() [2/4]** void delta::ProgressBar::operator() (  
    const std::pair< std::size\_t, std::size\_t > & p ) [inline]  
Print a progress bar for a progress of progress / total.

#### Parameters

|          |           |
|----------|-----------|
| <i>p</i> | Progress. |
|----------|-----------|

**0.15.392.2.3 operator() [3/4]** void delta::ProgressBar::operator() (  
    std::size\_t progress,  
    std::size\_t total ) [inline]

Print a progress bar for a progress of progress / total.

#### Parameters

|                 |           |
|-----------------|-----------|
| <i>progress</i> | Progress. |
| <i>total</i>    | Total.    |

**0.15.392.2.4 operator() [4/4]** void delta::ProgressBar::operator() (  
    std::size\_t steps ) [inline]

Increase progress by number of steps and show progress bar.

#### Parameters

|              |                        |
|--------------|------------------------|
| <i>steps</i> | Steps to move forward. |
|--------------|------------------------|

## 0.15.393 smrat::cad::Projection< incrementality, backtracking, Settings > Class Template Reference

#include <Projection.h>

### Public Member Functions

- std::size\_t **dim** () const  
*Returns the dimension of the projection.*

### 0.15.393.1 Member Typedef Documentation

**0.15.393.1.1 Constraints** template<typename Settings >  
using smtrat::cad::BaseProjection< Settings >::Constraints = CADConstraints<Settings::backtracking>  
[protected], [inherited]

### 0.15.393.2 Member Function Documentation

**0.15.393.2.1 addEqConstraint() [1/2]** template<typename Settings >  
carl::Bitset smtrat::cad::BaseProjection< Settings >::addEqConstraint (  
 const Poly & p,  
 std::size\_t cid,  
 bool isBound ) [inline], [inherited]

Adds the given polynomial of an equational constraint to the projection. Converts to a UPoly and calls the appropriate overload.

**0.15.393.2.2 addEqConstraint() [2/2]** template<typename Settings >  
virtual carl::Bitset smtrat::cad::BaseProjection< Settings >::addEqConstraint (  
 const UPoly & p,  
 std::size\_t cid,  
 bool isBound ) [inline], [virtual], [inherited]

Adds the given polynomial of an equational constraint to the projection.

Reimplemented in smtrat::cad::Projection< Incrementality::FULL, Backtracking::HIDE, Settings >.

**0.15.393.2.3 addPolynomial() [1/2]** template<typename Settings >  
carl::Bitset smtrat::cad::BaseProjection< Settings >::addPolynomial (  
 const Poly & p,  
 std::size\_t cid,  
 bool isBound ) [inline], [inherited]

Adds the given polynomial to the projection. Converts to a UPoly and calls the appropriate overload.

**0.15.393.2.4 addPolynomial() [2/2]** template<typename Settings >  
virtual carl::Bitset smtrat::cad::BaseProjection< Settings >::addPolynomial (  
 const UPoly & p,  
 std::size\_t cid,  
 bool isBound ) [pure virtual], [inherited]

Adds the given polynomial to the projection.

Implemented in smtrat::cad::Projection< Incrementality::NONE, Backtracking::UNORDERED, Settings >, smtrat::cad::Projection< Incrementality::NONE, Backtracking::ORDERED, Settings >, smtrat::cad::Projection< Incrementality::SIMPLE, Backtracking::HIDE, Settings >, smtrat::cad::Projection< Incrementality::FULL, Backtracking::HIDE, Settings >, and smtrat::cad::Projection< Incrementality::SIMPLE, Backtracking::SIMPLE, Settings >.

**0.15.393.2.5 callRemoveCallback()** template<typename Settings >  
void smtrat::cad::BaseProjection< Settings >::callRemoveCallback (  
 std::size\_t level,  
 const SampleLiftedWith & slw ) const [inline], [protected], [inherited]

**0.15.393.2.6 canBePurgedByBounds()** template<typename Settings >  
 bool [smtrat::cad::BaseProjection< Settings >](#)::canBePurgedByBounds ( const UPoly & p ) const [inline], [protected], [inherited]

Checks whether a polynomial can safely be ignored due to the bounds.

**0.15.393.2.7 dim()** template<typename Settings >  
 std::size\_t [smtrat::cad::BaseProjection< Settings >](#)::dim () const [inline], [inherited]

Returns the dimension of the projection.

**0.15.393.2.8 empty() [1/2]** template<typename Settings >  
 virtual bool [smtrat::cad::BaseProjection< Settings >](#)::empty () [inline], [virtual], [inherited]

**0.15.393.2.9 empty() [2/2]** template<typename Settings >  
 virtual bool [smtrat::cad::BaseProjection< Settings >](#)::empty ( std::size\_t level ) const [pure virtual], [inherited]

Implemented in [smtrat::qe::cad::Projection< Settings >](#), [smtrat::cad::Projection< Incrementality::NONE, Backtracking::UNORDERED >](#)

[smtrat::cad::Projection< Incrementality::NONE, Backtracking::ORDERED, Settings >](#), [smtrat::cad::ModelBasedProjection< Incrementality::NONE, BT, Settings >](#)

[smtrat::cad::Projection< Incrementality::FULL, BT, Settings >](#), and [smtrat::cad::Projection< Incrementality::FULL, Backtracking::HIDDEN >](#)

**0.15.393.2.10 exportAsDot()** template<typename Settings >  
 virtual void [smtrat::cad::BaseProjection< Settings >](#)::exportAsDot ( std::ostream & ) const [inline], [virtual], [inherited]

Reimplemented in [smtrat::cad::Projection< Incrementality::FULL, BT, Settings >](#), and [smtrat::cad::Projection< Incrementality::FULL, Backtracking::HIDDEN >](#)

**0.15.393.2.11 freeID()** template<typename Settings >  
 void [smtrat::cad::BaseProjection< Settings >](#)::freeID ( std::size\_t level, std::size\_t id ) [inline], [protected], [inherited]

Frees a currently used polynomial id for the given level.

**0.15.393.2.12 getID()** template<typename Settings >  
 std::size\_t [smtrat::cad::BaseProjection< Settings >](#)::getID ( std::size\_t level ) [inline], [protected], [inherited]

Returns a fresh polynomial id for the given level.

**0.15.393.2.13 getOrigin()** template<typename Settings >  
 virtual [Origin smtrat::cad::BaseProjection< Settings >](#)::getOrigin ( std::size\_t level, std::size\_t id ) const [inline], [virtual], [inherited]

Reimplemented in [smtrat::cad::Projection< Incrementality::FULL, BT, Settings >](#).

**0.15.393.2.14 getPolyForLifting()** template<typename Settings >  
 OptionalID [smtrat::cad::BaseProjection< Settings >](#)::getPolyForLifting ( std::size\_t level, SampleLiftedWith & slw ) [inline], [inherited]

Get a polynomial from this level suited for lifting.

```
0.15.393.2.15 getPolynomialById() template<typename Settings >
virtual const UPoly& smtrat::cad::BaseProjection< Settings >::getPolynomialById (
 std::size_t level,
 std::size_t id) const [pure virtual], [inherited]
```

Retrieves a polynomial from its id.

Implemented in `smtrat::qe::cad::Projection< Settings >`, `smtrat::cad::Projection< Incrementality::NONE, Backtracking::UNORDERED, Settings >`, `smtrat::cad::Projection< Incrementality::NONE, Backtracking::ORDERED, Settings >`, `smtrat::cad::ModelBasedProjection< Incrementality::NONE, Backtracking::HIDE, Settings >`, `smtrat::cad::Projection< Incrementality::FULL, BT, Settings >`, and `smtrat::cad::Projection< Incrementality::FULL, Backtracking::HIDE, Settings >`.

```
0.15.393.2.16 hasPolynomialById() template<typename Settings >
virtual bool smtrat::cad::BaseProjection< Settings >::hasPolynomialById (
 std::size_t level,
 std::size_t id) const [pure virtual], [inherited]
```

Implemented in `smtrat::qe::cad::Projection< Settings >`, `smtrat::cad::Projection< Incrementality::NONE, Backtracking::UNORDERED, Settings >`, `smtrat::cad::Projection< Incrementality::NONE, Backtracking::ORDERED, Settings >`, `smtrat::cad::ModelBasedProjection< Incrementality::NONE, Backtracking::HIDE, Settings >`, `smtrat::cad::Projection< Incrementality::FULL, BT, Settings >`, and `smtrat::cad::Projection< Incrementality::FULL, Backtracking::HIDE, Settings >`.

```
0.15.393.2.17 isPurged() template<typename Settings >
bool smtrat::cad::BaseProjection< Settings >::isPurged (
 std::size_t level,
 std::size_t id) [inline], [protected], [inherited]
```

```
0.15.393.2.18 removePolynomial() [1/2] template<typename Settings >
void smtrat::cad::BaseProjection< Settings >::removePolynomial (
 const Poly & p,
 std::size_t cid,
 bool isBound) [inline], [inherited]
```

Removes the given polynomial from the projection. Converts to a UPoly and calls the appropriate overload.

```
0.15.393.2.19 removePolynomial() [2/2] template<typename Settings >
virtual void smtrat::cad::BaseProjection< Settings >::removePolynomial (
 const UPoly & p,
 std::size_t cid,
 bool isBound) [pure virtual], [inherited]
```

Removes the given polynomial from the projection.

Implemented in `smtrat::cad::Projection< Incrementality::NONE, Backtracking::ORDERED, Settings >`, `smtrat::cad::ModelBasedProjection< Incrementality::NONE, Backtracking::HIDE, Settings >`, `smtrat::cad::Projection< Incrementality::FULL, BT, Settings >`, `smtrat::cad::Projection< Incrementality::FULL, Backtracking::HIDE, Settings >`, `smtrat::cad::Projection< Incrementality::SIMPLE, BT, Settings >`, and `smtrat::cad::Projection< Incrementality::NONE, Backtracking::HIDE, Settings >`.

```
0.15.393.2.20 reset() template<typename Settings >
void smtrat::cad::BaseProjection< Settings >::reset () [inline], [inherited]
```

Resets all datastructures, use the given variables from now on.

```
0.15.393.2.21 setRemoveCallback() template<typename Settings >
template<typename F >
void smtrat::cad::BaseProjection< Settings >::setRemoveCallback (
 F && f) [inline], [inherited]
```

Sets a callback that is called whenever polynomials are removed.

**0.15.393.2.22 size() [1/2]** template<typename Settings >  
`std::size_t smtrat::cad::BaseProjection< Settings >::size ( ) const [inline], [inherited]`

**0.15.393.2.23 size() [2/2]** template<typename Settings >  
`virtual std::size_t smtrat::cad::BaseProjection< Settings >::size (`  
`std::size_t level ) const [pure virtual], [inherited]`

Implemented in `smtrat::qe::cad::Projection< Settings >`, `smtrat::cad::Projection< Incrementality::NONE, Backtracking::UNORDERED, smtrat::cad::Projection< Incrementality::NONE, Backtracking::ORDERED, Settings >`, `smtrat::cad::ModelBasedProjection< Incrementality::NONE, smtrat::cad::Projection< Incrementality::FULL, BT, Settings >`, and `smtrat::cad::Projection< Incrementality::FULL, Backtracking::HIDDEN, Settings >`.

**0.15.393.2.24 var()** template<typename Settings >  
`carl::Variable smtrat::cad::BaseProjection< Settings >::var (`  
`std::size_t level ) const [inline], [protected], [inherited]`

Returns the variable that corresponds to the given level, that is the variable eliminated in this level.

**0.15.393.2.25 vars()** template<typename Settings >  
`const auto& smtrat::cad::BaseProjection< Settings >::vars ( ) const [inline], [inherited]`

Returns the variables used for projection.

### 0.15.393.3 Field Documentation

**0.15.393.3.1 mConstraints** template<typename Settings >  
`const Constraints& smtrat::cad::BaseProjection< Settings >::mConstraints [protected], [inherited]`

**0.15.393.3.2 mInfo** template<typename Settings >  
`ProjectionInformation smtrat::cad::BaseProjection< Settings >::mInfo [protected], [inherited]`

Additional info on projection, projection levels and projection polynomials.

**0.15.393.3.3 mLiftingQueues** template<typename Settings >  
`std::vector<PolynomialLiftingQueue<BaseProjection> > smtrat::cad::BaseProjection< Settings >::mLiftingQueues [protected], [inherited]`

List of lifting queues that can be used for incremental projection.

**0.15.393.3.4 mOperator** template<typename Settings >  
`ProjectionOperator smtrat::cad::BaseProjection< Settings >::mOperator [protected], [inherited]`

The projection operator.

**0.15.393.3.5 mRemoveCallback** template<typename Settings >  
`std::function<void(std::size_t, const SampleLiftedWith&)> smtrat::cad::BaseProjection< Settings >::mRemoveCallback [protected], [inherited]`

Callback to be called when polynomials are removed. The arguments are the projection level and a bitset that indicate which polynomials were removed in this level.

## 0.15.394 smtrat::qe::cad::Projection< Settings > Class Template Reference

```
#include <Projection.h>
```

### 0.15.394.1 Constructor & Destructor Documentation

**0.15.394.1.1 `Projection()`** `template<typename Settings> smrat::qe::cad::Projection< Settings >::Projection( const Constraints & c ) [inline]`

### 0.15.394.2 Member Function Documentation

**0.15.394.2.1 `addEqConstraint()` [1/2]** `template<typename Settings> carl::Bitset smrat::cad::BaseProjection< Settings >::addEqConstraint( const Poly & p, std::size_t cid, bool isBound ) [inline], [inherited]`

Adds the given polynomial of an equational constraint to the projection. Converts to a UPoly and calls the appropriate overload.

**0.15.394.2.2 `addEqConstraint()` [2/2]** `template<typename Settings> virtual carl::Bitset smrat::cad::BaseProjection< Settings >::addEqConstraint( const UPoly & p, std::size_t cid, bool isBound ) [inline], [virtual], [inherited]`

Adds the given polynomial of an equational constraint to the projection.

Reimplemented in `smrat::cad::Projection< Incrementality::FULL, Backtracking::HIDE, Settings >`.

**0.15.394.2.3 `addPolynomial()` [1/3]** `template<typename Settings> carl::Bitset smrat::cad::BaseProjection< Settings >::addPolynomial( const Poly & p, std::size_t cid, bool isBound ) [inline], [inherited]`

Adds the given polynomial to the projection. Converts to a UPoly and calls the appropriate overload.

**0.15.394.2.4 `addPolynomial()` [2/3]** `template<typename Settings> virtual carl::Bitset smrat::cad::BaseProjection< Settings >::addPolynomial( const UPoly & p, std::size_t cid, bool isBound ) [pure virtual], [inherited]`

Adds the given polynomial to the projection.

Implemented in `smtrat::cad::Projection< Incrementality::NONE, Backtracking::UNORDERED, Settings >`, `smtrat::cad::Projection< Incrementality::NONE, Backtracking::ORDERED, Settings >`, `smtrat::cad::Projection< Incrementality::FULL, Backtracking::HIDE, Settings >`, and `smtrat::cad::Projection< Incrementality::SIMPLE, Backtracking::HIDE, Settings >`.

**0.15.394.2.5 addPolynomial() [3/3]** `template<typename Settings >`  
`carl::Bitset smtrat::qe::cad::Projection< Settings >::addPolynomial (`  
    `const UPoly & p,`  
    `std::size_t cid,`

### 0.15.395.1 Constructor & Destructor Documentation

**0.15.395.1.1 Projection()** template<typename Settings >  
`smtrat::cad::Projection< Incrementality::FULL, Backtracking::HIDE, Settings >::Projection (`  
`const Constraints & c ) [inline]`

### 0.15.395.2 Member Function Documentation

**0.15.395.2.1 addEqConstraint() [1/2]** template<typename Settings >  
`carl::Bitset smtrat::cad::BaseProjection< Settings >::addEqConstraint (`  
`const Poly & p,`  
`std::size_t cid,`  
`bool isBound ) [inline], [inherited]`

Adds the given polynomial of an equational constraint to the projection. Converts to a UPoly and calls the appropriate overload.

**0.15.395.2.2 addEqConstraint() [2/2]** template<typename Settings >  
`carl::Bitset smtrat::cad::Projection< Incrementality::FULL, Backtracking::HIDE, Settings >::addEqConstraint (`  
`const UPoly & p,`  
`std::size_t cid,`  
`bool isBound ) [inline], [override], [virtual]`

Adds the given polynomial of an equational constraint to the projection.

Polynomial already exists.

Reimplemented from `smtrat::cad::BaseProjection< Settings >`.

**0.15.395.2.3 addPolynomial() [1/2]** template<typename Settings >  
`carl::Bitset smtrat::cad::BaseProjection< Settings >::addPolynomial (`  
`const Poly & p,`  
`std::size_t cid,`  
`bool isBound ) [inline], [inherited]`

Adds the given polynomial to the projection. Converts to a UPoly and calls the appropriate overload.

**0.15.395.2.4 addPolynomial() [2/2]** template<typename Settings >  
`carl::Bitset smtrat::cad::Projection< Incrementality::FULL, Backtracking::HIDE, Settings >::addPolynomial (`  
`const UPoly & p,`  
`std::size_t cid,`  
`bool isBound ) [inline], [override], [virtual]`

Adds the given polynomial to the projection.

Implements `smtrat::cad::BaseProjection< Settings >`.

**0.15.395.2.5 callRemoveCallback()** template<typename Settings >  
`void smtrat::cad::BaseProjection< Settings >::callRemoveCallback (`  
`std::size_t level,`  
`const SampleLiftedWith & slw ) const [inline], [protected], [inherited]`

**0.15.395.2.6 canBePurgedByBounds()** template<typename Settings >  
bool smtrat::cad::BaseProjection< Settings >::canBePurgedByBounds ( const UPoly & p ) const [inline], [protected], [inherited]  
Checks whether a polynomial can safely be ignored due to the bounds.

**0.15.395.2.7 dim() [1/2]** template<typename Settings >  
std::size\_t smtrat::cad::BaseProjection< Settings >::dim () const [inline], [inherited]  
Returns the dimension of the projection.

**0.15.395.2.8 dim() [2/2]** template<typename Settings >  
std::size\_t smtrat::cad::BaseProjection< Settings >::dim [inline]  
Returns the dimension of the projection.

**0.15.395.2.9 empty() [1/2]** template<typename Settings >  
virtual bool smtrat::cad::BaseProjection< Settings >::empty () [inline], [virtual], [inherited]

**0.15.395.2.10 empty() [2/2]** template<typename Settings >  
bool smtrat::cad::Projection< Incrementality::FULL, Backtracking::HIDE, Settings >::empty ( std::size\_t level ) const [inline], [override], [virtual]  
Implements smtrat::cad::BaseProjection< Settings >.

**0.15.395.2.11 exportAsDot()** template<typename Settings >  
void smtrat::cad::Projection< Incrementality::FULL, Backtracking::HIDE, Settings >::exportAsDot ( std::ostream & out ) const [inline], [override], [virtual]  
Reimplemented from smtrat::cad::BaseProjection< Settings >.

**0.15.395.2.12 freeID()** template<typename Settings >  
void smtrat::cad::BaseProjection< Settings >::freeID ( std::size\_t level, std::size\_t id ) [inline], [protected], [inherited]  
Frees a currently used polynomial id for the given level.

**0.15.395.2.13 getID()** template<typename Settings >  
std::size\_t smtrat::cad::BaseProjection< Settings >::getID ( std::size\_t level ) [inline], [protected], [inherited]  
Returns a fresh polynomial id for the given level.

**0.15.395.2.14 getOrigin()** template<typename Settings >  
virtual Origin smtrat::cad::BaseProjection< Settings >::getOrigin ( std::size\_t level, std::size\_t id ) const [inline], [virtual], [inherited]  
Reimplemented in smtrat::cad::Projection< Incrementality::FULL, BT, Settings >.

```
0.15.395.2.15 getPolyForLifting() template<typename Settings >
OptionalID smtrat::cad::BaseProjection< Settings >::getPolyForLifting (
 std::size_t level,
 SampleLiftedWith & slw) [inline], [inherited]
```

Get a polynomial from this level suited for lifting.

```
0.15.395.2.16 getPolynomialById() template<typename Settings >
const UPoly& smtrat::cad::Projection< Incrementality::FULL, Backtracking::HIDE, Settings >::getPolynomialById (
 std::size_t level,
 std::size_t id) const [inline], [override], [virtual]
```

Retrieves a polynomial from its id.

Implements [smtrat::cad::BaseProjection< Settings >](#).

```
0.15.395.2.17 hasPolynomialById() template<typename Settings >
bool smtrat::cad::Projection< Incrementality::FULL, Backtracking::HIDE, Settings >::hasPolynomialById (
 std::size_t level,
 std::size_t id) const [inline], [override], [virtual]
```

Implements [smtrat::cad::BaseProjection< Settings >](#).

```
0.15.395.2.18 isPurged() template<typename Settings >
bool smtrat::cad::BaseProjection< Settings >::isPurged (
 std::size_t level,
 std::size_t id) [inline], [protected], [inherited]
```

```
0.15.395.2.19 printPolynomialIDs() template<typename Settings >
void smtrat::cad::Projection< Incrementality::FULL, Backtracking::HIDE, Settings >::printPolynomialIDs () const [inline]
```

```
0.15.395.2.20 projectNewPolynomial() template<typename Settings >
carl::Bitset smtrat::cad::Projection< Incrementality::FULL, Backtracking::HIDE, Settings >::projectNewPolynomial (
 const ConstraintSelection & cs = carl::Bitset(true)) [inline]
```

```
0.15.395.2.21 removePolynomial() [1/2] template<typename Settings >
void smtrat::cad::BaseProjection< Settings >::removePolynomial (
 const Poly & p,
 std::size_t cid,
 bool isBound) [inline], [inherited]
```

Removes the given polynomial from the projection. Converts to a UPoly and calls the appropriate overload.

```
0.15.395.2.22 removePolynomial() [2/2] template<typename Settings >
void smtrat::cad::Projection< Incrementality::FULL, Backtracking::HIDE, Settings >::removePolynomial (
 const UPoly & p,
 std::size_t cid,
 bool isBound) [inline], [override], [virtual]
```

Removes the given polynomial from the projection.

Implements [smtrat::cad::BaseProjection< Settings >](#).

**0.15.395.2.23 `reset()`** template<typename Settings >  
void [smtrat::cad::Projection< Incrementality::FULL, Backtracking::HIDE, Settings >](#)::reset ( )  
[inline]

**0.15.395.2.24 `setRemoveCallback()`** template<typename Settings >  
template<typename F >  
void [smtrat::cad::BaseProjection< Settings >](#)::setRemoveCallback ( F && f ) [inline], [inherited]

Sets a callback that is called whenever polynomials are removed.

**0.15.395.2.25 `size() [1/4]`** template<typename Settings >  
std::size\_t [smtrat::cad::BaseProjection< Settings >](#)::size ( ) const [inline], [inherited]

std::size\_t [smtrat::cad::BaseProjection< Settings >](#)::size ( void ) [inline]

**0.15.395.2.27 `size() [3/4]`** template<typename Settings >  
std::size\_t [smtrat::cad::Projection< Incrementality::FULL, Backtracking::HIDE, Settings >](#)::size ( std::size\_t level ) const [inline], [override], [virtual]  
Implements [smtrat::cad::BaseProjection< Settings >](#).

**0.15.395.2.28 `size() [4/4]`** template<typename Settings >  
virtual std::size\_t [smtrat::cad::BaseProjection< Settings >](#)::size ( void )

**0.15.395.2.29 `var()`** template<typename Settings >  
carl::Variable [smtrat::cad::BaseProjection< Settings >](#)::var ( std::size\_t level ) const [inline], [protected], [inherited]  
Returns the variable that corresponds to the given level, that is the variable eliminated in this level.

**0.15.395.2.30 `vars()`** template<typename Settings >  
const auto& [smtrat::cad::BaseProjection< Settings >](#)::vars ( ) const [inline], [inherited]  
Returns the variables used for projection.

### 0.15.395.3 Friends And Related Function Documentation

**0.15.395.3.1 `operator<<`** template<typename Settings >  
template<typename S >  
std::ostream& operator<< ( std::ostream & os, const [Projection< Incrementality::FULL, Backtracking::HIDE, S >](#) & p ) [friend]

### 0.15.395.4 Field Documentation

**0.15.395.4.1 mRemoveCallback** template<typename Settings >  
 std::function<void(std::size\_t, const SampleLiftedWith&) > smtrat::cad::BaseProjection< Settings >::mRemoveCallback [protected], [inherited]  
 Callback to be called when polynomials are removed. The arguments are the projection level and a bitset that indicate which polynomials were removed in this level.

## 0.15.396 smtrat::cad::Projection< Incrementality::FULL, BT, Settings > Class Template Reference

```
#include <Projection_F.h>
```

### 0.15.397.1 Detailed Description

```
template<typename Settings>
class smrat::cad::Projection< Incrementality::NONE, Backtracking::ORDERED, Settings >
```

This class implements a projection that supports no incrementality and expects backtracking to be in order.  
It is based on the following data structures:

- mPolynomialIDs: maps polynomials to a (per level) unique id
- mPolynomials: stores polynomials as a list (per level) with their origin

The origin of a polynomial in level zero is the id of the corresponding constraint. For all other levels, it is the id of some polynomial from level zero such that the polynomial must be removed if the origin is removed. For a single projection operation, the resulting origin is the largest of the participating polynomials. If a polynomial is derived from multiple projection operations, the origin is the earliest and thus smallest, at least for this non-incremental setting.

### 0.15.397.2 Constructor & Destructor Documentation

```
0.15.397.2.1 Projection() template<typename Settings >
smrat::cad::Projection< Incrementality::NONE, Backtracking::ORDERED, Settings >::Projection (
 const Constraints & c) [inline]
```

### 0.15.397.3 Member Function Documentation

```
0.15.397.3.1 addEqConstraint() [1/2] template<typename Settings >
carl::Bitset smrat::cad::BaseProjection< Settings >::addEqConstraint (
 const Poly & p,
 std::size_t cid,
 bool isBound) [inline], [inherited]
```

Adds the given polynomial of an equational constraint to the projection. Converts to a UPoly and calls the appropriate overload.

```
0.15.397.3.2 addEqConstraint() [2/2] template<typename Settings >
virtual carl::Bitset smrat::cad::BaseProjection< Settings >::addEqConstraint (
 const UPoly & p,
 std::size_t cid,
 bool isBound) [inline], [virtual], [inherited]
```

Adds the given polynomial of an equational constraint to the projection.

Reimplemented in [smrat::cad::Projection< Incrementality::FULL, Backtracking::HIDE, Settings >](#).

```
0.15.397.3.3 addPolynomial() [1/2] template<typename Settings >
carl::Bitset smrat::cad::BaseProjection< Settings >::addPolynomial (
 const Poly & p,
 std::size_t cid,
 bool isBound) [inline], [inherited]
```

Adds the given polynomial to the projection. Converts to a UPoly and calls the appropriate overload.

```
0.15.397.3.4 addPolynomial() [2/2] template<typename Settings >
carl::Bitset smtrat::cad::Projection< Incrementality::NONE, Backtracking::ORDERED, Settings
>::addPolynomial (
 const UPoly & p,
 std::size_t cid,
 bool) [inline], [override], [virtual]
```

Adds the given polynomial to the projection with the given constraint id as origin.

Asserts that the main variable of the polynomial is the first variable.

Implements [smtrat::cad::BaseProjection< Settings >](#).

```
0.15.397.3.5 callRemoveCallback() template<typename Settings >
void smtrat::cad::BaseProjection< Settings >::callRemoveCallback (
 std::size_t level,
 const SampleLiftedWith & slw) const [inline], [protected], [inherited]
```

```
0.15.397.3.6 canBePurgedByBounds() template<typename Settings >
bool smtrat::cad::BaseProjection< Settings >::canBePurgedByBounds (
 const UPoly & p) const [inline], [protected], [inherited]
```

Checks whether a polynomial can safely be ignored due to the bounds.

```
0.15.397.3.7 dim() [1/2] template<typename Settings >
std::size_t smtrat::cad::BaseProjection< Settings >::dim () const [inline], [inherited]
```

Returns the dimension of the projection.

```
0.15.397.3.8 dim() [2/2] template<typename Settings >
std::size_t smtrat::cad::BaseProjection< Settings >::dim [inline]
```

Returns the dimension of the projection.

```
0.15.397.3.9 empty() [1/2] template<typename Settings >
virtual bool smtrat::cad::BaseProjection< Settings >::empty () [inline], [virtual], [inherited]
```

```
0.15.397.3.10 empty() [2/2] template<typename Settings >
bool smtrat::cad::Projection< Incrementality::NONE, Backtracking::ORDERED, Settings >::empty (
 std::size_t level) const [inline], [override], [virtual]
```

Returns whether the number of polynomials in this level is zero.

Implements [smtrat::cad::BaseProjection< Settings >](#).

```
0.15.397.3.11 exportAsDot() template<typename Settings >
virtual void smtrat::cad::BaseProjection< Settings >::exportAsDot (
 std::ostream &) const [inline], [virtual], [inherited]
```

Reimplemented in [smtrat::cad::Projection< Incrementality::FULL, BT, Settings >](#), and [smtrat::cad::Projection< Incrementality::FULL, BT, Settings >](#).

```
0.15.397.3.12 freeID() template<typename Settings >
void smtrat::cad::BaseProjection< Settings >::freeID (
 std::size_t level,
 std::size_t id) [inline], [protected], [inherited]
```

Frees a currently used polynomial id for the given level.

**0.15.397.3.13 `getID()`** template<typename `Settings`>  
std::size\_t `smtrat::cad::BaseProjection< Settings >`::`getID` (  
 std::size\_t `level`) [inline], [protected], [inherited]  
Returns a fresh polynomial id for the given level.

**0.15.397.3.14 `getOrigin()`** template<typename `Settings`>  
virtual `Origin` `smtrat::cad::BaseProjection< Settings >`::`getOrigin` (  
 std::size\_t `level`,  
 std::size\_t `id`) const [inline], [virtual], [inherited]  
Reimplemented in `smtrat::cad::Projection< Incrementality::FULL, BT, Settings >`.

**0.15.397.3.15 `getPolyForLifting()`** template<typename `Settings`>  
`OptionalID` `smtrat::cad::BaseProjection< Settings >`::`getPolyForLifting` (  
 std::size\_t `level`,  
 `SampleLiftedWith` & `slw`) [inline], [inherited]  
Get a polynomial from this level suited for lifting.

**0.15.397.3.16 `getPolynomialById()`** template<typename `Settings`>  
const `UPoly&` `smtrat::cad::Projection< Incrementality::NONE, Backtracking::ORDERED, Settings >`::`getPolynomialById` (  
 std::size\_t `level`,  
 std::size\_t `id`) const [inline], [override], [virtual]  
Get the polynomial from this level with the given id.  
Implements `smtrat::cad::BaseProjection< Settings >`.

**0.15.397.3.17 `hasPolynomialById()`** template<typename `Settings`>  
bool `smtrat::cad::Projection< Incrementality::NONE, Backtracking::ORDERED, Settings >`::`hasPolynomialById` (  
 std::size\_t `level`,  
 std::size\_t `id`) const [inline], [override], [virtual]  
Implements `smtrat::cad::BaseProjection< Settings >`.

**0.15.397.3.18 `isPurged()`** template<typename `Settings`>  
bool `smtrat::cad::BaseProjection< Settings >`::`isPurged` (  
 std::size\_t `level`,  
 std::size\_t `id`) [inline], [protected], [inherited]

**0.15.397.3.19 `projectNewPolynomial()`** template<typename `Settings`>  
carl::Bitset `smtrat::cad::Projection< Incrementality::NONE, Backtracking::ORDERED, Settings >`::`projectNewPolynomial` (  
 const `ConstraintSelection` & = `carl::Bitset(true)`) [inline]  
Returns false, as the projection is not incremental.

**0.15.397.3.20 `removePolynomial()` [1/2]** template<typename `Settings`>  
void `smtrat::cad::BaseProjection< Settings >`::`removePolynomial` (  
 const `Poly` & `p`,  
 std::size\_t `cid`,  
 bool `isBound`) [inline], [inherited]

Removes the given polynomial from the projection. Converts to a `UPoly` and calls the appropriate overload.

**0.15.397.3.21 removePolynomial() [2/2]** template<typename Settings >  
void smrat::cad::Projection< Incrementality::NONE, Backtracking::ORDERED, Settings >::remove←  
Polynomial ( const UPoly & p, std::size\_t cid, bool ) [inline], [override], [virtual]

Removed the given polynomial from the projection.

Asserts that this polynomial was the one added last and has the given constraint id as origin. Calls the callback function for every level with a mask designating the polynomials removed from this level.

Implements [smrat::cad::BaseProjection< Settings >](#).

**0.15.397.3.22 reset()** template<typename Settings >  
void smrat::cad::Projection< Incrementality::NONE, Backtracking::ORDERED, Settings >::reset ( ) [inline]

Resets all datastructures, use the given variables from now on.

**0.15.397.3.23 setRemoveCallback()** template<typename Settings >  
template<typename F >  
void smrat::cad::BaseProjection< Settings >::setRemoveCallback ( F && f ) [inline], [inherited]

Sets a callback that is called whenever polynomials are removed.

**0.15.397.3.24 size() [1/4]** template<typename Settings >  
std::size\_t smrat::cad::BaseProjection< Settings >::size ( ) const [inline], [inherited]

**0.15.397.3.25 size() [2/4]** template<typename Settings >  
std::size\_t smrat::cad::BaseProjection< Settings >::size ( void ) [inline]

**0.15.397.3.26 size() [3/4]** template<typename Settings >  
std::size\_t smrat::cad::Projection< Incrementality::NONE, Backtracking::ORDERED, Settings >::size ( std::size\_t level ) const [inline], [override], [virtual]

Returns the number of polynomials in this level.

Implements [smrat::cad::BaseProjection< Settings >](#).

**0.15.397.3.27 size() [4/4]** template<typename Settings >  
virtual std::size\_t smrat::cad::BaseProjection< Settings >::size ( void )

**0.15.397.3.28 var()** template<typename Settings >  
carl::Variable smrat::cad::BaseProjection< Settings >::var ( std::size\_t level ) const [inline], [protected], [inherited]

Returns the variable that corresponds to the given level, that is the variable eliminated in this level.

**0.15.397.3.29 vars()** template<typename Settings >  
const auto& smrat::cad::BaseProjection< Settings >::vars ( ) const [inline], [inherited]

Returns the variables used for projection.

#### 0.15.397.4 Friends And Related Function Documentation

```
0.15.397.4.1 operator<< template<typename Settings >
template<typename S >
std::ostream& operator<< (
 std::ostream & os,
 const Projection< Incrementality::NONE, Backtracking::ORDERED, S > & p) [friend]
```

#### 0.15.397.5 Field Documentation

```
0.15.397.5.1 mConstraints template<typename Settings >
const Constraints& smrat::cad::BaseProjection< Settings >::mConstraints [protected], [inherited]
```

**0.15.397.5.2 mInfo** template<typename Settings >  
*ProjectionInformation* smrat::cad::BaseProjection< Settings >::mInfo [protected], [inherited]  
Additional info on projection, projection levels and projection polynomials.

**0.15.397.5.3 mRemoveCallback** template<typename Settings >  
std::function<void(std::size\_t, const SampleLiftedWith&)> smrat::cad::BaseProjection< Settings >::mRemoveCallback [protected], [inherited]  
Callback to be called when polynomials are removed. The arguments are the projection level and a bitset that indicate which polynomials were removed in this level.

### 0.15.398 smrat::cad::Projection< Incrementality::NONE, Backtracking::UNORDERED, Settings > Class Template Reference

This class implements a projection that supports no incrementality and allows backtracking to be out of order.  
`#include <Projection_NU.h>`

### 0.15.398.1 Detailed Description

```
template<typename Settings>
class smrat::cad::Projection< Incrementality::NONE, Backtracking::UNORDERED, Settings >
```

This class implements a projection that supports no incrementality and allows backtracking to be out of order.

## 0.15.398.2 Constructor & Destructor Documentation

**0.15.398.2.1 Projection()** template<typename Settings >  
smrat::cad::Projection< Incrementality::NONE, Backtracking::UNORDERED, Settings >::Projection  
(  
    const Constraints & c ) [inline]

## 0.15.398.3 Member Function Documentation

**0.15.398.3.1 addEqConstraint() [1/2]** template<typename Settings >  
carl::Bitset smrat::cad::BaseProjection< Settings >::addEqConstraint (  
    const Poly & p,  
    std::size\_t cid,  
    bool isBound ) [inline], [inherited]

Adds the given polynomial of an equational constraint to the projection. Converts to a UPoly and calls the appropriate overload.

**0.15.398.3.2 addEqConstraint() [2/2]** template<typename Settings >  
virtual carl::Bitset smrat::cad::BaseProjection< Settings >::addEqConstraint (  
    const UPoly & p,  
    std::size\_t cid,  
    bool isBound ) [inline], [virtual], [inherited]

Adds the given polynomial of an equational constraint to the projection.

Reimplemented in smrat::cad::Projection< Incrementality::FULL, Backtracking::HIDE, Settings >.

**0.15.398.3.3 addPolynomial() [1/2]** template<typename Settings >  
carl::Bitset smrat::cad::BaseProjection< Settings >::addPolynomial (  
    const Poly & p,  
    std::size\_t cid,  
    bool isBound ) [inline], [inherited]

Adds the given polynomial to the projection. Converts to a UPoly and calls the appropriate overload.

**0.15.398.3.4 addPolynomial() [2/2]** template<typename Settings >  
carl::Bitset smrat::cad::Projection< Incrementality::NONE, Backtracking::UNORDERED, Settings >::addPolynomial (  
    const UPoly & p,  
    std::size\_t cid,  
    bool isBound ) [inline], [override], [virtual]

Adds the given polynomial to the projection.

Implements smrat::cad::BaseProjection< Settings >.

Reimplemented in smrat::cad::Projection< Incrementality::SIMPLE, BT, Settings >.

**0.15.398.3.5 callRemoveCallback()** template<typename Settings >  
void smrat::cad::BaseProjection< Settings >::callRemoveCallback (  
    std::size\_t level,  
    const SampleLiftedWith & slw ) const [inline], [protected], [inherited]

**0.15.398.3.6 canBePurgedByBounds()** template<typename Settings >  
bool smtrat::cad::BaseProjection< Settings >::canBePurgedByBounds ( const UPoly & p ) const [inline], [protected], [inherited]  
Checks whether a polynomial can safely be ignored due to the bounds.

**0.15.398.3.7 dim() [1/2]** template<typename Settings >  
std::size\_t smtrat::cad::BaseProjection< Settings >::dim () const [inline], [inherited]  
Returns the dimension of the projection.

**0.15.398.3.8 dim() [2/2]** template<typename Settings >  
std::size\_t smtrat::cad::BaseProjection< Settings >::dim [inline]  
Returns the dimension of the projection.

**0.15.398.3.9 empty() [1/2]** template<typename Settings >  
virtual bool smtrat::cad::BaseProjection< Settings >::empty () [inline], [virtual], [inherited]

**0.15.398.3.10 empty() [2/2]** template<typename Settings >  
bool smtrat::cad::Projection< Incrementality::NONE, Backtracking::UNORDERED, Settings >::empty()  
( std::size\_t level ) const [inline], [override], [virtual]  
Implements smtrat::cad::BaseProjection< Settings >.

**0.15.398.3.11 exportAsDot()** template<typename Settings >  
virtual void smtrat::cad::BaseProjection< Settings >::exportAsDot ( std::ostream & ) const [inline], [virtual], [inherited]  
Reimplemented in smtrat::cad::Projection< Incrementality::FULL, BT, Settings >, and smtrat::cad::Projection< Incrementality::FULL,

**0.15.398.3.12 freeID()** template<typename Settings >  
void smtrat::cad::BaseProjection< Settings >::freeID ( std::size\_t level, std::size\_t id ) [inline], [protected], [inherited]  
Frees a currently used polynomial id for the given level.

**0.15.398.3.13 getID()** template<typename Settings >  
std::size\_t smtrat::cad::BaseProjection< Settings >::getID ( std::size\_t level ) [inline], [protected], [inherited]  
Returns a fresh polynomial id for the given level.

**0.15.398.3.14 getOrigin()** template<typename Settings >  
virtual Origin smtrat::cad::BaseProjection< Settings >::getOrigin ( std::size\_t level, std::size\_t id ) const [inline], [virtual], [inherited]  
Reimplemented in smtrat::cad::Projection< Incrementality::FULL, BT, Settings >.

```
0.15.398.3.15 getPolyForLifting() template<typename Settings >
OptionalID smrat::cad::BaseProjection< Settings >::getPolyForLifting (
 std::size_t level,
 SampleLiftedWith & slw) [inline], [inherited]
```

Get a polynomial from this level suited for lifting.

```
0.15.398.3.16 getPolynomialById() template<typename Settings >
const UPoly& smrat::cad::Projection< Incrementality::NONE, Backtracking::UNORDERED, Settings
>::getPolynomialById (
 std::size_t level,
 std::size_t id) const [inline], [override], [virtual]
```

Retrieves a polynomial from its id.

Implements [smrat::cad::BaseProjection< Settings >](#).

```
0.15.398.3.17 hasPolynomialById() template<typename Settings >
bool smrat::cad::Projection< Incrementality::NONE, Backtracking::UNORDERED, Settings >::has←

- carl::Bitset **addEqConstraint** (const `Poly` &p, std::size\_t cid, bool isBound)

- virtual carl::Bitset **addEqConstraint** (const UPoly &p, std::size\_t cid, bool isBound)
 

Adds the given polynomial of an equational constraint to the projection. Converts to a UPoly and calls the appropriate overload.
- virtual OptionalID **getPolyForLifting** (std::size\_t level, SampleLiftedWith &slw)
 

Get a polynomial from this level suited for lifting.
- virtual void **exportAsDot** (std::ostream &) const
- virtual Origin **getOrigin** (std::size\_t level, std::size\_t id) const

### Protected Member Functions

- void **callRemoveCallback** (std::size\_t level, const SampleLiftedWith &slw) const
- std::size\_t **getID** (std::size\_t level)
 

Returns a fresh polynomial id for the given level.
- void **freeID** (std::size\_t level, std::size\_t id)
 

Frees a currently used polynomial id for the given level.
- carl::Variable **var** (std::size\_t level) const
 

Returns the variable that corresponds to the given level, that is the variable eliminated in this level.
- bool **canBePurgedByBounds** (const UPoly &p) const
 

Checks whether a polynomial can safely be ignored due to the bounds.
- bool **isPurged** (std::size\_t level, std::size\_t id)

### Protected Attributes

- const Constraints & **mConstraints**
- ProjectionInformation **mInfo**

Additional info on projection, projection levels and projection polynomials.
- std::function< void(std::size\_t, const SampleLiftedWith &) > **mRemoveCallback**

Callback to be called when polynomials are removed. The arguments are the projection level and a bitset that indicate which polynomials were removed in this level.

## 0.15.399.1 Constructor & Destructor Documentation

```
0.15.399.1.1 Projection() template<typename Settings , Backtracking BT>
template<typename ... Args>
smrat::cad::Projection< Incrementality::SIMPLE, BT, Settings >::Projection (
 Args &&... args) [inline]
```

## 0.15.399.2 Member Function Documentation

```
0.15.399.2.1 addEqConstraint() [1/2] template<typename Settings >
carl::Bitset smrat::cad::BaseProjection< Settings >::addEqConstraint (
 const Poly & p,
 std::size_t cid,
 bool isBound) [inline], [inherited]
```

Adds the given polynomial of an equational constraint to the projection. Converts to a UPoly and calls the appropriate overload.

**0.15.399.2.2 addEqConstraint() [2/2]** template<typename Settings >  
virtual carl::Bitset smtrat::cad::BaseProjection< Settings >::addEqConstraint ( const UPoly & p, std::size\_t cid, bool isBound ) [inline], [virtual], [inherited]

Adds the given polynomial of an equational constraint to the projection.

Reimplemented in smtrat::cad::Projection< Incrementality::FULL, Backtracking::HIDE, Settings >.

**0.15.399.2.3 addPolynomial() [1/2]** template<typename Settings >  
carl::Bitset smtrat::cad::BaseProjection< Settings >::addPolynomial ( const Poly & p, std::size\_t cid, bool isBound ) [inline], [inherited]

Adds the given polynomial to the projection. Converts to a UPoly and calls the appropriate overload.

**0.15.399.2.4 addPolynomial() [2/2]** template<typename Settings , Backtracking BT>  
carl::Bitset smtrat::cad::Projection< Incrementality::SIMPLE, BT, Settings >::addPolynomial ( const UPoly & p, std::size\_t cid, bool isBound ) [inline], [virtual]

Adds the given polynomial to the projection.

Reimplemented from smtrat::cad::Projection< Incrementality::NONE, Backtracking::UNORDERED, Settings >.

**0.15.399.2.5 callRemoveCallback()** template<typename Settings >  
void smtrat::cad::BaseProjection< Settings >::callRemoveCallback ( std::size\_t level, const SampleLiftedWith & slw ) const [inline], [protected], [inherited]

**0.15.399.2.6 canBePurgedByBounds()** template<typename Settings >  
bool smtrat::cad::BaseProjection< Settings >::canBePurgedByBounds ( const UPoly & p ) const [inline], [protected], [inherited]

Checks whether a polynomial can safely be ignored due to the bounds.

**0.15.399.2.7 dim() [1/2]** template<typename Settings >  
std::size\_t smtrat::cad::BaseProjection< Settings >::dim ( ) const [inline], [inherited]  
Returns the dimension of the projection.

**0.15.399.2.8 dim() [2/2]** template<typename Settings >  
std::size\_t smtrat::cad::BaseProjection< Settings >::dim [inline], [inherited]  
Returns the dimension of the projection.

**0.15.399.2.9 empty() [1/2]** template<typename Settings >  
virtual bool smtrat::cad::BaseProjection< Settings >::empty ( ) [inline], [virtual], [inherited]

**0.15.399.2.10 empty() [2/2]** template<typename Settings >  
bool smtrat::cad::Projection< Incrementality::NONE, Backtracking::UNORDERED, Settings >::empty ( std::size\_t level ) const [inline], [override], [virtual], [inherited]

Implements [smtrat::cad::BaseProjection< Settings >](#).

**0.15.399.2.11 `exportAsDot()`** template<typename Settings >  
 virtual void [smtrat::cad::BaseProjection< Settings >](#)::exportAsDot ( std::ostream & ) const [inline], [virtual], [inherited]

Reimplemented in [smtrat::cad::Projection< Incrementality::FULL, BT, Settings >](#), and [smtrat::cad::Projection< Incrementality::FULL, BT, Settings >](#).

**0.15.399.2.12 `freeID()`** template<typename Settings >  
 void [smtrat::cad::BaseProjection< Settings >](#)::freeID ( std::size\_t level, std::size\_t id ) [inline], [protected], [inherited]

Frees a currently used polynomial id for the given level.

**0.15.399.2.13 `getID()`** template<typename Settings >  
 std::size\_t [smtrat::cad::BaseProjection< Settings >](#)::getID ( std::size\_t level ) [inline], [protected], [inherited]

Returns a fresh polynomial id for the given level.

**0.15.399.2.14 `getOrigin()`** template<typename Settings >  
 virtual Origin [smtrat::cad::BaseProjection< Settings >](#)::getOrigin ( std::size\_t level, std::size\_t id ) const [inline], [virtual], [inherited]

Reimplemented in [smtrat::cad::Projection< Incrementality::FULL, BT, Settings >](#).

**0.15.399.2.15 `getPolyForLifting()`** template<typename Settings >  
 OptionalID [smtrat::cad::BaseProjection< Settings >](#)::getPolyForLifting ( std::size\_t level, SampleLiftedWith & slw ) [inline], [inherited]

Get a polynomial from this level suited for lifting.

**0.15.399.2.16 `getPolynomialById()`** template<typename Settings >  
 const UPoly& [smtrat::cad::Projection< Incrementality::NONE, Backtracking::UNORDERED, Settings >](#)::getPolynomialById ( std::size\_t level, std::size\_t id ) const [inline], [override], [virtual], [inherited]

Retrieves a polynomial from its id.

Implements [smtrat::cad::BaseProjection< Settings >](#).

**0.15.399.2.17 `hasPolynomialById()`** template<typename Settings >  
 bool [smtrat::cad::Projection< Incrementality::NONE, Backtracking::UNORDERED, Settings >](#)::hasPolynomialById ( std::size\_t level, std::size\_t id ) const [inline], [override], [virtual], [inherited]

Implements [smtrat::cad::BaseProjection< Settings >](#).

**0.15.399.2.18 `isPurged()`** template<typename Settings >  
 bool [smtrat::cad::BaseProjection< Settings >](#)::isPurged (

```
 std::size_t level,
 std::size_t id) [inline], [protected], [inherited]
```

**0.15.399.2.19 `projectNewPolynomial()`** template<typename Settings , Backtracking BT>  
carl::Bitset smtrat::cad::Projection< Incrementality::SIMPLE, BT, Settings >::projectNew←  
Polynomial (   
 const ConstraintSelection & = carl::Bitset(true) ) [inline]

**0.15.399.2.20 `removePolynomial()` [1/2]** template<typename Settings >  
void smtrat::cad::BaseProjection< Settings >::removePolynomial (   
 const Poly & p,  
 std::size\_t cid,  
 bool isBound ) [inline], [inherited]

Removes the given polynomial from the projection. Converts to a UPoly and calls the appropriate overload.

**0.15.399.2.21 `removePolynomial()` [2/2]** template<typename Settings , Backtracking BT>  
void smtrat::cad::Projection< Incrementality::SIMPLE, BT, Settings >::removePolynomial (   
 const UPoly & p,  
 std::size\_t cid,  
 bool isBound ) [inline], [virtual]

Removes the given polynomial from the projection.

Reimplemented from [smtrat::cad::Projection< Incrementality::NONE, Backtracking::UNORDERED, Settings >](#).

**0.15.399.2.22 `reset()`** template<typename Settings , Backtracking BT>  
void smtrat::cad::Projection< Incrementality::SIMPLE, BT, Settings >::reset ( ) [inline]

**0.15.399.2.23 `setRemoveCallback()`** template<typename Settings >  
template<typename F >  
void smtrat::cad::BaseProjection< Settings >::setRemoveCallback (   
 F && f ) [inline], [inherited]

Sets a callback that is called whenever polynomials are removed.

**0.15.399.2.24 `size()` [1/4]** template<typename Settings >  
std::size\_t smtrat::cad::BaseProjection< Settings >::size ( ) const [inline], [inherited]

**0.15.399.2.25 `size()` [2/4]** template<typename Settings >  
std::size\_t smtrat::cad::BaseProjection< Settings >::size (   
 void ) [inline], [inherited]

**0.15.399.2.26 `size()` [3/4]** template<typename Settings >  
std::size\_t smtrat::cad::Projection< Incrementality::NONE, Backtracking::UNORDERED, Settings >::size (   
 std::size\_t level ) const [inline], [override], [virtual], [inherited]  
Implements [smtrat::cad::BaseProjection< Settings >](#).

**0.15.399.2.27 `size()` [4/4]** template<typename Settings >  
 virtual std::size\_t smtrat::cad::BaseProjection< Settings >::size ( void ) [inherited]

**0.15.399.2.28 `var()`** template<typename Settings >  
 carl::Variable smtrat::cad::BaseProjection< Settings >::var ( std::size\_t level ) const [inline], [protected], [inherited]  
 Returns the variable that corresponds to the given level, that is the variable eliminated in this level.

**0.15.399.2.29 `vars()`** template<typename Settings >  
 const auto& smtrat::cad::BaseProjection< Settings >::vars ( ) const [inline], [inherited]  
 Returns the variables used for projection.

### 0.15.399.3 Friends And Related Function Documentation

### 0.15.416 smtrat::cadcells::datastructures::PropertiesT< Ts > Struct Template Reference

Set of properties.

```
#include <properties.h>
```

#### 0.15.416.1 Detailed Description

```
template<typename... Ts>
struct smtrat::cadcells::datastructures::PropertiesT< Ts >
```

Set of properties.

This is a recursive template. The list of template parameters specifies the type of properties which can be hold by this set.

Note that only properties of the same level should be stored within this datastructure.

Properties have the following requirements:

- They need to implement `level()`.
- They need to implement `hash_on_level()`, `operator<` and `operator==` for comparing with properties of the same type and level.

- They need to have a member `static constexpr bool is_flag`. If set to `true`, this indicates that there is only one property of this kind per level and thus, it is not stored in a set but only a Boolean flag is stored.
- They need to implement operator`<<`.

- [FormulaT generateVarChain](#) (const std::set< carl::Variable > &vars, carl::FormulaType type)

#### 0.15.422.1 Detailed Description

Base class for a PseudoBoolean Encoder.

It takes a arithmetic constraint and converts it to a boolean Formula

#### 0.15.422.2 Member Function Documentation

```
0.15.422.2.1 canEncode() virtual bool smtrat::PseudoBoolEncoder::canEncode (
 const ConstraintT & constraint) [pure virtual]
```

Implemented in [smtrat::TotalizerEncoder](#), [smtrat::ShortFormulaEncoder](#), [smtrat::RNSEncoder](#), [smtrat::MixedSignEncoder](#), [smtrat::LongFormulaEncoder](#), [smtrat::ExactlyOneCommanderEncoder](#), and [smtrat::CardinalityEncoder](#).

```
0.15.422.2.2 doEncode() virtual std::optional<FormulaT> smtrat::PseudoBoolEncoder::doEncode (
 const ConstraintT & constraint) [protected], [pure virtual]
```

Implemented in [smtrat::TotalizerEncoder](#), [smtrat::ShortFormulaEncoder](#), [smtrat::RNSEncoder](#), [smtrat::MixedSignEncoder](#), [smtrat::LongFormulaEncoder](#), [smtrat::ExactlyOneCommanderEncoder](#), and [smtrat::CardinalityEncoder](#).

```
0.15.422.2.3 encode() std::optional< FormulaT > smtrat::PseudoBoolEncoder::encode (
 const ConstraintT & constraint)
```

Encodes an arbitrary constraint.

#### Returns

encoded formula

```
0.15.422.2.4 encodingSize() Rational smtrat::PseudoBoolEncoder::encodingSize (
 const ConstraintT & constraint) [virtual]
```

Reimplemented in [smtrat::TotalizerEncoder](#), [smtrat::ShortFormulaEncoder](#), [smtrat::MixedSignEncoder](#), [smtrat::LongFormulaEncoder](#), [smtrat::ExactlyOneCommanderEncoder](#), and [smtrat::CardinalityEncoder](#).

```
0.15.422.2.5 generateVarChain() FormulaT smtrat::PseudoBoolEncoder::generateVarChain (
 const std::set< carl::Variable > & vars,
 carl::FormulaType type) [protected]
```

```
0.15.422.2.6 name() virtual std::string smtrat::PseudoBoolEncoder::name () [inline], [virtual]
```

Reimplemented in [smtrat::TotalizerEncoder](#), [smtrat::ShortFormulaEncoder](#), [smtrat::MixedSignEncoder](#), [smtrat::LongFormulaEncoder](#), [smtrat::ExactlyOneCommanderEncoder](#), and [smtrat::CardinalityEncoder](#).

## 0.15.422.3 Field Documentation

**0.15.422.3.1 problem\_size** std::size\_t smtrat::PseudoBoolEncoder::problem\_size

## 0.15.423 smtrat::PseudoBoolNormalizer Class Reference

```
#include <PseudoBoolNormalizer.h>
```

### Public Member Functions

- std::pair< std::optional< [FormulaT](#) >, [ConstraintT](#) > **normalize** (const [ConstraintT](#) &constraint)
   
*Modifies the constraint in-place and returns an additional boolean formula.*
- std::map< carl::Variable, carl::Variable > & **substitutedVariables** ()
   
*returns all variable substitutions done by this normalizer instance.*
- [ConstraintT](#) **trim** (const [ConstraintT](#) &constraint)

## 0.15.423.1 Member Function Documentation

```
0.15.423.1.1 normalize() std::pair< std::optional< FormulaT >, ConstraintT > smtrat::PseudoBoolNormalizer::normalize (
 const ConstraintT & constraint)
```

Modifies the constraint in-place and returns an additional boolean formula.

Consider  $-4x \leq 2$

This is equivalent to  $-4*(1 - \text{not } x) \leq 2$  iff.  $-4 + 4 \text{ not } x \leq 2$  iff  $4 \text{ not } x \leq 6$  Since we can not represent this negation in the constraint itself we add a variable y and get  $y \leftrightarrow \text{not } x$  and  $4y \leq 6$

In this particular case we can later on remove y again since the constraint is trivially satisfied.

**0.15.423.1.2 substitutedVariables()** `std::map<carl::Variable, carl::Variable>& smtrat::PseudoBoolNormalizer::substitutedVariables () [inline]`  
returns all variable substitutions done by this normalizer instance.  
An entry {x: y} correlates to the boolean expression y <-> not x  
Useful if all occurrences of the substituted variable should be substituted as well or in general when the correlation is needed.

**0.15.423.1.3 trim()** `ConstraintT smtrat::PseudoBoolNormalizer::trim (const ConstraintT & constraint)`

## 0.15.424 smtrat::parser::QEParser Struct Reference

## 0.15.430 **benchmax::RandomizationAdaptor< T >** Class Template Reference

Provides iteration over a given std::vector in a pseudo-randomized order.

```
#include <Jobs.h>
```

### Data Structures

- struct **iterator**

### Public Member Functions

- **RandomizationAdaptor** (const std::vector< T > &data)  
*Construct a randomized view on the given vector.*
- auto **begin** () const  
*Return begin of the randomized range.*
- auto **end** () const  
*Return end of the randomized range.*

### 0.15.430.1 Detailed Description

```
template<typename T>
class benchmax::RandomizationAdaptor< T >
```

Provides iteration over a given std::vector in a pseudo-randomized order.

Internally, it computes a factor that is coprime to the number of jobs (and thus generates all indices). We choose the factor in the order of the square root of the number of jobs.

### 0.15.430.2 Constructor & Destructor Documentation

**0.15.430.2.1 RandomizationAdaptor()** template<typename T >
benchmax::RandomizationAdaptor< T >::RandomizationAdaptor (
 const std::vector< T > & data ) [inline]

Construct a randomized view on the given vector.

### 0.15.430.3 Member Function Documentation

**0.15.430.3.1 begin()** template<typename T >
auto benchmax::RandomizationAdaptor< T >::begin ( ) const [inline]

Return begin of the randomized range.

**0.15.430.3.2 end()** template<typename T>  
auto **benchmark::RandomizationAdaptor**< T >::end( ) const [inline]  
Return end of the randomized range.

## 0.15.431 smtrat::RationalCapsule Class Reference

```
#include <RationalCapsule.h>

## 0.15.432 smtrat::parser::RationalPolicies Struct Reference

Specialization of qi::real\_policies for a Rational.

```
#include <Lexicon.h>
```

### Static Public Member Functions

- template<typename It , typename Attr >  
  static bool [parse\\_nan](#) (It &, It const &, Attr &)
- template<typename It , typename Attr >  
  static bool [parse\\_inf](#) (It &, It const &, Attr &)

### 0.15.432.1 Detailed Description

Specialization of qi::real\_policies for a Rational.

Specifies that neither NaN nor Inf is allowed.

### 0.15.432.2 Member Function Documentation

```
0.15.432.2.1 parse_inf() template<typename It , typename Attr >
static bool smtrat::parser::RationalPolicies::parse_inf (
 It & ,
 It const & ,
 Attr &) [inline], [static]
```

```
0.15.432.2.2 parse_nan() template<typename It , typename Attr >
static bool smtrat::parser::RationalPolicies::parse_nan (
 It & ,
 It const & ,
 Attr &) [inline], [static]
```

## 0.15.433 smtrat::mcsat::onecellcad::RealAlgebraicPoint< Number > Class Template Reference

Represent a multidimensional point whose components are algebraic reals.

```
#include <RealAlgebraicPoint.h>
```

### Public Member Functions

- [RealAlgebraicPoint](#) () noexcept=default  
*Create an empty point of dimension 0.*

- `RealAlgebraicPoint conjoin (const carl::IntRepRealAlgebraicNumber< Number > &r)`  
*Create a new point with another given component added at the end of this point, thereby increasing its dimension by 1.*
- `const carl::IntRepRealAlgebraicNumber< Number > & operator[] (std::size_t index) const`  
*Retrieve the component of this point at the given index.*
- `carl::IntRepRealAlgebraicNumber< Number > & operator[] (std::size_t index)`  
*Retrieve the component of this point at the given index.*

### 0.15.433.1 Detailed Description

```
template<typename Number>
class smrat::mcsat::oncellcad::RealAlgebraicPoint< Number >
```

Represent a multidimensional point whose components are algebraic reals.  
This class is just a thin wrapper around vector to have a clearer semantic meaning.

### 0.15.433.2 Constructor & Destructor Documentation

**0.15.433.2.1 RealAlgebraicPoint() [1/5]** template<typename Number >  
`smrat::mcsat::oncellcad::RealAlgebraicPoint< Number >::RealAlgebraicPoint ( ) [default],`  
`[noexcept]`

Create an empty point of dimension 0.

**0.15.433.2.2 RealAlgebraicPoint() [2/5]** template<typename Number >  
`smrat::mcsat::oncellcad::RealAlgebraicPoint< Number >::RealAlgebraicPoint (`  
`const std::vector< carl::IntRepRealAlgebraicNumber< Number >> & v ) [inline],`  
`[explicit]`

Convert from a vector using its numbers in the same order as components.

**0.15.433.2.3 RealAlgebraicPoint() [3/5]** template<typename Number >  
`smrat::mcsat::oncellcad::RealAlgebraicPoint< Number >::RealAlgebraicPoint (`  
`std::vector< carl::IntRepRealAlgebraicNumber< Number >> && v ) [inline], [explicit]`

Convert from a vector using its numbers in the same order as components.

**0.15.433.2.4 RealAlgebraicPoint() [4/5]** template<typename Number >  
`smrat::mcsat::oncellcad::RealAlgebraicPoint< Number >::RealAlgebraicPoint (`  
`const std::list< carl::IntRepRealAlgebraicNumber< Number >> & v ) [inline],`  
`[explicit]`

Convert from a list using its numbers in the same order as components.

**0.15.433.2.5 RealAlgebraicPoint() [5/5]** template<typename Number >  
`smrat::mcsat::oncellcad::RealAlgebraicPoint< Number >::RealAlgebraicPoint (`  
`const std::initializer_list< carl::IntRepRealAlgebraicNumber< Number >> & v )`  
`[inline]`

Convert from a initializer\_list using its numbers in the same order as components.

### 0.15.433.3 Member Function Documentation

**0.15.433.3.1 `conjoin()`** template<typename Number >  
RealAlgebraicPoint smtrat::mcsat::oncellcad::RealAlgebraicPoint< Number >::conjoin ( const carl::IntRepRealAlgebraicNumber< Number > & r ) [inline]  
Create a new point with another given component added at the end of this point, thereby increasing its dimension by 1.  
The original point remains untouched.

**0.15.433.3.2 `dim()`** template<typename Number >  
std::size\_t smtrat::mcsat::oncellcad::RealAlgebraicPoint< Number >::dim ( ) const [inline]  
Give the dimension/number of components of this point.

**0.15.433.3.3 `operator[]() [1/2]`** template<typename Number >  
carl::IntRepRealAlgebraicNumber<Number>& smtrat::mcsat::oncellcad::RealAlgebraicPoint< Number >::operator[] ( std::size\_t index ) [inline]  
Retrieve the component of this point at the given index.

**0.15.433.3.4 `operator[]() [2/2]`** template<typename Number >  
const carl::IntRepRealAlgebraicNumber<Number>& smtrat::mcsat::oncellcad::RealAlgebraicPoint< Number >::operator[] ( std::size\_t index ) const [inline]  
Retrieve the component of this point at the given index.

**0.15.433.3.5 `prefixPoint()`** template<typename Number >  
RealAlgebraicPoint smtrat::mcsat::oncellcad::RealAlgebraicPoint< Number >::prefixPoint ( size\_t componentCount ) const [inline]  
Make a (lower dimensional) copy that contains only the first 'componentCount'-many components.

## 0.15.434 `smtrat::fixedsize_allocator< T >::rebind< U >` Struct Template Reference

```
#include <alloc.h>
```

### Public Types

- `typedef fixedsize_allocator< U > other`

#### 0.15.434.1 Member TypeDef Documentation

### 0.15.435.1 Member Function Documentation

**0.15.435.1.1 coeffNonNull()** std::optional<Poly> smtrat::mcsat::onecellcad::OneCellCAD::coeffNonNull (const TagPoly & boundCandidate ) [inline], [inherited]

**0.15.435.1.2 hasPolyLastVariableRootWithinBounds()** bool smtrat::mcsat::onecellcad::recursive::RecursiveCAD::hasPolyLastVariableRootWithinBounds (const RAN & low, const RAN & high, const Poly & poly, const std::size\_t polyLevel ) [inline]

Check if there is a root of the given polynomial—that becomes univariate after pluggin in all but the last variable wrt. the given variableOrder—, that lies between the given 'low' and 'high' bounds.

**0.15.435.1.3 isAlreadyProcessed()** `bool smtrat::mcsat::oncellcad::recursive::RecursiveCAD::isAlreadyProcessed ( const TagPoly & poly ) [inline]`

**0.15.435.1.4 isMainPointInsideCell()** `bool smtrat::mcsat::oncellcad::OneCellCAD::isMainPointInsideCell ( const CADCell & cell ) [inline], [inherited]`

**0.15.435.1.5 isolateLastVariableRoots()** `std::vector<RAN> smtrat::mcsat::oncellcad::OneCellCAD::isolateLastVariableRoots ( const std::size_t polyLevel, const Poly & poly ) [inline], [inherited]`  
src/lib/datastructures/mcsat/oncellcad/OneCellCAD.h Given a poly  $p(x_1, \dots, x_n)$ , return all roots of the univariate poly  $p(a_1, \dots, a_{n-1}, x_n)$ , where  $a_1, \dots, a_{n-1}$  are the first algebraic real components from 'point' (SORTED!).

**0.15.435.1.6 isPointRootOfPoly() [1/2]** `bool smtrat::mcsat::oncellcad::OneCellCAD::isPointRootOfPoly ( const std::size_t polyLevel, const Poly & poly ) [inline], [inherited]`

**0.15.435.1.7 isPointRootOfPoly() [2/2]** `bool smtrat::mcsat::oncellcad::OneCellCAD::isPointRootOfPoly ( const TagPoly & poly ) [inline], [inherited]`

**0.15.435.1.8 OneCellCAD()** `smtrat::mcsat::oncellcad::OneCellCAD::OneCellCAD [inline]`

**0.15.435.1.9 partialDerivativesLayerWithSomeNonEarlyVanishingPoly()** `std::vector<Poly> smtrat::mcsat::oncellcad::recursive::RecursiveCAD::partialDerivativesLayerWithSomeNonEarlyVanishingPoly ( const TagPoly & mainPoly ) [inline]`

Find the smallest index  $m$  such that in the set  $S$  of all  $m$ -th partial derivatives of the given poly, such that there is a derivative that does not vanish early [brown15].

Note that  $m > 0$  i.e, this function never just returns the given poly, which is the 0th partial derivative of itself.

#### Parameters

|                   |                                                                              |
|-------------------|------------------------------------------------------------------------------|
| <code>poly</code> | must not be a const-poly like 2, otherwise this function does not terminate. |
|-------------------|------------------------------------------------------------------------------|

#### Returns

Actually only returns the set  $S$

**0.15.435.1.10 pointEnclosingCADCell()** `std::optional<CADCell> smtrat::mcsat::oncellcad::recursive::RecursiveCAD::pointEnclosingCADCell ( const std::vector< std::vector< oncellcad::TagPoly >> & polys ) [inline]`

Construct a single CADCell that contains the given 'point' and is sign-invariant for the given polynomials in 'polys'. The construction fails if 'polys' are not well-oriented [mccallum84]. Note that this cell is cylindrical only with respect to the given 'variableOrder'.

## Parameters

|                      |                                                                                                                     |
|----------------------|---------------------------------------------------------------------------------------------------------------------|
| <i>variableOrder</i> | must contain unique variables and at least one, because constant polynomials (without a variable) are prohibited.   |
| <i>point</i>         | <i>point.size() &gt;= variables.size()</i> .                                                                        |
| <i>polys</i>         | must contain only non-constant, irreducible polynomials that mention only variables that appear in 'variableOrder'. |

**0.15.435.1.11 `prefixPointToStdMap()`** `std::map<carl::Variable, RAN> smtrat::mcsat::oncellcad::prefixPointToStdMap (`

`const std::size_t componentCount ) [inline], [inherited]`

Create a mapping from the first variables (with index 0 to 'componentCount') in the 'variableOrder' to the first components of the given 'point'.

**0.15.435.1.12 `refineNonNull()`** `ShrinkResult smtrat::mcsat::oncellcad::recursive::RecursiveCAD::refineNonNull (`

`const TagPoly & boundCandidate,`  
`CADCell & cell ) [inline]`

**0.15.435.1.13 `refineNull()`** `ShrinkResult smtrat::mcsat::oncellcad::recursive::RecursiveCAD::refineNull (`

`const TagPoly & boundCandidate,`  
`CADCell & cell ) [inline]`

**0.15.435.1.14 `shrinkCell()`** `ShrinkResult smtrat::mcsat::oncellcad::recursive::RecursiveCAD::shrinkCell (`

`const TagPoly & boundCandidate,`  
`CADCell & cell ) [inline]`

Merge the given open OpenCADCell 'cell' that contains the given 'point' (called "alpha" in [brown15]) with a polynomial 'poly'.

Before the merge 'cell' represents a region that is sign-invariant on other (previously merged) polynomials (all signs are non-zero). The returned cell represents a region that is additionally sign-invariant on 'poly' (also with non-zero sign).

## Returns

either an OpenCADCell or nothing (representing a failed construction)

**0.15.435.1.15 `shrinkCellWithEarlyVanishingPoly()`** `ShrinkResult smtrat::mcsat::oncellcad::recursive::RecursiveCAD::shrinkCellWithEarlyVanishingPoly (`

`const TagPoly & boundCandidate,`  
`CADCell & cell ) [inline]`

**0.15.435.1.16 `shrinkCellWithIrreducibleFactorsOfPoly()`** `ShrinkResult smtrat::mcsat::oncellcad::recursive::RecursiveCAD::shrinkCellWithIrreducibleFactorsOfPoly (`

`const TagPoly & poly,`  
`CADCell & cell ) [inline]`

---

**0.15.435.1.17 shrinkCellWithNonRootPoint()** `ShrinkResult smtrat::mcsat::oncellcad::recursive::←  
RecursiveCAD::shrinkCellWithNonRootPoint (const TagPoly & boundCandidate,  
CADCell & cell ) [inline]`

**0.15.435.1.18 shrinkCellWithPolyHavingPointAsRoot()** `ShrinkResult smtrat::mcsat::oncellcad::←  
::recursive::RecursiveCAD::shrinkCellWithPolyHavingPointAsRoot (const TagPoly & boundCandidate,  
CADCell & cell ) [inline]`

**0.15.435.1.19 shrinkSingleComponent()** `void smtrat::mcsat::oncellcad::recursive::RecursiveCAD::←  
::shrinkSingleComponent (const std::size_t polyLevel,  
const Poly & poly,  
CADCell & cell ) [inline]`

Shrink the component of the 'cell' at the 'boundCandidate's level around the given point if the 'boundCandidate' is a tighter bound.

Don't recursively shrink lower level components of the cell. Note that a cell's sector may collapse into a section, which is why we need to pass in a cell and not only its sector. Note that this shrink function is always "successful", even if the cell was not shrunk.

#### Parameters

|                             |                                                                        |
|-----------------------------|------------------------------------------------------------------------|
| <code>boundCandidate</code> | Must be a non-const irreducible polynomial that does not vanish early. |
|-----------------------------|------------------------------------------------------------------------|

**0.15.435.1.20 vanishesEarly()** `bool smtrat::mcsat::oncellcad::OneCellCAD::vanishesEarly (const std::size_t polyLevel,  
const Poly & poly ) [inline], [inherited]`

Check if an n-variate 'poly'  $p(x_1, \dots, x_n)$  with  $n \geq 1$  already becomes the zero poly after plugging in  $p(a_1, \dots, a_{n-1}, x_n)$ , where  $a_1, \dots, a_{n-1}$  are the first  $n-1$  algebraic real components from 'point'.

## 0.15.435.2 Field Documentation

**0.15.435.2.1 point** `const RealAlgebraicPoint<Rational>& smtrat::mcsat::oncellcad::OneCellCAD::point [inherited]`

**0.15.435.2.2 variableOrder** `const std::vector<carl::Variable>& smtrat::mcsat::oncellcad::OneCellCAD::variableOrder [inherited]`

Variables can also be indexed by level.

Polys with mathematical level 1 contain the variable in `variableOrder[0]`

## 0.15.436 smtrat::cad::projection::Reducta< Poly > Struct Template Reference

Construct the set of reducta of the given polynomial.

```
#include <utils.h>
```

#### Public Member Functions

- `Reducta (const Poly &p)`

## Data Fields

- **T elements**

*STL member.*

### 0.15.436.1 Detailed Description

```
template<typename Poly>
struct smtrat::cad::projection::Reducta< Poly >
```

Construct the set of reducta of the given polynomial.  
This only adds a custom constructor to a std::

### 0.15.436.2 Constructor & Destructor Documentation

```

```

## 0.15.443 benchmax::Results Class Reference

Stores results for for whole benchmax run.

```
#include <Results.h>
```

### Public Member Functions

- std::optional< std::reference\_wrapper< const BenchmarkResult > > **get** (const Tool \*tool, const fs::path &file) const
- const auto & **data** () const
- void **addResult** (const Tool \*tool, const fs::path &file, BenchmarkResult &&results)  
*Add a new result.*
- void **store** (Database &db)  
*Store all results to some database.*
- void **store** (XMLWriter &xml, const Jobs &jobs) const  
*Store all results to a xml file.*

### 0.15.443.1 Detailed Description

Stores results for for whole benchmax run.

Allows for (concurrent) insertion of the individual results via **addResult()**. Eventually results can be stored to a database (if enabled) or to a xml file.

## 0.15.443.2 Member Function Documentation

```
0.15.443.2.1 addResult() void benchmax::Results::addResult (
 const Tool * tool,
 const fs::path & file,
 BenchmarkResult && results) [inline]
```

Add a new result.

```
0.15.443.2.2 data() const auto& benchmax::Results::data () const [inline]
```

```
0.15.443.2.3 get() std::optional<std::reference_wrapper<const BenchmarkResult>> benchmax::←
Results::get (
 const Tool * tool,
 const fs::path & file) const [inline]
```

**0.15.443.2.4 `store()` [1/2]** void benchmax::Results::store ( Database & db ) [inline]  
Store all results to some database.

**0.15.443.2.5 `store()` [2/2]** void benchmax::Results::store ( XMLWriter & xml, const Jobs & jobs ) const [inline]  
Store all results to a xml file.

## 0.15.444 smtrat::RNSEncoder Class Reference

```
#include <RNSEncoder.h>
```

### Public Member Functions

- `RNSEncoder ()`
- bool `canEncode (const ConstraintT &constraint)`
- std::optional< `FormulaT` > `encode (const ConstraintT &constraint)`  
*Encodes an arbitrary constraint.*
- virtual Rational `encodingSize (const ConstraintT &constraint)`
- virtual std::string `name ()`

### Data Fields

- std::size\_t `problem_size`

### Protected Member Functions

- std::optional< `FormulaT` > `doEncode (const ConstraintT &constraint)`
- `FormulaT generateVarChain (const std::set< carl::Variable > &vars, carl::FormulaType type)`

#### 0.15.444.1 Constructor & Destructor Documentation

**0.15.444.1.1 `RNSEncoder()`** smtrat::RNSEncoder::RNSEncoder ( ) [inline]

#### 0.15.444.2 Member Function Documentation

**0.15.444.2.1 `canEncode()`** bool smtrat::RNSEncoder::canEncode ( const ConstraintT & constraint ) [virtual]  
Implements `smtrat::PseudoBoolEncoder`.

**0.15.444.2.2 `doEncode()`** std::optional< `FormulaT` > smtrat::RNSEncoder::doEncode ( const ConstraintT & constraint ) [protected], [virtual]  
Implements `smtrat::PseudoBoolEncoder`.

**0.15.444.2.3 encode()** `std::optional< FormulaT > smtrat::PseudoBoolEncoder::encode (`  
    `const ConstraintT & constraint ) [inherited]`

Encodes an arbitrary constraint.

#### Returns

encoded formula

**0.15.444.2.4 encodingSize()** `Rational smtrat::PseudoBoolEncoder::encodingSize (`  
    `const ConstraintT & constraint ) [virtual], [inherited]`

Reimplemented in [smtrat::TotalizerEncoder](#), [smtrat::ShortFormulaEncoder](#), [smtrat::MixedSignEncoder](#), [smtrat::LongFormulaEncoder](#), [smtrat::ExactlyOneCommanderEncoder](#), and [smtrat::CardinalityEncoder](#).

**0.15.444.2.5 generateVarChain()** `FormulaT smtrat::PseudoBoolEncoder::generateVarChain (`  
    `const std::set< carl::Variable > & vars,`  
    `carl::FormulaType type ) [protected], [inherited]`

**0.15.444.2.6 name()** `virtual std::string smtrat::PseudoBoolEncoder::name ( ) [inline], [virtual], [inherited]`

Reimplemented in [smtrat::TotalizerEncoder](#), [smtrat::ShortFormulaEncoder](#), [smtrat::MixedSignEncoder](#), [smtrat::LongFormulaEncoder](#), [smtrat::ExactlyOneCommanderEncoder](#), and [smtrat::CardinalityEncoder](#).

### 0.15.444.3 Field Documentation

**0.15.444.3.1 problem\_size** `std::size_t smtrat::PseudoBoolEncoder::problem_size [inherited]`

#### 0.15.464.1 Detailed Description

```
template<typename Properties>
class smrat::cadcells::datastructures::SampledDerivation< Properties >
```

A **SampledDerivation** is a **DelineatedDerivation** with a sample and an **DelineationInterval** w.r.t. to this sample.

##### Template Parameters

|                   |                   |
|-------------------|-------------------|
| <i>Properties</i> | Set of properties |
|-------------------|-------------------|

- bool `probablyLooping (const typename Poly::PolyType &_branchingPolynomial, const Rational &_branchingValue) const`  
*Checks whether given the current branching value and branching variable/polynomial it is (highly) probable that this branching is part of an infinite loop of branchings.*
- bool `branchAt (const Poly &_polynomial, bool _integral, const Rational &_value, std::vector< FormulaT > &&_premise, bool _leftCaseWeak=true, bool _preferLeftCase=true, bool _useReceivedFormulaAsPremise=false)`  
*Adds a lemmas which provoke a branching for the given variable at the given value, if this module returns Unknown and there exists a preceding SATModule.*
- bool `branchAt (const Poly &_polynomial, bool _integral, const Rational &_value, bool _leftCaseWeak=true, bool _preferLeftCase=true, bool _useReceivedFormulaAsPremise=false, const std::vector< FormulaT > &&_premise=std::vector< FormulaT >())`
- bool `branchAt (carl::Variable::Arg _var, const Rational &_value, std::vector< FormulaT > &&_premise, bool _leftCaseWeak=true, bool _preferLeftCase=true, bool _useReceivedFormulaAsPremise=false)`
- bool `branchAt (carl::Variable::Arg _var, const Rational &_value, bool _leftCaseWeak=true, bool _preferLeftCase=true, bool _useReceivedFormulaAsPremise=false, const std::vector< FormulaT > &_premise=std::vector< FormulaT >())`
- void `splitUnequalConstraint (const FormulaT &)`  
*Adds the following lemmas for the given constraint  $p \neq 0$ .*
- unsigned `checkModel () const`
- void `addInformationRelevantFormula (const FormulaT &formula)`  
*Adds a formula to the InformationRelevantFormula.*
- const std::set< `FormulaT` > & `getInformationRelevantFormulas ()`  
*Gets all InformationRelevantFormulas.*
- bool `isLemmaLevel (LemmaLevel level)`  
*Checks if current lemma level is greater or equal to given level.*

### Static Protected Member Functions

- static bool `modelsDisjoint (const Model &_modelA, const Model &_modelB)`  
*Checks whether there is no variable assigned by both models.*

### Protected Attributes

- std::vector< `FormulaSetT` > `mInfeasibleSubsets`  
*Stores the infeasible subsets.*
- `Manager *const mpManager`  
*A reference to the manager.*
- `Model mModel`  
*Stores the assignment of the current satisfiable result, if existent.*
- std::vector< `Model` > `mAllModels`  
*Stores all satisfying assignments.*

- bool `mModelComputed`  
*True, if the model has already been computed.*
- bool `mFinalCheck`  
*true, if the check procedure should perform a final check which especially means not to postpone splitting decisions*
- bool `mFullCheck`  
*false, if this module should avoid too expensive procedures and rather return unknown instead.*
- carl::Variable `mObjectiveVariable`  
*Objective variable to be minimized. If set to NO\_VARIABLE, a normal sat check should be performed.*
- std::vector< `TheoryPropagation` > `mTheoryPropagations`
- std::atomic< `Answer` > `mSolverState`  
*States whether the received formula is known to be satisfiable or unsatisfiable otherwise it is set to unknown.*
- std::atomic\_bool \* `mBackendsFoundAnswer`  
*This flag is passed to any backend and if it determines an answer to a prior check call, this flag is fired.*
- `Conditionals mFoundAnswer`  
*Vector of Booleans: If any of them is true, we have to terminate a running check procedure.*
- std::vector< `Module *` > `mUsedBackends`  
*The backends of this module which are currently used (conditions to use this module are fulfilled for the passed formula).*
- std::vector< `Module *` > `mAllBackends`  
*The backends of this module which have been used.*
- `ModuleInput::iterator mFirstSubformulaToPass`  
*Stores the position of the first sub-formula in the passed formula, which has not yet been considered for a consistency check of the backends.*
- carl::FastSet< `FormulaT` > `mConstraintsToInform`  
*Stores the constraints which the backends must be informed about.*
- carl::FastSet< `FormulaT` > `mInformedConstraints`  
*Stores the position of the first constraint of which no backend has been informed about.*
- `ModuleInput::const_iterator mFirstUncheckedReceivedSubformula`  
*Stores the position of the first (by this module) unchecked sub-formula of the received formula.*
- unsigned `mSmallerMusesCheckCounter`  
*Counter used for the generation of the smt2 files to check for smaller muses.*
- std::vector< std::size\_t > `mVariableCounters`  
*Maps variables to the number of their occurrences.*

## Friends

- class `VarSchedulerBase`
- class `VarSchedulerMcsatBase`

### 0.15.469.1 Detailed Description

```
template<class Settings>
class smrat::SATModule< Settings >
```

Implements a module performing DPLL style SAT checking.

It is mainly based on [Minisat](#) 2.0 and extends it by enabling the SMT-RAT module interfaces and some optimizations.

### 0.15.469.2 Member Typedef Documentation

```
0.15.469.2.1 SettingsType template<class Settings >
typedef Settings smrat::SATModule< Settings >::SettingsType
```

### 0.15.469.3 Member Enumeration Documentation

#### 0.15.469.3.1 LemmaType enum smtrat::Module::LemmaType : unsigned [strong], [inherited]

Enumerator

|           |  |
|-----------|--|
| NORMAL    |  |
| PERMANENT |  |

### 0.15.469.4 Constructor & Destructor Documentation

#### 0.15.469.4.1 SATModule() template<class Settings > smtrat::SATModule< Settings >::SATModule (

```
 const ModuleInput * _formula,
 Conditionals & _foundAnswer,
 Manager *const _manager = nullptr)
```

Constructs a **SATModule**.

Parameters

|                           |                                                                                             |
|---------------------------|---------------------------------------------------------------------------------------------|
| <code>_type</code>        | The type of this module being <b>SATModule</b> .                                            |
| <code>_formula</code>     | The formula passed to this module, called received formula.                                 |
| <code>_settings</code>    | [Not yet used.]                                                                             |
| <code>_foundAnswer</code> | Vector of Booleans: If any of them is true, we have to terminate a running check procedure. |
| <code>_manager</code>     | A reference to the manager of the solver using this module.                                 |

#### 0.15.469.4.2 ~SATModule() template<class Settings > smtrat::SATModule< Settings >::~SATModule ( )

Destructs this **SATModule**.

### 0.15.469.5 Member Function Documentation

#### 0.15.469.5.1 add() bool smtrat::Module::add (

```
 ModuleInput::const_iterator _subformula) [inherited]
```

The module has to take the given sub-formula of the received formula into account.

Parameters

|                          |                                                    |
|--------------------------|----------------------------------------------------|
| <code>_subformula</code> | The sub-formula to take additionally into account. |
|--------------------------|----------------------------------------------------|

Returns

false, if it can be easily decided that this sub-formula causes a conflict with the already considered sub-formulas; true, otherwise.

#### 0.15.469.5.2 addBooleanAssignments() template<class Settings >

```
void smtrat::SATModule< Settings >::addBooleanAssignments (
 RationalAssignment & _rationalAssignment) const
Adds the Boolean assignments to the given assignments, which were determined by the Minisat procedure.
Note: Assignments in the given map are not overwritten.
```

#### Parameters

|                                  |                                                    |
|----------------------------------|----------------------------------------------------|
| <code>_rationalAssignment</code> | The assignments to add the Boolean assignments to. |
|----------------------------------|----------------------------------------------------|

**0.15.469.5.3 `addConstraintToInform()`** template<class Settings >  
void smtrat::SATModule< Settings >::addConstraintToInform (
 const FormulaT & \_constraint ) [inline], [virtual]  
Adds a constraint to the collection of constraints of this module, which are informed to a freshly generated backend.

#### Parameters

|                          |                        |
|--------------------------|------------------------|
| <code>_constraint</code> | The constraint to add. |
|--------------------------|------------------------|

Reimplemented from [smtrat::Module](#).

**0.15.469.5.4 `addConstraintToInform_()`** template<class Settings >  
void smtrat::SATModule< Settings >::addConstraintToInform\_ (
 const FormulaT & \_formula ) [inline]

**0.15.469.5.5 `addCore()`** template<class Settings >  
bool smtrat::SATModule< Settings >::addCore (
 ModuleInput::const\_iterator ) [virtual]

The module has to take the given sub-formula of the received formula into account.

#### Parameters

|                          |                                                    |
|--------------------------|----------------------------------------------------|
| <code>_subformula</code> | The sub-formula to take additionally into account. |
|--------------------------|----------------------------------------------------|

#### Returns

false, if it can be easily decided that this sub-formula causes a conflict with the already considered sub-formulas; true, otherwise.

Reimplemented from [smtrat::Module](#).

**0.15.469.5.6 `addInformationRelevantFormula()`** void smtrat::Module::addInformationRelevantFormula
(
 const FormulaT & formula ) [protected], [inherited]

Adds a formula to the InformationRelevantFormula.

#### Parameters

|                      |                |
|----------------------|----------------|
| <code>formula</code> | Formula to add |
|----------------------|----------------|

```
0.15.469.5.7 addLemma() void smtrat::Module::addLemma (
 const FormulaT & _lemma,
 const LemmaType & _lt = LemmaType::NORMAL,
 const FormulaT & _preferredFormula = FormulaT(carl::FormulaType::TRUE)) [inline],
[inherited]
```

Stores a lemma being a valid formula.

#### Parameters

|                   |                                                                       |
|-------------------|-----------------------------------------------------------------------|
| _lemma            | The eduction/lemma to store.                                          |
| _lt               | The type of the lemma.                                                |
| _preferredFormula | Hint for the next decision, which formula should be assigned to true. |

```
0.15.469.5.8 addOrigin() void smtrat::Module::addOrigin (
 ModuleInput::iterator _formula,
 const FormulaT & _origin) [inline], [protected], [inherited]
```

Adds the given set of formulas in the received formula to the origins of the given passed formula.

#### Parameters

|          |                                                           |
|----------|-----------------------------------------------------------|
| _formula | The passed formula to set the origins for.                |
| _origin  | A set of formulas in the received formula of this module. |

```
0.15.469.5.9 addReceivedSubformulaToPassedFormula() std::pair<ModuleInput::iterator,bool>
smtrat::Module::addReceivedSubformulaToPassedFormula (
```

```
 ModuleInput::const_iterator _subformula) [inline], [protected], [inherited]
```

Copies the given sub-formula of the received formula to the passed formula.

Note, that there is always a link between sub-formulas of the passed formulas to sub-formulas of the received formulas, which are responsible for its occurrence.

#### Parameters

|             |                                                  |
|-------------|--------------------------------------------------|
| _subformula | The sub-formula of the received formula to copy. |
|-------------|--------------------------------------------------|

```
0.15.469.5.10 addSubformulaToPassedFormula() [1/3] std::pair<ModuleInput::iterator,bool>
smtrat::Module::addSubformulaToPassedFormula (
```

```
 const FormulaT & _formula) [inline], [protected], [inherited]
```

Adds the given formula to the passed formula with no origin.

Note that in the next call of this module's removeSubformula, all formulas in the passed formula without origins will be removed.

#### Parameters

|          |                                           |
|----------|-------------------------------------------|
| _formula | The formula to add to the passed formula. |
|----------|-------------------------------------------|

#### Returns

A pair to the position where the formula to add has been inserted (or its first sub-formula which has not yet been in the passed formula, in case the formula to add is a conjunction), and a Boolean stating whether anything has been added to the passed formula.

**0.15.469.5.11 addSubformulaToPassedFormula()** [2/3] std::pair<ModuleInput::iterator,bool>  
smrat::Module::addSubformulaToPassedFormula (const FormulaT & \_formula, const FormulaT & \_origin) [inline], [protected], [inherited]

Adds the given formula to the passed formula.

#### Parameters

|          |                                                                                                                           |
|----------|---------------------------------------------------------------------------------------------------------------------------|
| _formula | The formula to add to the passed formula.                                                                                 |
| _origin  | The sub-formula of the received formula being responsible for the occurrence of the formula to add to the passed formula. |

#### Returns

A pair to the position where the formula to add has been inserted (or its first sub-formula which has not yet been in the passed formula, in case the formula to add is a conjunction), and a Boolean stating whether anything has been added to the passed formula.

**0.15.469.5.12 addSubformulaToPassedFormula()** [3/3] std::pair<ModuleInput::iterator,bool>

smrat::Module::addSubformulaToPassedFormula (const FormulaT & \_formula, const std::shared\_ptr<std::vector<FormulaT>> & \_origins) [inline], [protected], [inherited]

Adds the given formula to the passed formula.

#### Parameters

|          |                                                                                                                                         |
|----------|-----------------------------------------------------------------------------------------------------------------------------------------|
| _formula | The formula to add to the passed formula.                                                                                               |
| _origins | The link of the formula to add to the passed formula to sub-formulas of the received formulas, which are responsible for its occurrence |

#### Returns

A pair to the position where the formula to add has been inserted (or its first sub-formula which has not yet been in the passed formula, in case the formula to add is a conjunction), and a Boolean stating whether anything has been added to the passed formula.

**0.15.469.5.13 allModels()** const std::vector<Model>& smrat::Module::allModels () const [inline], [inherited]

#### Returns

All satisfying assignments, if existent.

**0.15.469.5.14 anAnswerFound()** bool smrat::Module::anAnswerFound () const [inline], [protected], [inherited]

Checks for all antecedent modules and those which run in parallel with the same antecedent modules, whether one of them has determined a result.

#### Returns

True, if one of them has determined a result.

**0.15.469.5.15 answerFound()** const `smtrat::Conditionals`& `smtrat::Module::answerFound` ( ) const [inline], [inherited]

#### Returns

A vector of Booleans: If any of them is true, we have to terminate a running check procedure.

**0.15.469.5.16 backendsModel()** const `Model` & `smtrat::Module::backendsModel` ( ) const [protected], [inherited]

Stores the model of a backend which determined satisfiability of the passed formula in the model of this module.

**0.15.469.5.17 branchAt() [1/4]** bool `smtrat::Module::branchAt` (  
`carl::Variable::Arg _var,`  
`const Rational & _value,`  
`bool _leftCaseWeak = true,`  
`bool _preferLeftCase = true,`  
`bool _useReceivedFormulaAsPremise = false,`  
`const std::vector< FormulaT > & _premise = std::vector<FormulaT>()` ) [inline], [protected], [inherited]

**0.15.469.5.18 branchAt() [2/4]** bool `smtrat::Module::branchAt` (  
`carl::Variable::Arg _var,`  
`const Rational & _value,`  
`std::vector< FormulaT > && _premise,`  
`bool _leftCaseWeak = true,`  
`bool _preferLeftCase = true,`  
`bool _useReceivedFormulaAsPremise = false`) [inline], [protected], [inherited]

**0.15.469.5.19 branchAt() [3/4]** bool `smtrat::Module::branchAt` (  
`const Poly & _polynomial,`  
`bool _integral,`  
`const Rational & _value,`  
`bool _leftCaseWeak = true,`  
`bool _preferLeftCase = true,`  
`bool _useReceivedFormulaAsPremise = false,`  
`const std::vector< FormulaT > & _premise = std::vector<FormulaT>()` ) [inline], [protected], [inherited]

**0.15.469.5.20 branchAt() [4/4]** bool `smtrat::Module::branchAt` (  
`const Poly & _polynomial,`  
`bool _integral,`  
`const Rational & _value,`  
`std::vector< FormulaT > && _premise,`  
`bool _leftCaseWeak = true,`  
`bool _preferLeftCase = true,`  
`bool _useReceivedFormulaAsPremise = false`) [protected], [inherited]

Adds a lemmas which provoke a branching for the given variable at the given value, if this module returns Unknown and there exists a preceding `SATModule`.

Note that the given value is rounded down and up, if the given variable is integer-valued.

#### Parameters

|                          |                             |
|--------------------------|-----------------------------|
| <code>_polynomial</code> | The variable to branch for. |
|--------------------------|-----------------------------|

## Parameters

|                                           |                                                                                                                                                                                                                |
|-------------------------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>_integral</code>                    | A flag being true, if all variables in the polynomial to branch for are integral.                                                                                                                              |
| <code>_value</code>                       | The value to branch at.                                                                                                                                                                                        |
| <code>_premise</code>                     | The sub-formulas of the received formula from which the branch is followed. Note, that a premise is not necessary, as every branch is a valid formula. But a premise can prevent from branching unnecessarily. |
| <code>_leftCaseWeak</code>                | true, if a branching in the form of (or ( $\leq p b$ ) ( $> p b$ )) is desired. false, if a branching in the form of (or ( $< p b$ ) ( $\geq p b$ )) is desired.                                               |
| <code>_preferLeftCase</code>              | true, if the left case (polynomial less(or equal) 0 shall be chosen first. false, otherwise.                                                                                                                   |
| <code>_useReceivedFormulaAsPremise</code> | true, if the whole received formula should be used as premise                                                                                                                                                  |

### 0.15.469.5.21 `check()`

```
Answer smtrat::Module::check (
 bool _final = false,
 bool _full = true,
 carl::Variable _objective = carl::Variable::NO_VARIABLE) [virtual], [inherited]
```

Checks the received formula for consistency.

Note, that this is an implementation of the satisfiability check of the conjunction of the so far received formulas, which does actually nothing but passing the problem to its backends. This implementation is only used internally and must be overwritten by any derived module.

## Parameters

|                         |                                                                                                                                       |
|-------------------------|---------------------------------------------------------------------------------------------------------------------------------------|
| <code>_final</code>     | true, if this satisfiability check will be the last one (for a global sat-check), if its result is SAT                                |
| <code>_full</code>      | false, if this module should avoid too expensive procedures and rather return unknown instead.                                        |
| <code>_objective</code> | if not set to NO_VARIABLE, the module should find an assignment minimizing this objective variable; otherwise any assignment is good. |

## Returns

True, if the received formula is satisfiable; False, if the received formula is not satisfiable; Unknown, otherwise.

Reimplemented in [smtrat::PModule](#).

### 0.15.469.5.22 `checkCore()`

```
template<class Settings >
Answer smtrat::SATModule< Settings >::checkCore () [virtual]
```

Checks the received formula for consistency.

## Returns

SAT, if the received formula is satisfiable; UNSAT, if the received formula is not satisfiable; Unknown, otherwise.

Reimplemented from [smtrat::Module](#).

### 0.15.469.5.23 `checkInfSubsetForMinimality()`

```
void smtrat::Module::checkInfSubsetForMinimality (
 std::vector< FormulaSetT >::const_iterator _infssubset,
 const std::string & _filename = "smaller_muses",
 unsigned _maxSizeDifference = 1) const [inherited]
```

Checks the given infeasible subset for minimality by storing all subsets of it, which have a smaller size which differs from the size of the infeasible subset not more than the given threshold.

## Parameters

|                                 |                                                                                                        |
|---------------------------------|--------------------------------------------------------------------------------------------------------|
| <code>_infsSubset</code>        | The infeasible subset to check for minimality.                                                         |
| <code>_filename</code>          | The name of the file to store the infeasible subsets in order to be able to check their infeasibility. |
| <code>_maxSizeDifference</code> | The maximal difference between the sizes of the subsets compared to the size of the infeasible subset. |

**0.15.469.5.24 `checkModel()`** `unsigned smrat::Module::checkModel () const [protected], [inherited]`

## Returns

false, if the current model of this module does not satisfy the current given formula; true, if it cannot be said whether the model satisfies the given formula.

**0.15.469.5.25 `cleanModel()`** `void smrat::Module::cleanModel () const [inline], [protected], [inherited]`

Substitutes variable occurrences by its model value in the model values of other variables.

**0.15.469.5.26 `cleanUpAfterOptimizing()`** `template<class Settings > void smrat::SATModule< Settings >::cleanUpAfterOptimizing ( const std::vector< Minisat::CRef > & _excludedAssignments )`

**0.15.469.5.27 `clearLemmas()`** `void smrat::Module::clearLemmas () [inline], [inherited]`  
Deletes all yet found lemmas.

**0.15.469.5.28 `clearModel()`** `void smrat::Module::clearModel () const [inline], [protected], [inherited]`  
Clears the assignment, if any was found.

**0.15.469.5.29 `clearModels()`** `void smrat::Module::clearModels () const [inline], [protected], [inherited]`  
Clears all assignments, if any was found.

**0.15.469.5.30 `clearPassedFormula()`** `void smrat::Module::clearPassedFormula () [protected], [inherited]`

**0.15.469.5.31 `collectOrigins() [1/2]`** `void smrat::Module::collectOrigins ( const FormulaT & _formula, FormulaSetT & _origins ) const [inherited]`

**0.15.469.5.32 `collectOrigins() [2/2]`** `void smrat::Module::collectOrigins ( const FormulaT & _formula, FormulasT & _origins ) const [inherited]`

Collects the formulas in the given formula, which are part of the received formula.

If the given formula directly occurs in the received formula, it is inserted into the given set. Otherwise, the given formula must be of type AND and all its sub-formulas part of the received formula. Hence, they will be added to the given set.

#### Parameters

|                       |                                                                                                      |
|-----------------------|------------------------------------------------------------------------------------------------------|
| <code>_formula</code> | The formula from which to collect the formulas being sub-formulas of the received formula (origins). |
| <code>_origins</code> | The set in which to store the origins.                                                               |

**0.15.469.5.33 `collectStats()`** `template<class Settings >`  
`void smtrat::SATModule< Settings >::collectStats ( )`  
Collects the taken statistics.

**0.15.469.5.34 `collectTheoryPropagations()`** `void smtrat::Module::collectTheoryPropagations ( )`  
[inherited]

**0.15.469.5.35 `constraintsToInform()`** `const carl::FastSet<FormulaT>& smtrat::Module::constraintsToInform ( ) const [inline], [inherited]`

#### Returns

The constraints which the backends must be informed about.

**0.15.469.5.36 `currentlySatisfied()`** `virtual unsigned smtrat::Module::currentlySatisfied (`  
`const FormulaT & ) const [inline], [virtual], [inherited]`

#### Returns

0, if the given formula is conflicted by the current model; 1, if the given formula is satisfied by the current model; 2, otherwise; 3, if we do not know anything (default)

Reimplemented in `smtrat::LRAbstractModule< Settings >`, `smtrat::LRAbstractModule< LRASettingsICP >`, and `smtrat::LRAbstractModule< LRASettings >`.

**0.15.469.5.37 `currentlySatisfiedByBackend()`** `unsigned smtrat::Module::currentlySatisfiedByBackend (`  
`const FormulaT & _formula ) const [inherited]`

#### Returns

0, if the given formula is conflicted by the current model; 1, if the given formula is satisfied by the current model; 2, otherwise 3, if we do not know anything (default)

**0.15.469.5.38 `deinform()`** `void smtrat::Module::deinform (`  
`const FormulaT & _constraint ) [inherited]`

The inverse of informing about a constraint.

All data structures which were kept regarding this constraint are going to be removed. Note, that this makes only sense if it is not likely enough that a formula with this constraint must be solved again.

#### Parameters

|                          |                                                         |
|--------------------------|---------------------------------------------------------|
| <code>_constraint</code> | The constraint to remove from internal data structures. |
|--------------------------|---------------------------------------------------------|

**0.15.469.5.39 `deinformCore()`** `virtual void smtrat::Module::deinformCore (`  
 `const FormulaT & _constraint )` [inline], [protected], [virtual], [inherited]

The inverse of informing about a constraint.

All data structures which were kept regarding this constraint are going to be removed. Note, that this makes only sense if it is not likely enough that a formula with this constraint must be solved again.

#### Parameters

|                          |                                                         |
|--------------------------|---------------------------------------------------------|
| <code>_constraint</code> | The constraint to remove from internal data structures. |
|--------------------------|---------------------------------------------------------|

Reimplemented in [smtrat::LRAModule< Settings >](#), [smtrat::LRAModule< LRASettingsICP >](#), and [smtrat::LRAModule< LRASettings1 >](#).

**0.15.469.5.40 `determine_smallest_origin()`** `size_t smtrat::Module::determine_smallest_origin (`  
 `const std::vector< FormulaT > & origins )` const [protected], [inherited]

#### Parameters

|                      |                              |
|----------------------|------------------------------|
| <code>origins</code> | A vector of sets of origins. |
|----------------------|------------------------------|

#### Returns

The index of the smallest (regarding the size of the sets) element of origins

**0.15.469.5.41 `eraseSubformulaFromPassedFormula()`** `ModuleInput::iterator smtrat::Module::eraseSubformulaFromPassedFormula (`  
 `ModuleInput::iterator _subformula,`  
 `bool _ignoreOrigins = false )` [protected], [virtual], [inherited]

Removes everything related to the sub-formula to remove from the passed formula in the backends of this module.  
 Afterwards the sub-formula is removed from the passed formula.

#### Parameters

|                             |                                                                                                              |
|-----------------------------|--------------------------------------------------------------------------------------------------------------|
| <code>_subformula</code>    | The sub-formula to remove from the passed formula.                                                           |
| <code>_ignoreOrigins</code> | True, if the sub-formula shall be removed regardless of its origins (should only be applied with expertise). |

#### Returns

Reimplemented in [smtrat::ICPModule< Settings >](#), [smtrat::ICPModule< ICPSettings4 >](#), and [smtrat::ICPModule< ICPSettings1 >](#).

**0.15.469.5.42 `excludeNotReceivedVariablesFromModel()`** `void smtrat::Module::excludeNotReceivedVariablesFromModel ( )` const [inherited]

Excludes all variables from the current model, which do not occur in the received formula.

**0.15.469.5.43 `findBestOrigin()`** `std::vector< FormulaT >::const_iterator smtrat::Module::findBestOrigin (`  
 `const std::vector< FormulaT > & _origins )` const [protected], [inherited]

**Parameters**

|                 |  |
|-----------------|--|
| <i>_origins</i> |  |
|-----------------|--|

**Returns**

**0.15.469.5.44 `firstSubformulaToPass()`** `ModuleInput::const_iterator smtrat::Module::firstSubformulaToPass () const [inline], [inherited]`

**Returns**

The position of the first sub-formula in the passed formula, which has not yet been considered for a consistency check of the backends.

**0.15.469.5.45 `firstUncheckedReceivedSubformula()`** `ModuleInput::const_iterator smtrat::Module::firstUncheckedReceivedSubformula () const [inline], [inherited]`

**Returns**

The position of the first (by this module) unchecked sub-formula of the received formula.

**0.15.469.5.46 `freeSplittingVariable()`** `static void smtrat::Module::freeSplittingVariable (const FormulaT & _splittingVariable) [inline], [static], [inherited]`

**0.15.469.5.47 `generateTrivialInfeasibleSubset()`** `void smtrat::Module::generateTrivialInfeasibleSubset () [inline], [protected], [inherited]`

Stores the trivial infeasible subset being the set of received formulas.

**0.15.469.5.48 `getBackendsAllModels()`** `void smtrat::Module::getBackendsAllModels () const [protected], [inherited]`

Stores all models of a backend in the list of all models of this module.

**0.15.469.5.49 `getBackendsModel()`** `void smtrat::Module::getBackendsModel () const [protected], [inherited]`

**0.15.469.5.50 `getInfeasibleSubsets() [1/2]`** `void smtrat::Module::getInfeasibleSubsets () [protected], [inherited]`

Copies the infeasible subsets of the passed formula.

**0.15.469.5.51 `getInfeasibleSubsets() [2/2]`** `std::vector< FormulaSetT > smtrat::Module::getInfeasibleSubsets (const Module & _backend) const [protected], [inherited]`

Get the infeasible subsets the given backend provides.

Note, that an infeasible subset in a backend contains sub formulas of the passed formula and an infeasible subset of this module contains sub formulas of the received formula. In this method the LATTER is returned.

**Parameters**

|                       |                                                          |
|-----------------------|----------------------------------------------------------|
| <code>_backend</code> | The backend from which to obtain the infeasible subsets. |
|-----------------------|----------------------------------------------------------|

**Returns**

The infeasible subsets the given backend provides.

**0.15.469.5.52 `getInformationRelevantFormulas()`** `const std::set< FormulaT > & smtrat::Module::getInformationRelevantFormulas ( ) [protected], [inherited]`  
Gets all InformationRelevantFormulas.

**Returns**

Set of all formulas

**0.15.469.5.53 `getModelEqualities()`** `std::list< std::vector< carl::Variable > > smtrat::Module::getModelEqualities ( ) const [virtual], [inherited]`  
Partition the variables from the current model into equivalence classes according to their assigned value.  
The result is a set of equivalence classes of variables where all variables within one class are assigned the same value. Note that the number of classes may not be minimal, i.e. two classes may actually be equivalent.

**Returns**

Equivalence classes.

**0.15.469.5.54 `getOrigins() [1/3]`** `void smtrat::Module::getOrigins ( const FormulaT & _formula, FormulaSetT & _origins ) const [inline], [protected], [inherited]`

**Parameters**

|                       |  |
|-----------------------|--|
| <code>_formula</code> |  |
| <code>_origins</code> |  |

**0.15.469.5.55 `getOrigins() [2/3]`** `void smtrat::Module::getOrigins ( const FormulaT & _formula, FormulasT & _origins ) const [inline], [protected], [inherited]`

**Parameters**

|                       |  |
|-----------------------|--|
| <code>_formula</code> |  |
| <code>_origins</code> |  |

**0.15.469.5.56 `getOrigins() [3/3]`** `const FormulaT& smtrat::Module::getOrigins ( ModuleInput::const_iterator _formula ) const [inline], [protected], [inherited]`  
Gets the origins of the passed formula at the given position.

**Parameters**

|                 |                                                   |
|-----------------|---------------------------------------------------|
| <i>_formula</i> | The position of a formula in the passed formulas. |
|-----------------|---------------------------------------------------|

**Returns**

The origins of the passed formula at the given position.

**0.15.469.5.57 `getReceivedFormulaSimplified()`** `std::pair< bool, FormulaT >` `smtrat::Module::getReceivedFormulaSimplified( )` [virtual], [inherited]

**Returns**

A pair of a Boolean and a formula, where the Boolean is true, if the received formula could be simplified to an equisatisfiable formula. The formula is equisatisfiable to this module's received formula, if the Boolean is true.

Reimplemented in [smtrat::PModule](#).

**0.15.469.5.58 `hasLemmas()`** `bool smtrat::Module::hasLemmas( )` [inline], [inherited]

Checks whether this module or any of its backends provides any lemmas.

**0.15.469.5.59 `hasValidInfeasibleSubset()`** `bool smtrat::Module::hasValidInfeasibleSubset( ) const` [inherited]

**Returns**

true, if the module has at least one valid infeasible subset, that is all its elements are sub-formulas of the received formula (pointer must be equal).

**0.15.469.5.60 `id()`** `std::size_t smtrat::Module::id( ) const` [inline], [inherited]

**Returns**

A unique ID to identify this module instance.

**0.15.469.5.61 `infeasibleSubsets()`** `const std::vector<FormulaSetT>& smtrat::Module::infeasibleSubsets( ) const` [inline], [inherited]

**Returns**

The infeasible subsets of the set of received formulas (empty, if this module has not detected unsatisfiability of the conjunction of received formulas).

**0.15.469.5.62 `inform()`** `bool smtrat::Module::inform( const FormulaT & _constraint )` [inherited]

Informs the module about the given constraint.

It should be tried to inform this module about any constraint it could receive eventually before `assertSubformula` is called (preferably for the first time, but at least before adding a formula containing that constraint).

**Parameters**

|                    |                                 |
|--------------------|---------------------------------|
| <i>_constraint</i> | The constraint to inform about. |
|--------------------|---------------------------------|

**Returns**

false, if it can be easily decided whether the given constraint is inconsistent; true, otherwise.

**0.15.469.5.63 informBackends()** void smrat::Module::informBackends ( const FormulaT & \_constraint ) [inline], [protected], [inherited]

Informs all backends of this module about the given constraint.

**Parameters**

|                    |                                 |
|--------------------|---------------------------------|
| <i>_constraint</i> | The constraint to inform about. |
|--------------------|---------------------------------|

**0.15.469.5.64 informCore()** virtual bool smrat::Module::informCore (

const FormulaT & \_constraint ) [inline], [protected], [virtual], [inherited]

Informs the module about the given constraint.

It should be tried to inform this module about any constraint it could receive eventually before assertSubformula is called (preferably for the first time, but at least before adding a formula containing that constraint).

**Parameters**

|                    |                                 |
|--------------------|---------------------------------|
| <i>_constraint</i> | The constraint to inform about. |
|--------------------|---------------------------------|

**Returns**

false, if it can be easily decided whether the given constraint is inconsistent; true, otherwise.

Reimplemented in [smrat::UnionFindModule< Settings >](#), [smrat::PBPPModule< Settings >](#), [smrat::PBGaussModule< Settings >](#), [smrat::NRAILModule< Settings >](#), [smrat::NewCoveringModule< Settings >](#), [smrat::NewCADModule< Settings >](#), [smrat::LRAModule< Settings >](#), [smrat::LRAModule< LRASettingsICP >](#), [smrat::LRAModule< LRASettings1 >](#), [smrat::IntBlastModule< Settings >](#), [smrat::FPPModule< Settings >](#), [smrat::EQModule< Settings >](#), [smrat::CurryModule< Settings >](#), [smrat::BVMModule< Settings >](#), [smrat::ICPModule< Settings >](#), [smrat::ICPModule< ICPSettings4 >](#), and [smrat::ICPModule< ICPSettings1 >](#).

**0.15.469.5.65 informedConstraints()** const carl::FastSet<FormulaT>& smrat::Module::informedConstraints ( ) const [inline], [inherited]

**Returns**

The position of the first constraint of which no backend has been informed about.

**0.15.469.5.66 init()** void smrat::Module::init ( ) [virtual], [inherited]

Informs all backends about the so far encountered constraints, which have not yet been communicated.

This method must not be called twice and only before the first runBackends call.

Reimplemented in [smrat::PBPPModule< Settings >](#), [smrat::PBGaussModule< Settings >](#), [smrat::NRAILModule< Settings >](#), [smrat::NewCoveringModule< Settings >](#), [smrat::NewCADModule< Settings >](#), [smrat::LRAModule< Settings >](#), [smrat::LRAModule< LRASettingsICP >](#), [smrat::LRAModule< LRASettings1 >](#), [smrat::IntBlastModule< Settings >](#), [smrat::FPPModule< Settings >](#), [smrat::EQModule< Settings >](#), [smrat::CurryModule< Settings >](#), and [smrat::BVMModule< Settings >](#).

**0.15.469.5.67 is\_minimizing()** bool smrat::Module::is\_minimizing ( ) const [inline], [inherited]

**0.15.469.5.68 isLemmaLevel()** `bool smtrat::Module::isLemmaLevel (``LemmaLevel level ) [protected], [inherited]`

Checks if current lemma level is greater or equal to given level.

**Parameters**

|                    |                 |
|--------------------|-----------------|
| <code>level</code> | Level to check. |
|--------------------|-----------------|

**0.15.469.5.69 isPreprocessor()** `bool smtrat::Module::isPreprocessor ( ) const [inline], [inherited]`**Returns**

true, if this module is a preprocessor that is a module, which simplifies its received formula to an equisatisfiable formula being passed to its backends. The simplified formula can be obtained with [getReceivedFormulaSimplified\(\)](#).

**0.15.469.5.70 lemmas()** `const std::vector<Lemma>& smtrat::Module::lemmas ( ) const [inline], [inherited]`**Returns**

A constant reference to the lemmas being valid formulas this module or its backends made.

**0.15.469.5.71 merge()** `std::vector< FormulaT > smtrat::Module::merge (``const std::vector< FormulaT > & _vecSetA,``const std::vector< FormulaT > & _vecSetB ) const [protected], [inherited]`

Merges the two vectors of sets into the first one.

({a,b},{a,c}) and ({b,d},{b}) -> ({a,b,d},{a,b},{a,b,c,d},{a,b,c})

**Parameters**

|                       |                                  |
|-----------------------|----------------------------------|
| <code>_vecSetA</code> | A vector of sets of constraints. |
| <code>_vecSetB</code> | A vector of sets of constraints. |

**Returns**

The vector being the two given vectors merged.

**0.15.469.5.72 model()** `const Model& smtrat::Module::model ( ) const [inline], [inherited]`**Returns**

The assignment of the current satisfiable result, if existent.

**0.15.469.5.73 modelsDisjoint()** `bool smtrat::Module::modelsDisjoint (``const Model & _modelA,``const Model & _modelB ) [static], [protected], [inherited]`

Checks whether there is no variable assigned by both models.

**Parameters**

|                      |                                |
|----------------------|--------------------------------|
| <code>_modelA</code> | The first model to check for.  |
| <code>_modelB</code> | The second model to check for. |

**Returns**

true, if there is no variable assigned by both models; false, otherwise.

**0.15.469.5.74 `moduleName()`** `virtual std::string smtrat::Module::moduleName( ) const [inline], [virtual], [inherited]`

**Returns**

The name of the given module type as name.

Reimplemented in `smtrat::VSModule< Settings >`, `smtrat::UnionFindModule< Settings >`, `smtrat::UFCegarModule< Settings >`, `smtrat::STropModule< Settings >`, `smtrat::SplitSOSModule< Settings >`, `smtrat::PBPPModule< Settings >`, `smtrat::PBGaussModule< Settings >`, `smtrat::NRAILModule< Settings >`, `smtrat::NewCADModule< Settings >`, `smtrat::LVEModule< Settings >`, `smtrat::LRAModule< Settings >`, `smtrat::LRAModule< LRASettingsICP >`, `smtrat::LRAModule< LRASettings1 >`, `smtrat::IntEqModule< Settings >`, `smtrat::IntBlastModule< Settings >`, `smtrat::IncWidthModule< Settings >`, `smtrat::ICPModule< Settings >`, `smtrat::ICPModule< ICPSettings4 >`, `smtrat::ICPModule< ICPSettings1 >`, `smtrat::GBModule< Settings >`, `smtrat::FouMoModule< Settings >`, `smtrat::EQPreprocessingModule< Settings >`, `smtrat::EQModule< Settings >`, `smtrat::CurryModule< Settings >`, `smtrat::CubeLIAModule< Settings >`, `smtrat::CSplitModule< Settings >`, `smtrat::BVMModule< Settings >`, and `smtrat::BEModule< Settings >`.

**0.15.469.5.75 `objective()`** `carl::Variable smtrat::Module::objective( ) const [inline], [inherited]`

**0.15.469.5.76 `originInReceivedFormula()`** `bool smtrat::Module::originInReceivedFormula( const FormulaT & _origin ) const [protected], [inherited]`

**0.15.469.5.77 `passedFormulaBegin()`** `ModuleInput::iterator smtrat::Module::passedFormulaBegin( ) [inline], [protected], [inherited]`

**Returns**

An iterator to the end of the passed formula. TODO: disable this method

**0.15.469.5.78 `passedFormulaEnd()`** `ModuleInput::iterator smtrat::Module::passedFormulaEnd( ) [inline], [protected], [inherited]`

**Returns**

An iterator to the end of the passed formula.

**0.15.469.5.79 `pPassedFormula()`** `const ModuleInput* smtrat::Module::pPassedFormula( ) const [inline], [inherited]`

**Returns**

A pointer to the formula passed to the backends of this module.

**0.15.469.5.80 pReceivedFormula()** const `ModuleInput*` smtrat::Module::pReceivedFormula ( ) const  
[inline], [inherited]

**Returns**

A pointer to the formula passed to this module.

**0.15.469.5.81 print() [1/2]** void smtrat::Module::print (const std::string & *\_initiation* = "\*\*\*") const [inherited]  
Prints everything relevant of the solver.

**Parameters**

|                    |                      |
|--------------------|----------------------|
| <i>_initiation</i> | The line initiation. |
|--------------------|----------------------|

**0.15.469.5.82 print() [2/2]** template<class Settings> void smtrat::SATModule< Settings >::print (std::ostream & *\_out* = std::cout, const std::string & *\_init* = "") const

Prints everything.

**Parameters**

|              |                                                       |
|--------------|-------------------------------------------------------|
| <i>_out</i>  | The output stream where the answer should be printed. |
| <i>_init</i> | The line initiation.                                  |

**0.15.469.5.83 printAllModels()** void smtrat::Module::printAllModels (std::ostream & *\_out* = std::cout) [inherited]

Prints all assignments of this module satisfying its received formula if it satisfiable and this module could find an assignment.

**Parameters**

|             |                                        |
|-------------|----------------------------------------|
| <i>_out</i> | The stream to print the assignment on. |
|-------------|----------------------------------------|

**0.15.469.5.84 printBooleanConstraintMap()** template<class Settings> void smtrat::SATModule< Settings >::printBooleanConstraintMap (std::ostream & *\_out* = std::cout, const std::string & *\_init* = "") const

Prints the literal to constraint map.

**Parameters**

|              |                                                       |
|--------------|-------------------------------------------------------|
| <i>_out</i>  | The output stream where the answer should be printed. |
| <i>_init</i> | The line initiation.                                  |

**0.15.469.5.85 printBooleanVarMap()** template<class Settings>

```
void smtrat::SATModule< Settings >::printBooleanVarMap (
 std::ostream & _out = std::cout,
 const std::string & _init = "") const
```

Prints map of the Boolean within the SAT solver to the given Booleans.

#### Parameters

|                    |                                                       |
|--------------------|-------------------------------------------------------|
| <code>_out</code>  | The output stream where the answer should be printed. |
| <code>_init</code> | The line initiation.                                  |

#### 0.15.469.5.86 `printClause()` [1/2] template<class Settings >

```
void smtrat::SATModule< Settings >::printClause (
 const Minisat::vec< Minisat::Lit > & ,
 bool _withAssignment = false,
 std::ostream & _out = std::cout,
 const std::string & _init = "") const
```

Prints the clause resulting from the given vector of literals.

#### Parameters

|                              |                                                                        |
|------------------------------|------------------------------------------------------------------------|
| <code>_clause</code>         | The reference of the clause.                                           |
| <code>_withAssignment</code> | A flag indicating if true, that the assignments should be printed too. |
| <code>_out</code>            | The output stream where the answer should be printed.                  |
| <code>_init</code>           | The prefix of each printed line.                                       |

#### 0.15.469.5.87 `printClause()` [2/2] template<class Settings >

```
void smtrat::SATModule< Settings >::printClause (
 Minisat::CRef _clause,
 bool _withAssignment = false,
 std::ostream & _out = std::cout,
 const std::string & _init = "") const
```

Prints the clause at the given reference.

#### Parameters

|                              |                                                                        |
|------------------------------|------------------------------------------------------------------------|
| <code>_clause</code>         | The reference of the clause.                                           |
| <code>_withAssignment</code> | A flag indicating if true, that the assignments should be printed too. |
| <code>_out</code>            | The output stream where the answer should be printed.                  |
| <code>_init</code>           | The prefix of each printed line.                                       |

#### 0.15.469.5.88 `printClauseInformation()` template<class Settings >

```
void smtrat::SATModule< Settings >::printClauseInformation (
 std::ostream & _out = std::cout,
 const std::string & _init = "") const
```

Prints the clause information.

#### Parameters

|                    |                                                       |
|--------------------|-------------------------------------------------------|
| <code>_out</code>  | The output stream where the answer should be printed. |
| <code>_init</code> | The line initiation.                                  |

```
0.15.469.5.89 printClauses() template<class Settings >
void smtrat::SATModule< Settings >::printClauses (
 const Minisat::vec< Minisat::CRef > & _clauses,
 const std::string & _name,
 std::ostream & _out = std::cout,
 const std::string & _init = "",
 int = 0,
 bool _withAssignment = false,
 bool _onlyNotSatisfied = false) const
```

Prints all given clauses.

#### Parameters

|                              |                                                                               |
|------------------------------|-------------------------------------------------------------------------------|
| <code>_clauses</code>        | The clauses to print.                                                         |
| <code>_name</code>           | The name of the clauses to print. (e.g. learnts, clauses, ..)                 |
| <code>_out</code>            | The output stream where the answer should be printed.                         |
| <code>_init</code>           | The prefix of each printed line.                                              |
| <code>_from</code>           | The position of the first clause to print within the given vector of clauses. |
| <code>_withAssignment</code> | A flag indicating if true, that the assignments should be printed too.        |

```
0.15.469.5.90 printConstraintLiteralMap() template<class Settings >
void smtrat::SATModule< Settings >::printConstraintLiteralMap (
 std::ostream & _out = std::cout,
 const std::string & _init = "") const
```

Prints the constraints to literal map.

#### Parameters

|                    |                                                       |
|--------------------|-------------------------------------------------------|
| <code>_out</code>  | The output stream where the answer should be printed. |
| <code>_init</code> | The line initiation.                                  |

```
0.15.469.5.91 printCurrentAssignment() template<class Settings >
void smtrat::SATModule< Settings >::printCurrentAssignment (
 std::ostream & = std::cout,
 const std::string & = "") const
```

Prints the current assignment of the SAT solver.

#### Parameters

|                    |                                                       |
|--------------------|-------------------------------------------------------|
| <code>_out</code>  | The output stream where the answer should be printed. |
| <code>_init</code> | The line initiation.                                  |

```
0.15.469.5.92 printDecisions() template<class Settings >
void smtrat::SATModule< Settings >::printDecisions (
 std::ostream & _out = std::cout,
 const std::string & _init = "") const
```

Prints the decisions the SAT solver has made.

**Parameters**

|              |                                                       |
|--------------|-------------------------------------------------------|
| <i>_out</i>  | The output stream where the answer should be printed. |
| <i>_init</i> | The line initiation.                                  |

**0.15.469.5.93 printFormulaCNFInfosMap()** template<class Settings >  
void smtrat::SATModule< Settings >::printFormulaCNFInfosMap ( std::ostream & *\_out* = std::cout,  
const std::string & *\_init* = "" ) const  
Prints the formulas to clauses map.

**Parameters**

|              |                                                       |
|--------------|-------------------------------------------------------|
| <i>_out</i>  | The output stream where the answer should be printed. |
| <i>_init</i> | The line initiation.                                  |

**0.15.469.5.94 printInfeasibleSubsets()** void smtrat::Module::printInfeasibleSubsets ( const std::string & *\_initiation* = "\*\*\*" ) const [inherited]  
Prints the infeasible subsets.

**Parameters**

|                    |                      |
|--------------------|----------------------|
| <i>_initiation</i> | The line initiation. |
|--------------------|----------------------|

**0.15.469.5.95 printLiteralsActiveOccurrences()** template<class Settings >  
void smtrat::SATModule< Settings >::printLiteralsActiveOccurrences ( std::ostream & *\_out* = std::cout,  
const std::string & *\_init* = "" ) const  
Prints the literals' active occurrences in all clauses.

**Parameters**

|              |                                                       |
|--------------|-------------------------------------------------------|
| <i>_out</i>  | The output stream where the answer should be printed. |
| <i>_init</i> | The line initiation.                                  |

**0.15.469.5.96 printModel()** void smtrat::Module::printModel ( std::ostream & *\_out* = std::cout ) const [inherited]

Prints the assignment of this module satisfying its received formula if it satisfiable and this module could find an assignment.

**Parameters**

|             |                                        |
|-------------|----------------------------------------|
| <i>_out</i> | The stream to print the assignment on. |
|-------------|----------------------------------------|

**0.15.469.5.97 printPassedFormula()** void smtrat::Module::printPassedFormula (

---

```
 const std::string & _initiation = "***") const [inherited]
Prints the vector of passed formula.
```

**Parameters**

|                    |                      |
|--------------------|----------------------|
| <i>_initiation</i> | The line initiation. |
|--------------------|----------------------|

**0.15.469.5.98 printPropagatedLemmas()** template<class Settings >  
void smrat::SATModule< Settings >::printPropagatedLemmas (

```
 std::ostream & _out = std::cout,
 const std::string & _init = "") const
```

Prints the propagated lemmas for each variables which influence its value.

**Parameters**

|              |                                                       |
|--------------|-------------------------------------------------------|
| <i>_out</i>  | The output stream where the answer should be printed. |
| <i>_init</i> | The line initiation.                                  |

**0.15.469.5.99 printReceivedFormula()** void smrat::Module::printReceivedFormula (

```
 const std::string & _initiation = "***") const [inherited]
```

Prints the vector of the received formula.

**Parameters**

|                    |                      |
|--------------------|----------------------|
| <i>_initiation</i> | The line initiation. |
|--------------------|----------------------|

**0.15.469.5.100 probablyLooping()** bool smrat::Module::probablyLooping (

```
 const typename Poly::PolyType & _branchingPolynomial,
 const Rational & _branchingValue) const [protected], [inherited]
```

Checks whether given the current branching value and branching variable/polynomial it is (highly) probable that this branching is part of an infinite loop of branchings.

**Parameters**

|                             |                                                                                     |
|-----------------------------|-------------------------------------------------------------------------------------|
| <i>_branchingPolynomial</i> | The polynomial to branch at (in most branching strategies this is just a variable). |
| <i>_branchingValue</i>      | The value to branch at.                                                             |

**Returns**

true, if this branching is probably part of an infinite loop of branchings; false, otherwise.

**0.15.469.5.101 receivedFormulaChecked()** void smrat::Module::receivedFormulaChecked ( ) [inline], [inherited]

Notifies that the received formulas has been checked.

**0.15.469.5.102 receivedFormulasAsInfeasibleSubset()** void smrat::Module::receivedFormulasAsInfeasibleSubset (

```
 ModuleInput::const_iterator _subformula) [inline], [protected], [inherited]
```

Stores an infeasible subset consisting only of the given received formula.

**0.15.469.5.103 `receivedVariable()`** `bool smtrat::Module::receivedVariable ( carl::Variable::Arg _var ) const [inline], [inherited]`

**0.15.469.5.104 `remove()`** `void smtrat::Module::remove ( ModuleInput::const_iterator _subformula ) [virtual], [inherited]`

Removes everything related to the given sub-formula of the received formula.

However, it is desired not to lose track of search spaces where no satisfying assignment can be found for the remaining sub-formulas.

#### Parameters

|                          |                                                    |
|--------------------------|----------------------------------------------------|
| <code>_subformula</code> | The sub formula of the received formula to remove. |
|--------------------------|----------------------------------------------------|

Reimplemented in [smtrat::PModule](#).

**0.15.469.5.105 `removeCore()`** `template<class Settings > void smtrat::SATModule< Settings >::removeCore ( ModuleInput::const_iterator ) [virtual]`

Removes everything related to the given sub-formula of the received formula.

#### Parameters

|                          |                                                    |
|--------------------------|----------------------------------------------------|
| <code>_subformula</code> | The sub formula of the received formula to remove. |
|--------------------------|----------------------------------------------------|

Reimplemented from [smtrat::Module](#).

**0.15.469.5.106 `removeOrigin()`** `std::pair<ModuleInput::iterator,bool> smtrat::Module::removeOrigin ( ModuleInput::iterator _formula, const FormulaT & _origin ) [inline], [protected], [inherited]`

**0.15.469.5.107 `removeOrigins()`** `std::pair<ModuleInput::iterator,bool> smtrat::Module::removeOrigins ( ModuleInput::iterator _formula, const std::shared_ptr< std::vector< FormulaT >> & _origins ) [inline], [protected], [inherited]`

**0.15.469.5.108 `removeUpperBoundOnMinimal()`** `template<class Settings > void smtrat::SATModule< Settings >::removeUpperBoundOnMinimal ( )`

**0.15.469.5.109 `rPassedFormula()`** `const ModuleInput& smtrat::Module::rPassedFormula ( ) const [inline], [inherited]`

#### Returns

A reference to the formula passed to the backends of this module.

**0.15.469.5.110 rReceivedFormula()** const `ModuleInput`& smtrat::Module::rReceivedFormula ( ) const [inline], [inherited]

**Returns**

A reference to the formula passed to this module.

**0.15.469.5.111 runBackends() [1/2]** virtual `Answer` smtrat::Module::runBackends ( ) [inline], [protected], [virtual], [inherited]  
Reimplemented in [smtrat::PModule](#).

**0.15.469.5.112 runBackends() [2/2]** `Answer` smtrat::Module::runBackends (

```
 bool _final,
 bool _full,
 carl::Variable _objective) [protected], [virtual], [inherited]
```

Runs the backend solvers on the passed formula.

**Parameters**

|                         |                                                                                                                                       |
|-------------------------|---------------------------------------------------------------------------------------------------------------------------------------|
| <code>_final</code>     | true, if this satisfiability check will be the last one (for a global sat-check), if its result is SAT                                |
| <code>_full</code>      | false, if this module should avoid too expensive procedures and rather return unknown instead.                                        |
| <code>_objective</code> | if not set to NO_VARIABLE, the module should find an assignment minimizing this objective variable; otherwise any assignment is good. |

**Returns**

True, if the passed formula is consistent; False, if the passed formula is inconsistent; Unknown, otherwise.

Reimplemented in [smtrat::PModule](#).

**0.15.469.5.113 setId()** void smtrat::Module::setId ( std::size\_t `_id` ) [inline], [inherited]

Sets this modules unique ID to identify itself.

**Parameters**

|                                                                       |                                    |
|-----------------------------------------------------------------------|------------------------------------|
| $\leftrightarrow$<br>$\underline{\leftrightarrow}$<br><code>id</code> | The id to set this module's id to. |
|-----------------------------------------------------------------------|------------------------------------|

**0.15.469.5.114 setThreadPriority()** void smtrat::Module::setThreadPriority ( `thread_priority` `_threadPriority` ) [inline], [inherited]

Sets the priority of this module to get a thread for running its check procedure.

**Parameters**

|                              |                                                       |
|------------------------------|-------------------------------------------------------|
| <code>_threadPriority</code> | The priority to set this module's thread priority to. |
|------------------------------|-------------------------------------------------------|

**0.15.469.5.115 solverState()** `Answer` smtrat::Module::solverState ( ) const [inline], [inherited]

**Returns**

True, if this module is in a state, such that it has found a solution for its received formula; False, if this module is in a state, such that it has determined that there is no solution for its received formula; Unknown, otherwise.

**0.15.469.5.116 `splitUnequalConstraint()`** `void smtrat::Module::splitUnequalConstraint (`

`const FormulaT & _unequalConstraint ) [protected], [inherited]`

Adds the following lemmas for the given constraint  $p \neq 0$ .

$(p \neq 0 \Leftrightarrow (p < 0 \text{ or } p > 0))$

and  $\neg(p < 0 \text{ and } p > 0)$

**Parameters**

|                                 |                                                  |
|---------------------------------|--------------------------------------------------|
| <code>_unequalConstraint</code> | A constraint having the relation symbol $\neq$ . |
|---------------------------------|--------------------------------------------------|

**0.15.469.5.117 `threadPriority()`** `thread_priority smtrat::Module::threadPriority ( ) const [inline], [inherited]`**Returns**

The priority of this module to get a thread for running its check procedure.

**0.15.469.5.118 `updateAllModels()`** `template<class Settings >`

`void smtrat::SATModule< Settings >::updateAllModels ( ) [virtual]`

Updates all satisfying models, if the solver has detected the consistency of the received formula, beforehand.

Reimplemented from `smtrat::Module`.

**0.15.469.5.119 `updateInfeasibleSubset()`** `template<class Settings >`

`void smtrat::SATModule< Settings >::updateInfeasibleSubset ( )`

Updates the infeasible subset found by the `SATModule`, if the received formula is unsatisfiable.

**0.15.469.5.120 `updateLemmas()`** `void smtrat::Module::updateLemmas ( ) [inherited]`

Stores all lemmas of any backend of this module in its own lemma vector.

**0.15.469.5.121 `updateModel()`** `template<class Settings >`

`void smtrat::SATModule< Settings >::updateModel ( ) const [virtual]`

Updates the model, if the solver has detected the consistency of the received formula, beforehand.

Reimplemented from `smtrat::Module`.

**0.15.469.5.122 `usedBackends()`** `const std::vector<Module*>& smtrat::Module::usedBackends ( )`

`const [inline], [inherited]`

**Returns**

The backends of this module which are currently used (conditions to use this module are fulfilled for the passed formula).

## 0.15.469.6 Friends And Related Function Documentation

**0.15.469.6.1 VarSchedulerBase** template<class Settings >  
friend class [VarSchedulerBase](#) [friend]

**0.15.469.6.2 VarSchedulerMcsatBase** template<class Settings >  
friend class [VarSchedulerMcsatBase](#) [friend]

## 0.15.469.7 Field Documentation

**0.15.469.7.1 mAllBackends** std::vector<[Module](#)\*> smrat::Module::mAllBackends [protected],  
[inherited]

The backends of this module which have been used.

**0.15.469.7.2 mAllModels** std::vector<[Model](#)> smrat::Module::mAllModels [mutable], [protected],  
[inherited]

Stores all satisfying assignments.

**0.15.469.7.3 mBackendsFoundAnswer** std::atomic\_bool\* smrat::Module::mBackendsFoundAnswer  
[protected], [inherited]

This flag is passed to any backend and if it determines an answer to a prior check call, this flag is fired.

**0.15.469.7.4 mConstraintsToInform** carl::FastSet<[FormulaT](#)> smrat::Module::mConstraintsToInform  
[protected], [inherited]

Stores the constraints which the backends must be informed about.

**0.15.469.7.5 mFinalCheck** bool smrat::Module::mFinalCheck [protected], [inherited]  
true, if the check procedure should perform a final check which especially means not to postpone splitting decisions

**0.15.469.7.6 mFirstPosInLastBranches** std::size\_t smrat::Module::mFirstPosInLastBranches = 0  
[static], [inherited]

The beginning of the cyclic buffer storing the last branches.

**0.15.469.7.7 mFirstSubformulaToPass** [ModuleInput](#)::iterator smrat::Module::mFirstSubformulaTo→  
Pass [protected], [inherited]

Stores the position of the first sub-formula in the passed formula, which has not yet been considered for a consistency check of the backends.

**0.15.469.7.8 mFirstUncheckedReceivedSubformula** [ModuleInput](#)::const\_iterator smrat::Module→  
::mFirstUncheckedReceivedSubformula [protected], [inherited]

Stores the position of the first (by this module) unchecked sub-formula of the received formula.

**0.15.469.7.9 mFoundAnswer** `Conditionals` `smtrat::Module::mFoundAnswer` [protected], [inherited]  
Vector of Booleans: If any of them is true, we have to terminate a running check procedure.

**0.15.469.7.10 mFullCheck** `bool` `smtrat::Module::mFullCheck` [protected], [inherited]  
false, if this module should avoid too expensive procedures and rather return unknown instead.

**0.15.469.7.11 mInfeasibleSubsets** `std::vector<FormulaSetT>` `smtrat::Module::mInfeasibleSubsets`  
[protected], [inherited]  
Stores the infeasible subsets.

**0.15.469.7.12 mInformedConstraints** `carl::FastSet<FormulaT>` `smtrat::Module::mInformedConstraints`  
[protected], [inherited]  
Stores the position of the first constraint of which no backend has been informed about.

**0.15.469.7.13 mLastBranches** `std::vector< Branching >` `smtrat::Module::mLastBranches` = `std::vector<Branching>(mNumOfBranchVarsToStore, Branching(typename Poly::PolyType(), 0))` [static],  
[inherited]  
Stores the last branches in a cycle buffer.

**0.15.469.7.14 mModel** `Model` `smtrat::Module::mModel` [mutable], [protected], [inherited]  
Stores the assignment of the current satisfiable result, if existent.

**0.15.469.7.15 mModelComputed** `bool` `smtrat::Module::mModelComputed` [mutable], [protected],  
[inherited]  
True, if the model has already been computed.

**0.15.469.7.16 mNumOfBranchVarsToStore** `std::size_t` `smtrat::Module::mNumOfBranchVarsToStore` =  
5 [static], [inherited]  
The number of different variables to consider for a probable infinite loop of branchings.

**0.15.469.7.17 mObjectiveVariable** `carl::Variable` `smtrat::Module::mObjectiveVariable` [protected],  
[inherited]  
Objective variable to be minimized. If set to NO\_VARIABLE, a normal sat check should be performed.

**0.15.469.7.18 mOldSplittingVariables** `std::vector< FormulaT >` `smtrat::Module::mOldSplittingVariables`  
[static], [inherited]  
Reusable splitting variables.

**0.15.469.7.19 mpManager** `Manager*` `const smtrat::Module::mpManager` [protected], [inherited]  
A reference to the manager.

**0.15.469.7.20 mSmallerMusesCheckCounter** `unsigned` `smtrat::Module::mSmallerMusesCheckCounter`  
[mutable], [protected], [inherited]  
Counter used for the generation of the smt2 files to check for smaller muses.

**0.15.469.7.21 mSolverState** std::atomic<[Answer](#)> smrat::Module::mSolverState [protected],  
[inherited]

States whether the received formula is known to be satisfiable or unsatisfiable otherwise it is set to unknown.

**0.15.469.7.22 mTheoryPropagations** std::vector<[TheoryPropagation](#)> smrat::Module::mTheory←  
Propagations [protected], [inherited]

**0.15.469.7.23 mUsedBackends** std::vector<[Module\\*](#)> smrat::Module::mUsedBackends [protected],  
[inherited]

The backends of this module which are currently used (conditions to use this module are fulfilled for the passed formula).

**0.15.469.7.24 mVariableCounters** std::vector<std::size\_t> smrat::Module::mVariableCounters  
[protected], [inherited]

Maps variables to the number of their occurrences.

## 0.15.472 smtrat::mcsat::onecellcad::Section Struct Reference

Represent a cell's (closed-interval-boundary) component along th k-th axis.

```
#include <utils.h>
```

### Data Fields

- `MultivariateRootT boundFunction`
- `RAN isolatedRoot`

*For performance we cache the isolated root from 'boundFunction' that lies closest along this section's level to the main point.*

### 0.15.472.1 Detailed Description

Represent a cell's (closed-interval-boundary) component along th k-th axis.

A section is a function  $f: \text{algReal}^{\{k-1\}} \rightarrow \text{algReal}$ ; from a multi-dimensional input point of level  $k-1$  (whose components are algebraic reals) to an algebraic real. We use a root-expression with an irreducible, multivariate polynomial of level  $k$ .

### 0.15.472.2 Field Documentation

**0.15.472.2.1 boundFunction** `MultivariateRootT smtrat::mcsat::onecellcad::Section::boundFunction`

**0.15.472.2.2 isolatedRoot** `RAN smtrat::mcsat::onecellcad::Section::isolatedRoot`

For performance we cache the isolated root from 'boundFunction' that lies closest along this section's level to the main point.

## 0.15.473 smtrat::onecellcad::recursive::Section Struct Reference

Represent a cell's closed-interval-boundary object along one single axis by an irreducible, multivariate polynomial of level  $k$ .

```
#include <OpenCAD.h>
```

### Data Fields

- `MultiPoly poly`
- `RAN cachedPoint`

*A single, special bound after having plugged a specific point of level  $k-1$  can be cached for performance (needed for [1]).*

### 0.15.473.1 Detailed Description

Represent a cell's closed-interval-boundary object along one single axis by an irreducible, multivariate polynomial of level k.

A section is an algebraic/"moving" boundary, because it's basically a function f: algReal<sup>{k-1}</sup> -> algReal; from a multi-dimensional input point of level k-1 (whose components are algebraic reals) to an algebraic real (the bound along k-th axis that changes depending on the input point).

### 0.15.473.2 Field Documentation

#### 0.15.473.2.1 **cachedPoint** RAN smtrat::oncellcad::recursive::Section::cachedPoint

## 0.15.477 smtrat::mcsat::onecellcad::Sector Struct Reference

Represent a cell's open-interval boundary object along one single axis by two irreducible, multivariate polynomials of level k.

```
#include <utils.h>
```

### Data Fields

- `std::optional<Section> lowBound`  
*A std::nullopt lowBound represents negative infinity.*
- `std::optional<Section> highBound`  
*A std::nullopt highBound represents infinity.*

### 0.15.477.1 Detailed Description

Represent a cell's open-interval boundary object along one single axis by two irreducible, multivariate polynomials of level k.

A sector is an algebraic/"moving" boundary, because it's basically a function  $f: \text{algReal}^{k-1} \rightarrow (\text{algReal}, \text{algReal})$ ; from a multi-dimensional input point of level k-1 (whose components are algebraic reals) to a pair of algebraic reals (the lower and upper bound for an open interval along k-th axis that changes depending on the input point). Note that if 'lowBound' or 'highBound' is not defined, then this represents negative and positive infinity, respectively.

### 0.15.477.2 Field Documentation

**0.15.477.2.1 highBound** `std::optional<Section> smtrat::mcsat::onecellcad::Sector::highBound`  
A std::nullopt highBound represents infinity.

**0.15.477.2.2 lowBound** `std::optional<Section> smtrat::mcsat::onecellcad::Sector::lowBound`  
A std::nullopt lowBound represents negative infinity.

## 0.15.478 smtrat::onecellcad::recursive::Sector Struct Reference

Represent a cell's open-interval boundary object along one single axis by two irreducible, multivariate polynomials of level k.

```
#include <OpenCAD.h>
```

### Public Member Functions

- `bool isLowBoundNegInfty () const`
- `bool isHighBoundInfty () const`

### Data Fields

- `std::optional<Section> lowBound`
- `std::optional<Section> highBound`

### 0.15.478.1 Detailed Description

Represent a cell's open-interval boundary object along one single axis by two irreducible, multivariate polynomials of level k.

A sector is an algebraic/"moving" boundary, because it's basically a function f:  $\text{algReal}^{\wedge\{k-1\}} \rightarrow (\text{algReal}, \text{algReal})$ ; from a multi-dimensional input point of level k-1 (whose components are algebraic reals) to a pair of algebraic reals (the lower and upper bound for an open interval along k-th axis that changes depending on the input point). Note that if 'lowBound' or 'highBound' is not defined, then this represents negative and positive infinity, respectively.

## 0.15.482 smtrat::subtropical::Separator Struct Reference

Represents the class of all original constraints with the same left hand side after a normalization.

```
#include <Subtropical.h>
```

### Public Member Functions

- **Separator** (const **Poly** &normalization)

### Data Fields

- const carl::Variable **bias**  
*Bias variable of the separating hyperplane.*
- const std::vector<**Vertex**> **vertices**  
*Vertices for all terms of the normalized left hand side.*

### 0.15.482.1 Detailed Description

Represents the class of all original constraints with the same left hand side after a normalization.

Here, the set of all received relations of constraints with the same left hand side is stored. At any one time only one relation can be active and used for linearization.

### 0.15.482.2 Constructor & Destructor Documentation

*Streaming operator.*

#### 0.15.486.1 Detailed Description

This class loads and checks the command line options with help of `boost::program_options`.

#### 0.15.486.2 Constructor & Destructor Documentation

**0.15.486.2.1 Settings()** `delta::Settings::Settings (`  
`const std::string & executable ) [inline]`

Constructor.

**Parameters**

|                         |                      |
|-------------------------|----------------------|
| <code>executable</code> | Name of this binary. |
|-------------------------|----------------------|

**0.15.486.3 Member Function Documentation**

**0.15.486.3.1 `as()`** `template<typename T >`  
`const T& delta::Settings::as (`  
    `const std::string & s ) const [inline]`

Get option with given name as a given type.

If there is no such option or it has a different type, exceptions may be thrown.

**Parameters**

|                |                     |
|----------------|---------------------|
| <code>s</code> | Name of the option. |
|----------------|---------------------|

**Returns**

Value of the option as type T.

**0.15.486.3.2 `has()`** `bool delta::Settings::has (`  
    `const std::string & s ) const [inline]`

Checks if there is an option with this name.

**Parameters**

|                |                     |
|----------------|---------------------|
| <code>s</code> | Name of the option. |
|----------------|---------------------|

**Returns**

If option was set.

**0.15.486.3.3 `isDefault()`** `bool delta::Settings::isDefault (`  
    `const std::string & s ) const [inline]`

Check if the option with the given name was set due to its default value.

If there is no such option exceptions may be thrown.

**Parameters**

|                |                     |
|----------------|---------------------|
| <code>s</code> | Name of the option. |
|----------------|---------------------|

**Returns**

Whether it's value was set as the default.

**0.15.486.3.4 `load()`** `bool delta::Settings::load (`  
    `int argc,`  
    `char * argv[] ) [inline]`

Load options from command line.

**Parameters**

|             |                       |
|-------------|-----------------------|
| <i>argc</i> | Number of arguments.  |
| <i>argv</i> | Content of arguments. |

**0.15.486.3.5 set()** template<typename T >

```
void delta::Settings::set (
 const std::string & s,
 const T & t) [inline]
```

Set option with given name as a given type.

If there is no such option exceptions may be thrown.

**Parameters**

|          |                     |
|----------|---------------------|
| <i>s</i> | Name of the option. |
| <i>t</i> | New value.          |

**0.15.486.4 Friends And Related Function Documentation****0.15.486.4.1 operator<<** std::ostream& operator<< (

```
 std::ostream & os,
 const Settings & s) [friend]
```

Streaming operator.

**Parameters**

|           |                |
|-----------|----------------|
| <i>os</i> | Output stream. |
| <i>s</i>  | Settings.      |

**Returns**

os.

## 0.15.497 smtrat::parser::SimpleSymbolParser Struct Reference

Parses symbols: simple\_symbol | quoted\_symbol where.

```
#include <Lexicon.h>
```

### Public Member Functions

- [SimpleSymbolParser](#) ()

### Data Fields

- qi::rule< [Iterator](#), std::string(), [Skipper](#) > **main**

### 0.15.497.1 Detailed Description

Parses symbols: simple\_symbol | quoted\_symbol where.

- simple\_symbol is any string of [0-9a-zA-Z~!@#\$%^&\*\_+=<>.?/] that does not start with a digit and is not a reserved word.
- quoted\_symbol is any string of printable characters (including space, tab, line-breaks) except \ and | enclosed in | characters.

## 0.15.505 `benchmax::SlurmBackend` Class Reference

[Backend](#) for the Slurm workload manager.

```
#include <SlurmBackend.h>
```

### Public Member Functions

- bool `suspendable` () const
  - Run all tools on all benchmarks using Slurm.*
- void `run` (const [Jobs](#) &jobs, bool `wait_for_termination`)
  - Add a result.*
- void `process_results` (const [Jobs](#) &jobs, bool `check_finished`)
- void `addResult` (const [Tool](#) \*tool, const [fs::path](#) &file, [BenchmarkResult](#) &&result)
  - Add a result.*

### Protected Member Functions

- virtual void `startTool` (const [Tool](#) \*)
  - Hook for every tool at the beginning.*
- virtual void `finalize` ()
  - Hook to allow for asynchronous backends to wait for jobs to terminate.*
- virtual void `execute` (const [Tool](#) \*, const [fs::path](#) &)
  - Execute a single pair of tool and benchmark.*
- void `madeProgress` ([std::size\\_t](#) files=1)
  - Can be called to give information about the current progress, if available.*
- void `sanitize_results` (const [Jobs](#) &jobs) const
- void `write_results` (const [Jobs](#) &jobs) const

### Protected Attributes

- [std::size\\_t](#) `mExpectedJobs`
  - Number of jobs that should be run.*
- [std::atomic< std::size\\_t >](#) `mFinishedJobs`
  - Number of jobs that are finished.*
- [std::atomic< std::size\\_t >](#) `mLastPercent`
  - Percentage of finished jobs when `madeProgress()` was last called.*

### 0.15.505.1 Detailed Description

[Backend](#) for the Slurm workload manager.

The execution model is as follows: We create multiple jobs that each consists of multiple array jobs that each execute one slice of the task list. One array job executes `Settings::slice_size` entries of the task list. One job consists of `Settings::array_size` array jobs. We start as many jobs as necessary.

### 0.15.505.2 Member Function Documentation

**0.15.505.2.1 addResult()** void benchmax::Backend::addResult ( const [Tool](#) \* *tool*, const [fs::path](#) & *file*, [BenchmarkResult](#) && *result* ) [inline], [inherited]

Add a result.

**0.15.505.2.2 execute()** virtual void benchmax::Backend::execute ( const [Tool](#) \* , const [fs::path](#) & ) [inline], [protected], [virtual], [inherited]

Execute a single pair of tool and benchmark.

Reimplemented in [benchmax::LocalBackend](#), and [benchmax::CondorBackend](#).

**0.15.505.2.3 finalize()** virtual void benchmax::Backend::finalize ( ) [inline], [protected], [virtual], [inherited]

Hook to allow for asynchronous backends to wait for jobs to terminate.

**0.15.505.2.4 madeProgress()** void benchmax::Backend::madeProgress ( std::size\_t *files* = 1 ) [inline], [protected], [inherited]

Can be called to give information about the current progress, if available.

**0.15.505.2.5 process\_results()** void benchmax::Backend::process\_results ( const [Jobs](#) & *jobs*, bool *check\_finished* ) [inline], [inherited]

**0.15.505.2.6 run()** void benchmax::SlurmBackend::run ( const [Jobs](#) & *jobs*, bool *wait\_for\_termination* ) [inline]

Run all tools on all benchmarks using Slurm.

**0.15.505.2.7 sanitize\_results()** void benchmax::Backend::sanitize\_results ( const [Jobs](#) & *jobs* ) const [inline], [protected], [inherited]

**0.15.505.2.8 startTool()** virtual void benchmax::Backend::startTool ( const [Tool](#) \* ) [inline], [protected], [virtual], [inherited]

Hook for every tool at the beginning.

Can be used to upload the tool to some remote system.

**0.15.505.2.9 suspendable()** bool benchmax::SlurmBackend::suspendable ( ) const [inline]

**0.15.505.2.10 write\_results()** void benchmax::Backend::write\_results ( const [Jobs](#) & *jobs* ) const [inline], [protected], [inherited]

### 0.15.505.3 Field Documentation

**0.15.505.3.1 mExpectedJobs** std::size\_t benchmax::Backend::mExpectedJobs [protected], [inherited]  
Number of jobs that should be run.

**0.15.505.3.2 mFinishedJobs** std::atomic<std::size\_t> benchmax::Backend::mFinishedJobs [protected], [inherited]  
Number of jobs that are finished.

**0.15.505.3.3 mLastPercent** std::atomic<std::size\_t> benchmax::Backend::mLastPercent [protected], [inherited]  
Percentage of finished jobs when [madeProgress\(\)](#) was last called.

## 0.15.506 benchmax::settings::SlurmBackendSettings Struct Reference

[Settings](#) for the Slurm backend.

```
#include <SlurmSettings.h>
```

### Data Fields

- std::size\_t [array\\_size](#)  
*Number of array jobs within one job.*
- std::size\_t [slice\\_size](#)  
*Size of one slice that is handled in one array job.*
- std::string [tmp\\_dir](#)  
*Temporary directory for output files.*
- bool [keep\\_logs](#)  
*Do not remove logs from file system if set to true.*
- std::string [archive\\_log\\_file](#)  
*Puts logs to some archive.*
- std::string [sbatch\\_options](#)  
*Additional options passed on to slurm.*
- carl::settings::duration [submission\\_delay](#)  
*Delay between job submissions.*

### 0.15.506.1 Detailed Description

[Settings](#) for the Slurm backend.

### 0.15.506.2 Field Documentation

**0.15.506.2.1 archive\_log\_file** std::string benchmax::settings::SlurmBackendSettings::archive\_↔  
log\_file  
Puts logs to some archive.

**0.15.506.2.2 array\_size** std::size\_t benchmax::settings::SlurmBackendSettings::array\_size  
Number of array jobs within one job.

**0.15.506.2.3 keep\_logs** bool benchmax::settings::SlurmBackendSettings::keep\_logs  
Do not remove logs from file system if set to true.

**0.15.506.2.4 sbatch\_options** std::string benchmax::settings::SlurmBackendSettings::sbatch\_↔  
options  
Additional options passed on to slurm.

**0.15.506.2.5 slice\_size** std::size\_t benchmax::settings::SlurmBackendSettings::slice\_size  
Size of one slice that is handled in one array job.

**0.15.506.2.6 submission\_delay** carl::settings::duration benchmax::settings::SlurmBackend↔  
Settings::submission\_delay  
Delay between job submissions.

**0.15.506.2.7 tmp\_dir** std::string benchmax::settings::SlurmBackendSettings::tmp\_dir  
Temporary directory for output files.

**0.15.507.3.5** **theories** Theories smtrat::parser::SMTLIBParser::theories

## 0.15.508 benchmax::SMTRAT Class Reference

Tool wrapper for SMT-RAT for SMT-LIB.

```
#include <SMTRAT.h>
```

### Public Member Functions

- **SMTRAT** (const fs::path &**binary**, const std::string &**arguments**)  
*New SMT-RAT tool.*
- virtual bool **canHandle** (const fs::path &**path**) const override  
*Only handle .smt2 files.*
- std::string **getStatusFromOutput** (const BenchmarkResult &**result**) const

- Try to parse memouts from stderr.
- bool `parse_stats` (`BenchmarkResult` &`result`) const
- virtual void `additionalResults` (const `fs::path` &, `BenchmarkResult` &`result`) const override
 

Computes the answer string from the exit code and parses statistics output.
- `std::string name` () const
 

Common name of this tool.
- `fs::path binary` () const
 

Full path to the binary.
- const `std::map< std::string, std::string >` & `attributes` () const
 

A set of attributes, for example compilation options.
- `std::vector< std::string >` `resolveDependencies` () const
 

Get dependencies of binary required to run it (via ldd)
- `std::size_t attributeHash` () const
 

Hash of the attributes.
- virtual `std::string getCommandline` (const `std::string &file`) const
 

Compose commandline for this tool and the given input file.
- virtual `std::string getCommandline` (const `std::string &file`, const `std::string &localBinary`) const
 

Compose commandline for this tool with another binary name and the given input file.
- virtual `std::optional< std::string >` `parseCommandline` (const `std::string &cmdline`) const
 

Compose commandline for this tool and the given input file.

## Protected Attributes

- `std::string mName`

(Non-unique) identifier for the tool.
- `fs::path mBinary`

Path to the binary.
- `std::string mArguments`

Command line arguments that should be passed to the binary.
- `std::map< std::string, std::string >` `mAttributes`

Attributes of the tool obtained by introspection of the binary.

### 0.15.508.1 Detailed Description

`Tool` wrapper for SMT-RAT for SMT-LIB.

### 0.15.508.2 Constructor & Destructor Documentation

```
0.15.508.2.1 SMTRAT() benchmax::SMTRAT::SMTRAT (
 const fs::path & binary,
 const std::string & arguments) [inline]
```

New SMT-RAT tool.

### 0.15.508.3 Member Function Documentation

```
0.15.508.3.1 additionalResults() virtual void benchmax::SMTRAT::additionalResults (
 const fs::path & ,
 BenchmarkResult & result) const [inline], [override], [virtual]
```

Computes the answer string from the exit code and parses statistics output.

Reimplemented from `benchmax::Tool`.

**0.15.508.3.2 attributeHash()** `std::size_t benchmax::Tool::attributeHash () const [inline], [inherited]`  
Hash of the attributes.

**0.15.508.3.3 attributes()** `const std::map<std::string, std::string>& benchmax::Tool::attributes () const [inline], [inherited]`  
A set of attributes, for example compilation options.

**0.15.508.3.4 binary()** `fs::path benchmax::Tool::binary () const [inline], [inherited]`  
Full path to the binary.

**0.15.508.3.5 canHandle()** `virtual bool benchmax::SMTRAT::canHandle (const fs::path & path) const [inline], [override], [virtual]`  
Only handle .smt2 files.  
Reimplemented from [benchmax::Tool](#).  
Reimplemented in [benchmax::SMTRAT\\_OPB](#).

**0.15.508.3.6 getCommandline() [1/2]** `virtual std::string benchmax::Tool::getCommandline (const std::string & file) const [inline], [virtual], [inherited]`  
Compose commandline for this tool and the given input file.

**0.15.508.3.7 getCommandline() [2/2]** `virtual std::string benchmax::Tool::getCommandline (const std::string & file, const std::string & localBinary) const [inline], [virtual], [inherited]`  
Compose commandline for this tool with another binary name and the given input file.

**0.15.508.3.8 getStatusFromOutput()** `std::string benchmax::SMTRAT::getStatusFromOutput (const BenchmarkResult & result) const [inline]`  
Try to parse memouts from stderr.

**0.15.508.3.9 name()** `std::string benchmax::Tool::name () const [inline], [inherited]`  
Common name of this tool.

**0.15.508.3.10 parse\_stats()** `bool benchmax::SMTRAT::parse_stats (BenchmarkResult & result) const [inline]`

**0.15.508.3.11 parseCommandLine()** `virtual std::optional<std::string> benchmax::Tool::parseCommandline (const std::string & cmdline) const [inline], [virtual], [inherited]`  
Compose commandline for this tool and the given input file.

**0.15.508.3.12 resolveDependencies()** `std::vector<std::string> benchmax::Tool::resolveDependencies () const [inline], [inherited]`  
Get dependencies of binary required to run it (via ldd)

#### 0.15.508.4 Field Documentation

**0.15.508.4.1 mArguments** std::string benchmax::Tool::mArguments [protected], [inherited]  
Command line arguments that should be passed to the binary.

**0.15.508.4.2 mAttributes** std::map<std::string, std::string> benchmax::Tool::mAttributes [protected], [inherited]  
Attributes of the tool obtained by introspection of the binary.

**0.15.508.4.3 mBinary** fs::path benchmax::Tool::mBinary [protected], [inherited]  
Path to the binary.

**0.15.508.4.4 mName** std::string benchmax::Tool::mName [protected], [inherited]  
(Non-unique) identifier for the tool.

### 0.15.509 benchmax::SMTRAT\_Analyzer Class Reference

Tool wrapper for SMT-RAT for SMT-LIB.

```
#include <SMTRAT_Analyzer.h>
```

#### Public Member Functions

- **SMTRAT\_Analyzer** (const fs::path &**binary**, const std::string &**arguments**)  
*New SMT-RAT tool.*
- virtual bool **canHandle** (const fs::path &**path**) const override  
*Only handle .smt2 files.*
- virtual void **additionalResults** (const fs::path &, **BenchmarkResult** &**result**) const override  
*Computes the answer string from the exit code and parses statistics output.*
- std::string **name** () const  
*Common name of this tool.*
- fs::path **binary** () const  
*Full path to the binary.*
- const std::map<std::string, std::string> &**attributes** () const  
*A set of attributes, for example compilation options.*
- std::vector<std::string> **resolveDependencies** () const  
*Get dependencies of binary required to run it (via ldd)*
- std::size\_t **attributeHash** () const  
*Hash of the attributes.*
- virtual std::string **getCommandline** (const std::string &**file**) const  
*Compose commandline for this tool and the given input file.*
- virtual std::string **getCommandline** (const std::string &**file**, const std::string &**localBinary**) const  
*Compose commandline for this tool with another binary name and the given input file.*
- virtual std::optional<std::string> **parseCommandline** (const std::string &**cmdline**) const  
*Compose commandline for this tool and the given input file.*

## Protected Attributes

- std::string **mName**  
*(Non-unique) identifier for the tool.*
- fs::path **mBinary**  
*Path to the binary.*
- std::string **mArguments**  
*Command line arguments that should be passed to the binary.*
- std::map< std::string, std::string > **mAttributes**  
*Attributes of the tool obtained by introspection of the binary.*

### 0.15.509.1 Detailed Description

Tool wrapper for SMT-RAT for SMT-LIB.

### 0.15.509.2 Constructor & Destructor Documentation

```
0.15.509.2.1 SMTRAT_Analyzer() benchmax::SMTRAT_Analyzer::SMTRAT_Analyzer (
 const fs::path & binary,
 const std::string & arguments) [inline]
```

New SMT-RAT tool.

### 0.15.509.3 Member Function Documentation

```
0.15.509.3.1 additionalResults() virtual void benchmax::SMTRAT_Analyzer::additionalResults (
 const fs::path & ,
 BenchmarkResult & result) const [inline], [override], [virtual]
```

Computes the answer string from the exit code and parses statistics output.

Reimplemented from [benchmax::Tool](#).

```
0.15.509.3.2 attributeHash() std::size_t benchmax::Tool::attributeHash () const [inline],
[inherited]
```

Hash of the attributes.

```
0.15.509.3.3 attributes() const std::map<std::string, std::string>& benchmax::Tool::attributes (
) const [inline], [inherited]
```

A set of attributes, for example compilation options.

```
0.15.509.3.4 binary() fs::path benchmax::Tool::binary () const [inline], [inherited]
```

Full path to the binary.

```
0.15.509.3.5 canHandle() virtual bool benchmax::SMTRAT_Analyzer::canHandle (
 const fs::path & path) const [inline], [override], [virtual]
```

Only handle .smt2 files.

Reimplemented from [benchmax::Tool](#).

**0.15.509.3.6 `getCommandline()` [1/2]** `virtual std::string benchmax::Tool::getCommandline ( const std::string & file ) const [inline], [virtual], [inherited]`  
 Compose commandline for this tool and the given input file.

**0.15.509.3.7 `getCommandline()` [2/2]** `virtual std::string benchmax::Tool::getCommandline ( const std::string & file, const std::string & localBinary ) const [inline], [virtual], [inherited]`  
 Compose commandline for this tool with another binary name and the given input file.

**0.15.509.3.8 `name()`** `std::string benchmax::Tool::name ( ) const [inline], [inherited]`  
 Common name of this tool.

**0.15.509.3.9 `parseCommandLine()`** `virtual std::optional<std::string> benchmax::Tool::parseCommandline ( const std::string & cmdline ) const [inline], [virtual], [inherited]`  
 Compose commandline for this tool and the given input file.

**0.15.509.3.10 `resolveDependencies()`** `std::vector<std::string> benchmax::Tool::resolveDependencies ( ) const [inline], [inherited]`  
 Get dependencies of binary required to run it (via ldd)

#### 0.15.509.4 Field Documentation

**0.15.509.4.1 `mArguments`** `std::string benchmax::Tool::mArguments [protected], [inherited]`  
 Command line arguments that should be passed to the binary.

**0.15.509.4.2 `mAttributes`** `std::map<std::string, std::string> benchmax::Tool::mAttributes [protected], [inherited]`  
 Attributes of the tool obtained by introspection of the binary.

**0.15.509.4.3 `mBinary`** `fs::path benchmax::Tool::mBinary [protected], [inherited]`  
 Path to the binary.

**0.15.509.4.4 `mName`** `std::string benchmax::Tool::mName [protected], [inherited]`  
 (Non-unique) identifier for the tool.

### 0.15.510 `benchmax::SMTRAT_OPB` Class Reference

Adapts the [SMTRAT](#) solver for OPB files.

```
#include <SMTRAT_OPB.h>
```

#### Public Member Functions

- **`SMTRAT_OPB`** (`const fs::path &binary, const std::string &arguments`)
   
*Adds "-opb" to instruct SMT-RAT to parse .opb files.*
- **`virtual bool canHandle`** (`const fs::path &path`) `const override`
  
*Only handles .opb files.*

- std::string [getStatusFromOutput](#) (const [BenchmarkResult](#) &result) const  
*Try to parse memouts from stderr.*
- bool [parse\\_stats](#) ([BenchmarkResult](#) &result) const
- virtual void [additionalResults](#) (const fs::path &, [BenchmarkResult](#) &result) const override  
*Computes the answer string from the exit code and parses statistics output.*
- std::string [name](#) () const  
*Common name of this tool.*
- fs::path [binary](#) () const  
*Full path to the binary.*
- const std::map< std::string, std::string > & [attributes](#) () const  
*A set of attributes, for example compilation options.*
- std::vector< std::string > [resolveDependencies](#) () const  
*Get dependencies of binary required to run it (via ldd)*
- std::size\_t [attributeHash](#) () const  
*Hash of the attributes.*
- virtual std::string [getCommandline](#) (const std::string &file) const  
*Compose commandline for this tool and the given input file.*
- virtual std::string [getCommandline](#) (const std::string &file, const std::string &localBinary) const  
*Compose commandline for this tool with another binary name and the given input file.*
- virtual std::optional< std::string > [parseCommandline](#) (const std::string &cmdline) const  
*Compose commandline for this tool and the given input file.*

## Protected Attributes

- std::string [mName](#)  
*(Non-unique) identifier for the tool.*
- fs::path [mBinary](#)  
*Path to the binary.*
- std::string [mArguments](#)  
*Command line arguments that should be passed to the binary.*
- std::map< std::string, std::string > [mAttributes](#)  
*Attributes of the tool obtained by introspection of the binary.*

### 0.15.510.1 Detailed Description

Adapts the [SMTRAT](#) solver for OPB files.

### 0.15.510.2 Constructor & Destructor Documentation

**0.15.510.2.1 [SMTRAT\\_OPB\(\)](#)** `benchmax::SMTRAT_OPB::SMTRAT_OPB (`  
  `const fs::path & binary,`  
  `const std::string & arguments ) [inline]`

Adds "-opb" to instruct SMT-RAT to parse .opb files.

### 0.15.510.3 Member Function Documentation

**0.15.510.3.1 [additionalResults\(\)](#)** `virtual void benchmax::SMTRAT::additionalResults (`  
  `const fs::path &,`  
  `BenchmarkResult & result ) const [inline], [override], [virtual], [inherited]`

Computes the answer string from the exit code and parses statistics output.

Reimplemented from [benchmax::Tool](#).

**0.15.510.3.2 attributeHash()** `std::size_t benchmax::Tool::attributeHash () const [inline], [inherited]`  
Hash of the attributes.

**0.15.510.3.3 attributes()** `const std::map<std::string, std::string>& benchmax::Tool::attributes () const [inline], [inherited]`  
A set of attributes, for example compilation options.

**0.15.510.3.4 binary()** `fs::path benchmax::Tool::binary () const [inline], [inherited]`  
Full path to the binary.

**0.15.510.3.5 canHandle()** `virtual bool benchmax::SMTRAT_OPB::canHandle (const fs::path & path) const [inline], [override], [virtual]`  
Only handles .opb files.  
Reimplemented from `benchmax::SMTRAT`.

**0.15.510.3.6 getCommandLine() [1/2]** `virtual std::string benchmax::Tool::getCommandLine (const std::string & file) const [inline], [virtual], [inherited]`  
Compose commandline for this tool and the given input file.

**0.15.510.3.7 getCommandLine() [2/2]** `virtual std::string benchmax::Tool::getCommandLine (const std::string & file, const std::string & localBinary) const [inline], [virtual], [inherited]`  
Compose commandline for this tool with another binary name and the given input file.

**0.15.510.3.8 getStatusFromOutput()** `std::string benchmax::SMTRAT::getStatusFromOutput (const BenchmarkResult & result) const [inline], [inherited]`  
Try to parse memouts from stderr.

**0.15.510.3.9 name()** `std::string benchmax::Tool::name () const [inline], [inherited]`  
Common name of this tool.

**0.15.510.3.10 parse\_stats()** `bool benchmax::SMTRAT::parse_stats (BenchmarkResult & result) const [inline], [inherited]`

**0.15.510.3.11 parseCommandLine()** `virtual std::optional<std::string> benchmax::Tool::parseCommandline (const std::string & cmdline) const [inline], [virtual], [inherited]`  
Compose commandline for this tool and the given input file.

**0.15.510.3.12 resolveDependencies()** `std::vector<std::string> benchmax::Tool::resolveDependencies () const [inline], [inherited]`  
Get dependencies of binary required to run it (via ldd)

#### 0.15.510.4 Field Documentation

**0.15.510.4.1 mArguments** std::string benchmax::Tool::mArguments [protected], [inherited]  
Command line arguments that should be passed to the binary.

**0.15.510.4.2 mAttributes** std::map<std::string, std::string> benchmax::Tool::mAttributes [protected], [inherited]  
Attributes of the tool obtained by introspection of the binary.

**0.15.510.4.3 mBinary** fs::path benchmax::Tool::mBinary [protected], [inherited]  
Path to the binary.

**0.15.510.4.4 mName** std::string benchmax::Tool::mName [protected], [inherited]  
(Non-unique) identifier for the tool.

### 0.15.511 smtrat::execution::SoftAssertion Struct Reference

```
#include <ExecutionState.h>
```

#### Data Fields

- FormulaT formula
- Rational weight
- std::string id

#### 0.15.511.1 Field Documentation

**0.15.511.1.1 formula** FormulaT smtrat::execution::SoftAssertion::formula

**0.15.511.1.2 id** std::string smtrat::execution::SoftAssertion::id

**0.15.511.1.3 weight** Rational smtrat::execution::SoftAssertion::weight

### 0.15.512 smtrat::settings::SolverSettings Struct Reference

```
#include <Settings.h>
```

#### Data Fields

- bool print\_model
- bool print\_all\_models
- bool preprocess
- std::string preprocess\_output\_file
- bool convert\_to\_cnf\_dimacs
- bool convert\_to\_cnf\_smtlib

### 0.15.512.1 Field Documentation

**0.15.512.1.1 convert\_to\_cnf\_dimacs** bool smtrat::settings::SolverSettings::convert\_to\_cnf\_↔ dimacs

**0.15.512.1.2 convert\_to\_cnf\_smtlib** bool smtrat::settings::SolverSettings::convert\_to\_cnf\_smtlib

**0.15.512.1.3 preprocess** bool smtrat::settings::SolverSettings::preprocess

**0.15.512.1.4 preprocess\_output\_file** std::string smtrat::settings::SolverSettings::preprocess\_↔ output\_file

**0.15.512.1.5 print\_all\_models** bool smtrat::settings::SolverSettings::print\_all\_models

**0.15.512.1.6 print\_model** bool smtrat::settings::SolverSettings::print\_model

## 0.15.513 smtrat::parser::SortedVariableParser Struct Reference

```
#include <Term.h>
```

### Public Member Functions

- [SortedVariableParser \(\)](#)

### Data Fields

- [SymbolParser symbol](#)
- [SortParser sort](#)
- [qi::rule<Iterator, std::pair<std::string, carl::Sort>, Skipper> main](#)

### 0.15.513.1 Constructor & Destructor Documentation

**0.15.513.1.1 SortedVariableParser()** smtrat::parser::SortedVariableParser::SortedVariableParser ( ) [inline]

### 0.15.513.2 Field Documentation

**0.15.513.2.1 main** qi::rule<[Iterator](#), std::pair<std::string, carl::Sort>, [Skipper](#)> smtrat↔ ::parser::SortedVariableParser::main

**0.15.513.2.2 sort** SortParser smtrat::parser::SortedVariableParser::sort

**0.15.513.2.3 symbol** SymbolParser smtrat::parser::SortedVariableParser::symbol

## 0.15.514 smtrat::parser::SortParser Struct Reference

```
#include <Sort.h>
```

### Public Member Functions

- `SortParser ()`
- `void setParameters (const std::vector< std::string > &params)`
- `void clearParameters ()`
- `carl::Sort getSort (const Identifier &i)`
- `carl::Sort getSortWithParam (const Identifier &i, const std::vector< carl::Sort > &params)`

### 0.15.514.1 Constructor & Destructor Documentation

**0.15.514.1.1 SortParser()** smtrat::parser::SortParser::SortParser ( ) [inline]

### 0.15.514.2 Member Function Documentation

**0.15.514.2.1 clearParameters()** void smtrat::parser::SortParser::clearParameters ( ) [inline]

- const carl::FastSet< `FormulaT` > & `informedConstraints () const`
- void `addLemma (const FormulaT &_lemma, const LemmaType &_lt=Lemmatype::NORMAL, const FormulaT &_preferredFormula=FormulaT(carl::FormalType::TRUE))`

*Stores a lemma being a valid formula.*
- bool `hasLemmas ()`

*Checks whether this module or any of its backends provides any lemmas.*
- void `clearLemmas ()`

*Deletes all yet found lemmas.*
- const std::vector< `Lemma` > & `lemmas () const`
- `ModuleInput::const_iterator firstUncheckedReceivedSubformula () const`
- `ModuleInput::const_iterator firstSubformulaToPass () const`
- void `receivedFormulaChecked ()`

*Notifies that the received formulas has been checked.*
- const `smrat::Conditionals & answerFound () const`
- carl::Variable `objective () const`
- bool `is_minimizing () const`
- void `excludeNotReceivedVariablesFromModel () const`

*Excludes all variables from the current model, which do not occur in the received formula.*
- void `updateLemmas ()`

- Stores all lemmas of any backend of this module in its own lemma vector.
- void `collectTheoryPropagations ()`

*Collects the formulas in the given formula, which are part of the received formula.*
- void `collectOrigins (const FormulaT &_formula, FormulasT &_origins) const`

*Checks the given infeasible subset for minimality by storing all subsets of it, which have a smaller size which differs from the size of the infeasible subset not more than the given threshold.*
- void `print (const std::string &_initiation="***") const`

*Prints everything relevant of the solver.*
- void `printReceivedFormula (const std::string &_initiation="***") const`

*Prints the vector of the received formula.*
- void `printPassedFormula (const std::string &_initiation="***") const`

*Prints the vector of passed formula.*
- void `printInfeasibleSubsets (const std::string &_initiation="***") const`

*Prints the infeasible subsets.*
- void `printModel (std::ostream &_out=std::cout) const`

*Prints the assignment of this module satisfying its received formula if it satisfiable and this module could find an assignment.*
- void `printAllModels (std::ostream &_out=std::cout)`

*Prints all assignments of this module satisfying its received formula if it satisfiable and this module could find an assignment.*

## Static Public Member Functions

- static void `freeSplittingVariable (const FormulaT &_splittingVariable)`

## Static Public Attributes

- static size\_t `mNumOfBranchVarsToStore = 5`

*The number of different variables to consider for a probable infinite loop of branchings.*
- static std::vector< Branching > `mLastBranches = std::vector<Branching>(mNumOfBranchVarsToStore, Branching(typename Poly::PolyType(), 0))`

*Stores the last branches in a cycle buffer.*
- static size\_t `mFirstPosInLastBranches = 0`

*The beginning of the cyclic buffer storing the last branches.*
- static std::vector< FormulaT > `mOldSplittingVariables`

*Reusable splitting variables.*

## Protected Member Functions

- virtual bool `informCore (const FormulaT &_constraint)`

*Informs the module about the given constraint.*
- virtual void `deinformCore (const FormulaT &_constraint)`

*The inverse of informing about a constraint.*
- virtual bool `addCore (ModuleInput::const_iterator formula)`

*The module has to take the given sub-formula of the received formula into account.*
- virtual void `removeCore (ModuleInput::const_iterator formula)`

*Removes everything related to the given sub-formula of the received formula.*
- bool `anAnswerFound () const`

*Checks for all antecedent modules and those which run in parallel with the same antecedent modules, whether one of them has determined a result.*

- void `clearModel () const`  
*Clears the assignment, if any was found.*
- void `clearModels () const`  
*Clears all assignments, if any was found.*
- void `cleanModel () const`  
*Substitutes variable occurrences by its model value in the model values of other variables.*
- `ModuleInput::iterator passedFormulaBegin ()`
- `ModuleInput::iterator passedFormulaEnd ()`
- void `addOrigin (ModuleInput::iterator _formula, const FormulaT &_origin)`  
*Adds the given set of formulas in the received formula to the origins of the given passed formula.*
- const `FormulaT & getOrigins (ModuleInput::const_iterator _formula) const`  
*Gets the origins of the passed formula at the given position.*
- void `getOrigins (const FormulaT &_formula, FormulasT &_origins) const`
- void `getOrigins (const FormulaT &_formula, FormulaSetT &_origins) const`
- std::pair< `ModuleInput::iterator`, bool > `removeOrigin (ModuleInput::iterator _formula, const FormulaT &_origin)`
- std::pair< `ModuleInput::iterator`, bool > `removeOrigins (ModuleInput::iterator _formula, const std::shared_ptr< std::vector< FormulaT >> &_origins)`
- void `informBackends (const FormulaT &_constraint)`  
*Informs all backends of this module about the given constraint.*
- virtual void `addConstraintToInform (const FormulaT &_constraint)`  
*Adds a constraint to the collection of constraints of this module, which are informed to a freshly generated backend.*
- std::pair< `ModuleInput::iterator`, bool > `addReceivedSubformulaToPassedFormula (ModuleInput::const_iterator _subformula)`  
*Copies the given sub-formula of the received formula to the passed formula.*
- bool `originInReceivedFormula (const FormulaT &_origin) const`
- std::pair< `ModuleInput::iterator`, bool > `addSubformulaToPassedFormula (const FormulaT &_formula)`  
*Adds the given formula to the passed formula with no origin.*
- std::pair< `ModuleInput::iterator`, bool > `addSubformulaToPassedFormula (const FormulaT &_formula, const std::shared_ptr< std::vector< FormulaT >> &_origins)`  
*Adds the given formula to the passed formula.*
- std::pair< `ModuleInput::iterator`, bool > `addSubformulaToPassedFormula (const FormulaT &_formula, const FormulaT &_origin)`  
*Adds the given formula to the passed formula.*
- void `generateTrivialInfeasibleSubset ()`  
*Stores the trivial infeasible subset being the set of received formulas.*
- void `receivedFormulasAsInfeasibleSubset (ModuleInput::const_iterator _subformula)`  
*Stores an infeasible subset consisting only of the given received formula.*
- std::vector< `FormulaT` >::const\_iterator `findBestOrigin (const std::vector< FormulaT > &_origins) const`
- void `getInfeasibleSubsets ()`  
*Copies the infeasible subsets of the passed formula.*
- std::vector< `FormulaSetT` > `getInfeasibleSubsets (const Module &_backend) const`  
*Get the infeasible subsets the given backend provides.*
- const `Model & backendsModel () const`  
*Stores the model of a backend which determined satisfiability of the passed formula in the model of this module.*
- void `getBackendsModel () const`
- void `getBackendsAllModels () const`  
*Stores all models of a backend in the list of all models of this module.*
- virtual `ModuleInput::iterator eraseSubformulaFromPassedFormula (ModuleInput::iterator _subformula, bool _ignoreOrigins=false)`  
*Removes everything related to the sub-formula to remove from the passed formula in the backends of this module.*
- void `clearPassedFormula ()`

- std::vector< [FormulaT](#) > [merge](#) (const std::vector< [FormulaT](#) > &, const std::vector< [FormulaT](#) > &) const  
*Merges the two vectors of sets into the first one.*
- size\_t [determine\\_smallest\\_origin](#) (const std::vector< [FormulaT](#) > &origins) const
- bool [probablyLooping](#) (const typename Poly::PolyType &\_branchingPolynomial, const Rational &← branchingValue) const  
*Checks whether given the current branching value and branching variable/polynomial it is (highly) probable that this branching is part of an infinite loop of branchings.*
- bool [branchAt](#) (const Poly &\_polynomial, bool \_integral, const Rational &\_value, std::vector< [FormulaT](#) > &&\_premise, bool \_leftCaseWeak=true, bool \_preferLeftCase=true, bool \_useReceivedFormulaAsPremise=false)  
*Adds a lemmas which provoke a branching for the given variable at the given value, if this module returns Unknown and there exists a preceding SATModule.*
- bool [branchAt](#) (const Poly &\_polynomial, bool \_integral, const Rational &\_value, bool \_leftCaseWeak=true, bool \_preferLeftCase=true, bool \_useReceivedFormulaAsPremise=false, const std::vector< [FormulaT](#) > &← \_premise=std::vector< [FormulaT](#) >())
- bool [branchAt](#) (carl::Variable::Arg \_var, const Rational &\_value, std::vector< [FormulaT](#) > &&\_premise, bool \_leftCaseWeak=true, bool \_preferLeftCase=true, bool \_useReceivedFormulaAsPremise=false)
- bool [branchAt](#) (carl::Variable::Arg \_var, const Rational &\_value, bool \_leftCaseWeak=true, bool \_preferLeftCase=true, bool \_useReceivedFormulaAsPremise=false, const std::vector< [FormulaT](#) > &\_premise=std::vector< [FormulaT](#) >())
- void [splitUnequalConstraint](#) (const [FormulaT](#) &)  
*Adds the following lemmas for the given constraint p!=0.*
- unsigned [checkModel](#) () const
- void [addInformationRelevantFormula](#) (const [FormulaT](#) &formula)  
*Adds a formula to the InformationRelevantFormula.*
- const std::set< [FormulaT](#) > & [getInformationRelevantFormulas](#) ()  
*Gets all InformationRelevantFormulas.*
- bool [isLemmaLevel](#) ([LemmaLevel](#) level)  
*Checks if current lemma level is greater or equal to given level.*

## Static Protected Member Functions

- static bool [modelsDisjoint](#) (const Model &\_modelA, const Model &\_modelB)  
*Checks whether there is no variable assigned by both models.*

## Protected Attributes

- std::vector< [FormulaSetT](#) > [mInfeasibleSubsets](#)  
*Stores the infeasible subsets.*
- Manager \*const [mpManager](#)  
*A reference to the manager.*
- Model [mModel](#)  
*Stores the assignment of the current satisfiable result, if existent.*
- std::vector< Model > [mAllModels](#)  
*Stores all satisfying assignments.*
- bool [mModelComputed](#)  
*True, if the model has already been computed.*
- bool [mFinalCheck](#)  
*true, if the check procedure should perform a final check which especially means not to postpone splitting decisions*
- bool [mFullCheck](#)  
*false, if this module should avoid too expensive procedures and rather return unknown instead.*
- carl::Variable [mObjectiveVariable](#)  
*Objective variable to be minimized. If set to NO\_VARIABLE, a normal sat check should be performed.*
- std::vector< TheoryPropagation > [mTheoryPropagations](#)

- std::atomic< [Answer](#) > mSolverState
  - States whether the received formula is known to be satisfiable or unsatisfiable otherwise it is set to unknown.*
- std::atomic\_bool \* mBackendsFoundAnswer
  - This flag is passed to any backend and if it determines an answer to a prior check call, this flag is fired.*
- [Conditionals](#) mFoundAnswer
  - Vector of Booleans: If any of them is true, we have to terminate a running check procedure.*
- std::vector< [Module](#) \* > mUsedBackends
  - The backends of this module which are currently used (conditions to use this module are fulfilled for the passed formula).*
- std::vector< [Module](#) \* > mAllBackends
  - The backends of this module which have been used.*
- std::vector< [Lemma](#) > mLemmas
  - Stores the lemmas being valid formulas this module or its backends made.*
- [ModuleInput](#)::iterator mFirstSubformulaToPass
  - Stores the position of the first sub-formula in the passed formula, which has not yet been considered for a consistency check of the backends.*
- carl::FastSet< [FormulaT](#) > mConstraintsToInform
  - Stores the constraints which the backends must be informed about.*
- carl::FastSet< [FormulaT](#) > mInformedConstraints
  - Stores the position of the first constraint of which no backend has been informed about.*
- [ModuleInput](#)::const\_iterator mFirstUncheckedReceivedSubformula
  - Stores the position of the first (by this module) unchecked sub-formula of the received formula.*
- unsigned mSmallerMusesCheckCounter
  - Counter used for the generation of the smt2 files to check for smaller muses.*
- std::vector< std::size\_t > mVariableCounters
  - Maps variables to the number of their occurrences.*

#### 0.15.516.4 Member Function Documentation

##### 0.15.516.4.1 add() bool smrat::PModule::add (

`ModuleInput::const_iterator _subformula ) [inherited]`

The module has to take the given sub-formula of the received formula into account.

###### Parameters

|                          |                                                    |
|--------------------------|----------------------------------------------------|
| <code>_subformula</code> | The sub-formula to take additionally into account. |
|--------------------------|----------------------------------------------------|

###### Returns

false, if it can be easily decided that this sub-formula causes a conflict with the already considered sub-formulas; true, otherwise.

##### 0.15.516.4.2 addConstraintToInform() void smrat::Module::addConstraintToInform (

`const FormulaT & _constraint ) [protected], [virtual], [inherited]`

Adds a constraint to the collection of constraints of this module, which are informed to a freshly generated backend.

###### Parameters

|                          |                        |
|--------------------------|------------------------|
| <code>_constraint</code> | The constraint to add. |
|--------------------------|------------------------|

Reimplemented in `smrat::SATModule< Settings >`.

##### 0.15.516.4.3 addCore() virtual bool smrat::Module::addCore (

`ModuleInput::const_iterator formula ) [inline], [protected], [virtual], [inherited]`

The module has to take the given sub-formula of the received formula into account.

###### Parameters

|                      |                                                    |
|----------------------|----------------------------------------------------|
| <code>formula</code> | The sub-formula to take additionally into account. |
|----------------------|----------------------------------------------------|

###### Returns

false, if it can be easily decided that this sub-formula causes a conflict with the already considered sub-formulas; true, otherwise.

Reimplemented in `smrat::VSModule< Settings >`, `smrat::SATModule< Settings >`, `smrat::PFEModule< Settings >`, `smrat::ICPModule< Settings >`, `smrat::ICPModule< ICPSettings4 >`, `smrat::ICPModule< ICPSettings1 >`, `smrat::UnionFindModule< Settings >`, `smrat::UFCegarModule< Settings >`, `smrat::STropModule< Settings >`, `smrat::PBPPModule< Settings >`, `smrat::PBGaussModule< Settings >`, `smrat::NRAILModule< Settings >`, `smrat::NewCoveringModule< Settings >`, `smrat::NewCADModule< Settings >`, `smrat::LRAModule< Settings >`, `smrat::LRAModule< LRASettingsICP >`, `smrat::LRAModule< LRASettings1 >`, `smrat::IntEqModule< Settings >`, `smrat::IntBlastModule< Settings >`, `smrat::IncWidthModule< Settings >`, `smrat::ICEModule< Settings >`,

`smrat::FPPModule< Settings >, smrat::FouMoModule< Settings >, smrat::EQModule< Settings >, smrat::CurryModule< Settings >, smrat::CubeLIAModule< Settings >, smrat::CSplitModule< Settings >, smrat::BVMModule< Settings >, and smrat::GBModule< Settings >.`

**0.15.516.4.4 addInformationRelevantFormula()** `void smrat::Module::addInformationRelevantFormula(`

`const FormulaT & formula ) [protected], [inherited]`

Adds a formula to the InformationRelevantFormula.

#### Parameters

|                      |                |
|----------------------|----------------|
| <code>formula</code> | Formula to add |
|----------------------|----------------|

**0.15.516.4.5 addLemma()** `void smrat::Module::addLemma(`

`const FormulaT & _lemma,`

`const LemmaType & _lt = LemmaType::NORMAL,`

`const FormulaT & _preferredFormula = FormulaT( carl::FormulaType::TRUE ) ) [inline],`

[inherited]

Stores a lemma being a valid formula.

#### Parameters

|                                |                                                                       |
|--------------------------------|-----------------------------------------------------------------------|
| <code>_lemma</code>            | The eduction/lemma to store.                                          |
| <code>_lt</code>               | The type of the lemma.                                                |
| <code>_preferredFormula</code> | Hint for the next decision, which formula should be assigned to true. |

**0.15.516.4.6 addOrigin()** `void smrat::Module::addOrigin(`

`ModuleInput::iterator _formula,`

`const FormulaT & _origin ) [inline], [protected], [inherited]`

Adds the given set of formulas in the received formula to the origins of the given passed formula.

#### Parameters

|                       |                                                           |
|-----------------------|-----------------------------------------------------------|
| <code>_formula</code> | The passed formula to set the origins for.                |
| <code>_origin</code>  | A set of formulas in the received formula of this module. |

**0.15.516.4.7 addReceivedSubformulaToPassedFormula()** `std::pair<ModuleInput::iterator, bool> smrat::Module::addReceivedSubformulaToPassedFormula(`

`ModuleInput::const_iterator _subformula ) [inline], [protected], [inherited]`

Copies the given sub-formula of the received formula to the passed formula.

Note, that there is always a link between sub-formulas of the passed formulas to sub-formulas of the received formulas, which are responsible for its occurrence.

#### Parameters

|                          |                                                  |
|--------------------------|--------------------------------------------------|
| <code>_subformula</code> | The sub-formula of the received formula to copy. |
|--------------------------|--------------------------------------------------|

```
0.15.516.4.8 addSubformulaToPassedFormula() [1/3] std::pair<ModuleInput::iterator,bool> smtrat<->
::Module::addSubformulaToPassedFormula (
 const FormulaT & _formula) [inline], [protected], [inherited]
```

Adds the given formula to the passed formula with no origin.

Note that in the next call of this module's removeSubformula, all formulas in the passed formula without origins will be removed.

#### Parameters

|                       |                                           |
|-----------------------|-------------------------------------------|
| <code>_formula</code> | The formula to add to the passed formula. |
|-----------------------|-------------------------------------------|

#### Returns

A pair to the position where the formula to add has been inserted (or its first sub-formula which has not yet been in the passed formula, in case the formula to add is a conjunction), and a Boolean stating whether anything has been added to the passed formula.

```
0.15.516.4.9 addSubformulaToPassedFormula() [2/3] std::pair<ModuleInput::iterator,bool> smtrat<->
::Module::addSubformulaToPassedFormula (
 const FormulaT & _formula,
 const FormulaT & _origin) [inline], [protected], [inherited]
```

Adds the given formula to the passed formula.

#### Parameters

|                       |                                                                                                                           |
|-----------------------|---------------------------------------------------------------------------------------------------------------------------|
| <code>_formula</code> | The formula to add to the passed formula.                                                                                 |
| <code>_origin</code>  | The sub-formula of the received formula being responsible for the occurrence of the formula to add to the passed formula. |

#### Returns

A pair to the position where the formula to add has been inserted (or its first sub-formula which has not yet been in the passed formula, in case the formula to add is a conjunction), and a Boolean stating whether anything has been added to the passed formula.

```
0.15.516.4.10 addSubformulaToPassedFormula() [3/3] std::pair<ModuleInput::iterator,bool>
```

```
smtrat::Module::addSubformulaToPassedFormula (
 const FormulaT & _formula,
 const std::shared_ptr< std::vector< FormulaT >> & _origins) [inline], [protected],
[inherited]
```

Adds the given formula to the passed formula.

#### Parameters

|                       |                                                                                                                                         |
|-----------------------|-----------------------------------------------------------------------------------------------------------------------------------------|
| <code>_formula</code> | The formula to add to the passed formula.                                                                                               |
| <code>_origins</code> | The link of the formula to add to the passed formula to sub-formulas of the received formulas, which are responsible for its occurrence |

#### Returns

A pair to the position where the formula to add has been inserted (or its first sub-formula which has not yet been in the passed formula, in case the formula to add is a conjunction), and a Boolean stating whether anything has been added to the passed formula.

**0.15.516.4.11 allModels()** const std::vector<[Model](#)>& smtrat::Module::allModels () const [inline], [inherited]

**Returns**

All satisfying assignments, if existent.

**0.15.516.4.12 anAnswerFound()** bool smtrat::Module::anAnswerFound () const [inline], [protected], [inherited]

Checks for all antecedent modules and those which run in parallel with the same antecedent modules, whether one of them has determined a result.

**Returns**

True, if one of them has determined a result.

**0.15.516.4.13 answerFound()** const [smtrat::Conditionals](#)& smtrat::Module::answerFound () const [inline], [inherited]

**Returns**

A vector of Booleans: If any of them is true, we have to terminate a running check procedure.

**0.15.516.4.14 appliedPreprocessing()** bool smtrat::PModule::appliedPreprocessing () const [inline], [inherited]

**Returns**

true, if the current received formula has been simplified and the result of this simplification is stored in the passed formula.

**0.15.516.4.15 backendsModel()** const [Model](#) & smtrat::Module::backendsModel () const [protected], [inherited]

Stores the model of a backend which determined satisfiability of the passed formula in the model of this module.

**0.15.516.4.16 branchAt() [1/4]** bool smtrat::Module::branchAt (

```
carl::Variable::Arg _var,
const Rational & _value,
bool _leftCaseWeak = true,
bool _preferLeftCase = true,
bool _useReceivedFormulaAsPremise = false,
const std::vector< FormulaT > & _premise = std::vector< FormulaT > ()) [inline],
[protected], [inherited]
```

**0.15.516.4.17 branchAt() [2/4]** bool smtrat::Module::branchAt (

```
carl::Variable::Arg _var,
const Rational & _value,
std::vector< FormulaT > && _premise,
bool _leftCaseWeak = true,
bool _preferLeftCase = true,
bool _useReceivedFormulaAsPremise = false) [inline], [protected], [inherited]
```

```
0.15.516.4.18 branchAt() [3/4] bool smtrat::Module::branchAt (
 const Poly & _polynomial,
 bool _integral,
 const Rational & _value,
 bool _leftCaseWeak = true,
 bool _preferLeftCase = true,
 bool _useReceivedFormulaAsPremise = false,
 const std::vector< FormulaT > & _premise = std::vector<FormulaT>()) [inline],
[protected], [inherited]
```

```
0.15.516.4.19 branchAt() [4/4] bool smtrat::Module::branchAt (
 const Poly & _polynomial,
 bool _integral,
 const Rational & _value,
 std::vector< FormulaT > && _premise,
 bool _leftCaseWeak = true,
 bool _preferLeftCase = true,
 bool _useReceivedFormulaAsPremise = false) [protected], [inherited]
```

Adds a lemmas which provoke a branching for the given variable at the given value, if this module returns Unknown and there exists a preceding [SATModule](#).

Note that the given value is rounded down and up, if the given variable is integer-valued.

#### Parameters

|                                           |                                                                                                                                                                                                                |
|-------------------------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>_polynomial</code>                  | The variable to branch for.                                                                                                                                                                                    |
| <code>_integral</code>                    | A flag being true, if all variables in the polynomial to branch for are integral.                                                                                                                              |
| <code>_value</code>                       | The value to branch at.                                                                                                                                                                                        |
| <code>_premise</code>                     | The sub-formulas of the received formula from which the branch is followed. Note, that a premise is not necessary, as every branch is a valid formula. But a premise can prevent from branching unnecessarily. |
| <code>_leftCaseWeak</code>                | true, if a branching in the form of (or ( $\leq p b$ ) ( $> p b$ )) is desired. false, if a branching in the form of (or ( $< p b$ ) ( $\geq p b$ )) is desired.                                               |
| <code>_preferLeftCase</code>              | true, if the left case (polynomial less(or equal) 0 shall be chosen first. false, otherwise.                                                                                                                   |
| <code>_useReceivedFormulaAsPremise</code> | true, if the whole received formula should be used as premise                                                                                                                                                  |

```
0.15.516.4.20 check() Answer smtrat::PModule::check (
```

```
 bool _final = false,
 bool _full = true,
 carl::Variable _objective = carl::Variable::NO_VARIABLE) [virtual], [inherited]
```

Checks the received formula for consistency.

Note, that this is an implementation of the satisfiability check of the conjunction of the so far received formulas, which does actually nothing but passing the problem to its backends. This implementation is only used internally and must be overwritten by any derived module.

#### Parameters

|                         |                                                                                                                                       |
|-------------------------|---------------------------------------------------------------------------------------------------------------------------------------|
| <code>_final</code>     | true, if this satisfiability check will be the last one (for a global sat-check), if its result is SAT                                |
| <code>_full</code>      | false, if this module should avoid too expensive procedures and rather return unknown instead.                                        |
| <code>_objective</code> | if not set to NO_VARIABLE, the module should find an assignment minimizing this objective variable; otherwise any assignment is good. |

**Returns**

True, if the received formula is satisfiable; False, if the received formula is not satisfiable; Unknown, otherwise.

Reimplemented from [smrat::Module](#).

**0.15.516.4.21 checkCore()** `template<typename Settings >  
Answer smrat::SplitsSOSModule< Settings >::checkCore () [virtual]  
Checks the received formula for consistency.`

**Returns**

SAT, if the received formula is satisfiable; UNSAT, if the received formula is not satisfiable; Unknown, otherwise.

Reimplemented from [smrat::Module](#).

**0.15.516.4.22 checkInfSubsetForMinimality()** `void smrat::Module::checkInfSubsetForMinimality (  
std::vector< FormulaSetT >::const_iterator _infsSubset,  
const std::string & _filename = "smaller_muses",  
unsigned _maxSizeDifference = 1 ) const [inherited]`

Checks the given infeasible subset for minimality by storing all subsets of it, which have a smaller size which differs from the size of the infeasible subset not more than the given threshold.

**Parameters**

|                                 |                                                                                                        |
|---------------------------------|--------------------------------------------------------------------------------------------------------|
| <code>_infsSubset</code>        | The infeasible subset to check for minimality.                                                         |
| <code>_filename</code>          | The name of the file to store the infeasible subsets in order to be able to check their infeasibility. |
| <code>_maxSizeDifference</code> | The maximal difference between the sizes of the subsets compared to the size of the infeasible subset. |

**0.15.516.4.23 checkModel()** `unsigned smrat::Module::checkModel () const [protected], [inherited]`

**Returns**

false, if the current model of this module does not satisfy the current given formula; true, if it cannot be said whether the model satisfies the given formula.

**0.15.516.4.24 cleanModel()** `void smrat::Module::cleanModel () const [inline], [protected], [inherited]`

Substitutes variable occurrences by its model value in the model values of other variables.

**0.15.516.4.25 clearLemmas()** `void smrat::Module::clearLemmas () [inline], [inherited]`

Deletes all yet found lemmas.

**0.15.516.4.26 clearModel()** `void smrat::Module::clearModel () const [inline], [protected], [inherited]`

Clears the assignment, if any was found.

**0.15.516.4.27 `clearModels()`** `void smtrat::Module::clearModels () const [inline], [protected], [inherited]`  
 Clears all assignments, if any was found.

**0.15.516.4.28 `clearPassedFormula()`** `void smtrat::Module::clearPassedFormula () [protected], [inherited]`

**0.15.516.4.29 `collectOrigins() [1/2]`** `void smtrat::Module::collectOrigins (const FormulaT & _formula, FormulaSetT & _origins ) const [inherited]`

**0.15.516.4.30 `collectOrigins() [2/2]`** `void smtrat::Module::collectOrigins (const FormulaT & _formula, FormulasT & _origins ) const [inherited]`

Collects the formulas in the given formula, which are part of the received formula.

If the given formula directly occurs in the received formula, it is inserted into the given set. Otherwise, the given formula must be of type AND and all its sub-formulas part of the received formula. Hence, they will be added to the given set.

#### Parameters

|                       |                                                                                                      |
|-----------------------|------------------------------------------------------------------------------------------------------|
| <code>_formula</code> | The formula from which to collect the formulas being sub-formulas of the received formula (origins). |
| <code>_origins</code> | The set in which to store the origins.                                                               |

**0.15.516.4.31 `collectTheoryPropagations()`** `void smtrat::Module::collectTheoryPropagations () [inherited]`

**0.15.516.4.32 `constraintsToInform()`** `const carl::FastSet<FormulaT>& smtrat::Module::constraintsToInform () const [inline], [inherited]`

#### Returns

The constraints which the backends must be informed about.

**0.15.516.4.33 `currentlySatisfied()`** `virtual unsigned smtrat::Module::currentlySatisfied (const FormulaT & ) const [inline], [virtual], [inherited]`

#### Returns

0, if the given formula is conflicted by the current model; 1, if the given formula is satisfied by the current model; 2, otherwise; 3, if we do not know anything (default)

Reimplemented in `smtrat::LRAModule< Settings >`, `smtrat::LRAModule< LRASettingsICP >`, and `smtrat::LRAModule< LRASettings >`

**0.15.516.4.34 `currentlySatisfiedByBackend()`** `unsigned smtrat::Module::currentlySatisfiedByBackend (const FormulaT & _formula ) const [inherited]`

**Returns**

0, if the given formula is conflicted by the current model; 1, if the given formula is satisfied by the current model; 2, otherwise 3, if we do not know anything (default)

**0.15.516.4.35 `deinform()`** `void smtrat::Module::deinform ( const FormulaT & _constraint ) [inherited]`

The inverse of informing about a constraint.

All data structures which were kept regarding this constraint are going to be removed. Note, that this makes only sense if it is not likely enough that a formula with this constraint must be solved again.

**Parameters**

|                          |                                                         |
|--------------------------|---------------------------------------------------------|
| <code>_constraint</code> | The constraint to remove from internal data structures. |
|--------------------------|---------------------------------------------------------|

**0.15.516.4.36 `deinformCore()`** `virtual void smtrat::Module::deinformCore ( const FormulaT & _constraint ) [inline], [protected], [virtual], [inherited]`

The inverse of informing about a constraint.

All data structures which were kept regarding this constraint are going to be removed. Note, that this makes only sense if it is not likely enough that a formula with this constraint must be solved again.

**Parameters**

|                          |                                                         |
|--------------------------|---------------------------------------------------------|
| <code>_constraint</code> | The constraint to remove from internal data structures. |
|--------------------------|---------------------------------------------------------|

Reimplemented in [smtrat::LRAbstractModule< Settings >](#), [smtrat::LRAbstractModule< LRASettingsICP >](#), and [smtrat::LRAbstractModule< LRASettings >](#)

**0.15.516.4.37 `determine_smallest_origin()`** `size_t smtrat::Module::determine_smallest_origin ( const std::vector< FormulaT > & origins ) const [protected], [inherited]`

**Parameters**

|                      |                              |
|----------------------|------------------------------|
| <code>origins</code> | A vector of sets of origins. |
|----------------------|------------------------------|

**Returns**

The index of the smallest (regarding the size of the sets) element of `origins`

**0.15.516.4.38 `eraseSubformulaFromPassedFormula()`** `ModuleInput::iterator smtrat::Module::erasesubformulaFromPassedFormula ( ModuleInput::iterator _subformula, bool _ignoreOrigins = false ) [protected], [virtual], [inherited]`

Removes everything related to the sub-formula to remove from the passed formula in the backends of this module. Afterwards the sub-formula is removed from the passed formula.

**Parameters**

|                             |                                                                                                              |
|-----------------------------|--------------------------------------------------------------------------------------------------------------|
| <code>_subformula</code>    | The sub-formula to remove from the passed formula.                                                           |
| <code>_ignoreOrigins</code> | True, if the sub-formula shall be removed regardless of its origins (should only be applied with expertise). |

**Returns**

Reimplemented in [smtrat::ICPModule< Settings >](#), [smtrat::ICPModule< ICPSettings4 >](#), and [smtrat::ICPModule< ICPSettings1 >](#).

**0.15.516.4.39 excludeNotReceivedVariablesFromModel()** `void smtrat::Module::excludeNotReceivedVariablesFromModel ( ) const [inherited]`  
 Excludes all variables from the current model, which do not occur in the received formula.

**0.15.516.4.40 findBestOrigin()** `std::vector< FormulaT >::const_iterator smtrat::Module::findBestOrigin (`  
`const std::vector< FormulaT > & _origins ) const [protected], [inherited]`

**Parameters**

|                       |  |
|-----------------------|--|
| <code>_origins</code> |  |
|-----------------------|--|

**Returns**

**0.15.516.4.41 firstSubformulaToPass()** `ModuleInput::const_iterator smtrat::Module::firstSubformulaToPass ( ) const [inline], [inherited]`

**Returns**

The position of the first sub-formula in the passed formula, which has not yet been considered for a consistency check of the backends.

**0.15.516.4.42 firstUncheckedReceivedSubformula()** `ModuleInput::const_iterator smtrat::Module::firstUncheckedReceivedSubformula ( ) const [inline], [inherited]`

**Returns**

The position of the first (by this module) unchecked sub-formula of the received formula.

**0.15.516.4.43 freeSplittingVariable()** `static void smtrat::Module::freeSplittingVariable (`  
`const FormulaT & _splittingVariable ) [inline], [static], [inherited]`

**0.15.516.4.44 generateTrivialInfeasibleSubset()** `void smtrat::Module::generateTrivialInfeasibleSubset ( ) [inline], [protected], [inherited]`

Stores the trivial infeasible subset being the set of received formulas.

**0.15.516.4.45 getBackendsAllModels()** `void smtrat::Module::getBackendsAllModels ( ) const [protected], [inherited]`

Stores all models of a backend in the list of all models of this module.

**0.15.516.4.46 getBackendsModel()** void smtrat::Module::getBackendsModel ( ) const [protected], [inherited]

**0.15.516.4.47 getInfeasibleSubsets() [1/2]** void smtrat::Module::getInfeasibleSubsets ( ) [protected], [inherited]

Copies the infeasible subsets of the passed formula.

**0.15.516.4.48 getInfeasibleSubsets() [2/2]** std::vector< [FormulaSetT](#) > smtrat::Module::getInfeasibleSubsets (

const [Module](#) & *\_backend* ) const [protected], [inherited]

Get the infeasible subsets the given backend provides.

Note, that an infeasible subset in a backend contains sub formulas of the passed formula and an infeasible subset of this module contains sub formulas of the received formula. In this method the LATTER is returned.

#### Parameters

|                 |                                                          |
|-----------------|----------------------------------------------------------|
| <i>_backend</i> | The backend from which to obtain the infeasible subsets. |
|-----------------|----------------------------------------------------------|

#### Returns

The infeasible subsets the given backend provides.

**0.15.516.4.49 getInformationRelevantFormulas()** const std::set< [FormulaT](#) > & smtrat::Module::getInformationRelevantFormulas ( ) [protected], [inherited]

Gets all InformationRelevantFormulas.

#### Returns

Set of all formulas

**0.15.516.4.50 getModelEqualities()** std::list< std::vector< [carl::Variable](#) > > smtrat::Module::getModelEqualities ( ) const [virtual], [inherited]

Partition the variables from the current model into equivalence classes according to their assigned value.

The result is a set of equivalence classes of variables where all variables within one class are assigned the same value. Note that the number of classes may not be minimal, i.e. two classes may actually be equivalent.

#### Returns

Equivalence classes.

**0.15.516.4.51 getOrigins()** [1/3] void smtrat::Module::getOrigins (

const [FormulaT](#) & *\_formula*,

[FormulaSetT](#) & *\_origins* ) const [inline], [protected], [inherited]

#### Parameters

|                 |  |
|-----------------|--|
| <i>_formula</i> |  |
| <i>_origins</i> |  |

**0.15.516.4.52 getOrigins() [2/3]** void smtrat::Module::getOrigins ( const FormulaT & \_formula, FormulasT & \_origins ) const [inline], [protected], [inherited]

#### Parameters

|          |  |
|----------|--|
| _formula |  |
| _origins |  |

**0.15.516.4.53 getOrigins() [3/3]** const FormulaT& smtrat::Module::getOrigins ( ModuleInput::const\_iterator \_formula ) const [inline], [protected], [inherited]

Gets the origins of the passed formula at the given position.

#### Parameters

|          |                                                   |
|----------|---------------------------------------------------|
| _formula | The position of a formula in the passed formulas. |
|----------|---------------------------------------------------|

#### Returns

The origins of the passed formula at the given position.

**0.15.516.4.54 getReceivedFormulaSimplified()** std::pair< bool, FormulaT > smtrat::PModule::getReceivedFormulaSimplified ( ) [virtual], [inherited]

#### Returns

A pair of a Boolean and a formula, where the Boolean is true, if the received formula could be simplified to an equisatisfiable formula. The formula is equisatisfiable to this module's received formula, if the Boolean is true.

Reimplemented from [smtrat::Module](#).

**0.15.516.4.55 hasLemmas()** bool smtrat::Module::hasLemmas ( ) [inline], [inherited]

Checks whether this module or any of its backends provides any lemmas.

**0.15.516.4.56 hasValidInfeasibleSubset()** bool smtrat::Module::hasValidInfeasibleSubset ( ) const [inherited]

#### Returns

true, if the module has at least one valid infeasible subset, that is all its elements are sub-formulas of the received formula (pointer must be equal).

**0.15.516.4.57 id()** std::size\_t smtrat::Module::id ( ) const [inline], [inherited]

#### Returns

A unique ID to identify this module instance.

**0.15.516.4.58 infeasibleSubsets()** const std::vector<[FormulaSetT](#)>& smrat::Module::infeasibleSubsets () const [inline], [inherited]

**Returns**

The infeasible subsets of the set of received formulas (empty, if this module has not detected unsatisfiability of the conjunction of received formulas).

**0.15.516.4.59 inform()** bool smrat::Module::inform (const [FormulaT](#) & \_constraint ) [inherited]

Informs the module about the given constraint.

It should be tried to inform this module about any constraint it could receive eventually before assertSubformula is called (preferably for the first time, but at least before adding a formula containing that constraint).

**Parameters**

|                          |                                 |
|--------------------------|---------------------------------|
| <code>_constraint</code> | The constraint to inform about. |
|--------------------------|---------------------------------|

**Returns**

false, if it can be easily decided whether the given constraint is inconsistent; true, otherwise.

**0.15.516.4.60 informBackends()** void smrat::Module::informBackends (const [FormulaT](#) & \_constraint ) [inline], [protected], [inherited]

Informs all backends of this module about the given constraint.

**Parameters**

|                          |                                 |
|--------------------------|---------------------------------|
| <code>_constraint</code> | The constraint to inform about. |
|--------------------------|---------------------------------|

**0.15.516.4.61 informCore()** virtual bool smrat::Module::informCore (const [FormulaT](#) & \_constraint ) [inline], [protected], [virtual], [inherited]

Informs the module about the given constraint.

It should be tried to inform this module about any constraint it could receive eventually before assertSubformula is called (preferably for the first time, but at least before adding a formula containing that constraint).

**Parameters**

|                          |                                 |
|--------------------------|---------------------------------|
| <code>_constraint</code> | The constraint to inform about. |
|--------------------------|---------------------------------|

**Returns**

false, if it can be easily decided whether the given constraint is inconsistent; true, otherwise.

Reimplemented in [smrat::UnionFindModule< Settings >](#), [smrat::PBPPModule< Settings >](#), [smrat::PBGaussModule< Settings >](#), [smrat::NRAILModule< Settings >](#), [smrat::NewCoveringModule< Settings >](#), [smrat::NewCADModule< Settings >](#), [smrat::LRAModule< Settings >](#), [smrat::LRAModule< LRASettingsICP >](#), [smrat::LRAModule< LRASettings1 >](#), [smrat::IntBlastModule< Settings >](#), [smrat::FPPModule< Settings >](#), [smrat::EQModule< Settings >](#), [smrat::CurryModule< Settings >](#), [smrat::BVMModule< Settings >](#), [smrat::ICPModule< Settings >](#), [smrat::ICPModule< ICPSettings4 >](#), and [smrat::ICPModule< ICPSettings1 >](#).

**0.15.516.4.62 informedConstraints()** const carl::FastSet<[FormulaT](#)>& smtrat::Module::informedConstraints ( ) const [inline], [inherited]

#### Returns

The position of the first constraint of which no backend has been informed about.

**0.15.516.4.63 init()** void smtrat::Module::init ( ) [virtual], [inherited]

Informs all backends about the so far encountered constraints, which have not yet been communicated.

This method must not be called twice and only before the first runBackends call.

Reimplemented in [smtrat::PBPPModule< Settings >](#), [smtrat::PBGaussModule< Settings >](#), [smtrat::NRAILModule< Settings >](#), [smtrat::NewCoveringModule< Settings >](#), [smtrat::NewCADModule< Settings >](#), [smtrat::LRAModule< Settings >](#), [smtrat::LRAModule< LRASettingsICP >](#), [smtrat::LRAModule< LRASettings1 >](#), [smtrat::IntBlastModule< Settings >](#), [smtrat::FPPModule< Settings >](#), [smtrat::EQModule< Settings >](#), [smtrat::CurryModule< Settings >](#), and [smtrat::BVModule< Settings >](#).

**0.15.516.4.64 is\_minimizing()** bool smtrat::Module::is\_minimizing ( ) const [inline], [inherited]

**0.15.516.4.65 isLemmaLevel()** bool smtrat::Module::isLemmaLevel (

[LemmaLevel](#) level ) [protected], [inherited]

Checks if current lemma level is greater or equal to given level.

#### Parameters

|              |                 |
|--------------|-----------------|
| <i>level</i> | Level to check. |
|--------------|-----------------|

**0.15.516.4.66 isPreprocessor()** bool smtrat::PModule::isPreprocessor ( ) const [inline], [inherited]

#### Returns

true, if this module is a preprocessor that is a module, which simplifies its received formula to an equisatisfiable formula being passed to its backends. The simplified formula can be obtained with [getReceivedFormulaSimplified\(\)](#).

**0.15.516.4.67 lemmas()** const std::vector<[Lemma](#)>& smtrat::Module::lemmas ( ) const [inline], [inherited]

#### Returns

A constant reference to the lemmas being valid formulas this module or its backends made.

**0.15.516.4.68 merge()** std::vector< [FormulaT](#) > smtrat::Module::merge (

const std::vector< [FormulaT](#) > & \_vecSetA,

const std::vector< [FormulaT](#) > & \_vecSetB ) const [protected], [inherited]

Merges the two vectors of sets into the first one.

({a,b},{a,c}) and ({b,d},{b}) -> ({a,b,d},{a,b},{a,b,c,d},{a,b,c})

#### Parameters

|                 |                                  |
|-----------------|----------------------------------|
| <i>_vecSetA</i> | A vector of sets of constraints. |
| <i>_vecSetB</i> | A vector of sets of constraints. |

**Returns**

The vector being the two given vectors merged.

**0.15.516.4.69 `model()`** `const Model& smtrat::Module::model () const [inline], [inherited]`**Returns**

The assignment of the current satisfiable result, if existent.

**0.15.516.4.70 `modelsDisjoint()`** `bool smtrat::Module::modelsDisjoint (`

`const Model & _modelA,`

`const Model & _modelB ) [static], [protected], [inherited]`

Checks whether there is no variable assigned by both models.

**Parameters**

|                      |                                |
|----------------------|--------------------------------|
| <code>_modelA</code> | The first model to check for.  |
| <code>_modelB</code> | The second model to check for. |

**Returns**

true, if there is no variable assigned by both models; false, otherwise.

**0.15.516.4.71 `moduleName()`** `template<typename Settings >`

`std::string smtrat::SplitsOSModule< Settings >::moduleName () const [inline], [virtual]`

**Returns**

The name of the given module type as name.

Reimplemented from [smtrat::Module](#).

**0.15.516.4.72 `objective()`** `carl::Variable smtrat::Module::objective () const [inline], [inherited]`**0.15.516.4.73 `originInReceivedFormula()`** `bool smtrat::Module::originInReceivedFormula (`

`const FormulaT & _origin ) const [protected], [inherited]`

**0.15.516.4.74 `passedFormulaBegin()`** `ModuleInput::iterator smtrat::Module::passedFormulaBegin () [inline], [protected], [inherited]`**Returns**

An iterator to the end of the passed formula. TODO: disable this method

**0.15.516.4.75 `passedFormulaEnd()`** `ModuleInput::iterator smtrat::Module::passedFormulaEnd () [inline], [protected], [inherited]`**Returns**

An iterator to the end of the passed formula.

**0.15.516.4.76 pPassedFormula()** const `ModuleInput*` smtrat::Module::pPassedFormula ( ) const [inline], [inherited]

**Returns**

A pointer to the formula passed to the backends of this module.

**0.15.516.4.77 pReceivedFormula()** const `ModuleInput*` smtrat::Module::pReceivedFormula ( ) const [inline], [inherited]

**Returns**

A pointer to the formula passed to this module.

**0.15.516.4.78 print()** void smtrat::Module::print (const std::string & `_initiation` = "\*\*\*") const [inherited]

Prints everything relevant of the solver.

**Parameters**

|                          |                      |
|--------------------------|----------------------|
| <code>_initiation</code> | The line initiation. |
|--------------------------|----------------------|

**0.15.516.4.79 printAllModels()** void smtrat::Module::printAllModels (std::ostream & `_out` = `std::cout`) [inherited]

Prints all assignments of this module satisfying its received formula if it satisfiable and this module could find an assignment.

**Parameters**

|                   |                                        |
|-------------------|----------------------------------------|
| <code>_out</code> | The stream to print the assignment on. |
|-------------------|----------------------------------------|

**0.15.516.4.80 printInfeasibleSubsets()** void smtrat::Module::printInfeasibleSubsets (const std::string & `_initiation` = "\*\*\*") const [inherited]

Prints the infeasible subsets.

**Parameters**

|                          |                      |
|--------------------------|----------------------|
| <code>_initiation</code> | The line initiation. |
|--------------------------|----------------------|

**0.15.516.4.81 printModel()** void smtrat::Module::printModel (std::ostream & `_out` = `std::cout`) const [inherited]

Prints the assignment of this module satisfying its received formula if it satisfiable and this module could find an assignment.

**Parameters**

|                   |                                        |
|-------------------|----------------------------------------|
| <code>_out</code> | The stream to print the assignment on. |
|-------------------|----------------------------------------|

**0.15.516.4.82 printPassedFormula()** void smrat::Module::printPassedFormula ( const std::string & *\_initiation* = "\*\*\*" ) const [inherited]  
Prints the vector of passed formula.

Parameters

|                    |                      |
|--------------------|----------------------|
| <i>_initiation</i> | The line initiation. |
|--------------------|----------------------|

**0.15.516.4.83 printReceivedFormula()** void smrat::Module::printReceivedFormula ( const std::string & *\_initiation* = "\*\*\*" ) const [inherited]  
Prints the vector of the received formula.

Parameters

|                    |                      |
|--------------------|----------------------|
| <i>_initiation</i> | The line initiation. |
|--------------------|----------------------|

**0.15.516.4.84 probablyLooping()** bool smrat::Module::probablyLooping ( const typename Poly::PolyType & *\_branchingPolynomial*, const Rational & *\_branchingValue* ) const [protected], [inherited]  
Checks whether given the current branching value and branching variable/polynomial it is (highly) probable that this branching is part of an infinite loop of branchings.

Parameters

|                             |                                                                                     |
|-----------------------------|-------------------------------------------------------------------------------------|
| <i>_branchingPolynomial</i> | The polynomial to branch at (in most branching strategies this is just a variable). |
| <i>_branchingValue</i>      | The value to branch at.                                                             |

Returns

true, if this branching is probably part of an infinite loop of branchings; false, otherwise.

**0.15.516.4.85 receivedFormulaChecked()** void smrat::Module::receivedFormulaChecked ( ) [inline], [inherited]  
Notifies that the received formulas has been checked.

**0.15.516.4.86 receivedFormulasAsInfeasibleSubset()** void smrat::Module::receivedFormulasAsInfeasibleSubset ( ModuleInput::const\_iterator *\_subformula* ) [inline], [protected], [inherited]  
Stores an infeasible subset consisting only of the given received formula.

**0.15.516.4.87 receivedVariable()** bool smrat::Module::receivedVariable ( carl::Variable::Arg *\_var* ) const [inline], [inherited]

**0.15.516.4.88 remove()** void smrat::PModule::remove ( ModuleInput::const\_iterator *\_subformula* ) [virtual], [inherited]

Removes everything related to the given sub-formula of the received formula.

However, it is desired not to lose track of search spaces where no satisfying assignment can be found for the remaining sub-formulas.

#### Parameters

|                          |                                                    |
|--------------------------|----------------------------------------------------|
| <code>_subformula</code> | The sub formula of the received formula to remove. |
|--------------------------|----------------------------------------------------|

Reimplemented from [smtrat::Module](#).

**0.15.516.4.89 `removeCore()`** `virtual void smtrat::Module::removeCore ( ModuleInput::const_iterator formula ) [inline], [protected], [virtual], [inherited]`

Removes everything related to the given sub-formula of the received formula.

However, it is desired not to lose track of search spaces where no satisfying assignment can be found for the remaining sub-formulas.

#### Parameters

|                      |                                                    |
|----------------------|----------------------------------------------------|
| <code>formula</code> | The sub formula of the received formula to remove. |
|----------------------|----------------------------------------------------|

Reimplemented in [smtrat::VSModule< Settings >](#), [smtrat::SATModule< Settings >](#), [smtrat::PFEModule< Settings >](#), [smtrat::ICPModule< Settings >](#), [smtrat::ICPModule< ICPSettings4 >](#), [smtrat::ICPModule< ICPSettings1 >](#), [smtrat::UnionFindModule< Settings >](#), [smtrat::UFCegarModule< Settings >](#), [smtrat::STropModule< Settings >](#), [smtrat::PBPPModule< Settings >](#), [smtrat::PBGaussModule< Settings >](#), [smtrat::NRAILModule< Settings >](#), [smtrat::NewCoveringModule< Settings >](#), [smtrat::NewCADModule< Settings >](#), [smtrat::LRAModule< Settings >](#), [smtrat::LRAModule< LRASettingsICP >](#), [smtrat::LRAModule< LRASettings1 >](#), [smtrat::IntEqModule< Settings >](#), [smtrat::IntBlastModule< Settings >](#), [smtrat::IncWidthModule< Settings >](#), [smtrat::ICEModule< Settings >](#), [smtrat::FPPModule< Settings >](#), [smtrat::FouMoModule< Settings >](#), [smtrat::EQModule< Settings >](#), [smtrat::CurryModule< Settings >](#), [smtrat::CubeLIAModule< Settings >](#), [smtrat::CSplitModule< Settings >](#), [smtrat::BVMModule< Settings >](#), and [smtrat::GBModule< Settings >](#).

**0.15.516.4.90 `removeOrigin()`** `std::pair<ModuleInput::iterator,bool> smtrat::Module::removeOrigin ( ModuleInput::iterator _formula, const FormulaT & _origin ) [inline], [protected], [inherited]`

**0.15.516.4.91 `removeOrigins()`** `std::pair<ModuleInput::iterator,bool> smtrat::Module::removeOrigins ( ModuleInput::iterator _formula, const std::shared_ptr< std::vector< FormulaT >> & _origins ) [inline], [protected], [inherited]`

**0.15.516.4.92 `rPassedFormula()`** `const ModuleInput& smtrat::Module::rPassedFormula ( ) const [inline], [inherited]`

#### Returns

A reference to the formula passed to the backends of this module.

**0.15.516.4.93 `rReceivedFormula()`** `const ModuleInput& smtrat::Module::rReceivedFormula ( ) const [inline], [inherited]`

**Returns**

A reference to the formula passed to this module.

**0.15.516.4.94 runBackends() [1/2]** `virtual Answer smtrat::PModule::runBackends () [inline], [virtual], [inherited]`

Reimplemented from [smtrat::Module](#).

**0.15.516.4.95 runBackends() [2/2]** `Answer smtrat::PModule::runBackends (`

```
 bool _final,
 bool _full,
 carl::Variable _objective) [virtual], [inherited]
```

Runs the backend solvers on the passed formula.

**Parameters**

|                         |                                                                                                                                       |
|-------------------------|---------------------------------------------------------------------------------------------------------------------------------------|
| <code>_final</code>     | true, if this satisfiability check will be the last one (for a global sat-check), if its result is SAT.                               |
| <code>_full</code>      | false, if this module should avoid too expensive procedures and rather return unknown instead.                                        |
| <code>_objective</code> | if not set to NO_VARIABLE, the module should find an assignment minimizing this objective variable; otherwise any assignment is good. |

**Returns**

True, if the passed formula is consistent; False, if the passed formula is inconsistent; Unknown, otherwise.

Reimplemented from [smtrat::Module](#).

**0.15.516.4.96 setId()** `void smtrat::Module::setId (`

```
 std::size_t _id) [inline], [inherited]
```

Sets this modules unique ID to identify itself.

**Parameters**

|                   |                                    |
|-------------------|------------------------------------|
| <code>↔ id</code> | The id to set this module's id to. |
|-------------------|------------------------------------|

**0.15.516.4.97 setThreadPriority()** `void smtrat::Module::setThreadPriority (`

```
 thread_priority _threadPriority) [inline], [inherited]
```

Sets the priority of this module to get a thread for running its check procedure.

**Parameters**

|                              |                                                       |
|------------------------------|-------------------------------------------------------|
| <code>_threadPriority</code> | The priority to set this module's thread priority to. |
|------------------------------|-------------------------------------------------------|

**0.15.516.4.98 solverState()** `Answer smtrat::Module::solverState () const [inline], [inherited]`

**Returns**

True, if this module is in a state, such that it has found a solution for its received formula; False, if this module is in a state, such that it has determined that there is no solution for its received formula; Unknown, otherwise.

**0.15.516.4.99 splitUnequalConstraint()** `void smtrat::Module::splitUnequalConstraint (`

`const FormulaT & _unequalConstraint ) [protected], [inherited]`

Adds the following lemmas for the given constraint  $p \neq 0$ .

$(p \neq 0 \leftrightarrow (p < 0 \text{ or } p > 0))$

and  $\neg(p < 0 \text{ and } p > 0)$

**Parameters**

|                                 |                                                  |
|---------------------------------|--------------------------------------------------|
| <code>_unequalConstraint</code> | A constraint having the relation symbol $\neq$ . |
|---------------------------------|--------------------------------------------------|

**0.15.516.4.100 threadPriority()** `thread_priority smtrat::Module::threadPriority ( ) const [inline], [inherited]`**Returns**

The priority of this module to get a thread for running its check procedure.

**0.15.516.4.101 updateAllModels()** `void smtrat::Module::updateAllModels ( ) [virtual], [inherited]`

Updates all satisfying models, if the solver has detected the consistency of the received formula, beforehand.

Reimplemented in [smtrat::SATModule< Settings >](#).

**0.15.516.4.102 updateLemmas()** `void smtrat::Module::updateLemmas ( ) [inherited]`

Stores all lemmas of any backend of this module in its own lemma vector.

**0.15.516.4.103 updateModel()** `void smtrat::PModule::updateModel ( ) const [virtual], [inherited]`

Updates the current assignment into the model.

Note, that this is a unique but possibly symbolic assignment maybe containing newly introduced variables.

Reimplemented from [smtrat::Module](#).

**0.15.516.4.104 usedBackends()** `const std::vector<Module*>& smtrat::Module::usedBackends ( )`

`const [inline], [inherited]`

**Returns**

The backends of this module which are currently used (conditions to use this module are fulfilled for the passed formula).

**0.15.516.5 Field Documentation****0.15.516.5.1 mAllBackends** `std::vector<Module*> smtrat::Module::mAllBackends [protected], [inherited]`

The backends of this module which have been used.

**0.15.516.5.2 mAllModels** `std::vector<Model>` `smtrat::Module::mAllModels` [mutable], [protected], [inherited]  
Stores all satisfying assignments.

**0.15.516.5.3 mBackendsFoundAnswer** `std::atomic_bool*` `smtrat::Module::mBackendsFoundAnswer` [protected], [inherited]  
This flag is passed to any backend and if it determines an answer to a prior check call, this flag is fired.

**0.15.516.5.4 mConstraintsToInform** `carl::FastSet<FormulaT>` `smtrat::Module::mConstraintsToInform` [protected], [inherited]  
Stores the constraints which the backends must be informed about.

**0.15.516.5.5 mFinalCheck** `bool` `smtrat::Module::mFinalCheck` [protected], [inherited]  
true, if the check procedure should perform a final check which especially means not to postpone splitting decisions

**0.15.516.5.6 mFirstPosInLastBranches** `std::size_t` `smtrat::Module::mFirstPosInLastBranches` = 0 [static], [inherited]  
The beginning of the cyclic buffer storing the last branches.

**0.15.516.5.7 mFirstSubformulaToPass** `ModuleInput::iterator` `smtrat::Module::mFirstSubformulaToPass` [protected], [inherited]  
Stores the position of the first sub-formula in the passed formula, which has not yet been considered for a consistency check of the backends.

**0.15.516.5.8 mFirstUncheckedReceivedSubformula** `ModuleInput::const_iterator` `smtrat::Module::mFirstUncheckedReceivedSubformula` [protected], [inherited]  
Stores the position of the first (by this module) unchecked sub-formula of the received formula.

**0.15.516.5.9 mFoundAnswer** `Conditionals` `smtrat::Module::mFoundAnswer` [protected], [inherited]  
Vector of Booleans: If any of them is true, we have to terminate a running check procedure.

**0.15.516.5.10 mFullCheck** `bool` `smtrat::Module::mFullCheck` [protected], [inherited]  
false, if this module should avoid too expensive procedures and rather return unknown instead.

**0.15.516.5.11 mInfeasibleSubsets** `std::vector<FormulaSetT>` `smtrat::Module::mInfeasibleSubsets` [protected], [inherited]  
Stores the infeasible subsets.

**0.15.516.5.12 mInformedConstraints** `carl::FastSet<FormulaT>` `smtrat::Module::mInformedConstraints` [protected], [inherited]  
Stores the position of the first constraint of which no backend has been informed about.

**0.15.516.5.13 mLastBranches** std::vector< Branching > smtrat::Module::mLastBranches = std::vector<Branching> (mNumOfBranchVarsToStore, Branching(typename Poly::PolyType(), 0)) [static], [inherited]

Stores the last branches in a cycle buffer.

**0.15.516.5.14 mLemmas** std::vector<Lemma> smtrat::Module::mLemmas [protected], [inherited]

Stores the lemmas being valid formulas this module or its backends made.

**0.15.516.5.15 mModel** Model smtrat::Module::mModel [mutable], [protected], [inherited]

Stores the assignment of the current satisfiable result, if existent.

**0.15.516.5.16 mModelComputed** bool smtrat::Module::mModelComputed [mutable], [protected], [inherited]

True, if the model has already been computed.

**0.15.516.5.17 mNumOfBranchVarsToStore** std::size\_t smtrat::Module::mNumOfBranchVarsToStore =

5 [static], [inherited]

The number of different variables to consider for a probable infinite loop of branchings.

**0.15.516.5.18 mObjectiveVariable** carl::Variable smtrat::Module::mObjectiveVariable [protected], [inherited]

Objective variable to be minimized. If set to NO\_VARIABLE, a normal sat check should be performed.

**0.15.516.5.19 mOldSplittingVariables** std::vector< FormulaT > smtrat::Module::mOldSplittingVariables [static], [inherited]

Reusable splitting variables.

**0.15.516.5.20 mpManager** Manager\* const smtrat::Module::mpManager [protected], [inherited]

A reference to the manager.

**0.15.516.5.21 mSmallerMusesCheckCounter** unsigned smtrat::Module::mSmallerMusesCheckCounter [mutable], [protected], [inherited]

Counter used for the generation of the smt2 files to check for smaller muses.

**0.15.516.5.22 mSolverState** std::atomic<Answer> smtrat::Module::mSolverState [protected], [inherited]

States whether the received formula is known to be satisfiable or unsatisfiable otherwise it is set to unknown.

**0.15.516.5.23 mTheoryPropagations** std::vector<TheoryPropagation> smtrat::Module::mTheoryPropagations [protected], [inherited]

**0.15.516.5.24 mUsedBackends** std::vector<[Module](#)\*> smtrat::Module::mUsedBackends [protected], [inherited]

The backends of this module which are currently used (conditions to use this module are fulfilled for the passed formula).

**0.15.516.5.25 mVariableCounters** std::vector<std::size\_t> smtrat::Module::mVariableCounters [protected], [inherited]

Maps variables to the number of their occurrences.

## 0.15.517 benchmax::SSHBackend Class Reference

```
#include <SSHBackend.h>
```

### Public Member Functions

### 0.15.517.1 Constructor & Destructor Documentation

#### 0.15.517.1.1 [SSHBackend\(\)](#) benchmax::SSHBackend::SSHBackend ( ) [inline]

**0.15.517.1.2 ~SSHBackend()** `benchmax::SSHBackend::~SSHBackend( ) [inline]`

### 0.15.517.2 Member Function Documentation

**0.15.517.2.1 addResult()** `void benchmax::Backend::addResult( const Tool * tool, const fs::path & file, BenchmarkResult && result ) [inline], [inherited]`

Add a result.

**0.15.517.2.2 collect\_results()** `virtual bool benchmax::Backend::collect_results( const Jobs & , bool ) [inline], [protected], [virtual], [inherited]`

**0.15.517.2.3 execute()** `virtual void benchmax::Backend::execute( const Tool * , const fs::path & ) [inline], [protected], [virtual], [inherited]`

Execute a single pair of tool and benchmark.

Reimplemented in [benchmax::LocalBackend](#), and [benchmax::CondorBackend](#).

**0.15.517.2.4 finalize()** `virtual void benchmax::Backend::finalize( ) [inline], [protected], [virtual], [inherited]`

Hook to allow for asynchronous backends to wait for jobs to terminate.

**0.15.517.2.5 madeProgress()** `void benchmax::Backend::madeProgress( std::size_t files = 1 ) [inline], [protected], [inherited]`

Can be called to give information about the current progress, if available.

**0.15.517.2.6 process\_results()** `void benchmax::Backend::process_results( const Jobs & jobs, bool check_finished ) [inline], [inherited]`

**0.15.517.2.7 run()** `void benchmax::SSHBackend::run( const Jobs & , bool ) [inline]`

Dummy if SSH is disabled.

**0.15.517.2.8 sanitize\_results()** `void benchmax::Backend::sanitize_results( const Jobs & jobs ) const [inline], [protected], [inherited]`

**0.15.517.2.9 startTool()** `virtual void benchmax::Backend::startTool( const Tool * ) [inline], [protected], [virtual], [inherited]`

Hook for every tool at the beginning.

Can be used to upload the tool to some remote system.

**0.15.517.2.10 suspendable()** `bool benchmax::Backend::suspendable () const [inline], [inherited]`

**0.15.517.2.11 write\_results()** `void benchmax::Backend::write_results (const Jobs & jobs) const [inline], [protected], [inherited]`

### 0.15.517.3 Field Documentation

**0.15.517.3.1 mExpectedJobs** `std::size_t benchmax::Backend::mExpectedJobs [protected], [inherited]`  
Number of jobs that should be run.

**0.15.517.3.2 mFinishedJobs** `std::atomic<std::size_t> benchmax::Backend::mFinishedJobs [protected], [inherited]`  
Number of jobs that are finished.

**0.15.517.3.3 mLastPercent** `std::atomic<std::size_t> benchmax::Backend::mLastPercent [protected], [inherited]`  
Percentage of finished jobs when [madeProgress\(\)](#) was last called.

## 0.15.518 `benchmax::settings::SSHBackendSettings` Struct Reference

[Settings](#) for SSH backend.

```
#include <SSHSettings.h>
```

### Data Fields

- `std::vector< std::string > nodes`  
*List of nodes to connect to.*
- `std::string basedir`  
*Base directory for solvers.*
- `std::string tmpdir`  
*Temporary directory for benchmarks and output files.*
- `bool use_wallclock`  
*Use wallclock timeouts instead of CPU time.*
- `bool resolve_deps`  
*Resolve and upload dependencies of binary.*

### 0.15.518.1 Detailed Description

[Settings](#) for SSH backend.

### 0.15.518.2 Field Documentation

**0.15.518.2.1 basedir** `std::string benchmax::settings::SSHBackendSettings::basedir`  
Base directory for solvers.

**0.15.518.2.2 nodes** `std::vector<std::string> benchmax::settings::SSHBackendSettings::nodes`  
List of nodes to connect to.

**0.15.518.2.3 resolve\_deps** bool benchmax::settings::SSHBackendSettings::resolve\_deps  
Resolve and upload dependencies of binary.

**0.15.518.2.4 tmpdir** std::string benchmax::settings::SSHBackendSettings::tmpdir  
Temporary directory for benchmarks and output files.

**0.15.518.2.5 use\_wallclock** bool benchmax::settings::SSHBackendSettings::use\_wallclock  
Use wallclock timeouts instead of CPU time.

## 0.15.519 benchmax::ssh::SSHConnection Class Reference

A wrapper class that manages a single SSH connection as specified in a [Node](#) object (with all its channels).

```
#include <SSHConnection.h>
```

### Public Member Functions

- **SSHConnection** (const [Node](#) &n)  
*Create a new connection for the given node.*
- **~SSHConnection** ()  
*Wait for all channels to terminate.*
- const [Node](#) & **getNode** () const  
*Return the node.*
- bool **jobFree** ()  
*Check if a new job could be started.*
- void **newJob** ()  
*Increase job counter.*
- void **finishJob** ()  
*Decrease job counter.*
- std::size\_t **jobs** () const  
*Current number of jobs.*
- bool **busy** ()  
*Check if all channels are busy.*
- std::string **createTmpDir** (const std::string &folder)  
*Create a temporary directory on the remote.*
- void **removeDir** (const std::string &folder)  
*Remove a (temporary) directory on the remote.*
- bool **uploadFile** (const fs::path &local, const std::string &base, const std::string &remote, int mode=S\_←IRUSR|S\_IWUSR)  
*Upload a file to the remote.*
- bool **executeCommand** (const std::string &cmd, [BenchmarkResult](#) &result)  
*Execute a command on the remote.*

### 0.15.519.1 Detailed Description

A wrapper class that manages a single SSH connection as specified in a [Node](#) object (with all its channels).

### 0.15.519.2 Constructor & Destructor Documentation

**0.15.519.2.1 `SSHConnection()`** `benchmax::ssh::SSHConnection::SSHConnection (` `const Node & n ) [inline]`

Create a new connection for the given node.

**0.15.519.2.2 `~SSHConnection()`** `benchmax::ssh::SSHConnection::~SSHConnection ( ) [inline]`

Wait for all channels to terminate.

### 0.15.519.3 Member Function Documentation

**0.15.519.3.1 `busy()`** `bool benchmax::ssh::SSHConnection::busy ( ) [inline]`

Check if all channels are busy.

**0.15.519.3.2 `createTmpDir()`** `std::string benchmax::ssh::SSHConnection::createTmpDir (` `const std::string & folder ) [inline]`

Create a temporary directory on the remote.

**0.15.519.3.3 `executeCommand()`** `bool benchmax::ssh::SSHConnection::executeCommand (` `const std::string & cmd,` `BenchmarkResult & result ) [inline]`

Execute a command on the remote.

**0.15.519.3.4 `finishJob()`** `void benchmax::ssh::SSHConnection::finishJob ( ) [inline]`

Decrease job counter.

**0.15.519.3.5 `getNode()`** `const Node& benchmax::ssh::SSHConnection::getNode ( ) const [inline]`

Return the node.

**0.15.519.3.6 `jobFree()`** `bool benchmax::ssh::SSHConnection::jobFree ( ) [inline]`

Check if a new job could be started.

**0.15.519.3.7 `jobs()`** `std::size_t benchmax::ssh::SSHConnection::jobs ( ) const [inline]`

Current number of jobs.

**0.15.519.3.8 `newJob()`** `void benchmax::ssh::SSHConnection::newJob ( ) [inline]`

Increase job counter.

**0.15.519.3.9 `removeDir()`** `void benchmax::ssh::SSHConnection::removeDir (` `const std::string & folder ) [inline]`

Remove a (temporary) directory on the remote.

```
0.15.519.3.10 uploadFile() bool benchmax::ssh::SSHConnection::uploadFile (
 const fs::path & local,
 const std::string & base,
 const std::string & remote,
 int mode = S_IRUSR | S_IWUSR) [inline]
```

Upload a file to the remote.

## 0.15.520 smrat::vs::State Class Reference

```
#include <State.h>
```

### Public Types

- enum `Type` { `TEST_CANDIDATE_TO_GENERATE` , `SUBSTITUTION_TO_APPLY` , `COMBINE_SUBRESULTS` }
- typedef `carl::FastPointerMap< Substitution, ConditionSetSet > ConflictSets`
- typedef `std::vector< std::pair< ConditionList, bool > > SubstitutionResult`
- typedef `std::vector< SubstitutionResult > SubstitutionResults`
- typedef `std::vector< std::pair< unsigned, unsigned > > SubResultCombination`
- typedef `smrat::vb::VariableBounds< const Condition * > VariableBoundsCond`

### Public Member Functions

- `State (carl::IDPool *_conditionIdAllocator, bool _withVariableBounds)`

*Constructs an empty state (no conditions yet) being the root (hence neither a substitution) of the state tree which is going to be formed when applying the satisfiability check based on virtual substitution.*
- `State (State *const _father, const Substitution &_substitution, carl::IDPool *_conditionIdAllocator, bool _← withVariableBounds)`

*Constructs a state being a child of the given state and containing the given substitution, which maps from the index variable of the given state.*
- `State (const State &)=delete`
- `~State ()`

*Destructor.*
- `bool isRoot () const`
- `bool cannotBeSolved (bool _lazy) const`
- `bool & rCannotBeSolved ()`
- `bool & rCannotBeSolvedLazy ()`
- `bool markedAsDeleted () const`
- `bool & rMarkedAsDeleted ()`
- `bool hasChildrenToInsert () const`
- `bool & rHasChildrenToInsert ()`
- `carl::Variable::Arg index () const`
- `size_t valuation () const`
- `size_t backendCallValuation () const`
- `size_t id () const`
- `size_t & rID ()`
- `std::list< State * > & rChildren ()`
- `const std::list< State * > & children () const`
- `State * pFather () const`
- `const State & father () const`
- `State & rFather ()`
- `ConflictSets & rConflictSets ()`
- `const ConflictSets & conflictSets () const`
- `bool & rHasRecentlyAddedConditions ()`
- `bool hasRecentlyAddedConditions () const`
- `bool & rInconsistent ()`

- bool `isInconsistent () const`
- `ConditionList & rConditions ()`
- const `ConditionList & conditions () const`
- `Substitution & rSubstitution ()`
- const `Substitution & substitution () const`
- `SubstitutionResults & rSubstitutionResults ()`
- const `SubstitutionResults & substitutionResults () const`
- `SubResultCombination & rSubResultCombination ()`
- const `SubResultCombination & subResultCombination () const`
- const `Substitution * pSubstitution () const`
- bool `conditionsSimplified () const`
- bool `subResultsSimplified () const`
- bool & `rSubResultsSimplified ()`
- bool `takeSubResultCombAgain () const`
- bool & `rTakeSubResultCombAgain ()`
- bool `tryToRefreshIndex () const`
- bool `hasSubResultsCombination () const`
- bool `hasSubstitutionResults () const`
- bool `unfinished () const`
- `Type type () const`
- `Type & rType ()`
- const `Condition * pOriginalCondition () const`
- const `Condition & originalCondition () const`
- const `carl::PointerSet< Condition > & tooHighDegreeConditions () const`
- `carl::PointerSet< Condition > & rTooHighDegreeConditions ()`
- const `VariableBoundsCond & variableBounds () const`
- `VariableBoundsCond & rVariableBounds ()`
- void `setOriginalCondition (const Condition *_pOCondition)`

*Sets the pointer of the original condition of this state to the given pointer to a condition.*

- size\_t `currentRangeSize () const`
- void `resetCurrentRangeSize ()`
- const `smrat::Rational & minIntTestCandidate () const`
- const `smrat::Rational & maxIntTestCandidate () const`
- bool `hasInfinityChild () const`
- void `resetInfinityChild (const State *_state)`
- void `setInfinityChild (State *_state)`
- void `resetCannotBeSolvedLazyFlags ()`
- unsigned `treeDepth () const`
- bool `substitutionApplicable () const`

*Checks if a substitution can be applied.*

- bool `substitutionApplicable (const smrat::ConstraintT &_constraint) const`

*Checks if the substitution of this state can be applied to the given constraint.*

- bool `hasNoninvolvedCondition () const`

*Checks whether a condition exists, which was not involved in an elimination step.*

- bool `allTestCandidatesInvalidated (const Condition *_condition) const`
- bool `hasChildWithID () const`

*Checks whether a child exists, which has no ID (!=0).*

- bool `containsState (const State *_state) const`
- bool `hasOnlyInconsistentChildren () const`

*Checks whether a child exists, which is not yet marked as inconsistent.*

- bool `occursInEquation (const carl::Variable &) const`

*Checks whether the given variable occurs in a equation.*

- bool `hasFurtherUncheckedTestCandidates () const`

- Checks whether there exist more than one test candidate, which has still not been checked.
- void `variables` (carl::Variables &\_variables) const
  - Finds the variables, which occur in this state.*
- unsigned `numberOfNodes` () const
  - Determines the number of nodes in the tree with this state as root.*
- `State & root` ()
  - `bool getNextIntTestCandidate (smrat::Rational &_nextIntTestCandidate, size_t _maxIntRange)`
  - `bool updateIntTestCandidates ()`
  - `bool unfinishedAncestor (State *&_unfinAnt)`
    - Determines (if it exists) a ancestor node, which is unfinished, that is it has still substitution results to consider.*
- `bool bestCondition (const Condition *&_bestCondition, size_t _numberOfAllVariables, bool _preferEquation)`
  - Determines the most adequate condition and in it the most adequate variable in the state to generate test candidates for.*
- ConditionList::iterator `constraintExists (const smrat::ConstraintT &_constraint)`
  - Checks if the given constraint already exists as condition in the state.*
- void `simplify (ValuationMap &_ranking)`
  - Cleans up all conditions in this state according to comparison between the corresponding constraints.*
- `bool simplify (ConditionList &_conditionVectorToSimplify, ConditionSetSet &_conflictSet, ValuationMap &_ranking, bool _stateConditions=false)`
  - Simplifies the given conditions according to comparison between the corresponding constraints.*
- void `setIndex (const carl::Variable &_index)`
  - Sets the index of this state.*
- void `addConflictSet (const Substitution * _substitution, ConditionSetSet &&_condSetSet)`
  - Adds a conflict set to the map of substitutions to conflict sets.*
- void `addConflicts (const Substitution * _substitution, ConditionSetSet &&_condSetSet)`
  - Adds all conflicts to all sets of the conflict set of the given substitution.*
- void `resetConflictSets ()`
  - Clears the conflict sets.*
- `bool updateOCondsOfSubstitutions (const Substitution &_substitution, std::vector< State * > &_reactivatedStates)`
  - Updates the original conditions of substitutions having the same test candidate as the given.*
- void `addSubstitutionResults (std::vector< DisjunctionOfConditionConjunctions > &&_disjunctionsOfCond Conj)`
  - Adds the given substitution results to this state.*
- bool `extendSubResultCombination ()`
  - Extends the currently considered combination of conjunctions in the substitution results.*
- bool `nextSubResultCombination ()`
  - If the state contains a substitution result, which is a conjunction of disjunctions of conjunctions of conditions, this method sets the current combination to the disjunctions to the next combination.*
- size\_t `getNumberOfCurrentSubresultCombination () const`
- ConditionList `getCurrentSubresultCombination () const`
  - Gets the current substitution result combination as condition vector.*
- bool `refreshConditions (ValuationMap &_ranking)`
  - Determines the condition vector corresponding to the current combination of the conjunctions of conditions.*
- void `initConditionFlags ()`
  - Sets all flags of the conditions to true, if it contains the variable given by the states index.*
- bool `initIndex (const carl::Variables &_allVariables, const smrat::VariableValuationStrategy &_vvstrat, bool _preferEquation, bool _tryDifferentVarOrder=false, bool _useFixedVariableOrder=false)`
  - Sets, if it has not already happened, the index of the state to the name of the most adequate variable.*
- void `bestConstraintValuation (const std::vector< std::pair< carl::Variable, std::multiset< double >>> &_varVals)`

- void `averageConstraintValuation` (const std::vector< std::pair< carl::Variable, std::multiset< double >>> &\_varVals)
- void `worstConstraintValuation` (const std::vector< std::pair< carl::Variable, std::multiset< double >>> &\_varVals)
- void `addCondition` (const smrat::ConstraintT &\_constraint, const carl::PointerSet< Condition > &\_originalConditions, size\_t \_valuation, bool \_recentlyAdded, ValuationMap &\_ranking)  
*Adds a constraint to the conditions of this state.*
- bool `checkSubresultCombinations` () const  
*This is just for debug purpose.*
- int `deleteOrigins` (carl::PointerSet< Condition > &\_originsToDelete, ValuationMap &\_ranking)  
*Removes everything in this state originated by the given vector of conditions.*
- void `deleteOriginsFromChildren` (carl::PointerSet< Condition > &\_originsToDelete, ValuationMap &\_ranking)  
*Deletes everything originated by the given conditions in the children of this state.*
- void `deleteOriginsFromConflictSets` (carl::PointerSet< Condition > &\_originsToDelete, bool \_originsAreCurrentConditions)  
*Deletes everything originated by the given conditions in the conflict sets of this state.*
- void `deleteOriginsFromSubstitutionResults` (carl::PointerSet< Condition > &\_originsToDelete)  
*Deletes everything originated by the given conditions in the substitution results of this state.*
- void `deleteConditions` (carl::PointerSet< Condition > &\_conditionsToDelete, ValuationMap &\_ranking)  
*Delete everything originated by the given conditions from the entire subtree with this state as root.*
- std::vector< State \* > `addChild` (const Substitution &\_substitution)  
*Adds a state as child to this state with the given substitution.*
- void `updateValuation` (bool \_lazy)  
*Updates the valuation of this state.*
- void `updateBackendCallValuation` ()  
*Valuates the state's currently considered conditions according to a backend call.*
- void `passConflictToFather` (bool \_checkConflictForSideCondition, bool \_useBackjumping=true, bool \_includeInconsistentTestCandidates=false)  
*Passes the original conditions of the covering set of the conflicts of this state to its father.*
- bool `hasLocalConflict` ()  
*Checks whether the currently considered conditions, which have been considered for test candidate construction, form already a conflict.*
- bool `checkTestCandidatesForBounds` ()  
*Checks whether the test candidate of this state is valid against the variable intervals in the father of this state.*
- std::vector< smrat::DoubleInterval > `solutionSpace` (carl::PointerSet< Condition > &\_conflictReason) const  
*Determines the solution space of the test candidate of this state regarding to the variable bounds of the father.*
- bool `hasRootsInVariableBounds` (const Condition \* \_condition, bool \_useSturmSequence)  
*Checks whether there are no zeros for the left-hand side of the constraint of the given condition.*
- void `print` (const std::string \_initiation="\*\*\*", std::ostream &\_out=std::cout) const  
*Prints the conditions, the substitution and the substitution results of this state and all its children.*
- void `printAlone` (const std::string \_initiation="\*\*\*", std::ostream &\_out=std::cout) const  
*Prints the conditions, the substitution and the substitution results of this state.*
- void `printConditions` (const std::string \_initiation="\*\*\*", std::ostream &\_out=std::cout, bool=false) const  
*Prints the conditions of this state.*
- void `printSubstitutionResults` (const std::string \_initiation="\*\*\*", std::ostream &\_out=std::cout) const  
*Prints the substitution results of this state.*
- void `printSubstitutionResultCombination` (const std::string \_initiation="\*\*\*", std::ostream &\_out=std::cout) const  
*Prints the combination of substitution results used in this state.*
- void `printSubstitutionResultCombinationAsNumbers` (const std::string \_initiation="\*\*\*", std::ostream &\_out=std::cout) const  
*Prints the combination of substitution results, expressed in numbers, used in this state.*
- void `printConflictSets` (const std::string \_initiation="\*\*\*", std::ostream &\_out=std::cout) const  
*Prints the conflict sets of this state.*

## Static Public Member Functions

- static void `removeStatesFromRanking` (const `State` &`toRemove`, `ValuationMap` &`_ranking`)
- static size\_t `coveringSet` (const `ConditionSetSet` &`_conflictSets`, carl::PointerSet< `Condition` > &`_minCovSet`, unsigned `_currentTreeDepth`)

*Finds a covering set of a vector of sets of sets due to some heuristics.*

### 0.15.520.2 Member Enumeration Documentation

#### 0.15.520.2.1 `Type` `enum smtrat::vs::State::Type`

Enumerator

|                            |  |
|----------------------------|--|
| TEST_CANDIDATE_TO_GENERATE |  |
| SUBSTITUTION_TO_APPLY      |  |
| COMBINE_SUBRESULTS         |  |

### 0.15.520.3 Constructor & Destructor Documentation

#### 0.15.520.3.1 `State()` [1/3] `smtrat::vs::State::State (` `carl::IDPool * _conditionIdAllocator,` `bool _withVariableBounds )`

Constructs an empty state (no conditions yet) being the root (hence neither a substitution) of the state tree which is going to be formed when applying the satisfiability check based on virtual substitution.

Parameters

|                                  |                                                                              |
|----------------------------------|------------------------------------------------------------------------------|
| <code>_withVariableBounds</code> | A flag that indicates whether to use optimizations based on variable bounds. |
|----------------------------------|------------------------------------------------------------------------------|

#### 0.15.520.3.2 `State()` [2/3] `smtrat::vs::State::State (` `State *const _father,`

```
const Substitution & _substitution,
carl::IDPool * _conditionIdAllocator,
bool _withVariableBounds)
```

Constructs a state being a child of the given state and containing the given substitution, which maps from the index variable of the given state.

#### Parameters

|                                  |                                                                              |
|----------------------------------|------------------------------------------------------------------------------|
| <code>_father</code>             | The father of the state to be constructed.                                   |
| <code>_substitution</code>       | The substitution of the state to be constructed.                             |
| <code>_withVariableBounds</code> | A flag that indicates whether to use optimizations based on variable bounds. |

**0.15.520.3.3 State()** [3/3] smtrat::vs::State::State (

```
const State &) [delete]
```

**0.15.520.3.4 ~State()** smtrat::vs::State::~State ( )  
Destructor.

### 0.15.520.4 Member Function Documentation

**0.15.520.4.1 addChild()** std::vector< `State` \* > smtrat::vs::State::addChild (

```
const Substitution & _substitution)
```

Adds a state as child to this state with the given substitution.

#### Parameters

|                            |                                             |
|----------------------------|---------------------------------------------|
| <code>_substitution</code> | The substitution to generate the state for. |
|----------------------------|---------------------------------------------|

#### Returns

true, if a state has been added as child to this state; false, otherwise.

**0.15.520.4.2 addCondition()** void smtrat::vs::State::addCondition (

```
const smtrat::ConstraintT & _constraint,
const carl::PointerSet< Condition > & _originalConditions,
size_t _valuation,
bool _recentlyAdded,
ValuationMap & _ranking)
```

Adds a constraint to the conditions of this state.

#### Parameters

|                                  |                                                                                          |
|----------------------------------|------------------------------------------------------------------------------------------|
| <code>_constraint</code>         | The constraint of the condition to add.                                                  |
| <code>_originalConditions</code> | The original conditions of the condition to add.                                         |
| <code>_valuation</code>          | The valuation of the condition to add.                                                   |
| <code>_recentlyAdded</code>      | Is the condition a recently added one. @sideeffect The state can obtain a new condition. |

```
0.15.520.4.3 addConflicts() void smtrat::vs::State::addConflicts (
 const Substitution * _substitution,
 ConditionSetSet && _condSetSet)
```

Adds all conflicts to all sets of the conflict set of the given substitution.

#### Parameters

|                            |                                                                                                                    |
|----------------------------|--------------------------------------------------------------------------------------------------------------------|
| <code>_substitution</code> | The corresponding substitution generated the conflict. (NULL in the case a detected conflict without substitution) |
| <code>_condSetSet</code>   | The conflicts to add.                                                                                              |

```
0.15.520.4.4 addConflictSet() void smtrat::vs::State::addConflictSet (
 const Substitution * _substitution,
 ConditionSetSet && _condSetSet)
```

Adds a conflict set to the map of substitutions to conflict sets.

#### Parameters

|                            |                                                                                                                    |
|----------------------------|--------------------------------------------------------------------------------------------------------------------|
| <code>_substitution</code> | The corresponding substitution generated the conflict. (NULL in the case a detected conflict without substitution) |
| <code>_condSetSet</code>   | The conflicts to add.                                                                                              |

```
0.15.520.4.5 addSubstitutionResults() void smtrat::vs::State::addSubstitutionResults (
 std::vector< DisjunctionOfConditionConjunctions > && _disjunctionsOfCondConj)
```

Adds the given substitution results to this state.

#### Parameters

|                                      |                                                                                           |
|--------------------------------------|-------------------------------------------------------------------------------------------|
| <code>_disjunctionsOfCondConj</code> | The substitution results given by a vector of disjunctions of conjunctions of conditions. |
|--------------------------------------|-------------------------------------------------------------------------------------------|

```
0.15.520.4.6 allTestCandidatesInvalidated() bool smtrat::vs::State::allTestCandidatesInvalidated (
 const Condition * _condition) const
```

#### Parameters

|                |                                                                                              |
|----------------|----------------------------------------------------------------------------------------------|
| <code>A</code> | condition, which is one of the currently considered constraints to check for satisfiability. |
|----------------|----------------------------------------------------------------------------------------------|

#### Returns

true, if all test candidates provided by the given condition are no solution of the currently considered conjunction of constraints to check for satisfiability.

```
0.15.520.4.7 averageConstraintValuation() void smtrat::vs::State::averageConstraintValuation (
 const std::vector< std::pair< carl::Variable, std::multiset< double >>> & _←
 varVals)
```

```
0.15.520.4.8 backendCallValuation() size_t smtrat::vs::State::backendCallValuation () const
[inline]
```

**Returns**

The valuation of the state's considered conditions for a possible backend call.

```
0.15.520.4.9 bestCondition() bool smtrat::vs::State::bestCondition (
 const Condition *& _bestCondition,
 size_t _numberOfAllVariables,
 bool _preferEquation)
```

Determines the most adequate condition and in it the most adequate variable in the state to generate test candidates for.

**Parameters**

|                                    |                                                                             |
|------------------------------------|-----------------------------------------------------------------------------|
| <code>_bestCondition</code>        | The most adequate condition to be the next test candidate provider.         |
| <code>_numberOfAllVariables</code> | The number of all globally known variables.                                 |
| <code>_preferEquation</code>       | A flag that indicates to prefer equations in the heuristics of this method. |

**Returns**

true, if it has a condition and a variable in it to generate test candidates for; false, otherwise.

```
0.15.520.4.10 bestConstraintValuation() void smtrat::vs::State::bestConstraintValuation (
 const std::vector< std::pair< carl::Variable, std::multiset< double >>> & _←
 varVals)
```

```
0.15.520.4.11 cannotBeSolved() bool smtrat::vs::State::cannotBeSolved (
 bool _lazy) const [inline]
```

**Returns**

A constant reference to the flag indicating whether a condition with too high degree for the virtual substitution method must be considered.

```
0.15.520.4.12 checkSubresultCombinations() bool smtrat::vs::State::checkSubresultCombinations (
) const
```

This is just for debug purpose.

**Returns**

true, if no subresult combination is illegal.

```
0.15.520.4.13 checkTestCandidatesForBounds() bool smtrat::vs::State::checkTestCandidatesFor←
Bounds ()
```

Checks whether the test candidate of this state is valid against the variable intervals in the father of this state.

**Returns**

true, if the test candidate of this state is valid against the variable intervals; false, otherwise.

**0.15.520.4.14 children()** const std::list<[State](#)\*>& smtrat::vs::State::children () const [inline]**Returns**

A constant reference to the vector of the children of this state.

**0.15.520.4.15 conditions()** const [ConditionList](#)& smtrat::vs::State::conditions () const [inline]**Returns**

A constant reference to the currently considered conditions of this state.

**0.15.520.4.16 conditionsSimplified()** bool smtrat::vs::State::conditionsSimplified () const [inline]**Returns**

true, if the considered conditions of this state are already simplified.

**0.15.520.4.17 conflictSets()** const [ConflictSets](#)& smtrat::vs::State::conflictSets () const [inline]**Returns**

A constant reference to the conflict sets of this state.

**0.15.520.4.18 constraintExists()** ConditionList::iterator smtrat::vs::State::constraintExists (const [smtrat::ConstraintT](#) & *\_constraint*)

Checks if the given constraint already exists as condition in the state.

**Parameters**

|                    |                                                                                            |
|--------------------|--------------------------------------------------------------------------------------------|
| <i>_constraint</i> | The constraint, for which we want to know, if it already exists as condition in the state. |
|--------------------|--------------------------------------------------------------------------------------------|

**Returns**

An iterator to the condition, which involves the constraint or an iterator to the end of the vector of conditions of this state.

**0.15.520.4.19 containsState()** bool smtrat::vs::State::containsState (const [State](#) \* *\_state*) const**Returns**

true, if the given state is a node in the state tree starting at this node; false, otherwise.

**0.15.520.4.20 coveringSet()** size\_t smtrat::vs::State::coveringSet (const [ConditionSetSet](#) & *\_conflictSets*, carl::PointerSet< [Condition](#) > & *\_minCovSet*, unsigned *\_currentTreeDepth*) [static]

Finds a covering set of a vector of sets of sets due to some heuristics.

**Parameters**

|                                |                                                                                   |
|--------------------------------|-----------------------------------------------------------------------------------|
| <code>_conflictSets</code>     | The vector of sets of sets, for which the method finds all minimum covering sets. |
| <code>_minCovSet</code>        | The found minimum covering set.                                                   |
| <code>_currentTreeDepth</code> | The tree depth of the state from which this method is invoked.                    |

**Returns**

The greatest level, where a condition of the covering set has been created.

**0.15.520.4.21 `currentRangeSize()`** `size_t smtrat::vs::State::currentRangeSize ( ) const [inline]`

```
0.15.520.4.22 deleteConditions() void smtrat::vs::State::deleteConditions (
 carl::PointerSet< Condition > & _conditionsToDelete,
 ValuationMap & _ranking)
```

Delete everything originated by the given conditions from the entire subtree with this state as root.

**Parameters**

|                                  |                           |
|----------------------------------|---------------------------|
| <code>_conditionsToDelete</code> | The conditions to delete. |
|----------------------------------|---------------------------|

```
0.15.520.4.23 deleteOrigins() int smtrat::vs::State::deleteOrigins (
 carl::PointerSet< Condition > & _originsToDelete,
 ValuationMap & _ranking)
```

Removes everything in this state originated by the given vector of conditions.

**Parameters**

|                               |                                                                                                      |
|-------------------------------|------------------------------------------------------------------------------------------------------|
| <code>_originsToDelete</code> | The conditions for which everything in this state which has been originated by them must be removed. |
|-------------------------------|------------------------------------------------------------------------------------------------------|

**Returns**

0, if this state got invalid and must be deleted afterwards; -1, if this state got invalid and must be deleted afterwards and made other states unnecessary to consider; 1, otherwise.

```
0.15.520.4.24 deleteOriginsFromChildren() void smtrat::vs::State::deleteOriginsFromChildren (
 carl::PointerSet< Condition > & _originsToDelete,
 ValuationMap & _ranking)
```

Deletes everything originated by the given conditions in the children of this state.

**Parameters**

|                               |                                                                  |
|-------------------------------|------------------------------------------------------------------|
| <code>_originsToDelete</code> | The condition for which to delete everything originated by them. |
|-------------------------------|------------------------------------------------------------------|

```
0.15.520.4.25 deleteOriginsFromConflictSets() void smtrat::vs::State::deleteOriginsFromConflictSets (
```

```
carl::PointerSet< Condition > & _originsToDelete,
bool _originsAreCurrentConditions)
```

Deletes everything originated by the given conditions in the conflict sets of this state.

#### Parameters

|                                           |                                                                                                                                                                                                          |
|-------------------------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>_originsToDelete</code>             | The condition for which to delete everything originated by them.                                                                                                                                         |
| <code>_originsAreCurrentConditions</code> | A flag indicating whether the origins to remove stem from conditions of the currently considered condition vector of the father of this state and not, e.g., from somewhere in its substitution results. |

**0.15.520.4.26 `deleteOriginsFromSubstitutionResults()`** void smtrat::vs::State::deleteOriginsFromSubstitutionResults (

```
carl::PointerSet< Condition > & _originsToDelete)
```

Deletes everything originated by the given conditions in the substitution results of this state.

#### Parameters

|                               |                                                                   |
|-------------------------------|-------------------------------------------------------------------|
| <code>_originsToDelete</code> | The conditions for which to delete everything originated by them. |
|-------------------------------|-------------------------------------------------------------------|

**0.15.520.4.27 `extendSubResultCombination()`** bool smtrat::vs::State::extendSubResultCombination ( )

Extends the currently considered combination of conjunctions in the substitution results.

**0.15.520.4.28 `father()`** const State& smtrat::vs::State::father ( ) const [inline]

#### Returns

A constant reference to the father of this state. This method fails if this state is the root.

**0.15.520.4.29 `getCurrentSubresultCombination()`** ConditionList smtrat::vs::State::getCurrentSubresultCombination ( ) const

Gets the current substitution result combination as condition vector.

#### Returns

The current substitution result combination as condition vector.

**0.15.520.4.30 `getNextIntTestCandidate()`** bool smtrat::vs::State::getNextIntTestCandidate (

```
smtrat::Rational & _nextIntTestCandidate,
```

```
size_t _maxIntRange)
```

**0.15.520.4.31 `getNumberOfCurrentSubresultCombination()`** size\_t smtrat::vs::State::getNumberOfCurrentSubresultCombination ( ) const

#### Returns

The number of the current substitution result combination.

**0.15.520.4.32 hasChildrenToInsert()** `bool smtrat::vs::State::hasChildrenToInsert () const [inline]`

Returns

A constant reference to the flag indicating whether there are states that are children of this state and must be still considered in the further progress of finding a solution.

**0.15.520.4.33 hasChildWithID()** `bool smtrat::vs::State::hasChildWithID () const`

Checks whether a child exists, which has no ID ( $\neq 0$ ).

Returns

true, if there exists a child with ID ( $\neq 0$ ); false, otherwise.

**0.15.520.4.34 hasFurtherUncheckedTestCandidates()** `bool smtrat::vs::State::hasFurtherUncheckedTestCandidates () const`

Checks whether there exist more than one test candidate, which has still not been checked.

Returns

true, if there exist more than one test candidate, which has still not been checked; false, otherwise.

**0.15.520.4.35 hasInfinityChild()** `bool smtrat::vs::State::hasInfinityChild () const [inline]`**0.15.520.4.36 hasLocalConflict()** `bool smtrat::vs::State::hasLocalConflict ()`

Checks whether the currently considered conditions, which have been considered for test candidate construction, form already a conflict.

Returns

true, if they form a conflict; false, otherwise.

**0.15.520.4.37 hasNoninvolvedCondition()** `bool smtrat::vs::State::hasNoninvolvedCondition () const`

Checks whether a condition exists, which was not involved in an elimination step.

Returns

true, if there exists a condition in the state, which was not already involved in an elimination step; false, otherwise.

**0.15.520.4.38 hasOnlyInconsistentChildren()** `bool smtrat::vs::State::hasOnlyInconsistentChildren () const`

Checks whether a child exists, which is not yet marked as inconsistent.

Returns

true, if there exists such a child; false, otherwise.

**0.15.520.4.39 hasRecentlyAddedConditions()** `bool smtrat::vs::State::hasRecentlyAddedConditions( ) const [inline]`

**Returns**

true, if this state has a recently added condition in its considered conditions.

**0.15.520.4.40 hasRootsInVariableBounds()** `bool smtrat::vs::State::hasRootsInVariableBounds( const Condition * _condition, bool _useSturmSequence )`

Checks whether there are no zeros for the left-hand side of the constraint of the given condition.

**Parameters**

|                         |                                                                                            |
|-------------------------|--------------------------------------------------------------------------------------------|
| <code>_condition</code> | The condition to check.                                                                    |
| <code>A</code>          | flag that indicates whether to include Sturm's sequences and root counting in this method. |

**Returns**

true, if the constraint of the left-hand side of the given condition has no roots in the variable bounds of this state; false, otherwise.

**0.15.520.4.41 hasSubResultsCombination()** `bool smtrat::vs::State::hasSubResultsCombination( ) const [inline]`

**Returns**

true, if this state has a substitution result combination.

**0.15.520.4.42 hasSubstitutionResults()** `bool smtrat::vs::State::hasSubstitutionResults( ) const [inline]`

**Returns**

true, if this state has substitution results.

**0.15.520.4.43 id()** `size_t smtrat::vs::State::id( ) const [inline]`

**Returns**

The id of this state.

**0.15.520.4.44 index()** `carl::Variable::Arg smtrat::vs::State::index( ) const [inline]`

**Returns**

A constant reference to the variable which is going to be eliminated from this state's considered conditions.  
Note, if there is no variable decided to be eliminated, this method will fail.

**0.15.520.4.45 initConditionFlags()** `void smtrat::vs::State::initConditionFlags( )`

Sets all flags of the conditions to true, if it contains the variable given by the states index.

```
0.15.520.4.46 initIndex() bool smtrat::vs::State::initIndex (
 const carl::Variables & _allVariables,
 const smtrat::VariableValuationStrategy & _vvstrat,
 bool _preferEquation,
 bool _tryDifferentVarOrder = false,
 bool _useFixedVariableOrder = false)
```

Sets, if it has not already happened, the index of the state to the name of the most adequate variable.

Which variable is taken depends on heuristics.

#### Parameters

|                                    |                                                                             |
|------------------------------------|-----------------------------------------------------------------------------|
| <code>_allVariables</code>         | All globally known variables.                                               |
| <code>_vvstrat</code>              | The strategy according which we choose the variable.                        |
| <code>_preferEquation</code>       | A flag that indicates to prefer equations in the heuristics of this method. |
| <code>_tryDifferentVarOrder</code> |                                                                             |

```
0.15.520.4.47 isInconsistent() bool smtrat::vs::State::isInconsistent () const [inline]
```

#### Returns

true if this state's considered conditions are inconsistent; false, otherwise, which does not necessarily mean that this state is consistent.

```
0.15.520.4.48 isRoot() bool smtrat::vs::State::isRoot () const [inline]
```

#### Returns

The root of the state tree where this state is part from.

```
0.15.520.4.49 markedAsDeleted() bool smtrat::vs::State::markedAsDeleted () const [inline]
```

#### Returns

A constant reference to the flag indicating whether this state is marked as deleted, which means that there is no need to consider it in the further progress of finding a solution.

```
0.15.520.4.50 maxIntTestCandidate() const smtrat::Rational& smtrat::vs::State::maxIntTest<->
Candidate () const [inline]
```

```
0.15.520.4.51 minIntTestCandidate() const smtrat::Rational& smtrat::vs::State::minIntTest<->
Candidate () const [inline]
```

```
0.15.520.4.52 nextSubResultCombination() bool smtrat::vs::State::nextSubResultCombination ()
```

If the state contains a substitution result, which is a conjunction of disjunctions of conjunctions of conditions, this method sets the current combination to the disjunctions to the next combination.

#### Returns

true, if there is a next combination; false, otherwise.

**0.15.520.4.53 `numberOfNodes()`** `unsigned smtrat::vs::State::numberOfNodes ( ) const`  
Determines the number of nodes in the tree with this state as root.

**Returns**

The number of nodes in the tree with this state as root.

**0.15.520.4.54 `occursInEquation()`** `bool smtrat::vs::State::occursInEquation (`  
`const carl::Variable & _variable ) const`  
Checks whether the given variable occurs in a equation.

**Returns**

true, if the given variable occurs in a equation; false, otherwise.

**0.15.520.4.55 `originalCondition()`** `const Condition& smtrat::vs::State::originalCondition ( ) const [inline]`

**Returns**

A reference to the original conditions of this state. Note that if there is no such condition, this method fails. For further information see the description of the corresponding member.

**0.15.520.4.56 `passConflictToFather()`** `void smtrat::vs::State::passConflictToFather (`  
`bool _checkConflictForSideCondition,`  
`bool _useBackjumping = true,`  
`bool _includeInconsistentTestCandidates = false )`

Passes the original conditions of the covering set of the conflicts of this state to its father.

**Parameters**

|                                                 |                                                                                                                                                        |
|-------------------------------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>_checkConflictForSideCondition</code>     | If this flag is set to false it might save some computations but leads to an over-approximative behavior. Recommendation: set it to true.              |
| <code>_includeInconsistentTestCandidates</code> | If this flag is set to true the conflict analysis takes also the invalid test candidates' conflict sets into account. Recommendation: set it to false. |
| <code>_useBackjumping</code>                    | If true, we use the backjumping technique.                                                                                                             |

**0.15.520.4.57 `pFather()`** `State* smtrat::vs::State::pFather ( ) const [inline]`

**Returns**

A pointer to the father of this state. It is NULL if this state is the root.

**0.15.520.4.58 `pOriginalCondition()`** `const Condition* smtrat::vs::State::pOriginalCondition ( ) const [inline]`

**Returns**

A pointer to the original condition of this state or NULL, if there is no such condition. For further information see the description of the corresponding member.

```
0.15.520.4.59 print() void smtrat::vs::State::print (
 const std::string _initiation = "***",
 std::ostream & _out = std::cout) const
```

Prints the conditions, the substitution and the substitution results of this state and all its children.

#### Parameters

|                          |                                                          |
|--------------------------|----------------------------------------------------------|
| <code>_initiation</code> | A string which is printed in the beginning of every row. |
| <code>_out</code>        | The stream to print on.                                  |

```
0.15.520.4.60 printAlone() void smtrat::vs::State::printAlone (
 const std::string _initiation = "***",
 std::ostream & _out = std::cout) const
```

Prints the conditions, the substitution and the substitution results of this state.

#### Parameters

|                          |                                                          |
|--------------------------|----------------------------------------------------------|
| <code>_initiation</code> | A string which is printed in the beginning of every row. |
| <code>_out</code>        | The stream to print on.                                  |

```
0.15.520.4.61 printConditions() void smtrat::vs::State::printConditions (
 const std::string _initiation = "***",
 std::ostream & _out = std::cout,
 bool _onlyAsConstraints = false) const
```

Prints the conditions of this state.

#### Parameters

|                          |                                                          |
|--------------------------|----------------------------------------------------------|
| <code>_initiation</code> | A string which is printed in the beginning of every row. |
| <code>_out</code>        | The stream to print on.                                  |

```
0.15.520.4.62 printConflictSets() void smtrat::vs::State::printConflictSets (
 const std::string _initiation = "***",
 std::ostream & _out = std::cout) const
```

Prints the conflict sets of this state.

#### Parameters

|                          |                                                          |
|--------------------------|----------------------------------------------------------|
| <code>_initiation</code> | A string which is printed in the beginning of every row. |
| <code>_out</code>        | The stream to print on.                                  |

```
0.15.520.4.63 printSubstitutionResultCombination() void smtrat::vs::State::printSubstitution<-
ResultCombination (
 const std::string _initiation = "***",
 std::ostream & _out = std::cout) const
```

Prints the combination of substitution results used in this state.

## Parameters

|                    |                                                          |
|--------------------|----------------------------------------------------------|
| <i>_initiation</i> | A string which is printed in the beginning of every row. |
| <i>_out</i>        | The stream to print on.                                  |

**0.15.520.4.64 printSubstitutionResultCombinationAsNumbers()** void smtrat::vs::State::printSubstitutionResultCombinationAsNumbers (

```
 const std::string _initiation = "***",
 std::ostream & _out = std::cout) const
```

Prints the combination of substitution results, expressed in numbers, used in this state.

## Parameters

|                    |                                                          |
|--------------------|----------------------------------------------------------|
| <i>_initiation</i> | A string which is printed in the beginning of every row. |
| <i>_out</i>        | The stream to print on.                                  |

**0.15.520.4.65 printSubstitutionResults()** void smtrat::vs::State::printSubstitutionResults (

```
 const std::string _initiation = "***",
 std::ostream & _out = std::cout) const
```

Prints the substitution results of this state.

## Parameters

|                    |                                                          |
|--------------------|----------------------------------------------------------|
| <i>_initiation</i> | A string which is printed in the beginning of every row. |
| <i>_out</i>        | The stream to print on.                                  |

**0.15.520.4.66 pSubstitution()** const Substitution\* smtrat::vs::State::pSubstitution ( ) const

[inline]

## Returns

A pointer to the substitution of this state, which is NULL, if this state is the root.

**0.15.520.4.67 rCannotBeSolved()** bool& smtrat::vs::State::rCannotBeSolved ( ) [inline]

## Returns

A reference to the flag indicating whether a condition with too high degree for the virtual substitution method must be considered.

**0.15.520.4.68 rCannotBeSolvedLazy()** bool& smtrat::vs::State::rCannotBeSolvedLazy ( ) [inline]

## Returns

A reference to the flag indicating whether a condition with too high degree for the virtual substitution method must be considered.

**0.15.520.4.69 rChildren()** `std::list<State*>& smtrat::vs::State::rChildren () [inline]`

Returns

A reference to the vector of the children of this state.

**0.15.520.4.70 rConditions()** `ConditionList& smtrat::vs::State::rConditions () [inline]`

Returns

A reference to the currently considered conditions of this state.

**0.15.520.4.71 rConflictSets()** `ConflictSets& smtrat::vs::State::rConflictSets () [inline]`

Returns

A reference to the conflict sets of this state.

**0.15.520.4.72 refreshConditions()** `bool smtrat::vs::State::refreshConditions ( ValuationMap & _ranking )`

Determines the condition vector corresponding to the current combination of the conjunctions of conditions.

Returns

true, if there has been a change in the currently considered condition vector. false, otherwise.

**0.15.520.4.73 removeStatesFromRanking()** `void smtrat::vs::State::removeStatesFromRanking ( const State & toRemove, ValuationMap & _ranking ) [static]`

**0.15.520.4.74 resetCannotBeSolvedLazyFlags()** `void smtrat::vs::State::resetCannotBeSolvedLazyFlags ()`

**0.15.520.4.75 resetConflictSets()** `void smtrat::vs::State::resetConflictSets ()`  
Clears the conflict sets.

**0.15.520.4.76 resetCurrentRangeSize()** `void smtrat::vs::State::resetCurrentRangeSize () [inline]`

**0.15.520.4.77 resetInfinityChild()** `void smtrat::vs::State::resetInfinityChild ( const State * _state ) [inline]`

**0.15.520.4.78 rFather()** `State& smtrat::vs::State::rFather () [inline]`

Returns

A reference to the father of this state. This method fails if this state is the root.

**0.15.520.4.79 rHasChildrenToInsert()** `bool& smtrat::vs::State::rHasChildrenToInsert () [inline]`

Returns

A reference to the flag indicating whether there are states that are children of this state and must be still considered in the further progress of finding a solution.

**0.15.520.4.80 rHasRecentlyAddedConditions()** `bool& smtrat::vs::State::rHasRecentlyAddedConditions () [inline]`

Returns

A reference to the flag indicating that this state has a recently added condition in its considered conditions.

**0.15.520.4.81 rID()** `size_t& smtrat::vs::State::rID () [inline]`

Returns

A reference to the id of this state.

**0.15.520.4.82 rInconsistent()** `bool& smtrat::vs::State::rInconsistent () [inline]`

Returns

A reference to the flag indicating whether this state's considered conditions are inconsistent. Note that if it is false, it does not necessarily mean that this state is consistent.

**0.15.520.4.83 rMarkedAsDeleted()** `bool& smtrat::vs::State::rMarkedAsDeleted () [inline]`

Returns

A reference to the flag indicating whether this state is marked as deleted, which means that there is no need to consider it in the further progress of finding a solution.

**0.15.520.4.84 root()** `State & smtrat::vs::State::root ()`

Returns

The root of the tree, in which this state is located.

**0.15.520.4.85 rSubResultCombination()** `SubResultCombination& smtrat::vs::State::rSubResultCombination () [inline]`

Returns

A reference to the current combination of conjunction of constraints within the substitution results of this state. Make sure that a substitution result combination exists when calling this method. (using, e.g., [hasSubResultsCombination\(\)](#))

**0.15.520.4.86 rSubResultsSimplified()** `bool& smtrat::vs::State::rSubResultsSimplified ()` [inline]

Returns

A reference to the flag indicating whether the substitution results of this state are already simplified.

**0.15.520.4.87 rSubstitution()** `Substitution& smtrat::vs::State::rSubstitution ()` [inline]

Returns

A reference to the substitution this state considers. Note that this method fails, if this state is the root.

**0.15.520.4.88 rSubstitutionResults()** `SubstitutionResults& smtrat::vs::State::rSubstitutionResults ()` [inline]

Returns

A reference to the substitution results of this state. Make sure that the substitution results exist when calling this method. (using, e.g., `hasSubstitutionResults()`)

**0.15.520.4.89 rTakeSubResultCombAgain()** `bool& smtrat::vs::State::rTakeSubResultCombAgain ()` [inline]

Returns

A reference to the flag indicating whether the current substitution result combination has to be consider once again before considering the next one.

**0.15.520.4.90 rTooHighDegreeConditions()** `carl::PointerSet<Condition>& smtrat::vs::State::rTooHighDegreeConditions ()` [inline]

Returns

A reference to the conditions of those this state currently considers, which have a too high degree to be tackled of the virtual substitution method.

**0.15.520.4.91 rType()** `Type& smtrat::vs::State::rType ()` [inline]

Returns

A constant reference to the type of this state: This state has still a substitution to apply or either test candidates shall be generated or a new combination of the substitution results must be found in order to consider it next.

**0.15.520.4.92 rVariableBounds()** `VariableBoundsCond& smtrat::vs::State::rVariableBounds ()` [inline]

Returns

A reference to the object managing and storing the variable's bounds which were extracted from the currently considered conditions of this state.

**0.15.520.4.93 setIndex()** `void smtrat::vs::State::setIndex (const carl::Variable & _index )`

Sets the index of this state.

## Parameters

|                     |                                              |
|---------------------|----------------------------------------------|
| <code>_index</code> | The string to which the index should be set. |
|---------------------|----------------------------------------------|

**0.15.520.4.94 `setInfinityChild()`** `void smtrat::vs::State::setInfinityChild ( State * _state ) [inline]`

**0.15.520.4.95 `setOriginalCondition()`** `void smtrat::vs::State::setOriginalCondition ( const Condition * _pOCondition ) [inline]`

Sets the pointer of the original condition of this state to the given pointer to a condition.

## Parameters

|                           |                                               |
|---------------------------|-----------------------------------------------|
| <code>_pOCondition</code> | The pointer to set the original condition to. |
|---------------------------|-----------------------------------------------|

**0.15.520.4.96 `simplify()` [1/2]** `bool smtrat::vs::State::simplify ( ConditionList & _conditionVectorToSimplify, ConditionSetSet & _conflictSet, ValuationMap & _ranking, bool _stateConditions = false )`

Simplifies the given conditions according to comparison between the corresponding constraints.

## Parameters

|                                         |                                                                                                                                                                        |
|-----------------------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>_conditionVectorToSimplify</code> | The conditions to simplify. Note, that this method can change these conditions.                                                                                        |
| <code>_conflictSet</code>               | All conflicts this method detects in the given conditions are stored in here.                                                                                          |
| <code>_stateConditions</code>           | A flag indicating whether the conditions to simplify are from the considered condition vector of this state and not, e.g., from somewhere in its substitution results. |

## Returns

true, if the conditions are not obviously conflicting; false, otherwise.

**0.15.520.4.97 `simplify()` [2/2]** `void smtrat::vs::State::simplify ( ValuationMap & _ranking )`

Cleans up all conditions in this state according to comparison between the corresponding constraints.

**0.15.520.4.98 `solutionSpace()`** `std::vector< smtrat::DoubleInterval > smtrat::vs::State::solutionSpace ( carl::PointerSet< Condition > & _conflictReason ) const`

Determines the solution space of the test candidate of this state regarding to the variable bounds of the father. The solution space consists of one or two disjoint intervals.

## Parameters

|                              |                                                                                                        |
|------------------------------|--------------------------------------------------------------------------------------------------------|
| <code>_conflictReason</code> | If the solution space is empty, the conditions being responsible for this conflict are stored in here. |
|------------------------------|--------------------------------------------------------------------------------------------------------|

**Returns**

The disjoint intervals representing the solution space.

**0.15.520.4.99 subResultCombination()** const `SubResultCombination&` `smtrat::vs::State::subResultCombination()` const [inline]

**Returns**

A constant reference to the current combination of conjunction of constraints within the substitution results of this state. Make sure that a substitution result combination exists when calling this method. (using, e.g., `hasSubResultsCombination()`)

**0.15.520.4.100 subResultsSimplified()** bool `smtrat::vs::State::subResultsSimplified()` const [inline]

**Returns**

true, if the substitution results of this state are already simplified.

**0.15.520.4.101 substitution()** const `Substitution&` `smtrat::vs::State::substitution()` const [inline]

**Returns**

A constant reference to the substitution this state considers. Note that this method fails, if this state is the root.

**0.15.520.4.102 substitutionApplicable() [1/2]** bool `smtrat::vs::State::substitutionApplicable()` const  
Checks if a substitution can be applied.

**Returns**

true, if a substitution can be applied. false, else.

**0.15.520.4.103 substitutionApplicable() [2/2]** bool `smtrat::vs::State::substitutionApplicable()` const  
const `smtrat::ConstraintT & _constraint` const  
Checks if the substitution of this state can be applied to the given constraint.

**Parameters**

|                          |                                                                               |
|--------------------------|-------------------------------------------------------------------------------|
| <code>_constraint</code> | The constraint, for which we want to know, if the substitution is applicable. |
|--------------------------|-------------------------------------------------------------------------------|

**Returns**

true, if the substitution can be applied; false, otherwise.

**0.15.520.4.104 substitutionResults()** const `SubstitutionResults&` `smtrat::vs::State::substitutionResults()` const [inline]

**Returns**

A constant reference to the substitution results of this state. Make sure that the substitution results exist when calling this method. (using, e.g., [hasSubstitutionResults\(\)](#))

**0.15.520.4.105 `takeSubResultCombAgain()`** `bool smtrat::vs::State::takeSubResultCombAgain ( )`

`const [inline]`

**Returns**

true, if the current substitution result combination has to be consider once again before considering the next one.

**0.15.520.4.106 `tooHighDegreeConditions()`** `const carl::PointerSet<Condition>& smtrat::vs::vs::State::tooHighDegreeConditions ( ) const [inline]`**Returns**

A constant reference to the conditions of those this state currently considers, which have a too high degree to be tackled of the virtual substitution method.

**0.15.520.4.107 `treeDepth()`** `unsigned smtrat::vs::State::treeDepth ( ) const`**Returns**

The depth of the subtree with this state as root node.

**0.15.520.4.108 `tryToRefreshIndex()`** `bool smtrat::vs::State::tryToRefreshIndex ( ) const [inline]`**Returns**

true, if the index variable of this state shall be recalculated.

**0.15.520.4.109 `type()`** `Type smtrat::vs::State::type ( ) const [inline]`**Returns**

The type of this state: This state has still a substitution to apply or either test candidates shall be generated or a new combination of the substitution results must be found in order to consider it next.

**0.15.520.4.110 `unfinished()`** `bool smtrat::vs::State::unfinished ( ) const [inline]`**Returns**

true, if the currently considered substitution result combination can be extended by taking further substitution results into account.

**0.15.520.4.111 `unfinishedAncestor()`** `bool smtrat::vs::State::unfinishedAncestor ( State *& _unfinAnt )`

Determines (if it exists) a ancestor node, which is unfinished, that is it has still substitution results to consider.

**Parameters**

|                        |                               |
|------------------------|-------------------------------|
| <code>_unfinAnt</code> | The unfinished ancestor node. |
|------------------------|-------------------------------|

**Returns**

true, if it has a unfinished ancestor; false, otherwise.

**0.15.520.4.112 updateBackendCallValuation()** `void smtrat::vs::State::updateBackendCallValuation( )`

Valuates the state's currently considered conditions according to a backend call.

Note: The settings are currently optimized for CAD backend calls.

**0.15.520.4.113 updateIntTestCandidates()** `bool smtrat::vs::State::updateIntTestCandidates( )`

**0.15.520.4.114 updateOcondsOfSubstitutions()** `bool smtrat::vs::State::updateOcondsOfSubstitutions( )`

```
const Substitution & _substitution,
std::vector< State * > & _reactivatedStates)
```

Updates the original conditions of substitutions having the same test candidate as the given.

**Parameters**

|                                 |                                                              |
|---------------------------------|--------------------------------------------------------------|
| <code>_substitution</code>      | The substitution containing the test candidate to check for. |
| <code>_reactivatedStates</code> |                                                              |

**Returns**

true, if the test candidate of the given substitution was already generated; false, otherwise.

**0.15.520.4.115 updateValuation()** `void smtrat::vs::State::updateValuation( bool _lazy )`

Updates the valuation of this state.

**0.15.520.4.116 valuation()** `size_t smtrat::vs::State::valuation( ) const [inline]`

**Returns**

The heuristically determined valuation of this state (see for the description of the corresponding member).

**0.15.520.4.117 variableBounds()** `const VariableBoundsCond& smtrat::vs::State::variableBounds( ) const [inline]`

**Returns**

A constant reference to the object managing and storing the variable's bounds which were extracted from the currently considered conditions of this state.

**0.15.520.4.118 variables()** void smtrat::vs::State::variables ( carl::Variables & *\_variables* ) const  
Finds the variables, which occur in this state.

**Parameters**

|                         |                                          |
|-------------------------|------------------------------------------|
| <code>_variables</code> | The variables which occur in this state. |
|-------------------------|------------------------------------------|

```
0.15.520.4.119 worstConstraintValuation() void smtrat::vs::State::worstConstraintValuation (const std::vector< std::pair< carl::Variable, std::multiset< double >>> & _← varVals)
```

## 0.15.521 **smtrat::StaticUnionFind** Struct Reference

## 0.15.524 delta::String Class Reference

This class can be used to create `std::string` objects using streaming operators.  
`#include <utils.h>`

### Public Member Functions

- `template<typename T >`  
`String & operator<< (const T &t)`  
*Add some data to the string.*
- `operator std::string () const`  
*Return data as string.*

### 0.15.524.1 Detailed Description

This class can be used to create `std::string` objects using streaming operators.

### 0.15.524.2 Member Function Documentation

**0.15.524.2.1 operator std::string()** `delta::String::operator std::string ( ) const [inline]`  
 Return data as string.

Returns

Data as string.

**0.15.524.2.2 operator<<()** `template<typename T >`  
`String& delta::String::operator<< (`  
`const T & t ) [inline]`  
 Add some data to the string.

Parameters

|                |       |
|----------------|-------|
| <code>t</code> | Data. |
|----------------|-------|

Returns

`*this`

## 0.15.525 Minisat::StringOption Class Reference

#include <Options.h>

### Public Member Functions

- `StringOption` (const char \*c, const char \*n, const char \*d, const char \*def=NULL)
- `operator const char *` (void) const
- `StringOption & operator=` (const char \*x)
- virtual void `help` (bool verbose=false)

*Prints the vector of the received formula.*
- void `printPassedFormula` (const std::string & \_initiation="\*\*\*") const  
*Prints the vector of passed formula.*
- void `printInfeasibleSubsets` (const std::string & \_initiation="\*\*\*") const  
*Prints the infeasible subsets.*
- void `printModel` (std::ostream & \_out=std::cout) const  
*Prints the assignment of this module satisfying its received formula if it satisfiable and this module could find an assignment.*
- void `printAllModels` (std::ostream & \_out=std::cout)  
*Prints all assignments of this module satisfying its received formula if it satisfiable and this module could find an assignment.*

### Static Public Member Functions

- static void `freeSplittingVariable` (const `FormulaT` & \_splittingVariable)

### Static Public Attributes

- static size\_t `mNumOfBranchVarsToStore` = 5  
*The number of different variables to consider for a probable infinite loop of branchings.*
- static std::vector< `Branching` > `mLastBranches` = std::vector<`Branching`>(mNumOfBranchVarsToStore, `Branching`(typename Poly::PolyType(), 0))  
*Stores the last branches in a cycle buffer.*
- static size\_t `mFirstPosInLastBranches` = 0  
*The beginning of the cyclic buffer storing the last branches.*
- static std::vector< `FormulaT` > `mOldSplittingVariables`  
*Reusable splitting variables.*

### Protected Member Functions

- virtual bool `informCore` (const `FormulaT` & \_constraint)  
*Informs the module about the given constraint.*
- virtual void `deinformCore` (const `FormulaT` & \_constraint)  
*The inverse of informing about a constraint.*
- bool `anAnswerFound` () const  
*Checks for all antecedent modules and those which run in parallel with the same antecedent modules, whether one of them has determined a result.*
- void `clearModel` () const  
*Clears the assignment, if any was found.*
- void `clearModels` () const  
*Clears all assignments, if any was found.*
- void `cleanModel` () const  
*Substitutes variable occurrences by its model value in the model values of other variables.*
- `ModuleInput::iterator` `passedFormulaBegin` ()
- `ModuleInput::iterator` `passedFormulaEnd` ()
- void `addOrigin` (`ModuleInput::iterator` \_formula, const `FormulaT` & \_origin)  
*Adds the given set of formulas in the received formula to the origins of the given passed formula.*
- const `FormulaT` & `getOrigins` (`ModuleInput::const_iterator` \_formula) const  
*Gets the origins of the passed formula at the given position.*
- void `getOrigins` (const `FormulaT` & \_formula, `FormulasT` & \_origins) const

- void `getOrigins` (const `FormulaT` &\_formula, `FormulaSetT` &\_origins) const
  - std::pair< `ModuleInput::iterator`, bool > `removeOrigin` (`ModuleInput::iterator` \_formula, const `FormulaT` &\_origin)
    - std::pair< `ModuleInput::iterator`, bool > `removeOrigins` (`ModuleInput::iterator` \_formula, const std::shared\_ptr< std::vector< `FormulaT` >> &\_origins)
  - void `informBackends` (const `FormulaT` &\_constraint)
    - Informs all backends of this module about the given constraint.*
- virtual void `addConstraintToInform` (const `FormulaT` &\_constraint)
  - Adds a constraint to the collection of constraints of this module, which are informed to a freshly generated backend.*
- std::pair< `ModuleInput::iterator`, bool > `addReceivedSubformulaToPassedFormula` (`ModuleInput::const_iterator` \_subformula)
  - Copies the given sub-formula of the received formula to the passed formula.*
- bool `originInReceivedFormula` (const `FormulaT` &\_origin) const
  - std::pair< `ModuleInput::iterator`, bool > `addSubformulaToPassedFormula` (const `FormulaT` &\_formula)
    - Adds the given formula to the passed formula with no origin.*
  - std::pair< `ModuleInput::iterator`, bool > `addSubformulaToPassedFormula` (const `FormulaT` &\_formula, const std::shared\_ptr< std::vector< `FormulaT` >> &\_origins)
    - Adds the given formula to the passed formula.*
  - std::pair< `ModuleInput::iterator`, bool > `addSubformulaToPassedFormula` (const `FormulaT` &\_formula, const `FormulaT` &\_origin)
    - Adds the given formula to the passed formula.*
- void `generateTrivialInfeasibleSubset` ()
  - Stores the trivial infeasible subset being the set of received formulas.*
- void `receivedFormulasAsInfeasibleSubset` (`ModuleInput::const_iterator` \_subformula)
  - Stores an infeasible subset consisting only of the given received formula.*
- std::vector< `FormulaT` >::const\_iterator `findBestOrigin` (const std::vector< `FormulaT` > &\_origins) const
  - void `getInfeasibleSubsets` ()
    - Copies the infeasible subsets of the passed formula.*
  - std::vector< `FormulaSetT` > `getInfeasibleSubsets` (const `Module` &\_backend) const
    - Get the infeasible subsets the given backend provides.*
  - const `Model` & `backendsModel` () const
    - Stores the model of a backend which determined satisfiability of the passed formula in the model of this module.*
  - void `getBackendsModel` () const
    - Stores all models of a backend in the list of all models of this module.*
  - void `getBackendsAllModels` () const
    - Runs the backend solvers on the passed formula.*
  - virtual `Answer` `runBackends` (bool \_final, bool \_full, carl::Variable \_objective)
    - Runs the backend solvers on the passed formula.*
  - virtual `ModuleInput::iterator` `eraseSubformulaFromPassedFormula` (`ModuleInput::iterator` \_subformula, bool \_ignoreOrigins=false)
    - Removes everything related to the sub-formula to remove from the passed formula in the backends of this module.*
  - void `clearPassedFormula` ()
    - std::vector< `FormulaT` > `merge` (const std::vector< `FormulaT` > &, const std::vector< `FormulaT` > &) const
      - Merges the two vectors of sets into the first one.*
    - size\_t `determine_smallest_origin` (const std::vector< `FormulaT` > &origins) const
      - bool `probablyLooping` (const typename Poly::PolyType &\_branchingPolynomial, const Rational &\_branchingValue) const
        - Checks whether given the current branching value and branching variable/polynomial it is (highly) probable that this branching is part of an infinite loop of branchings.*
      - bool `branchAt` (const Poly &\_polynomial, bool \_integral, const Rational &\_value, std::vector< `FormulaT` > &&\_premise, bool \_leftCaseWeak=true, bool \_preferLeftCase=true, bool \_useReceivedFormulaAsPremise=false)
        - Branches at the given polynomial and value, using the given premise.*

- Adds a lemmas which provoke a branching for the given variable at the given value, if this module returns Unknown and there exists a preceding SATModule.
- bool `branchAt` (const `Poly` &\_polynomial, bool \_integral, const `Rational` &\_value, bool \_leftCaseWeak=true, bool \_preferLeftCase=true, bool \_useReceivedFormulaAsPremise=false, const std::vector<`FormulaT`> &\_premise=std::vector<`FormulaT`>())
  - bool `branchAt` (carl::Variable::Arg \_var, const `Rational` &\_value, std::vector<`FormulaT`> &&\_premise, bool \_leftCaseWeak=true, bool \_preferLeftCase=true, bool \_useReceivedFormulaAsPremise=false)
  - bool `branchAt` (carl::Variable::Arg \_var, const `Rational` &\_value, bool \_leftCaseWeak=true, bool \_preferLeftCase=true, bool \_useReceivedFormulaAsPremise=false, const std::vector<`FormulaT`> &\_premise=std::vector<`FormulaT`>())
    - void `splitUnequalConstraint` (const `FormulaT` &
 

Adds the following lemmas for the given constraint  $p \neq 0$ .
- unsigned `checkModel` () const
- void `addInformationRelevantFormula` (const `FormulaT` &formula)
  - Adds a formula to the InformationRelevantFormula.
- const std::set<`FormulaT`> & `getInformationRelevantFormulas` ()
  - Gets all InformationRelevantFormulas.
- bool `isLemmaLevel` (`LemmaLevel` level)
  - Checks if current lemma level is greater or equal to given level.

## Static Protected Member Functions

- static bool `modelsDisjoint` (const `Model` &\_modelA, const `Model` &\_modelB)
  - Checks whether there is no variable assigned by both models.

## Protected Attributes

- std::vector<`FormulaSetT`> `mInfeasibleSubsets`
  - Stores the infeasible subsets.
- `Manager` \*const `mpManager`
  - A reference to the manager.
- `Model` `mModel`
  - Stores the assignment of the current satisfiable result, if existent.
- std::vector<`Model`> `mAllModels`
  - Stores all satisfying assignments.
- bool `mModelComputed`
  - True, if the model has already been computed.
- bool `mFinalCheck`
  - true, if the check procedure should perform a final check which especially means not to postpone splitting decisions
- bool `mFullCheck`
  - false, if this module should avoid too expensive procedures and rather return unknown instead.
- carl::Variable `mObjectiveVariable`
  - Objective variable to be minimized. If set to NO\_VARIABLE, a normal sat check should be performed.
- std::vector<`TheoryPropagation`> `mTheoryPropagations`
- std::atomic<`Answer`> `mSolverState`
  - States whether the received formula is known to be satisfiable or unsatisfiable otherwise it is set to unknown.
- std::atomic\_bool \* `mBackendsFoundAnswer`
  - This flag is passed to any backend and if it determines an answer to a prior check call, this flag is fired.
- `Conditionals` `mFoundAnswer`
  - Vector of Booleans: If any of them is true, we have to terminate a running check procedure.
- std::vector<`Module`\*> `mUsedBackends`
  - The backends of this module which are currently used (conditions to use this module are fulfilled for the passed formula).

- `std::vector< Module * > mAllBackends`  
*The backends of this module which have been used.*
- `std::vector< Lemma > mLemmas`  
*Stores the lemmas being valid formulas this module or its backends made.*
- `ModuleInput::iterator mFirstSubformulaToPass`  
*Stores the position of the first sub-formula in the passed formula, which has not yet been considered for a consistency check of the backends.*
- `carl::FastSet< FormulaT > mConstraintsToInform`  
*Stores the constraints which the backends must be informed about.*
- `carl::FastSet< FormulaT > mInformedConstraints`  
*Stores the position of the first constraint of which no backend has been informed about.*
- `ModuleInput::const_iterator mFirstUncheckedReceivedSubformula`  
*Stores the position of the first (by this module) unchecked sub-formula of the received formula.*
- `unsigned mSmallerMusesCheckCounter`  
*Counter used for the generation of the smt2 files to check for smaller muses.*
- `std::vector< std::size_t > mVariableCounters`  
*Maps variables to the number of their occurrences.*

### 0.15.527.4 Member Function Documentation

**0.15.527.4.1 add()** `bool smtrat::Module::add (`  
 `ModuleInput::const_iterator _subformula ) [inherited]`

The module has to take the given sub-formula of the received formula into account.

**Parameters**

|                          |                                                    |
|--------------------------|----------------------------------------------------|
| <code>_subformula</code> | The sub-formula to take additionally into account. |
|--------------------------|----------------------------------------------------|

**Returns**

false, if it can be easily decided that this sub-formula causes a conflict with the already considered sub-formulas; true, otherwise.

**0.15.527.4.2 `addConstraintToInform()`** `void smtrat::Module::addConstraintToInform ( const FormulaT & _constraint ) [protected], [virtual], [inherited]`

Adds a constraint to the collection of constraints of this module, which are informed to a freshly generated backend.

**Parameters**

|                          |                        |
|--------------------------|------------------------|
| <code>_constraint</code> | The constraint to add. |
|--------------------------|------------------------|

Reimplemented in [smtrat::SATModule< Settings >](#).

**0.15.527.4.3 `addCore()`** `template<typename Settings > bool smtrat::STropModule< Settings >::addCore ( ModuleInput::const_iterator _subformula ) [virtual]`

The module has to take the given sub-formula of the received formula into account.

**Parameters**

|                          |                                                    |
|--------------------------|----------------------------------------------------|
| <code>_subformula</code> | The sub-formula to take additionally into account. |
|--------------------------|----------------------------------------------------|

**Returns**

False, if it can be easily decided that this sub-formula causes a conflict with the already considered sub-formulas; True, otherwise.

Reimplemented from [smtrat::Module](#).

**0.15.527.4.4 `addInformationRelevantFormula()`** `void smtrat::Module::addInformationRelevantFormula ( const FormulaT & formula ) [protected], [inherited]`

Adds a formula to the InformationRelevantFormula.

**Parameters**

|                      |                |
|----------------------|----------------|
| <code>formula</code> | Formula to add |
|----------------------|----------------|

**0.15.527.4.5 `addLemma()`** `void smtrat::Module::addLemma ( const FormulaT & _lemma, const LemmaType & _lt = LemmaType::NORMAL, const FormulaT & _preferredFormula = FormulaT( carl::FormulaType::TRUE ) ) [inline], [inherited]`

Stores a lemma being a valid formula.

**Parameters**

|                                |                                                                       |
|--------------------------------|-----------------------------------------------------------------------|
| <code>_lemma</code>            | The eduction/lemma to store.                                          |
| <code>_lt</code>               | The type of the lemma.                                                |
| <code>_preferredFormula</code> | Hint for the next decision, which formula should be assigned to true. |

**0.15.527.4.6 addOrigin()** `void smtrat::Module::addOrigin (`

```
 ModuleInput::iterator _formula,
 const FormulaT & _origin) [inline], [protected], [inherited]
```

Adds the given set of formulas in the received formula to the origins of the given passed formula.

**Parameters**

|                       |                                                           |
|-----------------------|-----------------------------------------------------------|
| <code>_formula</code> | The passed formula to set the origins for.                |
| <code>_origin</code>  | A set of formulas in the received formula of this module. |

**0.15.527.4.7 addReceivedSubformulaToPassedFormula()** `std::pair<ModuleInput::iterator,bool>`

```
smtrat::Module::addReceivedSubformulaToPassedFormula (
```

```
 ModuleInput::const_iterator _subformula) [inline], [protected], [inherited]
```

Copies the given sub-formula of the received formula to the passed formula.

Note, that there is always a link between sub-formulas of the passed formulas to sub-formulas of the received formulas, which are responsible for its occurrence.

**Parameters**

|                          |                                                  |
|--------------------------|--------------------------------------------------|
| <code>_subformula</code> | The sub-formula of the received formula to copy. |
|--------------------------|--------------------------------------------------|

**0.15.527.4.8 addSubformulaToPassedFormula() [1/3]** `std::pair<ModuleInput::iterator,bool>`

```
smtrat::Module::addSubformulaToPassedFormula (
```

```
 const FormulaT & _formula) [inline], [protected], [inherited]
```

Adds the given formula to the passed formula with no origin.

Note that in the next call of this module's removeSubformula, all formulas in the passed formula without origins will be removed.

**Parameters**

|                       |                                           |
|-----------------------|-------------------------------------------|
| <code>_formula</code> | The formula to add to the passed formula. |
|-----------------------|-------------------------------------------|

**Returns**

A pair to the position where the formula to add has been inserted (or its first sub-formula which has not yet been in the passed formula, in case the formula to add is a conjunction), and a Boolean stating whether anything has been added to the passed formula.

**0.15.527.4.9 addSubformulaToPassedFormula() [2/3]** `std::pair<ModuleInput::iterator,bool>`

```
smtrat::Module::addSubformulaToPassedFormula (
```

```
 const FormulaT & _formula,
```

```
 const FormulaT & _origin) [inline], [protected], [inherited]
```

Adds the given formula to the passed formula.

**Parameters**

|                       |                                                                                                                           |
|-----------------------|---------------------------------------------------------------------------------------------------------------------------|
| <code>_formula</code> | The formula to add to the passed formula.                                                                                 |
| <code>_origin</code>  | The sub-formula of the received formula being responsible for the occurrence of the formula to add to the passed formula. |

**Returns**

A pair to the position where the formula to add has been inserted (or its first sub-formula which has not yet been in the passed formula, in case the formula to add is a conjunction), and a Boolean stating whether anything has been added to the passed formula.

**0.15.527.4.10 `addSubformulaToPassedFormula()` [3/3] `std::pair<ModuleInput::iterator,bool>`**

```
smrat::Module::addSubformulaToPassedFormula (
 const FormulaT & _formula,
 const std::shared_ptr< std::vector< FormulaT >> & _origins) [inline], [protected],
[inherited]
```

Adds the given formula to the passed formula.

**Parameters**

|                       |                                                                                                                                         |
|-----------------------|-----------------------------------------------------------------------------------------------------------------------------------------|
| <code>_formula</code> | The formula to add to the passed formula.                                                                                               |
| <code>_origins</code> | The link of the formula to add to the passed formula to sub-formulas of the received formulas, which are responsible for its occurrence |

**Returns**

A pair to the position where the formula to add has been inserted (or its first sub-formula which has not yet been in the passed formula, in case the formula to add is a conjunction), and a Boolean stating whether anything has been added to the passed formula.

**0.15.527.4.11 `allModels()` `const std::vector<Model>& smrat::Module::allModels () const [inline], [inherited]`****Returns**

All satisfying assignments, if existent.

**0.15.527.4.12 `anAnswerFound()` `bool smrat::Module::anAnswerFound () const [inline], [protected], [inherited]`**

Checks for all antecedent modules and those which run in parallel with the same antecedent modules, whether one of them has determined a result.

**Returns**

True, if one of them has determined a result.

**0.15.527.4.13 `answerFound()` `const smrat::Conditionals& smrat::Module::answerFound () const [inline], [inherited]`****Returns**

A vector of Booleans: If any of them is true, we have to terminate a running check procedure.

**0.15.527.4.14 `backendsModel()`** const `Model` & smtrat::Module::backendsModel () const [protected], [inherited]

Stores the model of a backend which determined satisfiability of the passed formula in the model of this module.

**0.15.527.4.15 `branchAt() [1/4]`** bool smtrat::Module::branchAt ( carl::Variable::Arg \_var, const Rational & \_value, bool \_leftCaseWeak = true, bool \_preferLeftCase = true, bool \_useReceivedFormulaAsPremise = false, const std::vector< `FormulaT` > & \_premise = std::vector<`FormulaT`>() ) [inline], [protected], [inherited]

**0.15.527.4.16 `branchAt() [2/4]`** bool smtrat::Module::branchAt ( carl::Variable::Arg \_var, const Rational & \_value, std::vector< `FormulaT` > && \_premise, bool \_leftCaseWeak = true, bool \_preferLeftCase = true, bool \_useReceivedFormulaAsPremise = false ) [inline], [protected], [inherited]

**0.15.527.4.17 `branchAt() [3/4]`** bool smtrat::Module::branchAt ( const Poly & \_polynomial, bool \_integral, const Rational & \_value, bool \_leftCaseWeak = true, bool \_preferLeftCase = true, bool \_useReceivedFormulaAsPremise = false, const std::vector< `FormulaT` > & \_premise = std::vector<`FormulaT`>() ) [inline], [protected], [inherited]

**0.15.527.4.18 `branchAt() [4/4]`** bool smtrat::Module::branchAt ( const Poly & \_polynomial, bool \_integral, const Rational & \_value, std::vector< `FormulaT` > && \_premise, bool \_leftCaseWeak = true, bool \_preferLeftCase = true, bool \_useReceivedFormulaAsPremise = false ) [protected], [inherited]

Adds a lemmas which provoke a branching for the given variable at the given value, if this module returns Unknown and there exists a preceding SATModule.

Note that the given value is rounded down and up, if the given variable is integer-valued.

#### Parameters

|                            |                                                                                                                                                                                                                |
|----------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>_polynomial</code>   | The variable to branch for.                                                                                                                                                                                    |
| <code>_integral</code>     | A flag being true, if all variables in the polynomial to branch for are integral.                                                                                                                              |
| <code>_value</code>        | The value to branch at.                                                                                                                                                                                        |
| <code>_premise</code>      | The sub-formulas of the received formula from which the branch is followed. Note, that a premise is not necessary, as every branch is a valid formula. But a premise can prevent from branching unnecessarily. |
| <code>_leftCaseWeak</code> | true, if a branching in the form of (or ( $\leq p b$ ) ( $> p b$ )) is desired. false, if a branching in the form of (or ( $< p b$ ) ( $\geq p b$ )) is desired.                                               |

**Parameters**

|                                           |                                                                                              |
|-------------------------------------------|----------------------------------------------------------------------------------------------|
| <code>_preferLeftCase</code>              | true, if the left case (polynomial less(or equal) 0 shall be chosen first. false, otherwise. |
| <code>_useReceivedFormulaAsPremise</code> | true, if the whole received formula should be used as premise                                |

**0.15.527.4.19 `check()`** Answer smtrat::Module::check (

```
 bool _final = false,
 bool _full = true,
 carl::Variable _objective = carl::Variable::NO_VARIABLE) [virtual], [inherited]
```

Checks the received formula for consistency.

Note, that this is an implementation of the satisfiability check of the conjunction of the so far received formulas, which does actually nothing but passing the problem to its backends. This implementation is only used internally and must be overwritten by any derived module.

**Parameters**

|                         |                                                                                                                                       |
|-------------------------|---------------------------------------------------------------------------------------------------------------------------------------|
| <code>_final</code>     | true, if this satisfiability check will be the last one (for a global sat-check), if its result is SAT                                |
| <code>_full</code>      | false, if this module should avoid too expensive procedures and rather return unknown instead.                                        |
| <code>_objective</code> | if not set to NO_VARIABLE, the module should find an assignment minimizing this objective variable; otherwise any assignment is good. |

**Returns**

True, if the received formula is satisfiable; False, if the received formula is not satisfiable; Unknown, otherwise.

Reimplemented in [smtrat::PModule](#).

**0.15.527.4.20 `checkCore()`** template<typename Settings >

```
Answer smtrat::STropModule< Settings >::checkCore () [virtual]
```

Checks the received formula for consistency.

**Returns**

SAT, if the received formula is satisfiable; UNSAT, if the received formula is not satisfiable; UNKNOWN, otherwise.

Reimplemented from [smtrat::Module](#).

**0.15.527.4.21 `checkInfSubsetForMinimality()`** void smtrat::Module::checkInfSubsetForMinimality (

```
 std::vector< FormulaSetT >::const_iterator _infsSubset,
 const std::string & _filename = "smaller_muses",
 unsigned _maxSizeDifference = 1) const [inherited]
```

Checks the given infeasible subset for minimality by storing all subsets of it, which have a smaller size which differs from the size of the infeasible subset not more than the given threshold.

**Parameters**

|                                 |                                                                                                        |
|---------------------------------|--------------------------------------------------------------------------------------------------------|
| <code>_infsSubset</code>        | The infeasible subset to check for minimality.                                                         |
| <code>_filename</code>          | The name of the file to store the infeasible subsets in order to be able to check their infeasibility. |
| <code>_maxSizeDifference</code> | The maximal difference between the sizes of the subsets compared to the size of the infeasible subset. |

**0.15.527.4.22 `checkModel()`** `unsigned smtrat::Module::checkModel ( ) const [protected], [inherited]`

**Returns**

false, if the current model of this module does not satisfy the current given formula; true, if it cannot be said whether the model satisfies the given formula.

**0.15.527.4.23 `cleanModel()`** `void smtrat::Module::cleanModel ( ) const [inline], [protected], [inherited]`

Substitutes variable occurrences by its model value in the model values of other variables.

**0.15.527.4.24 `clearLemmas()`** `void smtrat::Module::clearLemmas ( ) [inline], [inherited]`  
Deletes all yet found lemmas.

**0.15.527.4.25 `clearModel()`** `void smtrat::Module::clearModel ( ) const [inline], [protected], [inherited]`

Clears the assignment, if any was found.

**0.15.527.4.26 `clearModels()`** `void smtrat::Module::clearModels ( ) const [inline], [protected], [inherited]`

Clears all assignments, if any was found.

**0.15.527.4.27 `clearPassedFormula()`** `void smtrat::Module::clearPassedFormula ( ) [protected], [inherited]`

**0.15.527.4.28 `collectOrigins() [1/2]`** `void smtrat::Module::collectOrigins ( const FormulaT & _formula, FormulaSetT & _origins ) const [inherited]`

**0.15.527.4.29 `collectOrigins() [2/2]`** `void smtrat::Module::collectOrigins ( const FormulaT & _formula, FormulasT & _origins ) const [inherited]`

Collects the formulas in the given formula, which are part of the received formula.

If the given formula directly occurs in the received formula, it is inserted into the given set. Otherwise, the given formula must be of type AND and all its sub-formulas part of the received formula. Hence, they will be added to the given set.

**Parameters**

|                       |                                                                                                      |
|-----------------------|------------------------------------------------------------------------------------------------------|
| <code>_formula</code> | The formula from which to collect the formulas being sub-formulas of the received formula (origins). |
| <code>_origins</code> | The set in which to store the origins.                                                               |

**0.15.527.4.30 `collectTheoryPropagations()`** `void smtrat::Module::collectTheoryPropagations ( ) [inherited]`

**0.15.527.4.31 constraintsToInform()** const carl::FastSet<[FormulaT](#)>& smrat::Module::constraintsToInform( ) const [inline], [inherited]

**Returns**

The constraints which the backends must be informed about.

**0.15.527.4.32 currentlySatisfied()** virtual unsigned smrat::Module::currentlySatisfied( const [FormulaT](#) & ) const [inline], [virtual], [inherited]

**Returns**

0, if the given formula is conflicted by the current model; 1, if the given formula is satisfied by the current model; 2, otherwise; 3, if we do not know anything (default)

Reimplemented in [smrat::LRAbstractModule< Settings >](#), [smrat::LRAbstractModule< LRASettingsICP >](#), and [smrat::LRAbstractModule< LRASettings >](#)

**0.15.527.4.33 currentlySatisfiedByBackend()** unsigned smrat::Module::currentlySatisfiedByBackend( const [FormulaT](#) & \_formula ) const [inherited]

**Returns**

0, if the given formula is conflicted by the current model; 1, if the given formula is satisfied by the current model; 2, otherwise 3, if we do not know anything (default)

**0.15.527.4.34 deinform()** void smrat::Module::deinform( const [FormulaT](#) & \_constraint ) [inherited]

The inverse of informing about a constraint.

All data structures which were kept regarding this constraint are going to be removed. Note, that this makes only sense if it is not likely enough that a formula with this constraint must be solved again.

**Parameters**

|                          |                                                         |
|--------------------------|---------------------------------------------------------|
| <code>_constraint</code> | The constraint to remove from internal data structures. |
|--------------------------|---------------------------------------------------------|

**0.15.527.4.35 deinformCore()** virtual void smrat::Module::deinformCore( const [FormulaT](#) & \_constraint ) [inline], [protected], [virtual], [inherited]

The inverse of informing about a constraint.

All data structures which were kept regarding this constraint are going to be removed. Note, that this makes only sense if it is not likely enough that a formula with this constraint must be solved again.

**Parameters**

|                          |                                                         |
|--------------------------|---------------------------------------------------------|
| <code>_constraint</code> | The constraint to remove from internal data structures. |
|--------------------------|---------------------------------------------------------|

Reimplemented in [smrat::LRAbstractModule< Settings >](#), [smrat::LRAbstractModule< LRASettingsICP >](#), and [smrat::LRAbstractModule< LRASettings >](#)

**0.15.527.4.36 determine\_smallest\_origin()** size\_t smrat::Module::determine\_smallest\_origin( const std::vector< [FormulaT](#) > & origins ) const [protected], [inherited]

## Parameters

|                       |                              |
|-----------------------|------------------------------|
| <code>_origins</code> | A vector of sets of origins. |
|-----------------------|------------------------------|

## Returns

The index of the smallest (regarding the size of the sets) element of origins

**0.15.527.4.37 `eraseSubformulaFromPassedFormula()`** `ModuleInput::iterator smtrat::Module::eraseSubformulaFromPassedFormula (`

```
ModuleInput::iterator _subformula,
bool _ignoreOrigins = false) [protected], [virtual], [inherited]
```

Removes everything related to the sub-formula to remove from the passed formula in the backends of this module. Afterwards the sub-formula is removed from the passed formula.

## Parameters

|                             |                                                                                                              |
|-----------------------------|--------------------------------------------------------------------------------------------------------------|
| <code>_subformula</code>    | The sub-formula to remove from the passed formula.                                                           |
| <code>_ignoreOrigins</code> | True, if the sub-formula shall be removed regardless of its origins (should only be applied with expertise). |

## Returns

Reimplemented in `smtrat::ICPModule< Settings >`, `smtrat::ICPModule< ICPSettings4 >`, and `smtrat::ICPModule< ICPSettings1 >`.

**0.15.527.4.38 `excludeNotReceivedVariablesFromModel()`** `void smtrat::Module::excludeNotReceivedVariablesFromModel ( ) const [inherited]`

Excludes all variables from the current model, which do not occur in the received formula.

**0.15.527.4.39 `findBestOrigin()`** `std::vector< FormulaT >::const_iterator smtrat::Module::findBestOrigin (`

```
const std::vector< FormulaT > & _origins) const [protected], [inherited]
```

## Parameters

|                       |  |
|-----------------------|--|
| <code>_origins</code> |  |
|-----------------------|--|

## Returns

**0.15.527.4.40 `firstSubformulaToPass()`** `ModuleInput::const_iterator smtrat::Module::firstSubformulaToPass ( ) const [inline], [inherited]`

## Returns

The position of the first sub-formula in the passed formula, which has not yet been considered for a consistency check of the backends.

**0.15.527.4.41 firstUncheckedReceivedSubformula()** `ModuleInput::const_iterator smtrat::Module::firstUncheckedReceivedSubformula ( ) const [inline], [inherited]`

**Returns**

The position of the first (by this module) unchecked sub-formula of the received formula.

**0.15.527.4.42 freeSplittingVariable()** `static void smtrat::Module::freeSplittingVariable ( const FormulaT & _splittingVariable ) [inline], [static], [inherited]`

**0.15.527.4.43 generateTrivialInfeasibleSubset()** `void smtrat::Module::generateTrivialInfeasibleSubset ( ) [inline], [protected], [inherited]`

Stores the trivial infeasible subset being the set of received formulas.

**0.15.527.4.44 getBackendsAllModels()** `void smtrat::Module::getBackendsAllModels ( ) const [protected], [inherited]`

Stores all models of a backend in the list of all models of this module.

**0.15.527.4.45 getBackendsModel()** `void smtrat::Module::getBackendsModel ( ) const [protected], [inherited]`

**0.15.527.4.46 getInfeasibleSubsets() [1/2]** `void smtrat::Module::getInfeasibleSubsets ( ) [protected], [inherited]`

Copies the infeasible subsets of the passed formula.

**0.15.527.4.47 getInfeasibleSubsets() [2/2]** `std::vector< FormulaSetT > smtrat::Module::getInfeasibleSubsets (`

`const Module & _backend ) const [protected], [inherited]`

Get the infeasible subsets the given backend provides.

Note, that an infeasible subset in a backend contains sub formulas of the passed formula and an infeasible subset of this module contains sub formulas of the received formula. In this method the LATTER is returned.

**Parameters**

|                       |                                                          |
|-----------------------|----------------------------------------------------------|
| <code>_backend</code> | The backend from which to obtain the infeasible subsets. |
|-----------------------|----------------------------------------------------------|

**Returns**

The infeasible subsets the given backend provides.

**0.15.527.4.48 getInformationRelevantFormulas()** `const std::set< FormulaT > & smtrat::Module::getInformationRelevantFormulas ( ) [protected], [inherited]`

Gets all InformationRelevantFormulas.

**Returns**

Set of all formulas

**0.15.527.4.49 getModelEqualities()** `std::list< std::vector< carl::Variable > > smtrat::Module::getModelEqualities ( ) const [virtual], [inherited]`

Partition the variables from the current model into equivalence classes according to their assigned value.

The result is a set of equivalence classes of variables where all variables within one class are assigned the same value. Note that the number of classes may not be minimal, i.e. two classes may actually be equivalent.

#### Returns

Equivalence classes.

**0.15.527.4.50 getOrigins() [1/3]** `void smtrat::Module::getOrigins (`

```
const FormulaT & _formula,
FormulaSetT & _origins) const [inline], [protected], [inherited]
```

#### Parameters

|                       |  |
|-----------------------|--|
| <code>_formula</code> |  |
| <code>_origins</code> |  |

**0.15.527.4.51 getOrigins() [2/3]** `void smtrat::Module::getOrigins (`

```
const FormulaT & _formula,
FormulasT & _origins) const [inline], [protected], [inherited]
```

#### Parameters

|                       |  |
|-----------------------|--|
| <code>_formula</code> |  |
| <code>_origins</code> |  |

**0.15.527.4.52 getOrigins() [3/3]** `const FormulaT& smtrat::Module::getOrigins (`

```
ModuleInput::const_iterator _formula) const [inline], [protected], [inherited]
```

Gets the origins of the passed formula at the given position.

#### Parameters

|                       |                                                   |
|-----------------------|---------------------------------------------------|
| <code>_formula</code> | The position of a formula in the passed formulas. |
|-----------------------|---------------------------------------------------|

#### Returns

The origins of the passed formula at the given position.

**0.15.527.4.53 getReceivedFormulaSimplified()** `std::pair< bool, FormulaT > smtrat::Module::getReceivedFormulaSimplified ( ) [virtual], [inherited]`

#### Returns

A pair of a Boolean and a formula, where the Boolean is true, if the received formula could be simplified to an equisatisfiable formula. The formula is equisatisfiable to this module's received formula, if the Boolean is true.

Reimplemented in [smtrat::PModule](#).

**0.15.527.4.54 hasLemmas()** `bool smrat::Module::hasLemmas () [inline], [inherited]`  
Checks whether this module or any of its backends provides any lemmas.

**0.15.527.4.55 hasValidInfeasibleSubset()** `bool smrat::Module::hasValidInfeasibleSubset () const [inherited]`

**Returns**

true, if the module has at least one valid infeasible subset, that is all its elements are sub-formulas of the received formula (pointer must be equal).

**0.15.527.4.56 id()** `std::size_t smrat::Module::id () const [inline], [inherited]`

**Returns**

A unique ID to identify this module instance.

**0.15.527.4.57 infeasibleSubsets()** `const std::vector<FormulaSetT>& smrat::Module::infeasibleSubsets () const [inline], [inherited]`

**Returns**

The infeasible subsets of the set of received formulas (empty, if this module has not detected unsatisfiability of the conjunction of received formulas).

**0.15.527.4.58 inform()** `bool smrat::Module::inform (const FormulaT & _constraint) [inherited]`

Informs the module about the given constraint.

It should be tried to inform this module about any constraint it could receive eventually before assertSubformula is called (preferably for the first time, but at least before adding a formula containing that constraint).

**Parameters**

|                          |                                 |
|--------------------------|---------------------------------|
| <code>_constraint</code> | The constraint to inform about. |
|--------------------------|---------------------------------|

**Returns**

false, if it can be easily decided whether the given constraint is inconsistent; true, otherwise.

**0.15.527.4.59 informBackends()** `void smrat::Module::informBackends (const FormulaT & _constraint) [inline], [protected], [inherited]`

Informs all backends of this module about the given constraint.

**Parameters**

|                          |                                 |
|--------------------------|---------------------------------|
| <code>_constraint</code> | The constraint to inform about. |
|--------------------------|---------------------------------|

**0.15.527.4.60 informCore()** `virtual bool smrat::Module::informCore (const FormulaT & _constraint) [inline], [protected], [virtual], [inherited]`

Informs the module about the given constraint.

It should be tried to inform this module about any constraint it could receive eventually before assertSubformula is called (preferably for the first time, but at least before adding a formula containing that constraint).

#### Parameters

|                          |                                 |
|--------------------------|---------------------------------|
| <code>_constraint</code> | The constraint to inform about. |
|--------------------------|---------------------------------|

#### Returns

`false`, if it can be easily decided whether the given constraint is inconsistent; `true`, otherwise.

Reimplemented in [smrat::UnionFindModule< Settings >](#), [smrat::PBPPModule< Settings >](#), [smrat::PBGaussModule< Settings >](#), [smrat::NRAILModule< Settings >](#), [smrat::NewCoveringModule< Settings >](#), [smrat::NewCADModule< Settings >](#), [smrat::LRAModule< Settings >](#), [smrat::LRAModule< LRASettingsICP >](#), [smrat::LRAModule< LRASettings1 >](#), [smrat::IntBlastModule< Settings >](#), [smrat::FPPModule< Settings >](#), [smrat::EQModule< Settings >](#), [smrat::CurryModule< Settings >](#), [smrat::BVMModule< Settings >](#), [smrat::ICPModule< Settings >](#), [smrat::ICPModule< ICPSettings4 >](#), and [smrat::ICPModule< ICPSettings1 >](#).

#### 0.15.527.4.61 informedConstraints()

```
const carl::FastSet<FormulaT>& smrat::Module::informed<→
Constraints () const [inline], [inherited]
```

#### Returns

The position of the first constraint of which no backend has been informed about.

#### 0.15.527.4.62 init()

```
void smrat::Module::init () [virtual], [inherited]
```

Informs all backends about the so far encountered constraints, which have not yet been communicated.

This method must not be called twice and only before the first runBackends call.

Reimplemented in [smrat::PBPPModule< Settings >](#), [smrat::PBGaussModule< Settings >](#), [smrat::NRAILModule< Settings >](#), [smrat::NewCoveringModule< Settings >](#), [smrat::NewCADModule< Settings >](#), [smrat::LRAModule< Settings >](#), [smrat::LRAModule< LRASettingsICP >](#), [smrat::LRAModule< LRASettings1 >](#), [smrat::IntBlastModule< Settings >](#), [smrat::FPPModule< Settings >](#), [smrat::EQModule< Settings >](#), [smrat::CurryModule< Settings >](#), and [smrat::BVMModule< Settings >](#).

#### 0.15.527.4.63 is\_minimizing()

```
bool smrat::Module::is_minimizing () const [inline], [inherited]
```

#### 0.15.527.4.64 isLemmaLevel()

```
bool smrat::Module::isLemmaLevel (
```

`LemmaLevel level`) [protected], [inherited]

Checks if current lemma level is greater or equal to given level.

#### Parameters

|                    |                 |
|--------------------|-----------------|
| <code>level</code> | Level to check. |
|--------------------|-----------------|

#### 0.15.527.4.65 isPreprocessor()

```
bool smrat::Module::isPreprocessor () const [inline], [inherited]
```

#### Returns

`true`, if this module is a preprocessor that is a module, which simplifies its received formula to an equisatisfiable formula being passed to its backends. The simplified formula can be obtained with [getReceivedFormulaSimplified\(\)](#).

**0.15.527.4.66 lemmas()** const std::vector<[Lemma](#)>& smtrat::Module::lemmas ( ) const [inline], [inherited]

**Returns**

A constant reference to the lemmas being valid formulas this module or its backends made.

**0.15.527.4.67 merge()** std::vector< [FormulaT](#) > smtrat::Module::merge ( const std::vector< [FormulaT](#) > & [\\_vecSetA](#), const std::vector< [FormulaT](#) > & [\\_vecSetB](#) ) const [protected], [inherited]

Merges the two vectors of sets into the first one.

({a,b},{a,c}) and ({b,d},{b}) -> ({a,b,d},{a,b},{a,b,c,d},{a,b,c})

**Parameters**

|                          |                                  |
|--------------------------|----------------------------------|
| <a href="#">_vecSetA</a> | A vector of sets of constraints. |
| <a href="#">_vecSetB</a> | A vector of sets of constraints. |

**Returns**

The vector being the two given vectors merged.

**0.15.527.4.68 model()** const [Model](#)& smtrat::Module::model ( ) const [inline], [inherited]

**Returns**

The assignment of the current satisfiable result, if existent.

**0.15.527.4.69 modelsDisjoint()** bool smtrat::Module::modelsDisjoint ( const [Model](#) & [\\_modelA](#), const [Model](#) & [\\_modelB](#) ) [static], [protected], [inherited]

Checks whether there is no variable assigned by both models.

**Parameters**

|                         |                                |
|-------------------------|--------------------------------|
| <a href="#">_modelA</a> | The first model to check for.  |
| <a href="#">_modelB</a> | The second model to check for. |

**Returns**

true, if there is no variable assigned by both models; false, otherwise.

**0.15.527.4.70 moduleName()** template<typename Settings > std::string smtrat::STropModule< [Settings](#) >::moduleName ( ) const [inline], [virtual]

**Returns**

The name of the given module type as name.

Reimplemented from [smtrat::Module](#).

**0.15.527.4.71 `objective()`** `carl::Variable smrat::Module::objective ( ) const [inline], [inherited]`

**0.15.527.4.72 `originInReceivedFormula()`** `bool smrat::Module::originInReceivedFormula ( const FormulaT & _origin ) const [protected], [inherited]`

**0.15.527.4.73 `passedFormulaBegin()`** `ModuleInput::iterator smrat::Module::passedFormulaBegin ( ) [inline], [protected], [inherited]`

**Returns**

An iterator to the end of the passed formula. TODO: disable this method

**0.15.527.4.74 `passedFormulaEnd()`** `ModuleInput::iterator smrat::Module::passedFormulaEnd ( ) [inline], [protected], [inherited]`

**Returns**

An iterator to the end of the passed formula.

**0.15.527.4.75 `pPassedFormula()`** `const ModuleInput* smrat::Module::pPassedFormula ( ) const [inline], [inherited]`

**Returns**

A pointer to the formula passed to the backends of this module.

**0.15.527.4.76 `pReceivedFormula()`** `const ModuleInput* smrat::Module::pReceivedFormula ( ) const [inline], [inherited]`

**Returns**

A pointer to the formula passed to this module.

**0.15.527.4.77 `print()`** `void smrat::Module::print ( const std::string & _initiation = "***" ) const [inherited]`

Prints everything relevant of the solver.

**Parameters**

|                          |                      |
|--------------------------|----------------------|
| <code>_initiation</code> | The line initiation. |
|--------------------------|----------------------|

**0.15.527.4.78 `printAllModels()`** `void smrat::Module::printAllModels ( std::ostream & _out = std::cout ) [inherited]`

Prints all assignments of this module satisfying its received formula if it satisfiable and this module could find an assignment.

**Parameters**

|                   |                                        |
|-------------------|----------------------------------------|
| <code>_out</code> | The stream to print the assignment on. |
|-------------------|----------------------------------------|

**0.15.527.4.79 printInfeasibleSubsets()** void smtrat::Module::printInfeasibleSubsets ( const std::string & *\_initiation* = "\*\*\*" ) const [inherited]  
Prints the infeasible subsets.

Parameters

|                    |                      |
|--------------------|----------------------|
| <i>_initiation</i> | The line initiation. |
|--------------------|----------------------|

**0.15.527.4.80 printModel()** void smtrat::Module::printModel ( std::ostream & *\_out* = std::cout ) const [inherited]  
Prints the assignment of this module satisfying its received formula if it satisfiable and this module could find an assignment.

Parameters

|             |                                        |
|-------------|----------------------------------------|
| <i>_out</i> | The stream to print the assignment on. |
|-------------|----------------------------------------|

**0.15.527.4.81 printPassedFormula()** void smtrat::Module::printPassedFormula ( const std::string & *\_initiation* = "\*\*\*" ) const [inherited]  
Prints the vector of passed formula.

Parameters

|                    |                      |
|--------------------|----------------------|
| <i>_initiation</i> | The line initiation. |
|--------------------|----------------------|

**0.15.527.4.82 printReceivedFormula()** void smtrat::Module::printReceivedFormula ( const std::string & *\_initiation* = "\*\*\*" ) const [inherited]  
Prints the vector of the received formula.

Parameters

|                    |                      |
|--------------------|----------------------|
| <i>_initiation</i> | The line initiation. |
|--------------------|----------------------|

**0.15.527.4.83 probablyLooping()** bool smtrat::Module::probablyLooping ( const typename Poly::PolyType & *\_branchingPolynomial*, const Rational & *\_branchingValue* ) const [protected], [inherited]  
Checks whether given the current branching value and branching variable/polynomial it is (highly) probable that this branching is part of an infinite loop of branchings.

Parameters

|                             |                                                                                     |
|-----------------------------|-------------------------------------------------------------------------------------|
| <i>_branchingPolynomial</i> | The polynomial to branch at (in most branching strategies this is just a variable). |
| <i>_branchingValue</i>      | The value to branch at.                                                             |

**Returns**

true, if this branching is probably part of an infinite loop of branchings; false, otherwise.

**0.15.527.4.84 receivedFormulaChecked()** void smtrat::Module::receivedFormulaChecked () [inline], [inherited]

Notifies that the received formulas has been checked.

**0.15.527.4.85 receivedFormulasAsInfeasibleSubset()** void smtrat::Module::receivedFormulasAsInfeasibleSubset (

    ModuleInput::const\_iterator \_subformula ) [inline], [protected], [inherited]

Stores an infeasible subset consisting only of the given received formula.

**0.15.527.4.86 receivedVariable()** bool smtrat::Module::receivedVariable (

    carl::Variable::Arg \_var ) const [inline], [inherited]

**0.15.527.4.87 remove()** void smtrat::Module::remove (

    ModuleInput::const\_iterator \_subformula ) [virtual], [inherited]

Removes everything related to the given sub-formula of the received formula.

However, it is desired not to lose track of search spaces where no satisfying assignment can be found for the remaining sub-formulas.

**Parameters**

|             |                                                    |
|-------------|----------------------------------------------------|
| _subformula | The sub formula of the received formula to remove. |
|-------------|----------------------------------------------------|

Reimplemented in [smtrat::PModule](#).

**0.15.527.4.88 removeCore()** template<typename Settings >

void smtrat::STropModule< Settings >::removeCore (

    ModuleInput::const\_iterator \_subformula ) [virtual]

Removes the subformula of the received formula at the given position to the considered ones of this module.

Note that this includes every stored calculation which depended on this subformula, but should keep the other stored calculation, if possible, untouched.

**Parameters**

|             |                                           |
|-------------|-------------------------------------------|
| _subformula | The position of the subformula to remove. |
|-------------|-------------------------------------------|

Reimplemented from [smtrat::Module](#).

**0.15.527.4.89 removeOrigin()** std::pair<ModuleInput::iterator, bool> smtrat::Module::removeOrigin (

    ModuleInput::iterator \_formula,

    const FormulaT & \_origin ) [inline], [protected], [inherited]

**0.15.527.4.90 removeOrigins()** std::pair<ModuleInput::iterator, bool> smtrat::Module::removeOrigins (

    ModuleInput::iterator \_formula,

```
 const std::shared_ptr< std::vector< FormulaT >> & _origins) [inline], [protected],
[inherited]
```

#### 0.15.527.4.91 **rPassedFormula()** const ModuleInput& smtrat::Module::rPassedFormula ( ) const [inline], [inherited]

##### Returns

A reference to the formula passed to the backends of this module.

#### 0.15.527.4.92 **rReceivedFormula()** const ModuleInput& smtrat::Module::rReceivedFormula ( ) const [inline], [inherited]

##### Returns

A reference to the formula passed to this module.

#### 0.15.527.4.93 **runBackends()** [1/2] virtual Answer smtrat::Module::runBackends ( ) [inline], [protected], [virtual], [inherited] Reimplemented in [smtrat::PModule](#).

#### 0.15.527.4.94 **runBackends()** [2/2] Answer smtrat::Module::runBackends (

```
 bool _final,
 bool _full,
 carl::Variable _objective) [protected], [virtual], [inherited]
```

Runs the backend solvers on the passed formula.

##### Parameters

|                         |                                                                                                                                       |
|-------------------------|---------------------------------------------------------------------------------------------------------------------------------------|
| <code>_final</code>     | true, if this satisfiability check will be the last one (for a global sat-check), if its result is SAT                                |
| <code>_full</code>      | false, if this module should avoid too expensive procedures and rather return unknown instead.                                        |
| <code>_objective</code> | if not set to NO_VARIABLE, the module should find an assignment minimizing this objective variable; otherwise any assignment is good. |

##### Returns

True, if the passed formula is consistent; False, if the passed formula is inconsistent; Unknown, otherwise.

Reimplemented in [smtrat::PModule](#).

#### 0.15.527.4.95 **setId()** void smtrat::Module::setId (

```
 std::size_t _id) [inline], [inherited]
```

Sets this modules unique ID to identify itself.

##### Parameters

|                                                                                                         |                                    |
|---------------------------------------------------------------------------------------------------------|------------------------------------|
| $\leftrightarrow$<br>$\overleftarrow{\phantom{d}}$<br>$\overrightarrow{\phantom{d}}$<br><code>id</code> | The id to set this module's id to. |
|---------------------------------------------------------------------------------------------------------|------------------------------------|

**0.15.527.4.96 `setThreadPriority()`** `void smtrat::Module::setThreadPriority ( thread_priority _threadPriority ) [inline], [inherited]`  
 Sets the priority of this module to get a thread for running its check procedure.

#### Parameters

|                              |                                                       |
|------------------------------|-------------------------------------------------------|
| <code>_threadPriority</code> | The priority to set this module's thread priority to. |
|------------------------------|-------------------------------------------------------|

**0.15.527.4.97 `solverState()`** `Answer smtrat::Module::solverState ( ) const [inline], [inherited]`

#### Returns

True, if this module is in a state, such that it has found a solution for its received formula; False, if this module is in a state, such that it has determined that there is no solution for its received formula; Unknown, otherwise.

**0.15.527.4.98 `splitUnequalConstraint()`** `void smtrat::Module::splitUnequalConstraint ( const FormulaT & _unequalConstraint ) [protected], [inherited]`

Adds the following lemmas for the given constraint  $p \neq 0$ .

$(p \neq 0 \Leftrightarrow (p < 0 \text{ or } p > 0))$

and  $\neg(p < 0 \text{ and } p > 0)$

#### Parameters

|                                 |                                                  |
|---------------------------------|--------------------------------------------------|
| <code>_unequalConstraint</code> | A constraint having the relation symbol $\neq$ . |
|---------------------------------|--------------------------------------------------|

**0.15.527.4.99 `threadPriority()`** `thread_priority smtrat::Module::threadPriority ( ) const [inline], [inherited]`

#### Returns

The priority of this module to get a thread for running its check procedure.

**0.15.527.4.100 `updateAllModels()`** `void smtrat::Module::updateAllModels ( ) [virtual], [inherited]`

Updates all satisfying models, if the solver has detected the consistency of the received formula, beforehand.

Reimplemented in [smtrat::SATModule< Settings >](#).

**0.15.527.4.101 `updateLemmas()`** `void smtrat::Module::updateLemmas ( ) [inherited]`

Stores all lemmas of any backend of this module in its own lemma vector.

**0.15.527.4.102 `updateModel()`** `template<typename Settings >`

`void smtrat::STropModule< Settings >::updateModel ( ) const [virtual]`

Updates the current assignment into the model.

Note, that this is a unique but possibly symbolic assignment maybe containing newly introduced variables.

Reimplemented from [smtrat::Module](#).

**0.15.527.4.103 usedBackends()** const std::vector<[Module](#)\*>& smrat::Module::usedBackends ( )  
const [inline], [inherited]

**Returns**

The backends of this module which are currently used (conditions to use this module are fulfilled for the passed formula).

## 0.15.527.5 Field Documentation

**0.15.527.5.1 mAllBackends** std::vector<[Module](#)\*> smrat::Module::mAllBackends [protected], [inherited]

The backends of this module which have been used.

**0.15.527.5.2 mAllModels** std::vector<[Model](#)> smrat::Module::mAllModels [mutable], [protected], [inherited]

Stores all satisfying assignments.

**0.15.527.5.3 mBackendsFoundAnswer** std::atomic\_bool\* smrat::Module::mBackendsFoundAnswer [protected], [inherited]

This flag is passed to any backend and if it determines an answer to a prior check call, this flag is fired.

**0.15.527.5.4 mConstraintsToInform** carl::FastSet<[FormulaT](#)> smrat::Module::mConstraintsToInform [protected], [inherited]

Stores the constraints which the backends must be informed about.

**0.15.527.5.5 mFinalCheck** bool smrat::Module::mFinalCheck [protected], [inherited]

true, if the check procedure should perform a final check which especially means not to postpone splitting decisions

**0.15.527.5.6 mFirstPosInLastBranches** std::size\_t smrat::Module::mFirstPosInLastBranches = 0 [static], [inherited]

The beginning of the cyclic buffer storing the last branches.

**0.15.527.5.7 mFirstSubformulaToPass** [ModuleInput](#)::iterator smrat::Module::mFirstSubformulaToPass [protected], [inherited]

Stores the position of the first sub-formula in the passed formula, which has not yet been considered for a consistency check of the backends.

**0.15.527.5.8 mFirstUncheckedReceivedSubformula** [ModuleInput](#)::const\_iterator smrat::Module::mFirstUncheckedReceivedSubformula [protected], [inherited]

Stores the position of the first (by this module) unchecked sub-formula of the received formula.

**0.15.527.5.9 mFoundAnswer** [Conditionals](#) smrat::Module::mFoundAnswer [protected], [inherited]

Vector of Booleans: If any of them is true, we have to terminate a running check procedure.

**0.15.527.5.10 mFullCheck** `bool smtrat::Module::mFullCheck` [protected], [inherited]  
false, if this module should avoid too expensive procedures and rather return unknown instead.

**0.15.527.5.11 mInfeasibleSubsets** `std::vector<FormulaSetT> smtrat::Module::mInfeasibleSubsets` [protected], [inherited]  
Stores the infeasible subsets.

**0.15.527.5.12 mInformedConstraints** `carl::FastSet<FormulaT> smtrat::Module::mInformedConstraints` [protected], [inherited]  
Stores the position of the first constraint of which no backend has been informed about.

**0.15.527.5.13 mLastBranches** `std::vector< Branching > smtrat::Module::mLastBranches = std::vector<Branching> (mNumOfBranchVarsToStore, Branching(typename Poly::PolyType(), 0))` [static], [inherited]  
Stores the last branches in a cycle buffer.

**0.15.527.5.14 mLemmas** `std::vector<Lemma> smtrat::Module::mLemmas` [protected], [inherited]  
Stores the lemmas being valid formulas this module or its backends made.

**0.15.527.5.15 mModel** `Model smtrat::Module::mModel` [mutable], [protected], [inherited]  
Stores the assignment of the current satisfiable result, if existent.

**0.15.527.5.16 mModelComputed** `bool smtrat::Module::mModelComputed` [mutable], [protected], [inherited]  
True, if the model has already been computed.

**0.15.527.5.17 mNumOfBranchVarsToStore** `std::size_t smtrat::Module::mNumOfBranchVarsToStore = 5` [static], [inherited]  
The number of different variables to consider for a probable infinite loop of branchings.

**0.15.527.5.18 mObjectiveVariable** `carl::Variable smtrat::Module::mObjectiveVariable` [protected], [inherited]  
Objective variable to be minimized. If set to NO\_VARIABLE, a normal sat check should be performed.

**0.15.527.5.19 mOldSplittingVariables** `std::vector< FormulaT > smtrat::Module::mOldSplittingVariables` [static], [inherited]  
Reusable splitting variables.

**0.15.527.5.20 mpManager** `Manager* const smtrat::Module::mpManager` [protected], [inherited]  
A reference to the manager.

**0.15.527.5.21 mSmallerMusesCheckCounter** `unsigned smtrat::Module::mSmallerMusesCheckCounter` [mutable], [protected], [inherited]  
Counter used for the generation of the smt2 files to check for smaller muses.

**0.15.527.5.22 mSolverState** std::atomic<[Answer](#)> smtrat::Module::mSolverState [protected], [inherited]

States whether the received formula is known to be satisfiable or unsatisfiable otherwise it is set to unknown.

**0.15.527.5.23 mTheoryPropagations** std::vector<[TheoryPropagation](#)> smtrat::Module::mTheory← Propagations [protected], [inherited]**0.15.527.5.24 mUsedBackends** std::vector<[Module\\*](#)> smtrat::Module::mUsedBackends [protected], [inherited]

The backends of this module which are currently used (conditions to use this module are fulfilled for the passed formula).

**0.15.527.5.25 mVariableCounters** std::vector<std::size\_t> smtrat::Module::mVariableCounters [protected], [inherited]

Maps variables to the number of their occurrences.

## 0.15.528 benchmax::slurm::SubmitfileProperties Struct Reference

All properties needed to create a submit file.

```
#include <SlurmUtilities.h>
```

### Data Fields

- std::string [file\\_suffix](#)  
*Suffix for job and submit file.*

### 0.15.528.1 Detailed Description

All properties needed to create a submit file.

### 0.15.528.2 Field Documentation

**0.15.528.2.1 file\_suffix** std::string benchmax::slurm::SubmitfileProperties::file\_suffix  
Suffix for job and submit file.

**0.15.528.2.2 filename\_jobs** std::string benchmax::slurm::SubmitfileProperties::filename\_jobs  
 Filename of the job list file.

**0.15.528.2.3 grace\_time** carl::settings::duration benchmax::slurm::SubmitfileProperties::grace\_time  
 Grace time in seconds.

**0.15.528.2.4 limit\_memory** carl::settings::binary\_quantity benchmax::slurm::SubmitfileProperties::limit\_memory  
 Memory limit in megabytes.

**0.15.528.2.5 limit\_time** carl::settings::duration benchmax::slurm::SubmitfileProperties::limit\_time  
 Time limit in seconds.

**0.15.528.2.6 slices** std::size\_t benchmax::slurm::SubmitfileProperties::slices  
 Number of slices.

**0.15.528.2.7 tasks** std::size\_t benchmax::slurm::SubmitfileProperties::tasks  
 Number of tasks.

**0.15.528.2.8 tmp\_dir** std::string benchmax::slurm::SubmitfileProperties::tmp\_dir  
 Temporary directory for log files.

*Prints this substitution on the given stream, with some additional information.*

### 0.15.529.1 Member Enumeration Documentation

#### 0.15.529.1.1 Type enum `smrat::vs::Substitution::Type`

The type of a substitution.

Enumerator

|                |  |
|----------------|--|
| NORMAL         |  |
| PLUS_EPSILON   |  |
| MINUS_INFINITY |  |
| PLUS_INFINITY  |  |
| INVALID        |  |

### 0.15.529.2 Constructor & Destructor Documentation

#### 0.15.529.2.1 Substitution() [1/3] `smrat::vs::Substitution::Substitution` (

```
 const carl::Variable & _variable,
 const Type & _type,
 carl::PointerSet< Condition > && _oConditions,
 smrat::ConstraintsT && _sideCondition = smrat::ConstraintsT())
```

Constructs a substitution with no square root term to map to.

Parameters

|                             |                                                                |
|-----------------------------|----------------------------------------------------------------|
| <code>_variable</code>      | The variable to substitute of the substitution to construct.   |
| <code>_type</code>          | The type of the substitution of the substitution to construct. |
| <code>_oConditions</code>   | The original conditions of the substitution to construct.      |
| <code>_sideCondition</code> | The side conditions of the substitution to construct.          |

#### 0.15.529.2.2 Substitution() [2/3] `smrat::vs::Substitution::Substitution` (

```
 const carl::Variable & _variable,
 const smrat::SqrtEx & _term,
 const Type & _type,
 carl::PointerSet< Condition > && _oConditions,
```

```
smtrat::ConstraintsT && _sideCondition = smtrat::ConstraintsT())
```

Constructs a substitution with a square root term to map to.

#### Parameters

|                             |                                                                |
|-----------------------------|----------------------------------------------------------------|
| <code>_variable</code>      | The variable to substitute of the substitution to construct.   |
| <code>_term</code>          | The square root term to which the variable maps to.            |
| <code>_type</code>          | The type of the substitution of the substitution to construct. |
| <code>_oConditions</code>   | The original conditions of the substitution to construct.      |
| <code>_sideCondition</code> | The side conditions of the substitution to construct.          |

**0.15.529.2.3 Substitution()** [3/3] `smtrat::vs::Substitution::Substitution (`  
`const Substitution & _substitution )`

Copy constructor.

**0.15.529.2.4 ~Substitution()** `smtrat::vs::Substitution::~Substitution ( )`  
The destructor.

### 0.15.529.3 Member Function Documentation

**0.15.529.3.1 operator==()** `bool smtrat::vs::Substitution::operator== (`  
`const Substitution & _substitution ) const`

#### Parameters

|                  |                               |
|------------------|-------------------------------|
| <code>The</code> | substitution to compare with. |
|------------------|-------------------------------|

#### Returns

true, if this substitution is equal to the given substitution; false, otherwise.

**0.15.529.3.2 originalConditions()** `const carl::PointerSet<Condition>& smtrat::vs::Substitution::originalConditions ( ) const [inline]`

#### Returns

A constant reference to the original conditions of this substitution.

**0.15.529.3.3 print()** `void smtrat::vs::Substitution::print (`  
`bool _withOrigins = false,`  
`bool _withSideConditions = false,`  
`std::ostream & _out = std::cout,`  
`const std::string & _init = "" ) const`

Prints this substitution on the given stream, with some additional information.

#### Parameters

|                  |                               |
|------------------|-------------------------------|
| <code>The</code> | substitution to compare with. |
|------------------|-------------------------------|

**Returns**

true, if this substitution is less than the given substitution; false, otherwise.

**Parameters**

|                                  |                                                                             |
|----------------------------------|-----------------------------------------------------------------------------|
| <code>_withOrigins</code>        | A flag indicating whether to print also the origins of this substitution.   |
| <code>_withSideConditions</code> | A flag indication whether to also the side conditions of this substitution. |
| <code>_out</code>                | The stream to print on.                                                     |
| <code>_init</code>               | The string to print at the beginning of every row.                          |

**0.15.529.3.4 `rOriginalConditions()`** `carl::PointerSet<Condition>& smtrat::vs::Substitution::rOriginalConditions () [inline]`

**Returns**

A reference to the original conditions of this substitution.

**0.15.529.3.5 `rType()`** `Type& smtrat::vs::Substitution::rType () [inline]`

**Returns**

A reference to the type of this substitution.

**0.15.529.3.6 `setTerm()`** `void smtrat::vs::Substitution::setTerm (const smtrat::Rational & _value) [inline]`

Sets the substitution term to the given rational.

**Parameters**

|                     |                                            |
|---------------------|--------------------------------------------|
| <code>_value</code> | The value to set the substitution term to. |
|---------------------|--------------------------------------------|

**0.15.529.3.7 `sideCondition()`** `const smtrat::ConstraintsT& smtrat::vs::Substitution::sideCondition () const [inline]`

**Returns**

A constant reference to the side condition of this substitution.

**0.15.529.3.8 `term()`** `const smtrat::SqrtEx& smtrat::vs::Substitution::term () const [inline]`

**Returns**

A constant reference to the term this substitution maps its variable to.

**0.15.529.3.9 `termVariables()`** `const carl::Variables& smtrat::vs::Substitution::termVariables () const [inline]`

**Returns**

A constant reference to the variables occurring in the substitution term.

**0.15.529.3.10 type()** const `Type& smtrat::vs::Substitution::type( ) const [inline]`**Returns**

A constant reference to the type of this substitution.

**0.15.529.3.11 valuate()** unsigned smtrat::vs::Substitution::valuate( bool \_preferMinusInf = true ) const**Parameters**

|                              |                                                                                     |
|------------------------------|-------------------------------------------------------------------------------------|
| <code>_preferMinusInf</code> | A flag indicating whether to valuate the substitution type best or otherwise worst. |
|------------------------------|-------------------------------------------------------------------------------------|

**Returns**

The valuation of this substitution according to a heuristic.

**0.15.529.3.12 variable()** const `carl::Variable& smtrat::vs::Substitution::variable( ) const [inline]`**Returns**

A constant reference to the variable this substitution substitutes.

**0.15.530 smtrat::vs::substitutionPointerEqual Struct Reference**

## 0.15.532 smtrat::cadcells::datastructures::SymbolicInterval Class Reference

A symbolic interal whose bounds are defined by indexed root expressions.

```
#include <roots.h>
```

### Public Member Functions

- [SymbolicInterval \(IndexedRoot root\)](#)  
*Constructs a section.*
- [SymbolicInterval \(Bound lower, Bound upper\)](#)  
*Constructs an interval iwth arbitrary bounds.*
- [SymbolicInterval \(\)](#)  
*Constructs (-oo, oo).*
- [bool is\\_section \(\) const](#)
- [const IndexedRoot & section\\_defining \(\) const](#)  
*In case of a section, the defining indexed root is returned.*
- [const auto & lower \(\) const](#)  
*Return the lower bound.*
- [const auto & upper \(\) const](#)  
*Returns the upper bound.*
- [void polys \(boost::container::flat\\_set< PolyRef > &result\) const](#)
- [boost::container::flat\\_set< PolyRef > polys \(\) const](#)
- [void set\\_to\\_closure \(\)](#)

### 0.15.532.1 Detailed Description

A symbolic interal whose bounds are defined by indexed root expressions.

Bounds can be infty, strict or weak. A special case is a section where the lower and upper bound are equal and weak.

### 0.15.532.2 Constructor & Destructor Documentation

```
0.15.532.2.1 SymbolicInterval() [1/3] smtrat::cadcells::datastructures::SymbolicInterval::←
SymbolicInterval (
 IndexedRoot root) [inline]
```

Constructs a section.

```
0.15.532.2.2 SymbolicInterval() [2/3] smtrat::cadcells::datastructures::SymbolicInterval::←
SymbolicInterval (
 Bound lower,
 Bound upper) [inline]
```

Constructs an interval iwth arbitrary bounds.

```
0.15.532.2.3 SymbolicInterval() [3/3] smtrat::cadcells::datastructures::SymbolicInterval::←
SymbolicInterval () [inline]
```

Constructs (-oo, oo).

### 0.15.532.3 Member Function Documentation

**0.15.532.3.1 `is_section()`** `bool smtrat::cadcells::datastructures::SymbolicInterval::is_section ( ) const [inline]`

**0.15.532.3.2 `lower()`** `const auto& smtrat::cadcells::datastructures::SymbolicInterval::lower ( ) const [inline]`  
Return the lower bound.

**0.15.532.3.3 `polys() [1/2]`** `boost::container::flat_set<PolyRef> smtrat::cadcells::datastructures::SymbolicInterval::polys ( ) const [inline]`

**0.15.532.3.4 `polys() [2/2]`** `void smtrat::cadcells::datastructures::SymbolicInterval::polys ( boost::container::flat_set< PolyRef > & result ) const [inline]`

**0.15.532.3.5 `section_defining()`** `const IndexedRoot& smtrat::cadcells::datastructures::SymbolicInterval::section_defining ( ) const [inline]`  
In case of a section, the defining indexed root is returned.

**0.15.532.3.6 `set_to_closure()`** `void smtrat::cadcells::datastructures::SymbolicInterval::set_to_closure ( ) [inline]`

**0.15.532.3.7 `upper()`** `const auto& smtrat::cadcells::datastructures::SymbolicInterval::upper ( ) const [inline]`  
Returns the upper bound.

## 0.15.533 `delta::SymbolParser` Struct Reference

This class is a `boost::spirit::qi` grammar that matches all kinds of smtlib symbols, numbers etc.  
`#include <Parser.h>`

### Public Member Functions

- [SymbolParser \(\)](#)

### Data Fields

- `qi::rule< Iterator, std::string(), Skipper > main`
- `qi::rule< Iterator, std::string(), Skipper > quoted`
- `qi::rule< Iterator, std::string(), Skipper > simple`

### 0.15.533.1 Detailed Description

## 0.15.535 smtrat::SymmetryModule< Settings > Class Template Reference

```
#include <SymmetryModule.h>
```

### Public Types

- `typedef Settings SettingsType`
- `enum class LemmaType : unsigned { NORMAL = 0, PERMANENT = 1 }`

## Public Member Functions

- `SymmetryModule (const ModuleInput *_formula, Conditionals &_conditionals, Manager *_manager=nullptr)`  
 Checks the received formula for consistency.
- `bool isPreprocessor () const`
- `bool appliedPreprocessing () const`
- `bool add (ModuleInput::const_iterator _subformula)`  
 The module has to take the given sub-formula of the received formula into account.
- `void remove (ModuleInput::const_iterator _subformula)`  
 Removes everything related to the given sub-formula of the received formula.
- `Answer check (bool _final=false, bool _full=true, carl::Variable _objective=carl::Variable::NO_VARIABLE)`  
 Checks the received formula for consistency.
- `Answer runBackends (bool _final, bool _full, carl::Variable _objective)`  
 Runs the backend solvers on the passed formula.
- `virtual Answer runBackends ()`
- `std::pair< bool, FormulaT > getReceivedFormulaSimplified ()`
- `void updateModel () const`  
 Updates the current assignment into the model.
- `bool inform (const FormulaT &_constraint)`  
 Informs the module about the given constraint.
- `void deinform (const FormulaT &_constraint)`  
 The inverse of informing about a constraint.
- `virtual void init ()`  
 Informs all backends about the so far encountered constraints, which have not yet been communicated.
- `virtual void updateAllModels ()`  
 Updates all satisfying models, if the solver has detected the consistency of the received formula, beforehand.
- `virtual std::list< std::vector< carl::Variable > > getModelEqualities () const`  
 Partition the variables from the current model into equivalence classes according to their assigned value.
  - `unsigned currentlySatisfiedByBackend (const FormulaT &_formula) const`
  - `virtual unsigned currentlySatisfied (const FormulaT &) const`
  - `bool receivedVariable (carl::Variable::Arg _var) const`
  - `Answer solverState () const`
  - `std::size_t id () const`
  - `void setId (std::size_t _id)`  
 Sets this modules unique ID to identify itself.
  - `thread_priority threadPriority () const`
  - `void setThreadPriority (thread_priority _threadPriority)`  
 Sets the priority of this module to get a thread for running its check procedure.
  - `const ModuleInput * pReceivedFormula () const`
  - `const ModuleInput & rReceivedFormula () const`
  - `const ModuleInput * pPassedFormula () const`
  - `const ModuleInput & rPassedFormula () const`
  - `const Model & model () const`
  - `const std::vector< Model > & allModels () const`
  - `const std::vector< FormulaSetT > & infeasibleSubsets () const`
  - `const std::vector< Module * > & usedBackends () const`
  - `const carl::FastSet< FormulaT > & constraintsToInform () const`
  - `const carl::FastSet< FormulaT > & informedConstraints () const`
  - `void addLemma (const FormulaT &_lemma, const LemmaType &_lt=LemmaType::NORMAL, const FormulaT &_preferredFormula=FormulaT(carl::FormulaType::TRUE))`  
 Stores a lemma being a valid formula.

- `bool hasLemmas ()`  
*Checks whether this module or any of its backends provides any lemmas.*
- `void clearLemmas ()`  
*Deletes all yet found lemmas.*
- `const std::vector< Lemma > & lemmas () const`
- `ModuleInput::const_iterator firstUncheckedReceivedSubformula () const`
- `ModuleInput::const_iterator firstSubformulaToPass () const`
- `void receivedFormulaChecked ()`  
*Notifies that the received formulas has been checked.*
- `const smrat::Conditionals & answerFound () const`
- `virtual std::string moduleName () const`
- `carl::Variable objective () const`
- `bool is_minimizing () const`
- `void excludeNotReceivedVariablesFromModel () const`  
*Excludes all variables from the current model, which do not occur in the received formula.*
- `void updateLemmas ()`  
*Stores all lemmas of any backend of this module in its own lemma vector.*
- `void collectTheoryPropagations ()`
- `void collectOrigins (const FormulaT &_formula, FormulasT &_origins) const`  
*Collects the formulas in the given formula, which are part of the received formula.*
- `void collectOrigins (const FormulaT &_formula, FormulaSetT &_origins) const`
- `bool hasValidInfeasibleSubset () const`
- `void checkInfSubsetForMinimality (std::vector< FormulaSetT >::const_iterator _infsSubset, const std::string &_filename="smaller_muses", unsigned _maxSizeDifference=1) const`  
*Checks the given infeasible subset for minimality by storing all subsets of it, which have a smaller size which differs from the size of the infeasible subset not more than the given threshold.*
- `void print (const std::string &_initiation="***") const`  
*Prints everything relevant of the solver.*
- `void printReceivedFormula (const std::string &_initiation="***") const`  
*Prints the vector of the received formula.*
- `void printPassedFormula (const std::string &_initiation="***") const`  
*Prints the vector of passed formula.*
- `void printInfeasibleSubsets (const std::string &_initiation="***") const`  
*Prints the infeasible subsets.*
- `void printModel (std::ostream &_out=std::cout) const`  
*Prints the assignment of this module satisfying its received formula if it satisfiable and this module could find an assignment.*
- `void printAllModels (std::ostream &_out=std::cout)`  
*Prints all assignments of this module satisfying its received formula if it satisfiable and this module could find an assignment.*

## Static Public Member Functions

- `static void freeSplittingVariable (const FormulaT &_splittingVariable)`

## Static Public Attributes

- `static size_t mNumOfBranchVarsToStore = 5`  
*The number of different variables to consider for a probable infinite loop of branchings.*
- `static std::vector< Branching > mLastBranches = std::vector<Branching>(mNumOfBranchVarsToStore, Branching(typename Poly::PolyType(), 0))`  
*Stores the last branches in a cycle buffer.*
- `static size_t mFirstPosInLastBranches = 0`  
*The beginning of the cyclic buffer storing the last branches.*
- `static std::vector< FormulaT > mOldSplittingVariables`  
*Reusable splitting variables.*

## Protected Member Functions

- virtual bool `informCore` (const `FormulaT` &\_constraint)
 

*Informs the module about the given constraint.*
- virtual void `deinformCore` (const `FormulaT` &\_constraint)
 

*The inverse of informing about a constraint.*
- virtual bool `addCore` (`ModuleInput::const_iterator` formula)
 

*The module has to take the given sub-formula of the received formula into account.*
- virtual void `removeCore` (`ModuleInput::const_iterator` formula)
 

*Removes everything related to the given sub-formula of the received formula.*
- bool `anAnswerFound` () const
 

*Checks for all antecedent modules and those which run in parallel with the same antecedent modules, whether one of them has determined a result.*
- void `clearModel` () const
 

*Clears the assignment, if any was found.*
- void `clearModels` () const
 

*Clears all assignments, if any was found.*
- void `cleanModel` () const
 

*Substitutes variable occurrences by its model value in the model values of other variables.*
- `ModuleInput::iterator` `passedFormulaBegin` ()
- `ModuleInput::iterator` `passedFormulaEnd` ()
- void `addOrigin` (`ModuleInput::iterator` \_formula, const `FormulaT` &\_origin)
 

*Adds the given set of formulas in the received formula to the origins of the given passed formula.*
- const `FormulaT` & `getOrigins` (`ModuleInput::const_iterator` \_formula) const
 

*Gets the origins of the passed formula at the given position.*
- void `getOrigins` (const `FormulaT` &\_formula, `FormulasT` &\_origins) const
- void `getOrigins` (const `FormulaT` &\_formula, `FormulaSetT` &\_origins) const
- std::pair< `ModuleInput::iterator`, bool > `removeOrigin` (`ModuleInput::iterator` \_formula, const `FormulaT` &\_origin)
- std::pair< `ModuleInput::iterator`, bool > `removeOrigins` (`ModuleInput::iterator` \_formula, const std::shared\_ptr< std::vector< `FormulaT` >> &\_origins)
- void `informBackends` (const `FormulaT` &\_constraint)
 

*Informs all backends of this module about the given constraint.*
- virtual void `addConstraintToInform` (const `FormulaT` &\_constraint)
 

*Adds a constraint to the collection of constraints of this module, which are informed to a freshly generated backend.*
- std::pair< `ModuleInput::iterator`, bool > `addReceivedSubformulaToPassedFormula` (`ModuleInput::const_iterator` \_subformula)
 

*Copies the given sub-formula of the received formula to the passed formula.*
- bool `originInReceivedFormula` (const `FormulaT` &\_origin) const
- std::pair< `ModuleInput::iterator`, bool > `addSubformulaToPassedFormula` (const `FormulaT` &\_formula)
 

*Adds the given formula to the passed formula with no origin.*
- std::pair< `ModuleInput::iterator`, bool > `addSubformulaToPassedFormula` (const `FormulaT` &\_formula, const std::shared\_ptr< std::vector< `FormulaT` >> &\_origins)
 

*Adds the given formula to the passed formula.*
- std::pair< `ModuleInput::iterator`, bool > `addSubformulaToPassedFormula` (const `FormulaT` &\_formula, const `FormulaT` &\_origin)
 

*Adds the given formula to the passed formula.*
- void `generateTrivialInfeasibleSubset` ()
 

*Stores the trivial infeasible subset being the set of received formulas.*
- void `receivedFormulasAsInfeasibleSubset` (`ModuleInput::const_iterator` \_subformula)
 

*Stores an infeasible subset consisting only of the given received formula.*
- std::vector< `FormulaT` >::const\_iterator `findBestOrigin` (const std::vector< `FormulaT` > &\_origins) const
- void `getInfeasibleSubsets` ()

- Copies the infeasible subsets of the passed formula.
- std::vector< `FormulaSetT` > `getInfeasibleSubsets` (const `Module` &\_backend) const
 

Get the infeasible subsets the given backend provides.
- const `Model` & `backendsModel` () const
 

Stores the model of a backend which determined satisfiability of the passed formula in the model of this module.
- void `getBackendsModel` () const
- void `getBackendsAllModels` () const
 

Stores all models of a backend in the list of all models of this module.
- virtual `ModuleInput`::iterator `eraseSubformulaFromPassedFormula` (`ModuleInput`::iterator \_subformula, bool \_ignoreOrigins=false)
 

Removes everything related to the sub-formula to remove from the passed formula in the backends of this module.
- void `clearPassedFormula` ()
- std::vector< `FormulaT` > `merge` (const std::vector< `FormulaT` > &, const std::vector< `FormulaT` > &) const
 

Merges the two vectors of sets into the first one.
- size\_t `determine_smallest_origin` (const std::vector< `FormulaT` > &origins) const
- bool `probablyLooping` (const typename `Poly`::`PolyType` &\_branchingPolynomial, const `Rational` &\_branchingValue) const
 

Checks whether given the current branching value and branching variable/polynomial it is (highly) probable that this branching is part of an infinite loop of branchings.
- bool `branchAt` (const `Poly` &\_polynomial, bool \_integral, const `Rational` &\_value, std::vector< `FormulaT` > &&\_premise, bool \_leftCaseWeak=true, bool \_preferLeftCase=true, bool \_useReceivedFormulaAsPremise=false)
 

Adds a lemmas which provoke a branching for the given variable at the given value, if this module returns Unknown and there exists a preceding SATModule.
- bool `branchAt` (const `Poly` &\_polynomial, bool \_integral, const `Rational` &\_value, bool \_leftCaseWeak=true, bool \_preferLeftCase=true, bool \_useReceivedFormulaAsPremise=false, const std::vector< `FormulaT` > &&\_premise=std::vector< `FormulaT` >())
 

Adds a lemmas which provoke a branching for the given variable at the given value, if this module returns Unknown and there exists a preceding SATModule.
- bool `branchAt` (carl::Variable::Arg \_var, const `Rational` &\_value, std::vector< `FormulaT` > &&\_premise, bool \_leftCaseWeak=true, bool \_preferLeftCase=true, bool \_useReceivedFormulaAsPremise=false)
 

Adds a lemmas which provoke a branching for the given variable at the given value, if this module returns Unknown and there exists a preceding SATModule.
- bool `branchAt` (carl::Variable::Arg \_var, const `Rational` &\_value, bool \_leftCaseWeak=true, bool \_preferLeftCase=true, bool \_useReceivedFormulaAsPremise=false, const std::vector< `FormulaT` > &\_premise=std::vector< `FormulaT` >())
 

Adds a lemmas which provoke a branching for the given variable at the given value, if this module returns Unknown and there exists a preceding SATModule.
- void `splitUnequalConstraint` (const `FormulaT` &)
 

Adds the following lemmas for the given constraint  $p \neq 0$ .
- unsigned `checkModel` () const
- void `addInformationRelevantFormula` (const `FormulaT` &formula)
 

Adds a formula to the InformationRelevantFormula.
- const std::set< `FormulaT` > & `getInformationRelevantFormulas` ()
 

Gets all InformationRelevantFormulas.
- bool `isLemmaLevel` (`LemmaLevel` level)
 

Checks if current lemma level is greater or equal to given level.

## Static Protected Member Functions

- static bool `modelsDisjoint` (const `Model` &\_modelA, const `Model` &\_modelB)
 

Checks whether there is no variable assigned by both models.

## Protected Attributes

- std::vector< `FormulaSetT` > `mInfeasibleSubsets`

Stores the infeasible subsets.
- `Manager` \*const `mpManager`

A reference to the manager.
- `Model` `mModel`

- std::vector< Model > mAllModels
 

*Stores the assignment of the current satisfiable result, if existent.*
- bool mModelComputed
 

*Stores all satisfying assignments.*
- bool mFinalCheck
 

*True, if the model has already been computed.*
- bool mFullCheck
 

*true, if the check procedure should perform a final check which especially means not to postpone splitting decisions*
- bool mFullCheck
 

*false, if this module should avoid too expensive procedures and rather return unknown instead.*
- carl::Variable mObjectiveVariable
 

*Objective variable to be minimized. If set to NO\_VARIABLE, a normal sat check should be performed.*
- std::vector< TheoryPropagation > mTheoryPropagations
- std::atomic< Answer > mSolverState
 

*States whether the received formula is known to be satisfiable or unsatisfiable otherwise it is set to unknown.*
- std::atomic\_bool \* mBackendsFoundAnswer
 

*This flag is passed to any backend and if it determines an answer to a prior check call, this flag is fired.*
- Conditionals mFoundAnswer
 

*Vector of Booleans: If any of them is true, we have to terminate a running check procedure.*
- std::vector< Module \* > mUsedBackends
 

*The backends of this module which are currently used (conditions to use this module are fulfilled for the passed formula).*
- std::vector< Module \* > mAllBackends
 

*The backends of this module which have been used.*
- std::vector< Lemma > mLemmas
 

*Stores the lemmas being valid formulas this module or its backends made.*
- ModuleInput::iterator mFirstSubformulaToPass
 

*Stores the position of the first sub-formula in the passed formula, which has not yet been considered for a consistency check of the backends.*
- carl::FastSet< FormulaT > mConstraintsToInform
 

*Stores the constraints which the backends must be informed about.*
- carl::FastSet< FormulaT > mInformedConstraints
 

*Stores the position of the first constraint of which no backend has been informed about.*
- ModuleInput::const\_iterator mFirstUncheckedReceivedSubformula
 

*Stores the position of the first (by this module) unchecked sub-formula of the received formula.*
- unsigned mSmallerMusesCheckCounter
 

*Counter used for the generation of the smt2 files to check for smaller muses.*
- std::vector< std::size\_t > mVariableCounters
 

*Maps variables to the number of their occurrences.*

### 0.15.535.1 Member Typedef Documentation

```
0.15.535.1.1 SettingsType template<typename Settings >
typedef Settings smtrat::SymmetryModule< Settings >::SettingsType
```

### 0.15.535.2 Member Enumeration Documentation

```
0.15.535.2.1 LemmaType enum smtrat::Module::LemmaType : unsigned [strong], [inherited]
```

**Enumerator**

|           |  |
|-----------|--|
| NORMAL    |  |
| PERMANENT |  |

**0.15.535.3 Constructor & Destructor Documentation****0.15.535.3.1 SymmetryModule()** `template<typename Settings >`

```
smtrat::SymmetryModule< Settings >::SymmetryModule (
 const ModuleInput * _formula,
 Conditionals & _conditionals,
 Manager * _manager = nullptr)
```

**0.15.535.3.2 ~SymmetryModule()** `template<typename Settings >`

```
smtrat::SymmetryModule< Settings >::~SymmetryModule ()
```

**0.15.535.4 Member Function Documentation****0.15.535.4.1 add()** `bool smtrat::PModule::add (`

```
 ModuleInput::const_iterator _subformula) [inherited]
```

The module has to take the given sub-formula of the received formula into account.

**Parameters**

|                          |                                                    |
|--------------------------|----------------------------------------------------|
| <code>_subformula</code> | The sub-formula to take additionally into account. |
|--------------------------|----------------------------------------------------|

**Returns**

false, if it can be easily decided that this sub-formula causes a conflict with the already considered sub-formulas; true, otherwise.

**0.15.535.4.2 addConstraintToInform()** `void smtrat::Module::addConstraintToInform (`

```
 const FormulaT & _constraint) [protected], [virtual], [inherited]
```

Adds a constraint to the collection of constraints of this module, which are informed to a freshly generated backend.

**Parameters**

|                          |                        |
|--------------------------|------------------------|
| <code>_constraint</code> | The constraint to add. |
|--------------------------|------------------------|

Reimplemented in `smtrat::SATModule< Settings >`.

**0.15.535.4.3 addCore()** `virtual bool smtrat::Module::addCore (`

```
 ModuleInput::const_iterator formula) [inline], [protected], [virtual], [inherited]
```

The module has to take the given sub-formula of the received formula into account.

**Parameters**

|                      |                                                    |
|----------------------|----------------------------------------------------|
| <code>formula</code> | The sub-formula to take additionally into account. |
|----------------------|----------------------------------------------------|

**Returns**

false, if it can be easily decided that this sub-formula causes a conflict with the already considered sub-formulas; true, otherwise.

Reimplemented in [smrat::VSModule< Settings >](#), [smrat::SATModule< Settings >](#), [smrat::PFEModule< Settings >](#), [smrat::ICPModule< Settings >](#), [smrat::ICPModule< ICPSettings4 >](#), [smrat::ICPModule< ICPSettings1 >](#), [smrat::UnionFindModule< Settings >](#), [smrat::UFCegarModule< Settings >](#), [smrat::STropModule< Settings >](#), [smrat::PBPPModule< Settings >](#), [smrat::PBGaussModule< Settings >](#), [smrat::NRAILModule< Settings >](#), [smrat::NewCoveringModule< Settings >](#), [smrat::NewCADModule< Settings >](#), [smrat::LRAModule< Settings >](#), [smrat::LRAModule< LRASettingsICP >](#), [smrat::LRAModule< LRASettings1 >](#), [smrat::IntEqModule< Settings >](#), [smrat::IntBlastModule< Settings >](#), [smrat::IncWidthModule< Settings >](#), [smrat::ICEModule< Settings >](#), [smrat::FPPModule< Settings >](#), [smrat::FouMoModule< Settings >](#), [smrat::EQModule< Settings >](#), [smrat::CurryModule< Settings >](#), [smrat::CubeLIAModule< Settings >](#), [smrat::CSplitModule< Settings >](#), [smrat::BVMModule< Settings >](#), and [smrat::GBModule< Settings >](#).

**0.15.535.4.4 addInformationRelevantFormula()** void smrat::Module::addInformationRelevantFormula (

const [FormulaT](#) & formula ) [protected], [inherited]

Adds a formula to the InformationRelevantFormula.

**Parameters**

|                |                |
|----------------|----------------|
| <i>formula</i> | Formula to add |
|----------------|----------------|

**0.15.535.4.5 addLemma()** void smrat::Module::addLemma (

const [FormulaT](#) & \_lemma,

const [LemmaType](#) & \_lt = [LemmaType::NORMAL](#),

const [FormulaT](#) & \_preferredFormula = [FormulaT\( carl::FormulaType::TRUE \)](#) ) [inline],

[inherited]

Stores a lemma being a valid formula.

**Parameters**

|                          |                                                                       |
|--------------------------|-----------------------------------------------------------------------|
| <i>_lemma</i>            | The eduction/lemma to store.                                          |
| <i>_lt</i>               | The type of the lemma.                                                |
| <i>_preferredFormula</i> | Hint for the next decision, which formula should be assigned to true. |

**0.15.535.4.6 addOrigin()** void smrat::Module::addOrigin (

[ModuleInput::iterator](#) \_formula,

const [FormulaT](#) & \_origin ) [inline], [protected], [inherited]

Adds the given set of formulas in the received formula to the origins of the given passed formula.

**Parameters**

|                 |                                                           |
|-----------------|-----------------------------------------------------------|
| <i>_formula</i> | The passed formula to set the origins for.                |
| <i>_origin</i>  | A set of formulas in the received formula of this module. |

**0.15.535.4.7 addReceivedSubformulaToPassedFormula()** std::pair<[ModuleInput::iterator](#), bool> smrat::Module::addReceivedSubformulaToPassedFormula (

---

```
ModuleInput::const_iterator _subformula) [inline], [protected], [inherited]
```

Copies the given sub-formula of the received formula to the passed formula.

Note, that there is always a link between sub-formulas of the passed formulas to sub-formulas of the received formulas, which are responsible for its occurrence.

#### Parameters

|                          |                                                  |
|--------------------------|--------------------------------------------------|
| <code>_subformula</code> | The sub-formula of the received formula to copy. |
|--------------------------|--------------------------------------------------|

**0.15.535.4.8 addSubformulaToPassedFormula()** [1/3] `std::pair<ModuleInput::iterator,bool> smtrat<->`  
`::Module::addSubformulaToPassedFormula (`  
 `const FormulaT & _formula ) [inline], [protected], [inherited]`

Adds the given formula to the passed formula with no origin.

Note that in the next call of this module's removeSubformula, all formulas in the passed formula without origins will be removed.

#### Parameters

|                       |                                           |
|-----------------------|-------------------------------------------|
| <code>_formula</code> | The formula to add to the passed formula. |
|-----------------------|-------------------------------------------|

#### Returns

A pair to the position where the formula to add has been inserted (or its first sub-formula which has not yet been in the passed formula, in case the formula to add is a conjunction), and a Boolean stating whether anything has been added to the passed formula.

**0.15.535.4.9 addSubformulaToPassedFormula()** [2/3] `std::pair<ModuleInput::iterator,bool> smtrat<->`  
`::Module::addSubformulaToPassedFormula (`  
 `const FormulaT & _formula,`  
 `const FormulaT & _origin ) [inline], [protected], [inherited]`

Adds the given formula to the passed formula.

#### Parameters

|                       |                                                                                                                           |
|-----------------------|---------------------------------------------------------------------------------------------------------------------------|
| <code>_formula</code> | The formula to add to the passed formula.                                                                                 |
| <code>_origin</code>  | The sub-formula of the received formula being responsible for the occurrence of the formula to add to the passed formula. |

#### Returns

A pair to the position where the formula to add has been inserted (or its first sub-formula which has not yet been in the passed formula, in case the formula to add is a conjunction), and a Boolean stating whether anything has been added to the passed formula.

**0.15.535.4.10 addSubformulaToPassedFormula()** [3/3] `std::pair<ModuleInput::iterator,bool>`  
`smtrat::Module::addSubformulaToPassedFormula (`  
 `const FormulaT & _formula,`  
 `const std::shared_ptr< std::vector< FormulaT >> & _origins ) [inline], [protected],`  
`[inherited]`

Adds the given formula to the passed formula.

**Parameters**

|                       |                                                                                                                                         |
|-----------------------|-----------------------------------------------------------------------------------------------------------------------------------------|
| <code>_formula</code> | The formula to add to the passed formula.                                                                                               |
| <code>_origins</code> | The link of the formula to add to the passed formula to sub-formulas of the received formulas, which are responsible for its occurrence |

**Returns**

A pair to the position where the formula to add has been inserted (or its first sub-formula which has not yet been in the passed formula, in case the formula to add is a conjunction), and a Boolean stating whether anything has been added to the passed formula.

**0.15.535.4.11 `allModels()`** `const std::vector<Model>& smtrat::Module::allModels () const [inline], [inherited]`

**Returns**

All satisfying assignments, if existent.

**0.15.535.4.12 `anAnswerFound()`** `bool smtrat::Module::anAnswerFound () const [inline], [protected], [inherited]`

Checks for all antecedent modules and those which run in parallel with the same antecedent modules, whether one of them has determined a result.

**Returns**

True, if one of them has determined a result.

**0.15.535.4.13 `answerFound()`** `const smtrat::Conditionals& smtrat::Module::answerFound () const [inline], [inherited]`

**Returns**

A vector of Booleans: If any of them is true, we have to terminate a running check procedure.

**0.15.535.4.14 `appliedPreprocessing()`** `bool smtrat::PModule::appliedPreprocessing () const [inline], [inherited]`

**Returns**

true, if the current received formula has been simplified and the result of this simplification is stored in the passed formula.

**0.15.535.4.15 `backendsModel()`** `const Model & smtrat::Module::backendsModel () const [protected], [inherited]`

Stores the model of a backend which determined satisfiability of the passed formula in the model of this module.

---

**0.15.535.4.16 branchAt() [1/4]** bool smrat::Module::branchAt (

```
carl::Variable::Arg _var,
const Rational & _value,
bool _leftCaseWeak = true,
bool _preferLeftCase = true,
bool _useReceivedFormulaAsPremise = false,
const std::vector< FormulaT > & _premise = std::vector<FormulaT>()) [inline],
[protected], [inherited]
```

**0.15.535.4.17 branchAt() [2/4]** bool smrat::Module::branchAt (

```
carl::Variable::Arg _var,
const Rational & _value,
std::vector< FormulaT > && _premise,
bool _leftCaseWeak = true,
bool _preferLeftCase = true,
bool _useReceivedFormulaAsPremise = false) [inline], [protected], [inherited]
```

**0.15.535.4.18 branchAt() [3/4]** bool smrat::Module::branchAt (

```
const Poly & _polynomial,
bool _integral,
const Rational & _value,
bool _leftCaseWeak = true,
bool _preferLeftCase = true,
bool _useReceivedFormulaAsPremise = false,
const std::vector< FormulaT > & _premise = std::vector<FormulaT>()) [inline],
[protected], [inherited]
```

**0.15.535.4.19 branchAt() [4/4]** bool smrat::Module::branchAt (

```
const Poly & _polynomial,
bool _integral,
const Rational & _value,
std::vector< FormulaT > && _premise,
bool _leftCaseWeak = true,
bool _preferLeftCase = true,
bool _useReceivedFormulaAsPremise = false) [protected], [inherited]
```

Adds a lemmas which provoke a branching for the given variable at the given value, if this module returns Unknown and there exists a preceding [SATModule](#).

Note that the given value is rounded down and up, if the given variable is integer-valued.

#### Parameters

|                                           |                                                                                                                                                                                                                |
|-------------------------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>_polynomial</code>                  | The variable to branch for.                                                                                                                                                                                    |
| <code>_integral</code>                    | A flag being true, if all variables in the polynomial to branch for are integral.                                                                                                                              |
| <code>_value</code>                       | The value to branch at.                                                                                                                                                                                        |
| <code>_premise</code>                     | The sub-formulas of the received formula from which the branch is followed. Note, that a premise is not necessary, as every branch is a valid formula. But a premise can prevent from branching unnecessarily. |
| <code>_leftCaseWeak</code>                | true, if a branching in the form of (or ( $\leq p b$ ) ( $> p b$ )) is desired. false, if a branching in the form of (or ( $< p b$ ) ( $\geq p b$ )) is desired.                                               |
| <code>_preferLeftCase</code>              | true, if the left case (polynomial less(or equal) 0 shall be chosen first. false, otherwise.                                                                                                                   |
| <code>_useReceivedFormulaAsPremise</code> | true, if the whole received formula should be used as premise                                                                                                                                                  |

```
0.15.535.4.20 check() Answer smrat::PModule::check (
 bool _final = false,
 bool _full = true,
 carl::Variable _objective = carl::Variable::NO_VARIABLE) [virtual], [inherited]
```

Checks the received formula for consistency.

Note, that this is an implementation of the satisfiability check of the conjunction of the so far received formulas, which does actually nothing but passing the problem to its backends. This implementation is only used internally and must be overwritten by any derived module.

#### Parameters

|                   |                                                                                                                                       |
|-------------------|---------------------------------------------------------------------------------------------------------------------------------------|
| <i>_final</i>     | true, if this satisfiability check will be the last one (for a global sat-check), if its result is SAT                                |
| <i>_full</i>      | false, if this module should avoid too expensive procedures and rather return unknown instead.                                        |
| <i>_objective</i> | if not set to NO_VARIABLE, the module should find an assignment minimizing this objective variable; otherwise any assignment is good. |

#### Returns

True, if the received formula is satisfiable; False, if the received formula is not satisfiable; Unknown, otherwise.

Reimplemented from [smrat::Module](#).

```
0.15.535.4.21 checkCore() template<typename Settings >
Answer smrat::SymmetryModule< Settings >::checkCore () [virtual]
```

Checks the received formula for consistency.

#### Returns

True, if the received formula is satisfiable; False, if the received formula is not satisfiable; Unknown, otherwise.

Reimplemented from [smrat::Module](#).

```
0.15.535.4.22 checkInfeasibleSubsetForMinimality() void smrat::Module::checkInfeasibleSubsetForMinimality (
 std::vector< FormulaSetT >::const_iterator _infssubset,
 const std::string & _filename = "smaller_muses",
 unsigned _maxSizeDifference = 1) const [inherited]
```

Checks the given infeasible subset for minimality by storing all subsets of it, which have a smaller size which differs from the size of the infeasible subset not more than the given threshold.

#### Parameters

|                           |                                                                                                        |
|---------------------------|--------------------------------------------------------------------------------------------------------|
| <i>_infssubset</i>        | The infeasible subset to check for minimality.                                                         |
| <i>_filename</i>          | The name of the file to store the infeasible subsets in order to be able to check their infeasibility. |
| <i>_maxSizeDifference</i> | The maximal difference between the sizes of the subsets compared to the size of the infeasible subset. |

```
0.15.535.4.23 checkModel() unsigned smrat::Module::checkModel () const [protected], [inherited]
```

**Returns**

false, if the current model of this module does not satisfy the current given formula; true, if it cannot be said whether the model satisfies the given formula.

**0.15.535.4.24 cleanModel()** void smtrat::Module::cleanModel ( ) const [inline], [protected], [inherited]

Substitutes variable occurrences by its model value in the model values of other variables.

**0.15.535.4.25 clearLemmas()** void smtrat::Module::clearLemmas ( ) [inline], [inherited]

Deletes all yet found lemmas.

**0.15.535.4.26 clearModel()** void smtrat::Module::clearModel ( ) const [inline], [protected], [inherited]

Clears the assignment, if any was found.

**0.15.535.4.27 clearModels()** void smtrat::Module::clearModels ( ) const [inline], [protected], [inherited]

Clears all assignments, if any was found.

**0.15.535.4.28 clearPassedFormula()** void smtrat::Module::clearPassedFormula ( ) [protected], [inherited]

**0.15.535.4.29 collectOrigins() [1/2]** void smtrat::Module::collectOrigins ( const `FormulaT` & `_formula`, `FormulaSetT` & `_origins` ) const [inherited]

**0.15.535.4.30 collectOrigins() [2/2]** void smtrat::Module::collectOrigins ( const `FormulaT` & `_formula`, `FormulasT` & `_origins` ) const [inherited]

Collects the formulas in the given formula, which are part of the received formula.

If the given formula directly occurs in the received formula, it is inserted into the given set. Otherwise, the given formula must be of type AND and all its sub-formulas part of the received formula. Hence, they will be added to the given set.

**Parameters**

|                       |                                                                                                      |
|-----------------------|------------------------------------------------------------------------------------------------------|
| <code>_formula</code> | The formula from which to collect the formulas being sub-formulas of the received formula (origins). |
| <code>_origins</code> | The set in which to store the origins.                                                               |

**0.15.535.4.31 collectTheoryPropagations()** void smtrat::Module::collectTheoryPropagations ( ) [inherited]

**0.15.535.4.32 constraintsToInform()** const carl::FastSet<`FormulaT`>& smtrat::Module::constraintsToInform ( ) const [inline], [inherited]

**Returns**

The constraints which the backends must be informed about.

**0.15.535.4.33 currentlySatisfied()** `virtual unsigned smtrat::Module::currentlySatisfied ( const FormulaT & ) const [inline], [virtual], [inherited]`

**Returns**

0, if the given formula is conflicted by the current model; 1, if the given formula is satisfied by the current model; 2, otherwise; 3, if we do not know anything (default)

Reimplemented in [smtrat::LRAModule< Settings >](#), [smtrat::LRAModule< LRASettingsICP >](#), and [smtrat::LRAModule< LRASettings >](#)

**0.15.535.4.34 currentlySatisfiedByBackend()** `unsigned smtrat::Module::currentlySatisfiedByBackend ( const FormulaT & _formula ) const [inherited]`

**Returns**

0, if the given formula is conflicted by the current model; 1, if the given formula is satisfied by the current model; 2, otherwise 3, if we do not know anything (default)

**0.15.535.4.35 deinform()** `void smtrat::Module::deinform ( const FormulaT & _constraint ) [inherited]`

The inverse of informing about a constraint.

All data structures which were kept regarding this constraint are going to be removed. Note, that this makes only sense if it is not likely enough that a formula with this constraint must be solved again.

**Parameters**

|                          |                                                         |
|--------------------------|---------------------------------------------------------|
| <code>_constraint</code> | The constraint to remove from internal data structures. |
|--------------------------|---------------------------------------------------------|

**0.15.535.4.36 deinformCore()** `virtual void smtrat::Module::deinformCore ( const FormulaT & _constraint ) [inline], [protected], [virtual], [inherited]`

The inverse of informing about a constraint.

All data structures which were kept regarding this constraint are going to be removed. Note, that this makes only sense if it is not likely enough that a formula with this constraint must be solved again.

**Parameters**

|                          |                                                         |
|--------------------------|---------------------------------------------------------|
| <code>_constraint</code> | The constraint to remove from internal data structures. |
|--------------------------|---------------------------------------------------------|

Reimplemented in [smtrat::LRAModule< Settings >](#), [smtrat::LRAModule< LRASettingsICP >](#), and [smtrat::LRAModule< LRASettings >](#)

**0.15.535.4.37 determine\_smallest\_origin()** `size_t smtrat::Module::determine_smallest_origin ( const std::vector< FormulaT > & origins ) const [protected], [inherited]`

**Parameters**

|                      |                              |
|----------------------|------------------------------|
| <code>origins</code> | A vector of sets of origins. |
|----------------------|------------------------------|

**Returns**

The index of the smallest (regarding the size of the sets) element of origins

**0.15.535.4.38 `eraseSubformulaFromPassedFormula()`** `ModuleInput::iterator smtrat::Module::eraseSubformulaFromPassedFormula ( ModuleInput::iterator _subformula, bool _ignoreOrigins = false )` [protected], [virtual], [inherited]

Removes everything related to the sub-formula to remove from the passed formula in the backends of this module. Afterwards the sub-formula is removed from the passed formula.

**Parameters**

|                             |                                                                                                              |
|-----------------------------|--------------------------------------------------------------------------------------------------------------|
| <code>_subformula</code>    | The sub-formula to remove from the passed formula.                                                           |
| <code>_ignoreOrigins</code> | True, if the sub-formula shall be removed regardless of its origins (should only be applied with expertise). |

**Returns**

Reimplemented in `smtrat::ICPModule< Settings >`, `smtrat::ICPModule< ICPSettings4 >`, and `smtrat::ICPModule< ICPSettings1 >`.

**0.15.535.4.39 `excludeNotReceivedVariablesFromModel()`** `void smtrat::Module::excludeNotReceivedVariablesFromModel ( ) const` [inherited]

Excludes all variables from the current model, which do not occur in the received formula.

**0.15.535.4.40 `findBestOrigin()`** `std::vector< FormulaT >::const_iterator smtrat::Module::findBestOrigin ( const std::vector< FormulaT > & _origins ) const` [protected], [inherited]

**Parameters**

|                       |  |
|-----------------------|--|
| <code>_origins</code> |  |
|-----------------------|--|

**Returns**

**0.15.535.4.41 `firstSubformulaToPass()`** `ModuleInput::const_iterator smtrat::Module::firstSubformulaToPass ( ) const` [inline], [inherited]

**Returns**

The position of the first sub-formula in the passed formula, which has not yet been considered for a consistency check of the backends.

**0.15.535.4.42 `firstUncheckedReceivedSubformula()`** `ModuleInput::const_iterator smtrat::Module::firstUncheckedReceivedSubformula ( ) const` [inline], [inherited]

**Returns**

The position of the first (by this module) unchecked sub-formula of the received formula.

**0.15.535.4.43 freeSplittingVariable()** static void smtrat::Module::freeSplittingVariable ( const `FormulaT` & `_splittingVariable` ) [inline], [static], [inherited]

**0.15.535.4.44 generateTrivialInfeasibleSubset()** void smtrat::Module::generateTrivialInfeasibleSubset ( ) [inline], [protected], [inherited]  
Stores the trivial infeasible subset being the set of received formulas.

**0.15.535.4.45 getBackendsAllModels()** void smtrat::Module::getBackendsAllModels ( ) const [protected], [inherited]  
Stores all models of a backend in the list of all models of this module.

**0.15.535.4.46 getBackendsModel()** void smtrat::Module::getBackendsModel ( ) const [protected], [inherited]

**0.15.535.4.47 getInfeasibleSubsets() [1/2]** void smtrat::Module::getInfeasibleSubsets ( ) [protected], [inherited]  
Copies the infeasible subsets of the passed formula.

**0.15.535.4.48 getInfeasibleSubsets() [2/2]** std::vector< `FormulaSetT` > smtrat::Module::getInfeasibleSubsets ( const `Module` & `_backend` ) const [protected], [inherited]

Get the infeasible subsets the given backend provides.  
Note, that an infeasible subset in a backend contains sub formulas of the passed formula and an infeasible subset of this module contains sub formulas of the received formula. In this method the LATTER is returned.

#### Parameters

|                       |                                                          |
|-----------------------|----------------------------------------------------------|
| <code>_backend</code> | The backend from which to obtain the infeasible subsets. |
|-----------------------|----------------------------------------------------------|

#### Returns

The infeasible subsets the given backend provides.

**0.15.535.4.49 getInformationRelevantFormulas()** const std::set< `FormulaT` > & smtrat::Module::getInformationRelevantFormulas ( ) [protected], [inherited]  
Gets all InformationRelevantFormulas.

#### Returns

Set of all formulas

**0.15.535.4.50 getModelEqualities()** std::list< std::vector< `carl::Variable` > > smtrat::Module::getModelEqualities ( ) const [virtual], [inherited]

Partition the variables from the current model into equivalence classes according to their assigned value.  
The result is a set of equivalence classes of variables where all variables within one class are assigned the same value. Note that the number of classes may not be minimal, i.e. two classes may actually be equivalent.

#### Returns

Equivalence classes.

**0.15.535.4.51 getOrigins() [1/3]** void smtrat::Module::getOrigins ( const FormulaT & \_formula, FormulaSetT & \_origins ) const [inline], [protected], [inherited]

**Parameters**

|          |  |
|----------|--|
| _formula |  |
| _origins |  |

**0.15.535.4.52 getOrigins() [2/3]** void smtrat::Module::getOrigins ( const FormulaT & \_formula, FormulasT & \_origins ) const [inline], [protected], [inherited]

**Parameters**

|          |  |
|----------|--|
| _formula |  |
| _origins |  |

**0.15.535.4.53 getOrigins() [3/3]** const FormulaT& smtrat::Module::getOrigins ( ModuleInput::const\_iterator \_formula ) const [inline], [protected], [inherited]

Gets the origins of the passed formula at the given position.

**Parameters**

|          |                                                   |
|----------|---------------------------------------------------|
| _formula | The position of a formula in the passed formulas. |
|----------|---------------------------------------------------|

**Returns**

The origins of the passed formula at the given position.

**0.15.535.4.54 getReceivedFormulaSimplified()** std::pair< bool, FormulaT > smtrat::PModule::getReceivedFormulaSimplified ( ) [virtual], [inherited]

**Returns**

A pair of a Boolean and a formula, where the Boolean is true, if the received formula could be simplified to an equisatisfiable formula. The formula is equisatisfiable to this module's received formula, if the Boolean is true.

Reimplemented from [smtrat::Module](#).

**0.15.535.4.55 hasLemmas()** bool smtrat::Module::hasLemmas ( ) [inline], [inherited]

Checks whether this module or any of its backends provides any lemmas.

**0.15.535.4.56 hasValidInfeasibleSubset()** bool smtrat::Module::hasValidInfeasibleSubset ( ) const [inherited]

**Returns**

true, if the module has at least one valid infeasible subset, that is all its elements are sub-formulas of the received formula (pointer must be equal).

**0.15.535.4.57 `id()`** `std::size_t smtrat::Module::id ( ) const [inline], [inherited]`

#### Returns

A unique ID to identify this module instance.

**0.15.535.4.58 `infeasibleSubsets()`** `const std::vector<FormulaSetT>& smtrat::Module::infeasibleSubsets ( ) const [inline], [inherited]`

#### Returns

The infeasible subsets of the set of received formulas (empty, if this module has not detected unsatisfiability of the conjunction of received formulas).

**0.15.535.4.59 `inform()`** `bool smtrat::Module::inform ( const FormulaT & _constraint ) [inherited]`

Informs the module about the given constraint.

It should be tried to inform this module about any constraint it could receive eventually before assertSubformula is called (preferably for the first time, but at least before adding a formula containing that constraint).

#### Parameters

|                          |                                 |
|--------------------------|---------------------------------|
| <code>_constraint</code> | The constraint to inform about. |
|--------------------------|---------------------------------|

#### Returns

false, if it can be easily decided whether the given constraint is inconsistent; true, otherwise.

**0.15.535.4.60 `informBackends()`** `void smtrat::Module::informBackends ( const FormulaT & _constraint ) [inline], [protected], [inherited]`

Informs all backends of this module about the given constraint.

#### Parameters

|                          |                                 |
|--------------------------|---------------------------------|
| <code>_constraint</code> | The constraint to inform about. |
|--------------------------|---------------------------------|

**0.15.535.4.61 `informCore()`** `virtual bool smtrat::Module::informCore ( const FormulaT & _constraint ) [inline], [protected], [virtual], [inherited]`

Informs the module about the given constraint.

It should be tried to inform this module about any constraint it could receive eventually before assertSubformula is called (preferably for the first time, but at least before adding a formula containing that constraint).

#### Parameters

|                          |                                 |
|--------------------------|---------------------------------|
| <code>_constraint</code> | The constraint to inform about. |
|--------------------------|---------------------------------|

#### Returns

false, if it can be easily decided whether the given constraint is inconsistent; true, otherwise.

Reimplemented in [smtrat::UnionFindModule< Settings >](#), [smtrat::PBPPModule< Settings >](#), [smtrat::PBGaussModule< Settings >](#), [smtrat::NRAILModule< Settings >](#), [smtrat::NewCoveringModule< Settings >](#), [smtrat::NewCADModule< Settings >](#),

`smrat::LRAModule< Settings >, smrat::LRAModule< LRASettingsICP >, smrat::LRAModule< LRASettings1 >, smrat::IntBlastModule< Settings >, smrat::FPPModule< Settings >, smrat::EQModule< Settings >, smrat::CurryModule< Settings >, smrat::BVMModule< Settings >, smrat::ICPModule< Settings >, smrat::ICPModule< ICPSettings4 >, and smrat::ICPModule< ICPSettings1 >.`

**0.15.535.4.62 informedConstraints()** `const carl::FastSet<FormulaT>& smrat::Module::informedConstraints( ) const [inline], [inherited]`

**Returns**

The position of the first constraint of which no backend has been informed about.

**0.15.535.4.63 init()** `void smrat::Module::init( ) [virtual], [inherited]`

Informs all backends about the so far encountered constraints, which have not yet been communicated.

This method must not be called twice and only before the first runBackends call.

Reimplemented in `smrat::PBPPModule< Settings >, smrat::PBGaussModule< Settings >, smrat::NRAILModule< Settings >, smrat::NewCoveringModule< Settings >, smrat::NewCADModule< Settings >, smrat::LRAModule< Settings >, smrat::LRAModule< LRASettingsICP >, smrat::LRAModule< LRASettings1 >, smrat::IntBlastModule< Settings >, smrat::FPPModule< Settings >, smrat::EQModule< Settings >, smrat::CurryModule< Settings >, and smrat::BVMModule< Settings >.`

**0.15.535.4.64 is\_minimizing()** `bool smrat::Module::is_minimizing( ) const [inline], [inherited]`

**0.15.535.4.65 isLemmaLevel()** `bool smrat::Module::isLemmaLevel( LemmaLevel level ) [protected], [inherited]`

Checks if current lemma level is greater or equal to given level.

**Parameters**

|                    |                 |
|--------------------|-----------------|
| <code>level</code> | Level to check. |
|--------------------|-----------------|

**0.15.535.4.66 isPreprocessor()** `bool smrat::PModule::isPreprocessor( ) const [inline], [inherited]`

**Returns**

true, if this module is a preprocessor that is a module, which simplifies its received formula to an equisatisfiable formula being passed to its backends. The simplified formula can be obtained with `getReceivedFormulaSimplified()`.

**0.15.535.4.67 lemmas()** `const std::vector<Lemma>& smrat::Module::lemmas( ) const [inline], [inherited]`

**Returns**

A constant reference to the lemmas being valid formulas this module or its backends made.

**0.15.535.4.68 merge()** `std::vector< FormulaT > smrat::Module::merge( const std::vector< FormulaT > & _vecSetA, const std::vector< FormulaT > & _vecSetB ) const [protected], [inherited]`

Merges the two vectors of sets into the first one.

({a,b},{a,c}) and ({b,d},{b}) -> ({a,b,d},{a,b},{a,b,c,d},{a,b,c})

**Parameters**

|                       |                                  |
|-----------------------|----------------------------------|
| <code>_vecSetA</code> | A vector of sets of constraints. |
| <code>_vecSetB</code> | A vector of sets of constraints. |

**Returns**

The vector being the two given vectors merged.

**0.15.535.4.69 `model()`** `const Model& smrat::Module::model () const [inline], [inherited]`**Returns**

The assignment of the current satisfiable result, if existent.

**0.15.535.4.70 `modelsDisjoint()`** `bool smrat::Module::modelsDisjoint (`

```
const Model & _modelA,
const Model & _modelB) [static], [protected], [inherited]
```

Checks whether there is no variable assigned by both models.

**Parameters**

|                      |                                |
|----------------------|--------------------------------|
| <code>_modelA</code> | The first model to check for.  |
| <code>_modelB</code> | The second model to check for. |

**Returns**

true, if there is no variable assigned by both models; false, otherwise.

**0.15.535.4.71 `moduleName()`** `virtual std::string smrat::Module::moduleName () const [inline], [virtual], [inherited]`**Returns**

The name of the given module type as name.

Reimplemented in [smrat::VSModule< Settings >](#), [smrat::UnionFindModule< Settings >](#), [smrat::UFCegarModule< Settings >](#), [smrat::STropModule< Settings >](#), [smrat::SplitSOSModule< Settings >](#), [smrat::PBPPModule< Settings >](#), [smrat::PBGaussModule< Settings >](#), [smrat::NRAILModule< Settings >](#), [smrat::NewCADModule< Settings >](#), [smrat::LVEModule< Settings >](#), [smrat::LRAModule< Settings >](#), [smrat::LRAModule< LRASettingsICP >](#), [smrat::LRAModule< LRASettings1 >](#), [smrat::IntEqModule< Settings >](#), [smrat::IntBlastModule< Settings >](#), [smrat::IncWidthModule< Settings >](#), [smrat::ICPModule< Settings >](#), [smrat::ICPModule< ICPSettings4 >](#), [smrat::ICPModule< ICPSettings1 >](#), [smrat::GBModule< Settings >](#), [smrat::FouMoModule< Settings >](#), [smrat::EQPreprocessingModule< Settings >](#), [smrat::EQModule< Settings >](#), [smrat::CurryModule< Settings >](#), [smrat::CubeLIAModule< Settings >](#), [smrat::CSplitModule< Settings >](#), [smrat::BVMModule< Settings >](#), and [smrat::BEModule< Settings >](#).

**0.15.535.4.72 `objective()`** `carl::Variable smrat::Module::objective () const [inline], [inherited]`**0.15.535.4.73 `originInReceivedFormula()`** `bool smrat::Module::originInReceivedFormula (`

```
const FormulaT & _origin) const [protected], [inherited]
```

**0.15.535.4.74 passedFormulaBegin()** `ModuleInput::iterator smtrat::Module::passedFormulaBegin ( )` [inline], [protected], [inherited]

**Returns**

An iterator to the end of the passed formula. TODO: disable this method

**0.15.535.4.75 passedFormulaEnd()** `ModuleInput::iterator smtrat::Module::passedFormulaEnd ( )` [inline], [protected], [inherited]

**Returns**

An iterator to the end of the passed formula.

**0.15.535.4.76 pPassedFormula()** `const ModuleInput* smtrat::Module::pPassedFormula ( ) const` [inline], [inherited]

**Returns**

A pointer to the formula passed to the backends of this module.

**0.15.535.4.77 pReceivedFormula()** `const ModuleInput* smtrat::Module::pReceivedFormula ( ) const` [inline], [inherited]

**Returns**

A pointer to the formula passed to this module.

**0.15.535.4.78 print()** `void smtrat::Module::print ( const std::string & _initiation = "***" ) const` [inherited]

Prints everything relevant of the solver.

**Parameters**

|                          |                      |
|--------------------------|----------------------|
| <code>_initiation</code> | The line initiation. |
|--------------------------|----------------------|

**0.15.535.4.79 printAllModels()** `void smtrat::Module::printAllModels ( std::ostream & _out = std::cout )` [inherited]

Prints all assignments of this module satisfying its received formula if it satisfiable and this module could find an assignment.

**Parameters**

|                   |                                        |
|-------------------|----------------------------------------|
| <code>_out</code> | The stream to print the assignment on. |
|-------------------|----------------------------------------|

**0.15.535.4.80 printInfeasibleSubsets()** `void smtrat::Module::printInfeasibleSubsets ( const std::string & _initiation = "***" ) const` [inherited]

Prints the infeasible subsets.

**Parameters**

|                          |                      |
|--------------------------|----------------------|
| <code>_initiation</code> | The line initiation. |
|--------------------------|----------------------|

**0.15.535.4.81 `printModel()`** `void smtrat::Module::printModel ( std::ostream & _out = std::cout ) const [inherited]`

Prints the assignment of this module satisfying its received formula if it satisfiable and this module could find an assignment.

**Parameters**

|                   |                                        |
|-------------------|----------------------------------------|
| <code>_out</code> | The stream to print the assignment on. |
|-------------------|----------------------------------------|

**0.15.535.4.82 `printPassedFormula()`** `void smtrat::Module::printPassedFormula ( const std::string & _initiation = "***" ) const [inherited]`

Prints the vector of passed formula.

**Parameters**

|                          |                      |
|--------------------------|----------------------|
| <code>_initiation</code> | The line initiation. |
|--------------------------|----------------------|

**0.15.535.4.83 `printReceivedFormula()`** `void smtrat::Module::printReceivedFormula ( const std::string & _initiation = "***" ) const [inherited]`

Prints the vector of the received formula.

**Parameters**

|                          |                      |
|--------------------------|----------------------|
| <code>_initiation</code> | The line initiation. |
|--------------------------|----------------------|

**0.15.535.4.84 `probablyLooping()`** `bool smtrat::Module::probablyLooping ( const typename Poly::PolyType & _branchingPolynomial, const Rational & _branchingValue ) const [protected], [inherited]`

Checks whether given the current branching value and branching variable/polynomial it is (highly) probable that this branching is part of an infinite loop of branchings.

**Parameters**

|                                   |                                                                                     |
|-----------------------------------|-------------------------------------------------------------------------------------|
| <code>_branchingPolynomial</code> | The polynomial to branch at (in most branching strategies this is just a variable). |
| <code>_branchingValue</code>      | The value to branch at.                                                             |

**Returns**

true, if this branching is probably part of an infinite loop of branchings; false, otherwise.

**0.15.535.4.85 `receivedFormulaChecked()`** `void smtrat::Module::receivedFormulaChecked ( ) [inline], [inherited]`

Notifies that the received formulas has been checked.

**0.15.535.4.86 `receivedFormulasAsInfeasibleSubset()`** void smtrat::Module::receivedFormulasAsInfeasibleSubset (

```
 ModuleInput::const_iterator _subformula) [inline], [protected], [inherited]
```

Stores an infeasible subset consisting only of the given received formula.

**0.15.535.4.87 `receivedVariable()`** bool smtrat::Module::receivedVariable (

```
 carl::Variable::Arg _var) const [inline], [inherited]
```

**0.15.535.4.88 `remove()`** void smtrat::PModule::remove (

```
 ModuleInput::const_iterator _subformula) [virtual], [inherited]
```

Removes everything related to the given sub-formula of the received formula.

However, it is desired not to lose track of search spaces where no satisfying assignment can be found for the remaining sub-formulas.

#### Parameters

|                          |                                                    |
|--------------------------|----------------------------------------------------|
| <code>_subformula</code> | The sub formula of the received formula to remove. |
|--------------------------|----------------------------------------------------|

Reimplemented from [smtrat::Module](#).

**0.15.535.4.89 `removeCore()`** virtual void smtrat::Module::removeCore (

```
 ModuleInput::const_iterator formula) [inline], [protected], [virtual], [inherited]
```

Removes everything related to the given sub-formula of the received formula.

However, it is desired not to lose track of search spaces where no satisfying assignment can be found for the remaining sub-formulas.

#### Parameters

|                      |                                                    |
|----------------------|----------------------------------------------------|
| <code>formula</code> | The sub formula of the received formula to remove. |
|----------------------|----------------------------------------------------|

Reimplemented in [smtrat::VSModule< Settings >](#), [smtrat::SATModule< Settings >](#), [smtrat::PFEModule< Settings >](#), [smtrat::ICPModule< Settings >](#), [smtrat::ICPModule< ICPSettings4 >](#), [smtrat::ICPModule< ICPSettings1 >](#), [smtrat::UnionFindModule< Settings >](#), [smtrat::UFCegarModule< Settings >](#), [smtrat::STropModule< Settings >](#), [smtrat::PBPPModule< Settings >](#), [smtrat::PBGaussModule< Settings >](#), [smtrat::NRAILModule< Settings >](#), [smtrat::NewCoveringModule< Settings >](#), [smtrat::NewCADModule< Settings >](#), [smtrat::LRAModule< Settings >](#), [smtrat::LRAModule< LRASettingsICP >](#), [smtrat::LRAModule< LRASettings1 >](#), [smtrat::IntEqModule< Settings >](#), [smtrat::IntBlastModule< Settings >](#), [smtrat::IncWidthModule< Settings >](#), [smtrat::ICEModule< Settings >](#), [smtrat::FPPModule< Settings >](#), [smtrat::FouMoModule< Settings >](#), [smtrat::EQModule< Settings >](#), [smtrat::CurryModule< Settings >](#), [smtrat::CubeLIAModule< Settings >](#), [smtrat::CSplitModule< Settings >](#), [smtrat::BVMModule< Settings >](#), and [smtrat::GBModule< Settings >](#).

**0.15.535.4.90 `removeOrigin()`** std::pair<ModuleInput::iterator, bool> smtrat::Module::removeOrigin (

```
 ModuleInput::iterator _formula,
 const FormulaT & _origin) [inline], [protected], [inherited]
```

**0.15.535.4.91 `removeOrigins()`** std::pair<ModuleInput::iterator, bool> smtrat::Module::removeOrigins (

```
 ModuleInput::iterator _formula,
 const std::shared_ptr< std::vector< FormulaT >> & _origins) [inline], [protected],
[inherited]
```

#### 0.15.535.4.92 rPassedFormula() const ModuleInput& smtrat::Module::rPassedFormula () const [inline], [inherited]

##### Returns

A reference to the formula passed to the backends of this module.

#### 0.15.535.4.93 rReceivedFormula() const ModuleInput& smtrat::Module::rReceivedFormula () const [inline], [inherited]

##### Returns

A reference to the formula passed to this module.

#### 0.15.535.4.94 runBackends() [1/2] virtual Answer smtrat::PModule::runBackends () [inline], [virtual], [inherited]

Reimplemented from [smtrat::Module](#).

#### 0.15.535.4.95 runBackends() [2/2] Answer smtrat::PModule::runBackends ( bool \_final, bool \_full, carl::Variable \_objective ) [virtual], [inherited]

Runs the backend solvers on the passed formula.

##### Parameters

|            |                                                                                                                                       |
|------------|---------------------------------------------------------------------------------------------------------------------------------------|
| _final     | true, if this satisfiability check will be the last one (for a global sat-check), if its result is SAT.                               |
| _full      | false, if this module should avoid too expensive procedures and rather return unknown instead.                                        |
| _objective | if not set to NO_VARIABLE, the module should find an assignment minimizing this objective variable; otherwise any assignment is good. |

##### Returns

True, if the passed formula is consistent; False, if the passed formula is inconsistent; Unknown, otherwise.

Reimplemented from [smtrat::Module](#).

#### 0.15.535.4.96 setId() void smtrat::Module::setId ( std::size\_t \_id ) [inline], [inherited]

Sets this modules unique ID to identify itself.

##### Parameters

|                     |                                    |
|---------------------|------------------------------------|
| ↔<br>↔<br><i>id</i> | The id to set this module's id to. |
|---------------------|------------------------------------|

**0.15.535.4.97 `setThreadPriority()`** `void smtrat::Module::setThreadPriority ( thread_priority _threadPriority ) [inline], [inherited]`  
Sets the priority of this module to get a thread for running its check procedure.

#### Parameters

|                              |                                                       |
|------------------------------|-------------------------------------------------------|
| <code>_threadPriority</code> | The priority to set this module's thread priority to. |
|------------------------------|-------------------------------------------------------|

**0.15.535.4.98 `solverState()`** `Answer smtrat::Module::solverState ( ) const [inline], [inherited]`

#### Returns

True, if this module is in a state, such that it has found a solution for its received formula; False, if this module is in a state, such that it has determined that there is no solution for its received formula; Unknown, otherwise.

**0.15.535.4.99 `splitUnequalConstraint()`** `void smtrat::Module::splitUnequalConstraint ( const FormulaT & _unequalConstraint ) [protected], [inherited]`

Adds the following lemmas for the given constraint  $p \neq 0$ .

$(p \neq 0 \leftrightarrow (p < 0 \text{ or } p > 0))$

and  $\text{not}(p < 0 \text{ and } p > 0)$

#### Parameters

|                                 |                                                  |
|---------------------------------|--------------------------------------------------|
| <code>_unequalConstraint</code> | A constraint having the relation symbol $\neq$ . |
|---------------------------------|--------------------------------------------------|

**0.15.535.4.100 `threadPriority()`** `thread_priority smtrat::Module::threadPriority ( ) const [inline], [inherited]`

#### Returns

The priority of this module to get a thread for running its check procedure.

**0.15.535.4.101 `updateAllModels()`** `void smtrat::Module::updateAllModels ( ) [virtual], [inherited]`

Updates all satisfying models, if the solver has detected the consistency of the received formula, beforehand.

Reimplemented in [smtrat::SATModule< Settings >](#).

**0.15.535.4.102 `updateLemmas()`** `void smtrat::Module::updateLemmas ( ) [inherited]`

Stores all lemmas of any backend of this module in its own lemma vector.

**0.15.535.4.103 `updateModel()`** `void smtrat::PModule::updateModel ( ) const [virtual], [inherited]`

Updates the current assignment into the model.

Note, that this is a unique but possibly symbolic assignment maybe containing newly introduced variables.

Reimplemented from [smtrat::Module](#).

**0.15.535.4.104 `usedBackends()`** `const std::vector<Module*>& smtrat::Module::usedBackends ( ) const [inline], [inherited]`

**Returns**

The backends of this module which are currently used (conditions to use this module are fulfilled for the passed formula).

**0.15.535.5 Field Documentation**

**0.15.535.5.1 mAllBackends** `std::vector<Module*> smrat::Module::mAllBackends [protected], [inherited]`

The backends of this module which have been used.

**0.15.535.5.2 mAllModels** `std::vector<Model> smrat::Module::mAllModels [mutable], [protected], [inherited]`

Stores all satisfying assignments.

**0.15.535.5.3 mBackendsFoundAnswer** `std::atomic_bool* smrat::Module::mBackendsFoundAnswer [protected], [inherited]`

This flag is passed to any backend and if it determines an answer to a prior check call, this flag is fired.

**0.15.535.5.4 mConstraintsToInform** `carl::FastSet<FormulaT> smrat::Module::mConstraintsToInform [protected], [inherited]`

Stores the constraints which the backends must be informed about.

**0.15.535.5.5 mFinalCheck** `bool smrat::Module::mFinalCheck [protected], [inherited]`  
true, if the check procedure should perform a final check which especially means not to postpone splitting decisions

**0.15.535.5.6 mFirstPosInLastBranches** `std::size_t smrat::Module::mFirstPosInLastBranches = 0 [static], [inherited]`

The beginning of the cyclic buffer storing the last branches.

**0.15.535.5.7 mFirstSubformulaToPass** `ModuleInput::iterator smrat::Module::mFirstSubformulaToPass [protected], [inherited]`

Stores the position of the first sub-formula in the passed formula, which has not yet been considered for a consistency check of the backends.

**0.15.535.5.8 mFirstUncheckedReceivedSubformula** `ModuleInput::const_iterator smrat::Module::mFirstUncheckedReceivedSubformula [protected], [inherited]`

Stores the position of the first (by this module) unchecked sub-formula of the received formula.

**0.15.535.5.9 mFoundAnswer** `Conditionals smrat::Module::mFoundAnswer [protected], [inherited]`  
Vector of Booleans: If any of them is true, we have to terminate a running check procedure.

**0.15.535.5.10 mFullCheck** `bool smrat::Module::mFullCheck [protected], [inherited]`  
false, if this module should avoid too expensive procedures and rather return unknown instead.

**0.15.535.5.11 mInfeasibleSubsets** std::vector<[FormulaSetT](#)> smtrat::Module::mInfeasibleSubsets  
[protected], [inherited]  
Stores the infeasible subsets.

**0.15.535.5.12 mInformedConstraints** carl::FastSet<[FormulaT](#)> smtrat::Module::mInformedConstraints  
[protected], [inherited]  
Stores the position of the first constraint of which no backend has been informed about.

**0.15.535.5.13 mLastBranches** std::vector< [Branching](#) > smtrat::Module::mLastBranches = std::vector<[Branching](#)>(mNumOfBranchVarsToStore, Branching(typename Poly::PolyType(), 0)) [static],  
[inherited]  
Stores the last branches in a cycle buffer.

**0.15.535.5.14 mLemmas** std::vector<[Lemma](#)> smtrat::Module::mLemmas [protected], [inherited]  
Stores the lemmas being valid formulas this module or its backends made.

**0.15.535.5.15 mModel** [Model](#) smtrat::Module::mModel [mutable], [protected], [inherited]  
Stores the assignment of the current satisfiable result, if existent.

**0.15.535.5.16 mModelComputed** bool smtrat::Module::mModelComputed [mutable], [protected],  
[inherited]  
True, if the model has already been computed.

**0.15.535.5.17 mNumOfBranchVarsToStore** std::size\_t smtrat::Module::mNumOfBranchVarsToStore = 5 [static], [inherited]  
The number of different variables to consider for a probable infinite loop of branchings.

**0.15.535.5.18 mObjectiveVariable** carl::Variable smtrat::Module::mObjectiveVariable [protected],  
[inherited]  
Objective variable to be minimized. If set to NO\_VARIABLE, a normal sat check should be performed.

**0.15.535.5.19 mOldSplittingVariables** std::vector< [FormulaT](#) > smtrat::Module::mOldSplittingVariables [static], [inherited]  
Reusable splitting variables.

**0.15.535.5.20 mpManager** [Manager](#)\* const smtrat::Module::mpManager [protected], [inherited]  
A reference to the manager.

**0.15.535.5.21 mSmallerMusesCheckCounter** unsigned smtrat::Module::mSmallerMusesCheckCounter [mutable], [protected], [inherited]  
Counter used for the generation of the smt2 files to check for smaller muses.

**0.15.535.5.22 mSolverState** std::atomic<[Answer](#)> smtrat::Module::mSolverState [protected], [inherited]

States whether the received formula is known to be satisfiable or unsatisfiable otherwise it is set to unknown.

**0.15.535.5.23 mTheoryPropagations** std::vector<[TheoryPropagation](#)> smtrat::Module::mTheory← Propagations [protected], [inherited]

**0.15.535.5.24 mUsedBackends** std::vector<[Module](#)\*> smtrat::Module::mUsedBackends [protected], [inherited]

The backends of this module which are currently used (conditions to use this module are fulfilled for the passed formula).

**0.15.535.5.25 mVariableCounters** std::vector<std::size\_t> smtrat::Module::mVariableCounters [protected], [inherited]

Maps variables to the number of their occurrences.

## 0.15.536 smtrat::lra::Tableau< Settings, T1, T2 > Class Template Reference

### 0.15.536.1 Constructor & Destructor Documentation

**0.15.536.1.1 Tableau()** template<class Settings , typename T1 , typename T2 >  
`smtrat::lra::Tableau< Settings, T1, T2 >::Tableau (`  
`ModuleInput::iterator _defaultBoundPosition )`

#### Parameters

|                                    |
|------------------------------------|
| <code>_defaultBoundPosition</code> |
|------------------------------------|

**0.15.536.1.2 ~Tableau()** template<class Settings , typename T1 , typename T2 >  
`smtrat::lra::Tableau< Settings, T1, T2 >::~Tableau ( )`

### 0.15.536.2 Member Function Documentation

```
0.15.536.2.1 activateBasicVar() template<class Settings , typename T1 , typename T2 >
void smtrat::lra::Tableau< Settings, T1, T2 >::activateBasicVar (
 Variable< T1, T2 > * _var)
g
```

**Parameters**

|      |  |
|------|--|
| _var |  |
|------|--|

```
0.15.536.2.2 activateBound() template<class Settings , typename T1 , typename T2 >
void smtrat::lra::Tableau< Settings, T1, T2 >::activateBound (
 const Bound< T1, T2 > * _bound,
 const FormulaT & _formula)
```

**Parameters**

|          |  |
|----------|--|
| _bound   |  |
| _formula |  |

```
0.15.536.2.3 adaptDelta() template<class Settings , typename T1 , typename T2 >
void smtrat::lra::Tableau< Settings, T1, T2 >::adaptDelta (
 const Variable< T1, T2 > & _variable,
 bool _upperBound,
 T1 & _minDelta) const
```

```
0.15.536.2.4 addToEntry() template<class Settings , typename T1 , typename T2 >
void smtrat::lra::Tableau< Settings, T1, T2 >::addToEntry (
 const T2 & _toAdd,
 Iterator & _horIter,
 bool _horIterLeftFromVertIter,
 Iterator & _vertIter,
 bool _vertIterBelowHorIter)
```

Adds the given value to the entry being at the position (i,j), where i is the vertical position of the given horizontal iterator and j is the horizontal position of the given vertical iterator.

Note, that the entry might not exist, if its current value is 0. Then the horizontal iterator is located horizontally before or after the entry to change and the vertical iterator is located vertically before or after the entry to add.

**Parameters**

|                          |                                                                                                                                                                                                                                                                    |
|--------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| _toAdd                   | The value to add to the content of the entry specified by the given iterators and their relative position to each other.                                                                                                                                           |
| _horIter                 | The iterator moving horizontally and, hence, giving the vertical position of the entry to add the given value to.                                                                                                                                                  |
| _horIterLeftFromVertIter | true, if the horizontally moving iterator is left from or equal to the horizontal position of the iterator moving vertically, and, hence, left from or equal to the position of the entry to add the given value to; false, it is right or equal to this position. |
| _vertIter                | The iterator moving vertically and, hence, giving the horizontal position of the entry to add the given value to.                                                                                                                                                  |

**Parameters**

|                                    |                                                                                                                                                                                                                                                                                                                                                                                                              |
|------------------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>_vertIterBelowHorIter</code> | true, if the vertically moving iterator is below or exactly at the vertical position of the iterator moving horizontally, and, hence, below or exactly at the position of the entry to add the given value to; false, it is above or equal to this position. @sideeffect If the entry existed (!=0) and is removed because of becoming 0, the iterators are set according to the given relative positioning. |
|------------------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|

```
0.15.536.2.5 betterEntry() template<class Settings , typename T1 , typename T2 >
bool smtrat::lra::Tableau< Settings, T1, T2 >::betterEntry (
 EntryID _isBetter,
 EntryID _than) const
```

**Parameters**

|                        |  |
|------------------------|--|
| <code>_isBetter</code> |  |
| <code>_than</code>     |  |

**Returns**

```
0.15.536.2.6 boundedVariables() template<class Settings , typename T1 , typename T2 >
size_t smtrat::lra::Tableau< Settings, T1, T2 >::boundedVariables (
 const Variable< T1, T2 > & _var,
 size_t _stopCriterium = 0) const
```

**Parameters**

|                             |  |
|-----------------------------|--|
| <code>_var</code>           |  |
| <code>_stopCriterium</code> |  |

**Returns**

```
0.15.536.2.7 checkCorrectness() template<class Settings , typename T1 , typename T2 >
size_t smtrat::lra::Tableau< Settings, T1, T2 >::checkCorrectness () const
```

**Returns**

```
0.15.536.2.8 collect_premises() template<class Settings , typename T1 , typename T2 >
void smtrat::lra::Tableau< Settings, T1, T2 >::collect_premises (
 const Variable< T1, T2 > * _rowVar,
 FormulasT & premises) const
```

Collects the premises for branch and bound and stores them in premises.

## Parameters

|                       |  |
|-----------------------|--|
| <code>_rowVar</code>  |  |
| <code>premises</code> |  |

**0.15.536.2.9 `columns()`** template<class Settings , typename T1 , typename T2 >  
 const std::vector<Variable<T1, T2>\*>& smtrat::lra::Tableau< Settings, T1, T2 >::columns ( )  
 const [inline]

## Returns

**0.15.536.2.10 `compressRows()`** template<class Settings , typename T1 , typename T2 >  
 void smtrat::lra::Tableau< Settings, T1, T2 >::compressRows ( )

**0.15.536.2.11 `compute_dVio()`** template<class Settings , typename T1 , typename T2 >  
 std::map<Value<T1>, Value<T1> > smtrat::lra::Tableau< Settings, T1, T2 >::compute\_dVio (   
     const std::vector< std::pair< Value< T1 >, Variable< T1, T2 > \* > > & candidates,  
     const Variable< T1, T2 > & nVar,  
     bool positive )

Updated Method to computed dVio more efficienty.

For this the fact is used, that VioSum is piecewise linear (the proof can be found in the Sol paper).

## Parameters

|                         |                                                                                |
|-------------------------|--------------------------------------------------------------------------------|
| <code>candidates</code> | Update candidates, IMPORTANT: Must be sorted with an stabloe sorting algorithm |
| <code>nVar</code>       | The updated nonbasic variable                                                  |
| <code>positive</code>   | Whether the positve or negative update values are checked                      |

**0.15.536.2.12 `computeLeavingCandidates()`** template<class Settings , typename T1 , typename T2 >

```
void smtrat::lra::Tableau< Settings, T1, T2 >::computeLeavingCandidates (

 const std::size_t i,

 std::vector< std::pair< Value< T1 >, Variable< T1, T2 > * > > & leaving_<-

 candidates)
```

Helper method to compute leavind candidates used in nextPivotingElementInfeasibilities.

Computes for every non-basic variable the breaking points. Updates from non-basic vars of 0 are omitted to prevent loops.

## Parameters

|                                 |                                                 |
|---------------------------------|-------------------------------------------------|
| <code>i</code>                  | : Index if entering (nonbasic ) variable.       |
| <code>leaving_candidates</code> | : Used as storage object for update candidates. |

**0.15.536.2.13 `constraintToBounds()`** template<class Settings , typename T1 , typename T2 >  
 const carl::FastMap<FormulaT, std::vector<const Bound<T1, T2>\*>>& smtrat::lra::Tableau< Settings, T1, T2 >::constraintToBounds ( ) const [inline]

Returns

**0.15.536.2.14 currentDelta()** template<class Settings , typename T1 , typename T2 >  
const T1& smtrat::lra::Tableau< Settings, T1, T2 >::currentDelta ( ) const [inline]

**0.15.536.2.15 deactivateBasicVar()** template<class Settings , typename T1 , typename T2 >  
void smtrat::lra::Tableau< Settings, T1, T2 >::deactivateBasicVar (  
    Variable< T1, T2 > \* \_var )

Parameters

|      |  |
|------|--|
| _var |  |
|------|--|

**0.15.536.2.16 defaultBoundPosition()** template<class Settings , typename T1 , typename T2 >  
auto smtrat::lra::Tableau< Settings, T1, T2 >::defaultBoundPosition ( ) const [inline]

Returns

**0.15.536.2.17 deleteVariable()** template<class Settings , typename T1 , typename T2 >  
void smtrat::lra::Tableau< Settings, T1, T2 >::deleteVariable (  
    Variable< T1, T2 > \* \_variable,  
    bool \_optimizationVar = false )

Parameters

|           |  |
|-----------|--|
| _variable |  |
|-----------|--|

**0.15.536.2.18 dViolationSum()** template<class Settings , typename T1 , typename T2 >  
Value<T1> smtrat::lra::Tableau< Settings, T1, T2 >::dViolationSum (  
    const Variable< T1, T2 > \* nVar,  
    const Value< T1 > & update )

Computes the change in the violation sum when an the update value is added to the assignment of the nonbassi variable nVar.

Parameters

|        |                        |
|--------|------------------------|
| nVar   | variable to be updated |
| update | Update value           |

**0.15.536.2.19 entryIsNegative()** template<class Settings , typename T1 , typename T2 >  
bool smtrat::lra::Tableau< Settings, T1, T2 >::entryIsNegative (  
    const TableauEntry< T1, T2 > & \_entry ) const [inline]

```
0.15.536.2.20 entryIsPositive() template<class Settings , typename T1 , typename T2 >
bool smtrat::lra::Tableau< Settings, T1, T2 >::entryIsPositive (
 const TableauEntry< T1, T2 > & _entry) const [inline]
```

**0.15.536.2.21 get\_dVioSum()** template<class Settings , typename T1 , typename T2 >

```
Value<T1> smtrat::lra::Tableau< Settings, T1, T2 >::get_dVioSum () [inline]
```

Used as assertion-function to check the progress of the tableau.

```
0.15.536.2.22 getConflict() template<class Settings , typename T1 , typename T2 >
std::vector< const Bound<T1, T2>* > smtrat::lra::Tableau< Settings, T1, T2 >::getConflict (
 EntryID _rowEntry) const
```

Parameters

|           |
|-----------|
| _rowEntry |
|-----------|

Returns

```
0.15.536.2.23 getConflictsFrom() template<class Settings , typename T1 , typename T2 >
std::vector< std::vector< const Bound<T1, T2>* > > smtrat::lra::Tableau< Settings, T1, T2 >::getConflictsFrom (
 EntryID _rowEntry) const
```

Parameters

|           |
|-----------|
| _rowEntry |
|-----------|

Returns

```
0.15.536.2.24 getInfeasibilityRow() template<class Settings , typename T1 , typename T2 >
std::vector<T2> smtrat::lra::Tableau< Settings, T1, T2 >::getInfeasibilityRow ()
```

Method to compute the infeasibility row to the current tableau.

```
0.15.536.2.25 getMultilineConflict() template<class Settings , typename T1 , typename T2 >
std::vector< const Bound<T1, T2>* > smtrat::lra::Tableau< Settings, T1, T2 >::getMultilineConflict ()
```

Returns

In SUM-Simplex a conflict is possibly created with multiple rows. This function returns the single conflict if possible and otherwise construct the multiline conflict.

```
0.15.536.2.26 getNumberOfEntries() template<class Settings , typename T1 , typename T2 >
size_t smtrat::lra::Tableau< Settings, T1, T2 >::getNumberOfEntries (
 Variable< T1, T2 > * _rowVar)
```

**Parameters**

|                      |  |
|----------------------|--|
| <code>_rowVar</code> |  |
|----------------------|--|

**Returns**

number of entries in the row belonging to `_rowVar`

**0.15.536.2.27 `getObjectiveVariable()`** template<class `Settings` , typename `T1` , typename `T2` >  
`Variable<T1,T2>* smtrat::lra::Tableau< Settings, T1, T2 >::getObjectiveVariable (`  
`const Poly & _lhs )`

**0.15.536.2.28 `getRationalAssignment()`** template<class `Settings` , typename `T1` , typename `T2` >  
`RationalAssignment smtrat::lra::Tableau< Settings, T1, T2 >::getRationalAssignment ( ) const`

**Returns**

**0.15.536.2.29 `getVariable()`** template<class `Settings` , typename `T1` , typename `T2` >  
`Variable<T1,T2>* smtrat::lra::Tableau< Settings, T1, T2 >::getVariable (`  
`const Poly & _lhs,`  
`T1 & _factor,`  
`T1 & _boundValue )`

**0.15.536.2.30 `gomoryCut()`** template<class `Settings` , typename `T1` , typename `T2` >  
const `Poly::PolyType* smtrat::lra::Tableau< Settings, T1, T2 >::gomoryCut (`  
`const T2 & _ass,`  
`Variable< T1, T2 > * _rowVar )`

Creates a constraint referring to Gomory Cuts, if possible.

**Parameters**

|                      |  |
|----------------------|--|
| <code>_ass</code>    |  |
| <code>_rowVar</code> |  |

**Returns**

NULL, if the cut can't be constructed; otherwise the valid constraint is returned.

**0.15.536.2.31 `hasConflict()`** template<class `Settings` , typename `T1` , typename `T2` >  
`std::pair<EntryID,bool> smtrat::lra::Tableau< Settings, T1, T2 >::hasConflict ( )`

Checks if a conflicting pair exists.

In a conflict is found, the cell and false is returned. If not, LAST\_ENTRY\_ID and true is returned.

**0.15.536.2.32 `hasMultilineConflict()`** template<class `Settings` , typename `T1` , typename `T2` >  
`bool smtrat::lra::Tableau< Settings, T1, T2 >::hasMultilineConflict ( )`

**Returns**

In SUM-Simplex a conflict is possibly created with multiple rows. This function returns true iff the multi-conflict settings occurred.

**0.15.536.2.33 isActive()** template<class Settings , typename T1 , typename T2 >  
 bool smtrat::lra::Tableau< Settings, T1, T2 >::isActive ( const Variable< T1, T2 > & \_var ) const [inline]

**0.15.536.2.34 isConflicting()** template<class Settings , typename T1 , typename T2 >  
 bool smtrat::lra::Tableau< Settings, T1, T2 >::isConflicting ( ) const

**0.15.536.2.35 isSuitable()** template<class Settings , typename T1 , typename T2 >  
 EntryID smtrat::lra::Tableau< Settings, T1, T2 >::isSuitable ( const Variable< T1, T2 > & \_basicVar, bool \_forIncreasingAssignment ) const

**Parameters**

|                                 |  |
|---------------------------------|--|
| <i>_basicVar</i>                |  |
| <i>_forIncreasingAssignment</i> |  |

**Returns**

**0.15.536.2.36 isSuitableConflictDetection()** template<class Settings , typename T1 , typename T2 >  
 EntryID smtrat::lra::Tableau< Settings, T1, T2 >::isSuitableConflictDetection ( const Variable< T1, T2 > & \_basicVar, bool \_forIncreasingAssignment ) const

Checks if the basic variable is pivotable.

Returns LAST\_ENTRY\_ID as EntryID if a conflict was found. In difference to isSuitable returns this function an EntryID as soon as the EntryID bestEntry is unequal to LAST\_ENTRY\_ID. The assertions are still checked.

**Parameters**

|                                 |  |
|---------------------------------|--|
| <i>_basicVar</i>                |  |
| <i>_forIncreasingAssignment</i> |  |

**Returns**

**0.15.536.2.37 newBasicVariable()** template<class Settings , typename T1 , typename T2 >  
 Variable<T1, T2>\* smtrat::lra::Tableau< Settings, T1, T2 >::newBasicVariable ( const typename Poly::PolyType \* \_poly, bool \_isInteger )

**Parameters**

|                      |  |
|----------------------|--|
| <i>_poly</i>         |  |
| <i>_originalVars</i> |  |
| <i>_isInteger</i>    |  |

**Returns**

**0.15.536.2.38 newBound()** template<class Settings , typename T1 , typename T2 >  
std::pair<const Bound<T1,T2>\*, bool> smtrat::lra::Tableau< Settings, T1, T2 >::newBound (  
    const FormulaT & *\_constraint* )

**Parameters**

|                    |  |
|--------------------|--|
| <i>_constraint</i> |  |
|--------------------|--|

**Returns**

**0.15.536.2.39 newNonbasicVariable()** template<class Settings , typename T1 , typename T2 >  
Variable<T1, T2>\* smtrat::lra::Tableau< Settings, T1, T2 >::newNonbasicVariable (  
    const typename Poly::PolyType \* *\_poly*,  
    bool *\_isInteger* )

**Parameters**

|                   |  |
|-------------------|--|
| <i>_poly</i>      |  |
| <i>_isInteger</i> |  |

**Returns**

**0.15.536.2.40 newTableauEntry()** template<class Settings , typename T1 , typename T2 >  
EntryID smtrat::lra::Tableau< Settings, T1, T2 >::newTableauEntry (  
    const T2 & *\_content* )

**Parameters**

|                 |  |
|-----------------|--|
| <i>_content</i> |  |
|-----------------|--|

**Returns**

**0.15.536.2.41 nextPivotingElement()** template<class Settings , typename T1 , typename T2 >  
std::pair<EntryID, bool> smtrat::lra::Tableau< Settings, T1, T2 >::nextPivotingElement ()

Returns

```
0.15.536.2.42 nextPivotingElementForOptimizing() template<class Settings , typename T1 , typename T2 >
std::pair<EntryID,bool> smtrat::lra::Tableau< Settings, T1, T2 >::nextPivotingElementForOptimizing (
 const Variable< T1, T2 > & _objective)
```

Returns

```
0.15.536.2.43 nextPivotingElementInfeasibilities() template<class Settings , typename T1 , typename T2 >
std::pair<EntryID, bool> smtrat::lra::Tableau< Settings, T1, T2 >::nextPivotingElementInfeasibilities ()
```

Method for next pivoting element according to "Simplex with Sum of Infeasibilities for SMT" by Tim King and Clark Barrett.

Therefore, one counts the violation of every bound and searches for elements who minimize the violation sum of the next iteration.

Returns

```
0.15.536.2.44 nextZeroPivotingElementForOptimizing() template<class Settings , typename T1 , typename T2 >
std::pair<EntryID,bool> smtrat::lra::Tableau< Settings, T1, T2 >::nextZeroPivotingElementForOptimizing (
 const Variable< T1, T2 > & _objective) const
```

```
0.15.536.2.45 numberOfPivotingSteps() template<class Settings , typename T1 , typename T2 >
size_t smtrat::lra::Tableau< Settings, T1, T2 >::numberOfPivotingSteps () const [inline]
```

Returns

```
0.15.536.2.46 optimizeIndependentNonbasics() template<class Settings , typename T1 , typename T2 >
std::pair<EntryID,bool> smtrat::lra::Tableau< Settings, T1, T2 >::optimizeIndependentNonbasics (
 const Variable< T1, T2 > & _objective)
```

Parameters

|            |
|------------|
| _objective |
|------------|

Returns

**0.15.536.2.47 originalVars()** template<class Settings , typename T1 , typename T2 >  
const carl::FastMap< carl::Variable, Variable<T1,T2>\*>& smtrat::lra::Tableau< Settings, T1,  
T2 >::originalVars ( ) const [inline]

Returns

**0.15.536.2.48 pivot()** template<class Settings , typename T1 , typename T2 >  
Variable<T1, T2>\* smtrat::lra::Tableau< Settings, T1, T2 >::pivot (  
    EntryID \_pivotingElement,  
    bool \_optimizing = false )

Parameters

|                          |  |
|--------------------------|--|
| <i>_pivotingElement</i>  |  |
| <i>updateAssignments</i> |  |

Returns

**0.15.536.2.49 print()** template<class Settings , typename T1 , typename T2 >  
void smtrat::lra::Tableau< Settings, T1, T2 >::print (  
    EntryID \_pivotingElement = LAST\_ENTRY\_ID,  
    std::ostream & \_out = std::cout,  
    const std::string \_init = "",  
    bool \_friendlyNames = true,  
    bool \_withZeroColumns = false ) const

Parameters

|                         |  |
|-------------------------|--|
| <i>_pivotingElement</i> |  |
| <i>_out</i>             |  |
| <i>_init</i>            |  |
| <i>_friendlyNames</i>   |  |
| <i>_withZeroColumns</i> |  |

**0.15.536.2.50 printEntries()** template<class Settings , typename T1 , typename T2 >  
void smtrat::lra::Tableau< Settings, T1, T2 >::printEntries ( ) [inline]

**0.15.536.2.51 printEntry()** template<class Settings , typename T1 , typename T2 >  
void smtrat::lra::Tableau< Settings, T1, T2 >::printEntry (  
    EntryID \_entry,

```
std::ostream & _out = std::cout,
int _maxEntryLength = 20) const
```

**Parameters**

|                 |  |
|-----------------|--|
| _entry          |  |
| _out            |  |
| _maxEntryLength |  |

**0.15.536.2.52 printHeap()** template<class Settings , typename T1 , typename T2 >  
void smtrat::lra::Tableau< Settings, T1, T2 >::printHeap (

```
std::ostream & _out = std::cout,
int _maxEntryLength = 30,
const std::string _init = "") const
```

**Parameters**

|                 |  |
|-----------------|--|
| _out            |  |
| _maxEntryLength |  |
| _init           |  |

**0.15.536.2.53 printLearnedBound()** template<class Settings , typename T1 , typename T2 >  
void smtrat::lra::Tableau< Settings, T1, T2 >::printLearnedBound (

```
const Variable< T1, T2 > & _var,
const LearnedBound & _learnedBound,
const std::string _init = "",
std::ostream & _out = std::cout) const
```

**Parameters**

|               |  |
|---------------|--|
| _var          |  |
| _learnedBound |  |
| _init         |  |
| _out          |  |

**0.15.536.2.54 printLearnedBounds()** template<class Settings , typename T1 , typename T2 >  
void smtrat::lra::Tableau< Settings, T1, T2 >::printLearnedBounds (

```
const std::string _init = "",
std::ostream & _out = std::cout) const
```

**Parameters**

|       |  |
|-------|--|
| _init |  |
| _out  |  |

**0.15.536.2.55 printVariables()** template<class Settings , typename T1 , typename T2 >  
void smtrat::lra::Tableau< Settings, T1, T2 >::printVariables (

```
bool _allBounds = true,
```

```
 std::ostream & _out = std::cout,
 const std::string _init = "") const
```

**Parameters**

|                         |  |
|-------------------------|--|
| <code>_allBounds</code> |  |
| <code>_out</code>       |  |
| <code>_init</code>      |  |

**0.15.536.2.56 `rConstraintToBound()`** template<class Settings , typename T1 , typename T2 >  
carl::FastMap<FormulaT, std::vector<const Bound<T1, T2>\*>>& smtrat::lra::Tableau< Settings,  
T1, T2 >::rConstraintToBound ( ) [inline]

**Returns**

**0.15.536.2.57 `removeBound()`** template<class Settings , typename T1 , typename T2 >  
void smtrat::lra::Tableau< Settings, T1, T2 >::removeBound (   
 const FormulaT & \_constraint )

**0.15.536.2.58 `removeEntry()`** template<class Settings , typename T1 , typename T2 >  
void smtrat::lra::Tableau< Settings, T1, T2 >::removeEntry (   
 EntryID \_entryID )

**Parameters**

|                       |  |
|-----------------------|--|
| <code>_entryID</code> |  |
|-----------------------|--|

**0.15.536.2.59 `resetAssignment()`** template<class Settings , typename T1 , typename T2 >  
void smtrat::lra::Tableau< Settings, T1, T2 >::resetAssignment ( )

**0.15.536.2.60 `resetNumberOfPivotingSteps()`** template<class Settings , typename T1 , typename T2 >  
void smtrat::lra::Tableau< Settings, T1, T2 >::resetNumberOfPivotingSteps ( ) [inline]

**0.15.536.2.61 `resetTheta()`** template<class Settings , typename T1 , typename T2 >  
void smtrat::lra::Tableau< Settings, T1, T2 >::resetTheta ( ) [inline]

**0.15.536.2.62 `rLearnedLowerBounds()`** template<class Settings , typename T1 , typename T2 >  
carl::FastPointerMap<Variable<T1,T2>, LearnedBound>& smtrat::lra::Tableau< Settings, T1, T2  
>::rLearnedLowerBounds ( ) [inline]

**Returns**

**0.15.536.2.63 `rLearnedUpperBounds()`** template<class Settings , typename T1 , typename T2 >  
carl::FastPointerMap<Variable<T1,T2>, LearnedBound>& smtrat::lra::Tableau< Settings, T1, T2  
>::rLearnedUpperBounds ( ) [inline]

Returns

**0.15.536.2.64 `rNewLearnedBounds()`** template<class Settings , typename T1 , typename T2 >  
std::vector<typename carl::FastPointerMap<Variable<T1,T2>, LearnedBound>::iterator>& smtrat::lra::Tableau<  
Settings, T1, T2 >::rNewLearnedBounds ( ) [inline]

Returns

**0.15.536.2.65 `rowCorrect()`** template<class Settings , typename T1 , typename T2 >  
bool smtrat::lra::Tableau< Settings, T1, T2 >::rowCorrect (   
size\_t \_rowNumber ) const

Parameters

|                         |
|-------------------------|
| <code>_rowNumber</code> |
|-------------------------|

Returns

**0.15.536.2.66 `rowRefinement()`** template<class Settings , typename T1 , typename T2 >  
void smtrat::lra::Tableau< Settings, T1, T2 >::rowRefinement (   
Variable< T1, T2 > \* \_basicVar )

Tries to refine the supremum and infimum of the given basic variable.

Parameters

|                        |                                                                  |
|------------------------|------------------------------------------------------------------|
| <code>_basicVar</code> | The basic variable for which to refine the supremum and infimum. |
|------------------------|------------------------------------------------------------------|

**0.15.536.2.67 `rows()`** template<class Settings , typename T1 , typename T2 >  
const std::vector<Variable<T1, T2>\*>& smtrat::lra::Tableau< Settings, T1, T2 >::rows ( )  
const [inline]

Returns

**0.15.536.2.68 `setBlandsRuleStart()`** template<class Settings , typename T1 , typename T2 >  
void smtrat::lra::Tableau< Settings, T1, T2 >::setBlandsRuleStart (   
size\_t \_start ) [inline]

**0.15.536.2.69 `setInfeasibilityRow()`** template<class Settings , typename T1 , typename T2 >  
void smtrat::lra::Tableau< Settings, T1, T2 >::setInfeasibilityRow ( )  
Method to set the initial infeasibility row to avoid recomputation in every round.

**0.15.536.2.70 `setSize()`** template<class Settings , typename T1 , typename T2 >  
void smtrat::lra::Tableau< Settings, T1, T2 >::setSize (   
    size\_t \_expectedHeight,  
    size\_t \_expectedWidth,  
    size\_t \_expectedNumberOfBounds ) [inline]

**Parameters**

|                                |  |
|--------------------------------|--|
| <i>_expectedHeight</i>         |  |
| <i>_expectedWidth</i>          |  |
| <i>_expectedNumberOfBounds</i> |  |

**0.15.536.2.71 `size()`** template<class Settings , typename T1 , typename T2 >  
size\_t smtrat::lra::Tableau< Settings, T1, T2 >::size ( ) const [inline]

**Returns**

**0.15.536.2.72 `slackVars()`** template<class Settings , typename T1 , typename T2 >  
const carl::FastPointerMap<typename Poly::PolyType, Variable<T1,T2>\*>& smtrat::lra::Tableau< Settings, T1, T2 >::slackVars ( ) const [inline]

**Returns**

**0.15.536.2.73 `storeAssignment()`** template<class Settings , typename T1 , typename T2 >  
void smtrat::lra::Tableau< Settings, T1, T2 >::storeAssignment ( )

**0.15.536.2.74 `unboundedVariables()`** template<class Settings , typename T1 , typename T2 >  
size\_t smtrat::lra::Tableau< Settings, T1, T2 >::unboundedVariables (   
    const Variable< T1, T2 > & \_var,  
    size\_t \_stopCriterium = 0 ) const

**Parameters**

|                       |  |
|-----------------------|--|
| <i>_var</i>           |  |
| <i>_stopCriterium</i> |  |

**Returns**

**0.15.536.2.75 `update()`** template<class Settings , typename T1 , typename T2 >

```
void smtrat::lra::Tableau< Settings, T1, T2 >::update (
 bool _downwards,
 EntryID _pivotingElement,
 std::vector< Iterator > & _pivotingRowLeftSide,
 std::vector< Iterator > & _pivotingRowRightSide,
 bool _optimizing = false)
```

Updates the tableau according to the new values in the pivoting row containing the given pivoting element.  
The updating is applied from the pivoting row downwards, if the given flag `_downwards` is true, and upwards, otherwise.

#### Parameters

|                                    |                                                                                                                                                                                                                                   |
|------------------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>_downwards</code>            | The flag indicating whether to update the tableau downwards or upwards starting from the pivoting row.                                                                                                                            |
| <code>_pivotingElement</code>      | The id of the current pivoting element.                                                                                                                                                                                           |
| <code>_pivotingRowLeftSide</code>  | For every element in the pivoting row, which is positioned left of the pivoting element, this vector contains an iterator. The closer the element is to the pivoting element, the smaller is the iterator's index in the vector.  |
| <code>_pivotingRowRightSide</code> | For every element in the pivoting row, which is positioned right of the pivoting element, this vector contains an iterator. The closer the element is to the pivoting element, the smaller is the iterator's index in the vector. |
| <code>_updateAssignments</code>    | If true, the assignments of all variables will be updated after pivoting.                                                                                                                                                         |

**0.15.536.2.76 updateBasicAssignments()** template<class Settings , typename T1 , typename T2 >  
void smtrat::lra::Tableau< Settings, T1, T2 >::updateBasicAssignments (  
 size\_t \_column,  
 const Value< T1 > & \_change )

#### Parameters

|                      |  |
|----------------------|--|
| <code>_column</code> |  |
| <code>_change</code> |  |

**0.15.536.2.77 updateNonbasicVariable() [1/2]** template<class Settings , typename T1 , typename T2 >  
void smtrat::lra::Tableau< Settings, T1, T2 >::updateNonbasicVariable (  
 EntryID \_pivotingElement )

Updates a nonbasic variable by the assignment stored in mpTheta and triggers updates of depending basic variables.

#### Parameters

|                               |                                             |
|-------------------------------|---------------------------------------------|
| <code>_pivotingElement</code> | Element in the row of the nonbasic variable |
|-------------------------------|---------------------------------------------|

**0.15.536.2.78 updateNonbasicVariable() [2/2]** template<class Settings , typename T1 , typename T2 >  
void smtrat::lra::Tableau< Settings, T1, T2 >::updateNonbasicVariable (  
 EntryID \_pivotingElement,  
 Value< T1 > update )

Updates a nonbasic variable by the given assignment and triggers updates of depending basic variables.

**Parameters**

|                         |                                               |
|-------------------------|-----------------------------------------------|
| <i>_pivotingElement</i> | Element in the row of the nonbasic variable   |
| <i>update</i>           | Update <a href="#">Value</a> of non-basic var |

**0.15.536.2.79 [usedBlndsRule\(\)](#)** template<class Settings , typename T1 , typename T2 >  
bool smtrat::lra::Tableau< Settings, T1, T2 >::usedBlndsRule ( )  
Returns true, if the next pivoting element is selected by blnds rule.

**0.15.536.2.80 [violationSum\(\)](#)** template<class Settings , typename T1 , typename T2 >  
[Value](#)<T1> smtrat::lra::Tableau< Settings, T1, T2 >::violationSum ( )  
Method to compute the sum of derivations to the closest bounds.

## 0.15.537 [smtrat::lra::TableauEntry< T1, T2 >](#) Class Template Reference

*Retrieve a filename for a temporary file that is not in use.*
- void [put](#) (const std::string &temp)  
*Returns a filename to the pool of available filenames.*

### 0.15.541.1 Detailed Description

This class generates and reuses temporary filenames with a common prefix.

### 0.15.541.2 Constructor & Destructor Documentation

**0.15.541.2.1 `TempFilenameGenerator()`** delta::TempFilenameGenerator::TempFilenameGenerator ( const std::string & prefix ) [inline]

Constructor.

#### Parameters

|               |                           |
|---------------|---------------------------|
| <i>prefix</i> | Prefix for all filenames. |
|---------------|---------------------------|

**0.15.541.2.2 `~TempFilenameGenerator()`** delta::TempFilenameGenerator::~TempFilenameGenerator ( ) [inline]

Destructor.

### 0.15.541.3 Member Function Documentation

**0.15.541.3.1 `get()`** std::string delta::TempFilenameGenerator::get ( ) [inline]

Retrieve a filename for a temporary file that is not in use.

**Returns**

Temporary filename.

**0.15.541.3.2 `put()`** `void delta::TempFilenameGenerator::put (`  
`const std::string & temp ) [inline]`

Returns a filename to the pool of available filenames.

**Parameters**

|                   |                     |
|-------------------|---------------------|
| <code>temp</code> | Temporary filename. |
|-------------------|---------------------|

### 0.15.544.1 Detailed Description

The [Theories](#) class combines all implemented theories and provides a single interface to interact with all theories at once.

### 0.15.544.2 Member Typedef Documentation

**0.15.544.2.1 Modules** `typedef boost::mpl::vector< CoreTheory*, ArithmeticTheory*, BitvectorTheory*, UninterpretedTheory*, BooleanEncodingTheory* >::type smrat::parser::Theories::Modules`

### 0.15.544.3 Constructor & Destructor Documentation

**0.15.544.3.1 Theories()** `smrat::parser::Theories::Theories ( ParserState * state ) [inline]`

**0.15.544.3.2 ~Theories()** `smrat::parser::Theories::~Theories ( ) [inline]`

### 0.15.544.4 Member Function Documentation

**0.15.544.4.1 addConstants()** `static void smrat::parser::Theories::addConstants ( qi::symbols< char, types::ConstType > & constants ) [inline], [static]`  
Collects constants from all theory modules.

**0.15.544.4.2 addGlobalFormulas()** `void smrat::parser::Theories::addGlobalFormulas ( FormulasT & formulas ) [inline]`

**0.15.544.4.3 addSimpleSorts()** `static void smrat::parser::Theories::addSimpleSorts ( qi::symbols< char, carl::Sort > & sorts ) [inline], [static]`  
Collects simple sorts from all theory modules.

**0.15.544.4.4 annotateTerm()** `const auto& smrat::parser::Theories::annotateTerm ( const types::TermType & term, const std::vector< Attribute > & attributes ) [inline]`

**0.15.544.4.5 declareFunction()** `void smrat::parser::Theories::declareFunction ( const std::string & name, const std::vector< carl::Sort > & args, const carl::Sort & sort ) [inline]`

**0.15.544.4.6 declareFunctionArgument()** `types::VariableType smrat::parser::Theories::declareFunctionArgument ( const std::pair< std::string, carl::Sort > & arg ) [inline]`

**0.15.544.4.7 declareVariable()** `void smrat::parser::Theories::declareVariable ( const std::string & name, const carl::Sort & sort ) [inline]`

```
0.15.544.4.8 defineFunction() void smtrat::parser::Theories::defineFunction (
 const std::string & name,
 const std::vector< types::VariableType > & arguments,
 const carl::Sort & sort,
 const types::TermType & definition) [inline]
```

**Todo** check that definition matches the sort

```

*Attributes of the tool obtained by introspection of the binary.*

### Friends

- `bool operator< (const Tool &lhs, const Tool &rhs)`  
*Compare two tools.*

### 0.15.554.1 Detailed Description

Base class for any tool.

A tool represents some executable that can be run with some input file. A tool is responsible for

- deciding it is applicable for a given file extension,
- building a command line to execute it and
- parse additional results from stdout / stderr after it has run.

A tool is not to be copied or moved around but should only exist a single time.

### 0.15.554.2 Constructor & Destructor Documentation

**0.15.554.2.1 Tool()** [1/5] `benchmax::Tool::Tool( ) [delete]`

**0.15.554.2.2 Tool()** [2/5] `benchmax::Tool::Tool( const Tool & ) [delete]`

**0.15.554.2.3 Tool()** [3/5] `benchmax::Tool::Tool( Tool && ) [delete]`

**0.15.554.2.4 Tool()** [4/5] `benchmax::Tool::Tool( const fs::path & binary, const std::string & arguments ) [inline]`

Creates a generic tool from a binary and command line arguments.

**0.15.554.2.5 Tool()** [5/5] `benchmax::Tool::Tool( const std::string & name, const fs::path & binary, const std::string & arguments ) [inline]`

Creates a named tool from a binary and command line arguments.

**0.15.554.2.6 ~Tool()** `virtual benchmax::Tool::~Tool( ) [virtual], [default]`

### 0.15.554.3 Member Function Documentation

**0.15.554.3.1 additionalResults()** `virtual void benchmax::Tool::additionalResults( const fs::path &, BenchmarkResult & ) const [inline], [virtual]`

Recover additional results from the tool output.

Reimplemented in [benchmax::Z3](#), [benchmax::SMTRAT\\_Analyzer](#), [benchmax::SMTRAT](#), [benchmax::Minisatp](#), [benchmax::Minisat](#), and [benchmax::MathSAT](#).

**0.15.554.3.2 attributeHash()** `std::size_t benchmax::Tool::attributeHash( ) const [inline]`

Hash of the attributes.

**0.15.554.3.3 `attributes()`** `const std::map<std::string, std::string>& benchmax::Tool::attributes( ) const [inline]`  
A set of attributes, for example compilation options.

**0.15.554.3.4 `binary()`** `fs::path benchmax::Tool::binary( ) const [inline]`  
Full path to the binary.

**0.15.554.3.5 `canHandle()`** `virtual bool benchmax::Tool::canHandle( const fs::path & ) const [inline], [virtual]`

Checks whether this cool can handle this file type.

Reimplemented in [benchmax::Z3](#), [benchmax::SMTRAT\\_OPB](#), [benchmax::SMTRAT\\_Analyzer](#), [benchmax::SMTRAT](#), [benchmax::Minisatp](#), [benchmax::Minisat](#), and [benchmax::MathSAT](#).

**0.15.554.3.6 `getCommandLine()` [1/2]** `virtual std::string benchmax::Tool::getCommandLine( const std::string & file ) const [inline], [virtual]`

Compose commandline for this tool and the given input file.

**0.15.554.3.7 `getCommandLine()` [2/2]** `virtual std::string benchmax::Tool::getCommandLine( const std::string & file, const std::string & localBinary ) const [inline], [virtual]`

Compose commandline for this tool with another binary name and the given input file.

**0.15.554.3.8 `name()`** `std::string benchmax::Tool::name( ) const [inline]`  
Common name of this tool.

**0.15.554.3.9 `operator=()` [1/2]** `Tool& benchmax::Tool::operator=( const Tool & ) [delete]`

**0.15.554.3.10 `operator=()` [2/2]** `Tool& benchmax::Tool::operator=( Tool && ) [delete]`

**0.15.554.3.11 `parseCommandLine()`** `virtual std::optional<std::string> benchmax::Tool::parseCommandline( const std::string & cmdline ) const [inline], [virtual]`  
Compose commandline for this tool and the given input file.

**0.15.554.3.12 `resolveDependencies()`** `std::vector<std::string> benchmax::Tool::resolveDependencies( ) const [inline]`  
Get dependencies of binary required to run it (via ldd)

#### 0.15.554.4 Friends And Related Function Documentation

```
0.15.554.4.1 operator< bool operator< (
 const Tool & lhs,
 const Tool & rhs) [friend]
```

Compare two tools.

#### 0.15.554.5 Field Documentation

**0.15.554.5.1 mArguments** std::string benchmax::Tool::mArguments [protected]  
Command line arguments that should be passed to the binary.

**0.15.554.5.2 mAttributes** std::map<std::string, std::string> benchmax::Tool::mAttributes [protected]  
Attributes of the tool obtained by introspection of the binary.

**0.15.554.5.3 mBinary** fs::path benchmax::Tool::mBinary [protected]  
Path to the binary.

**0.15.554.5.4 mName** std::string benchmax::Tool::mName [protected]  
(Non-unique) identifier for the tool.

### 0.15.555 benchmax::settings::ToolSettings Struct Reference

Tool-related settings.

```

 std::size_t rank_) [inline], [noexcept]
```

## 0.15.562 smtrat::uf\_impl::uf\_rank\_and\_class< compression > Class Template Reference

Wrapper class that contains the rank and parent class of some entry of the UF datastructure.

```
#include <union_find.h>
```

### Public Member Functions

- **uf\_rank\_and\_class** (std::size\_t class\_index)
- std::size\_t **rank** () const noexcept
- std::size\_t **class\_** () const noexcept
- void **set\_class** (std::size\_t newclass) noexcept
- void **increment\_rank** () noexcept
- void **set\_rank** (std::size\_t **rank**)

### 0.15.562.1 Detailed Description

```
template<bool compression>
class smtrat::uf_impl::uf_rank_and_class< compression >
```

Wrapper class that contains the rank and parent class of some entry of the UF datastructure.

The compression parameter (default to off, this seems to be faster, can only enabled if sizeof(std::size\_t) >= 8) controls whether the rank member is compressed together with the parent class. If this is true, sizeof(uf\_rank\_and\_class<true>) is just sizeof(std::size\_t), and the most significant byte of the class is interpreted as rank of the entry.

### 0.15.562.2 Constructor & Destructor Documentation

```
0.15.562.2.1 uf_rank_and_class() template<bool compression>
smtrat::uf_impl::uf_rank_and_class< compression >::uf_rank_and_class (
 std::size_t class_index) [inline]
```

### 0.15.562.3 Member Function Documentation

```
0.15.562.3.1 class_() template<bool compression>
std::size_t smtrat::uf_impl::uf_rank_and_class< compression >::class_ () const [inline], [noexcept]
```

## 0.15.564 smtrat::UFCegarModule< Settings > Class Template Reference

```
#include <UFCegarModule.h>
```

### Public Types

- **typedef Settings SettingsType**
- **enum class LemmaType : unsigned { NORMAL = 0 , PERMANENT = 1 }**

### Public Member Functions

- **std::string moduleName () const**
- **UFCegarModule (const ModuleInput \*\_formula, Conditionals &\_conditionals, Manager \*\_manager=nullptr)**
- **~UFCegarModule ()**
- **bool addCore (ModuleInput::const\_iterator \_subformula)**  
*The module has to take the given sub-formula of the received formula into account.*
- **void removeCore (ModuleInput::const\_iterator \_subformula)**  
*Removes the subformula of the received formula at the given position to the considered ones of this module.*
- **void updateModel () const**  
*Updates the current assignment into the model.*
- **Answer checkCore ()**  
*Checks the received formula for consistency.*
- **bool inform (const FormulaT &\_constraint)**  
*Informs the module about the given constraint.*
- **void deform (const FormulaT &\_constraint)**  
*The inverse of informing about a constraint.*
- **virtual void init ()**  
*Informs all backends about the so far encountered constraints, which have not yet been communicated.*

- bool `add (ModuleInput::const_iterator _subformula)`

*The module has to take the given sub-formula of the received formula into account.*
- virtual `Answer check (bool _final=false, bool _full=true, carl::Variable _objective=carl::Variable::NO_VARIABLE)`

*Checks the received formula for consistency.*
- virtual void `remove (ModuleInput::const_iterator _subformula)`

*Removes everything related to the given sub-formula of the received formula.*
- virtual void `updateAllModels ()`

*Updates all satisfying models, if the solver has detected the consistency of the received formula, beforehand.*
- virtual std::list< std::vector< carl::Variable > > `getModelEqualities () const`

*Partition the variables from the current model into equivalence classes according to their assigned value.*
- unsigned `currentlySatisfiedByBackend (const FormulaT &_formula) const`
- virtual unsigned `currentlySatisfied (const FormulaT &) const`
- bool `receivedVariable (carl::Variable::Arg _var) const`
- `Answer solverState () const`
- std::size\_t `id () const`
- void `setId (std::size_t _id)`

*Sets this modules unique ID to identify itself.*
- `thread_priority threadPriority () const`
- void `setThreadPriority (thread_priority _threadPriority)`

*Sets the priority of this module to get a thread for running its check procedure.*
- const `ModuleInput * pReceivedFormula () const`
- const `ModuleInput & rReceivedFormula () const`
- const `ModuleInput * pPassedFormula () const`
- const `ModuleInput & rPassedFormula () const`
- const `Model & model () const`
- const std::vector< Model > & `allModels () const`
- const std::vector< FormulaSetT > & `infeasibleSubsets () const`
- const std::vector< Module \* > & `usedBackends () const`
- const carl::FastSet< FormulaT > & `constraintsToInform () const`
- const carl::FastSet< FormulaT > & `informedConstraints () const`
- void `addLemma (const FormulaT &_lemma, const LemmaType &_lt=LemmaType::NORMAL, const FormulaT &_preferredFormula=FormulaT(carl::FormulaType::TRUE))`

*Stores a lemma being a valid formula.*
- bool `hasLemmas ()`

*Checks whether this module or any of its backends provides any lemmas.*
- void `clearLemmas ()`

*Deletes all yet found lemmas.*
- const std::vector< Lemma > & `lemmas () const`
- `ModuleInput::const_iterator firstUncheckedReceivedSubformula () const`
- `ModuleInput::const_iterator firstSubformulaToPass () const`
- void `receivedFormulaChecked ()`

*Notifies that the received formulas has been checked.*
- const `smrat::Conditionals & answerFound () const`
- bool `isPreprocessor () const`
- carl::Variable `objective () const`
- bool `is_minimizing () const`
- void `excludeNotReceivedVariablesFromModel () const`

*Excludes all variables from the current model, which do not occur in the received formula.*
- void `updateLemmas ()`

*Stores all lemmas of any backend of this module in its own lemma vector.*
- void `collectTheoryPropagations ()`
- void `collectOrigins (const FormulaT &_formula, FormulasT &_origins) const`

- Collects the formulas in the given formula, which are part of the received formula.*
- void `collectOrigins` (const `FormulaT` & `_formula`, `FormulaSetT` & `_origins`) const
  - bool `isValidInfeasibleSubset` () const
  - void `checkInfSubsetForMinimality` (`std::vector<FormulaSetT>`::const\_iterator `_infsSubset`, const `std::string` & `_filename`="smaller\_muses", unsigned `_maxSizeDifference`=1) const
- Checks the given infeasible subset for minimality by storing all subsets of it, which have a smaller size which differs from the size of the infeasible subset not more than the given threshold.*
- virtual `std::pair<bool, FormulaT>` `getReceivedFormulaSimplified` ()
  - void `print` (const `std::string` & `_initiation`="\*\*\*") const
- Prints everything relevant of the solver.*
- void `printReceivedFormula` (const `std::string` & `_initiation`="\*\*\*") const
- Prints the vector of the received formula.*
- void `printPassedFormula` (const `std::string` & `_initiation`="\*\*\*") const
- Prints the vector of passed formula.*
- void `printInfeasibleSubsets` (const `std::string` & `_initiation`="\*\*\*") const
- Prints the infeasible subsets.*
- void `printModel` (`std::ostream` & `_out`=`std::cout`) const
- Prints the assignment of this module satisfying its received formula if it satisfiable and this module could find an assignment.*
- void `printAllModels` (`std::ostream` & `_out`=`std::cout`)
- Prints all assignments of this module satisfying its received formula if it satisfiable and this module could find an assignment.*

## Static Public Member Functions

- static void `freeSplittingVariable` (const `FormulaT` & `_splittingVariable`)

## Static Public Attributes

- static `size_t` `mNumOfBranchVarsToStore` = 5  
*The number of different variables to consider for a probable infinite loop of branchings.*
- static `std::vector<Branching>` `mLastBranches` = `std::vector<Branching>(mNumOfBranchVarsToStore, Branching(typename Poly::PolyType(), 0))`  
*Stores the last branches in a cycle buffer.*
- static `size_t` `mFirstPosInLastBranches` = 0  
*The beginning of the cyclic buffer storing the last branches.*
- static `std::vector<FormulaT>` `mOldSplittingVariables`  
*Reusable splitting variables.*

## Protected Member Functions

- virtual bool `informCore` (const `FormulaT` & `_constraint`)  
*Informs the module about the given constraint.*
- virtual void `deinformCore` (const `FormulaT` & `_constraint`)  
*The inverse of informing about a constraint.*
- bool `anAnswerFound` () const  
*Checks for all antecedent modules and those which run in parallel with the same antecedent modules, whether one of them has determined a result.*
- void `clearModel` () const  
*Clears the assignment, if any was found.*
- void `clearModels` () const  
*Clears all assignments, if any was found.*
- void `cleanModel` () const  
*Substitutes variable occurrences by its model value in the model values of other variables.*

- `ModuleInput::iterator passedFormulaBegin ()`
- `ModuleInput::iterator passedFormulaEnd ()`
- `void addOrigin (ModuleInput::iterator _formula, const FormulaT &_origin)`

*Adds the given set of formulas in the received formula to the origins of the given passed formula.*
- `const FormulaT & getOrigins (ModuleInput::const_iterator _formula) const`

*Gets the origins of the passed formula at the given position.*
- `void getOrigins (const FormulaT &_formula, FormulasT &_origins) const`
- `void getOrigins (const FormulaT &_formula, FormulaSetT &_origins) const`
- `std::pair< ModuleInput::iterator, bool > removeOrigin (ModuleInput::iterator _formula, const FormulaT &_origin)`
- `std::pair< ModuleInput::iterator, bool > removeOrigins (ModuleInput::iterator _formula, const std::shared_ptr< std::vector< FormulaT >> &_origins)`
- `void informBackends (const FormulaT &_constraint)`

*Informs all backends of this module about the given constraint.*
- `virtual void addConstraintToInform (const FormulaT &_constraint)`

*Adds a constraint to the collection of constraints of this module, which are informed to a freshly generated backend.*
- `std::pair< ModuleInput::iterator, bool > addReceivedSubformulaToPassedFormula (ModuleInput::const_iterator _subformula)`

*Copies the given sub-formula of the received formula to the passed formula.*
- `bool originInReceivedFormula (const FormulaT &_origin) const`
- `std::pair< ModuleInput::iterator, bool > addSubformulaToPassedFormula (const FormulaT &_formula)`

*Adds the given formula to the passed formula with no origin.*
- `std::pair< ModuleInput::iterator, bool > addSubformulaToPassedFormula (const FormulaT &_formula, const std::shared_ptr< std::vector< FormulaT >> &_origins)`

*Adds the given formula to the passed formula.*
- `std::pair< ModuleInput::iterator, bool > addSubformulaToPassedFormula (const FormulaT &_formula, const FormulaT &_origin)`

*Adds the given formula to the passed formula.*
- `void generateTrivialInfeasibleSubset ()`

*Stores the trivial infeasible subset being the set of received formulas.*
- `void receivedFormulasAsInfeasibleSubset (ModuleInput::const_iterator _subformula)`

*Stores an infeasible subset consisting only of the given received formula.*
- `std::vector< FormulaT >::const_iterator findBestOrigin (const std::vector< FormulaT > &_origins) const`
- `void getInfeasibleSubsets ()`

*Copies the infeasible subsets of the passed formula.*
- `std::vector< FormulaSetT > getInfeasibleSubsets (const Module &backend) const`

*Get the infeasible subsets the given backend provides.*
- `const Model & backendsModel () const`

*Stores the model of a backend which determined satisfiability of the passed formula in the model of this module.*
- `void getBackendsModel () const`
- `void getBackendsAllModels () const`

*Stores all models of a backend in the list of all models of this module.*
- `virtual Answer runBackends (bool _final, bool _full, carl::Variable _objective)`

*Runs the backend solvers on the passed formula.*
- `virtual Answer runBackends ()`
- `virtual ModuleInput::iterator eraseSubformulaFromPassedFormula (ModuleInput::iterator _subformula, bool _ignoreOrigins=false)`

*Removes everything related to the sub-formula to remove from the passed formula in the backends of this module.*
- `void clearPassedFormula ()`
- `std::vector< FormulaT > merge (const std::vector< FormulaT > &, const std::vector< FormulaT > &) const`

*Merges the two vectors of sets into the first one.*
- `size_t determine_smallest_origin (const std::vector< FormulaT > &origins) const`

- bool `probablyLooping` (const typename Poly::PolyType &\_branchingPolynomial, const Rational &\_branchingValue) const  
*Checks whether given the current branching value and branching variable/polynomial it is (highly) probable that this branching is part of an infinite loop of branchings.*
- bool `branchAt` (const Poly &\_polynomial, bool \_integral, const Rational &\_value, std::vector< FormulaT > &&\_premise, bool \_leftCaseWeak=true, bool \_preferLeftCase=true, bool \_useReceivedFormulaAsPremise=false)  
*Adds a lemmas which provoke a branching for the given variable at the given value, if this module returns Unknown and there exists a preceding SATModule.*
- bool `branchAt` (const Poly &\_polynomial, bool \_integral, const Rational &\_value, bool \_leftCaseWeak=true, bool \_preferLeftCase=true, bool \_useReceivedFormulaAsPremise=false, const std::vector< FormulaT > &&\_premise=std::vector< FormulaT >())
- bool `branchAt` (carl::Variable::Arg \_var, const Rational &\_value, std::vector< FormulaT > &&\_premise, bool \_leftCaseWeak=true, bool \_preferLeftCase=true, bool \_useReceivedFormulaAsPremise=false)
- bool `branchAt` (carl::Variable::Arg \_var, const Rational &\_value, bool \_leftCaseWeak=true, bool \_preferLeftCase=true, bool \_useReceivedFormulaAsPremise=false, const std::vector< FormulaT > &\_premise=std::vector< FormulaT >())
- void `splitUnequalConstraint` (const FormulaT &)  
*Adds the following lemmas for the given constraint  $p \neq 0$ .*
- unsigned `checkModel` () const
- void `addInformationRelevantFormula` (const FormulaT &formula)  
*Adds a formula to the InformationRelevantFormula.*
- const std::set< FormulaT > & `getInformationRelevantFormulas` ()  
*Gets all InformationRelevantFormulas.*
- bool `isLemmaLevel` (LemmaLevel level)  
*Checks if current lemma level is greater or equal to given level.*

## Static Protected Member Functions

- static bool `modelsDisjoint` (const Model &\_modelA, const Model &\_modelB)  
*Checks whether there is no variable assigned by both models.*

## Protected Attributes

- std::vector< FormulaSetT > `mInfeasibleSubsets`  
*Stores the infeasible subsets.*
- Manager \*const `mpManager`  
*A reference to the manager.*
- Model `mModel`  
*Stores the assignment of the current satisfiable result, if existent.*
- std::vector< Model > `mAllModels`  
*Stores all satisfying assignments.*
- bool `mModelComputed`  
*True, if the model has already been computed.*
- bool `mFinalCheck`  
*true, if the check procedure should perform a final check which especially means not to postpone splitting decisions*
- bool `mFullCheck`  
*false, if this module should avoid too expensive procedures and rather return unknown instead.*
- carl::Variable `mObjectiveVariable`  
*Objective variable to be minimized. If set to NO\_VARIABLE, a normal sat check should be performed.*
- std::vector< TheoryPropagation > `mTheoryPropagations`
- std::atomic< Answer > `mSolverState`  
*States whether the received formula is known to be satisfiable or unsatisfiable otherwise it is set to unknown.*
- std::atomic\_bool \* `mBackendsFoundAnswer`

*This flag is passed to any backend and if it determines an answer to a prior check call, this flag is fired.*

- **Conditionals mFoundAnswer**

*Vector of Booleans: If any of them is true, we have to terminate a running check procedure.*

- std::vector< Module \* > mUsedBackends

*The backends of this module which are currently used (conditions to use this module are fulfilled for the passed formula).*

- std::vector< Module \* > mAllBackends

*The backends of this module which have been used.*

- std::vector< Lemma > mLemmas

*Stores the lemmas being valid formulas this module or its backends made.*

- ModuleInput::iterator mFirstSubformulaToPass

*Stores the position of the first sub-formula in the passed formula, which has not yet been considered for a consistency check of the backends.*

- carl::FastSet< FormulaT > mConstraintsToInform

*Stores the constraints which the backends must be informed about.*

- carl::FastSet< FormulaT > mInformedConstraints

*Stores the position of the first constraint of which no backend has been informed about.*

- ModuleInput::const\_iterator mFirstUncheckedReceivedSubformula

*Stores the position of the first (by this module) unchecked sub-formula of the received formula.*

- unsigned mSmallerMusesCheckCounter

*Counter used for the generation of the smt2 files to check for smaller muses.*

- std::vector< std::size\_t > mVariableCounters

*Maps variables to the number of their occurrences.*

#### 0.15.564.1 Member Typedef Documentation

**0.15.564.1.1 SettingsType** template<typename Settings >  
typedef smtrat::UFCegarModule< Settings >::SettingsType

#### 0.15.564.2 Member Enumeration Documentation

**0.15.564.2.1 LemmaType** enum smtrat::Module::LemmaType : unsigned [strong], [inherited]

Enumerator

|           |  |
|-----------|--|
| NORMAL    |  |
| PERMANENT |  |

#### 0.15.564.3 Constructor & Destructor Documentation

**0.15.564.3.1 UFCegarModule()** template<typename Settings >  
smtrat::UFCegarModule< Settings >::UFCegarModule (

```
 const ModuleInput * _formula,
 Conditionals & _conditionals,
 Manager * _manager = nullptr)
```

**0.15.564.3.2 ~UFCegarModule()** template<typename Settings >  
smtrat::UFCegarModule< Settings >::~UFCegarModule ( )

#### 0.15.564.4 Member Function Documentation

**0.15.564.4.1 add()** bool smtrat::Module::add (   
    ModuleInput::const\_iterator \_subformula ) [inherited]

The module has to take the given sub-formula of the received formula into account.

##### Parameters

|             |                                                    |
|-------------|----------------------------------------------------|
| _subformula | The sub-formula to take additionally into account. |
|-------------|----------------------------------------------------|

##### Returns

false, if it can be easily decided that this sub-formula causes a conflict with the already considered sub-formulas; true, otherwise.

**0.15.564.4.2 addConstraintToInform()** void smtrat::Module::addConstraintToInform (   
    const FormulaT & \_constraint ) [protected], [virtual], [inherited]

Adds a constraint to the collection of constraints of this module, which are informed to a freshly generated backend.

##### Parameters

|             |                        |
|-------------|------------------------|
| _constraint | The constraint to add. |
|-------------|------------------------|

Reimplemented in [smtrat::SATModule< Settings >](#).

**0.15.564.4.3 addCore()** template<typename Settings >  
bool smtrat::UFCegarModule< Settings >::addCore (   
    ModuleInput::const\_iterator \_subformula ) [virtual]

The module has to take the given sub-formula of the received formula into account.

##### Parameters

|             |                                                    |
|-------------|----------------------------------------------------|
| _subformula | The sub-formula to take additionally into account. |
|-------------|----------------------------------------------------|

##### Returns

false, if it can be easily decided that this sub-formula causes a conflict with the already considered sub-formulas; true, otherwise.

Reimplemented from [smtrat::Module](#).

**0.15.564.4.4 addInformationRelevantFormula()** void smtrat::Module::addInformationRelevantFormula (   
    const FormulaT & formula ) [protected], [inherited]

Adds a formula to the InformationRelevantFormula.

##### Parameters

|         |                |
|---------|----------------|
| formula | Formula to add |
|---------|----------------|

```
0.15.564.4.5 addLemma() void smtrat::Module::addLemma (
 const FormulaT & _lemma,
 const LemmaType & _lt = LemmaType::NORMAL,
 const FormulaT & _preferredFormula = FormulaT(carl::FormulaType::TRUE)) [inline],
[inherited]
```

Stores a lemma being a valid formula.

#### Parameters

|                          |                                                                       |
|--------------------------|-----------------------------------------------------------------------|
| <i>_lemma</i>            | The eduction/lemma to store.                                          |
| <i>_lt</i>               | The type of the lemma.                                                |
| <i>_preferredFormula</i> | Hint for the next decision, which formula should be assigned to true. |

```
0.15.564.4.6 addOrigin() void smtrat::Module::addOrigin (
```

```
 ModuleInput::iterator _formula,
 const FormulaT & _origin) [inline], [protected], [inherited]
```

Adds the given set of formulas in the received formula to the origins of the given passed formula.

#### Parameters

|                 |                                                           |
|-----------------|-----------------------------------------------------------|
| <i>_formula</i> | The passed formula to set the origins for.                |
| <i>_origin</i>  | A set of formulas in the received formula of this module. |

```
0.15.564.4.7 addReceivedSubformulaToPassedFormula() std::pair<ModuleInput::iterator,bool>
smtrat::Module::addReceivedSubformulaToPassedFormula (
```

```
 ModuleInput::const_iterator _subformula) [inline], [protected], [inherited]
```

Copies the given sub-formula of the received formula to the passed formula.

Note, that there is always a link between sub-formulas of the passed formulas to sub-formulas of the received formulas, which are responsible for its occurrence.

#### Parameters

|                    |                                                  |
|--------------------|--------------------------------------------------|
| <i>_subformula</i> | The sub-formula of the received formula to copy. |
|--------------------|--------------------------------------------------|

```
0.15.564.4.8 addSubformulaToPassedFormula() [1/3] std::pair<ModuleInput::iterator,bool> smtrat<-
::Module::addSubformulaToPassedFormula (
 const FormulaT & _formula) [inline], [protected], [inherited]
```

Adds the given formula to the passed formula with no origin.

Note that in the next call of this module's removeSubformula, all formulas in the passed formula without origins will be removed.

#### Parameters

|                 |                                           |
|-----------------|-------------------------------------------|
| <i>_formula</i> | The formula to add to the passed formula. |
|-----------------|-------------------------------------------|

**Returns**

A pair to the position where the formula to add has been inserted (or its first sub-formula which has not yet been in the passed formula, in case the formula to add is a conjunction), and a Boolean stating whether anything has been added to the passed formula.

**0.15.564.4.9 addSubformulaToPassedFormula()** [2/3] std::pair<ModuleInput::iterator,bool> smrat::Module::addSubformulaToPassedFormula (

```
 const FormulaT & _formula,
 const FormulaT & _origin) [inline], [protected], [inherited]
```

Adds the given formula to the passed formula.

**Parameters**

|                 |                                                                                                                           |
|-----------------|---------------------------------------------------------------------------------------------------------------------------|
| <i>_formula</i> | The formula to add to the passed formula.                                                                                 |
| <i>_origin</i>  | The sub-formula of the received formula being responsible for the occurrence of the formula to add to the passed formula. |

**Returns**

A pair to the position where the formula to add has been inserted (or its first sub-formula which has not yet been in the passed formula, in case the formula to add is a conjunction), and a Boolean stating whether anything has been added to the passed formula.

**0.15.564.4.10 addSubformulaToPassedFormula()** [3/3] std::pair<ModuleInput::iterator,bool> smrat::Module::addSubformulaToPassedFormula (

```
 const FormulaT & _formula,
 const std::shared_ptr< std::vector< FormulaT >> & _origins) [inline], [protected],
[inherited]
```

Adds the given formula to the passed formula.

**Parameters**

|                 |                                                                                                                                         |
|-----------------|-----------------------------------------------------------------------------------------------------------------------------------------|
| <i>_formula</i> | The formula to add to the passed formula.                                                                                               |
| <i>_origins</i> | The link of the formula to add to the passed formula to sub-formulas of the received formulas, which are responsible for its occurrence |

**Returns**

A pair to the position where the formula to add has been inserted (or its first sub-formula which has not yet been in the passed formula, in case the formula to add is a conjunction), and a Boolean stating whether anything has been added to the passed formula.

**0.15.564.4.11 allModels()** const std::vector<Model>& smrat::Module::allModels () const [inline], [inherited]

**Returns**

All satisfying assignments, if existent.

**0.15.564.4.12 `anAnswerFound()`** `bool smrat::Module::anAnswerFound ( ) const [inline], [protected], [inherited]`

Checks for all antecedent modules and those which run in parallel with the same antecedent modules, whether one of them has determined a result.

#### Returns

True, if one of them has determined a result.

**0.15.564.4.13 `answerFound()`** `const smrat::Conditionals& smrat::Module::answerFound ( ) const [inline], [inherited]`

#### Returns

A vector of Booleans: If any of them is true, we have to terminate a running check procedure.

**0.15.564.4.14 `backendsModel()`** `const Model & smrat::Module::backendsModel ( ) const [protected], [inherited]`

Stores the model of a backend which determined satisfiability of the passed formula in the model of this module.

**0.15.564.4.15 `branchAt() [1/4]`** `bool smrat::Module::branchAt ( carl::Variable::Arg _var, const Rational & _value, bool _leftCaseWeak = true, bool _preferLeftCase = true, bool _useReceivedFormulaAsPremise = false, const std::vector< FormulaT > & _premise = std::vector<FormulaT>() ) [inline], [protected], [inherited]`

**0.15.564.4.16 `branchAt() [2/4]`** `bool smrat::Module::branchAt ( carl::Variable::Arg _var, const Rational & _value, std::vector< FormulaT > && _premise, bool _leftCaseWeak = true, bool _preferLeftCase = true, bool _useReceivedFormulaAsPremise = false ) [inline], [protected], [inherited]`

**0.15.564.4.17 `branchAt() [3/4]`** `bool smrat::Module::branchAt ( const Poly & _polynomial, bool _integral, const Rational & _value, bool _leftCaseWeak = true, bool _preferLeftCase = true, bool _useReceivedFormulaAsPremise = false, const std::vector< FormulaT > & _premise = std::vector<FormulaT>() ) [inline], [protected], [inherited]`

**0.15.564.4.18 `branchAt() [4/4]`** `bool smrat::Module::branchAt ( const Poly & _polynomial, bool _integral, const Rational & _value,`

```
 std::vector< FormulaT > && _premise,
 bool _leftCaseWeak = true,
 bool _preferLeftCase = true,
 bool _useReceivedFormulaAsPremise = false) [protected], [inherited]
```

Adds a lemmas which provoke a branching for the given variable at the given value, if this module returns Unknown and there exists a preceding [SATModule](#).

Note that the given value is rounded down and up, if the given variable is integer-valued.

#### Parameters

|                                           |                                                                                                                                                                                                                |
|-------------------------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>_polynomial</code>                  | The variable to branch for.                                                                                                                                                                                    |
| <code>_integral</code>                    | A flag being true, if all variables in the polynomial to branch for are integral.                                                                                                                              |
| <code>_value</code>                       | The value to branch at.                                                                                                                                                                                        |
| <code>_premise</code>                     | The sub-formulas of the received formula from which the branch is followed. Note, that a premise is not necessary, as every branch is a valid formula. But a premise can prevent from branching unnecessarily. |
| <code>_leftCaseWeak</code>                | true, if a branching in the form of (or ( $\leq p b$ ) ( $> p b$ )) is desired. false, if a branching in the form of (or ( $< p b$ ) ( $\geq p b$ )) is desired.                                               |
| <code>_preferLeftCase</code>              | true, if the left case (polynomial less(or equal) 0 shall be chosen first. false, otherwise.                                                                                                                   |
| <code>_useReceivedFormulaAsPremise</code> | true, if the whole received formula should be used as premise                                                                                                                                                  |

#### 0.15.564.4.19 `check()`

```
Answer smtrat::Module::check (
 bool _final = false,
 bool _full = true,
 carl::Variable _objective = carl::Variable::NO_VARIABLE) [virtual], [inherited]
```

Checks the received formula for consistency.

Note, that this is an implementation of the satisfiability check of the conjunction of the so far received formulas, which does actually nothing but passing the problem to its backends. This implementation is only used internally and must be overwritten by any derived module.

#### Parameters

|                         |                                                                                                                                       |
|-------------------------|---------------------------------------------------------------------------------------------------------------------------------------|
| <code>_final</code>     | true, if this satisfiability check will be the last one (for a global sat-check), if its result is SAT                                |
| <code>_full</code>      | false, if this module should avoid too expensive procedures and rather return unknown instead.                                        |
| <code>_objective</code> | if not set to NO_VARIABLE, the module should find an assignment minimizing this objective variable; otherwise any assignment is good. |

#### Returns

True, if the received formula is satisfiable; False, if the received formula is not satisfiable; Unknown, otherwise.

Reimplemented in [smtrat::PModule](#).

#### 0.15.564.4.20 `checkCore()`

```
template<typename Settings >
Answer smtrat::UFCegarModule< Settings >::checkCore () [virtual]
```

Checks the received formula for consistency.

#### Returns

True, if the received formula is satisfiable; False, if the received formula is not satisfiable; Unknown, otherwise.

Reimplemented from [smtrat::Module](#).

```
0.15.564.4.21 checkInfSubsetForMinimality() void smtrat::Module::checkInfSubsetForMinimality (
 std::vector< FormulaSetT >::const_iterator _infssubset,
 const std::string & _filename = "smaller_muses",
 unsigned _maxSizeDifference = 1) const [inherited]
```

Checks the given infeasible subset for minimality by storing all subsets of it, which have a smaller size which differs from the size of the infeasible subset not more than the given threshold.

#### Parameters

|                                 |                                                                                                        |
|---------------------------------|--------------------------------------------------------------------------------------------------------|
| <code>_infssubset</code>        | The infeasible subset to check for minimality.                                                         |
| <code>_filename</code>          | The name of the file to store the infeasible subsets in order to be able to check their infeasibility. |
| <code>_maxSizeDifference</code> | The maximal difference between the sizes of the subsets compared to the size of the infeasible subset. |

```
0.15.564.4.22 checkModel() unsigned smtrat::Module::checkModel () const [protected], [inherited]
```

#### Returns

false, if the current model of this module does not satisfy the current given formula; true, if it cannot be said whether the model satisfies the given formula.

```
0.15.564.4.23 cleanModel() void smtrat::Module::cleanModel () const [inline], [protected], [inherited]
```

Substitutes variable occurrences by its model value in the model values of other variables.

```
0.15.564.4.24 clearLemmas() void smtrat::Module::clearLemmas () [inline], [inherited]
```

Deletes all yet found lemmas.

```
0.15.564.4.25 clearModel() void smtrat::Module::clearModel () const [inline], [protected], [inherited]
```

Clears the assignment, if any was found.

```
0.15.564.4.26 clearModels() void smtrat::Module::clearModels () const [inline], [protected], [inherited]
```

Clears all assignments, if any was found.

```
0.15.564.4.27 clearPassedFormula() void smtrat::Module::clearPassedFormula () [protected], [inherited]
```

```
0.15.564.4.28 collectOrigins() [1/2] void smtrat::Module::collectOrigins (
 const FormulaT & _formula,
 FormulaSetT & _origins) const [inherited]
```

---

**0.15.564.4.29 collectOrigins() [2/2]** void smtrat::Module::collectOrigins ( const FormulaT & \_formula, FormulasT & \_origins ) const [inherited]

Collects the formulas in the given formula, which are part of the received formula.

If the given formula directly occurs in the received formula, it is inserted into the given set. Otherwise, the given formula must be of type AND and all its sub-formulas part of the received formula. Hence, they will be added to the given set.

#### Parameters

|                 |                                                                                                      |
|-----------------|------------------------------------------------------------------------------------------------------|
| <i>_formula</i> | The formula from which to collect the formulas being sub-formulas of the received formula (origins). |
| <i>_origins</i> | The set in which to store the origins.                                                               |

**0.15.564.4.30 collectTheoryPropagations()** void smtrat::Module::collectTheoryPropagations ( ) [inherited]

**0.15.564.4.31 constraintsToInform()** const carl::FastSet<FormulaT>& smtrat::Module::constraintsToInform ( ) const [inline], [inherited]

#### Returns

The constraints which the backends must be informed about.

**0.15.564.4.32 currentlySatisfied()** virtual unsigned smtrat::Module::currentlySatisfied ( const FormulaT & ) const [inline], [virtual], [inherited]

#### Returns

0, if the given formula is conflicted by the current model; 1, if the given formula is satisfied by the current model; 2, otherwise; 3, if we do not know anything (default)

Reimplemented in [smtrat::LRAModule< Settings >](#), [smtrat::LRAModule< LRASettingsICP >](#), and [smtrat::LRAModule< LRASettings >](#)

**0.15.564.4.33 currentlySatisfiedByBackend()** unsigned smtrat::Module::currentlySatisfiedByBackend ( const FormulaT & \_formula ) const [inherited]

#### Returns

0, if the given formula is conflicted by the current model; 1, if the given formula is satisfied by the current model; 2, otherwise 3, if we do not know anything (default)

**0.15.564.4.34 deinform()** void smtrat::Module::deinform ( const FormulaT & \_constraint ) [inherited]

The inverse of informing about a constraint.

All data structures which were kept regarding this constraint are going to be removed. Note, that this makes only sense if it is not likely enough that a formula with this constraint must be solved again.

#### Parameters

|                    |                                                         |
|--------------------|---------------------------------------------------------|
| <i>_constraint</i> | The constraint to remove from internal data structures. |
|--------------------|---------------------------------------------------------|

**0.15.564.4.35 `deinformCore()`** `virtual void smtrat::Module::deinformCore (`  
 `const FormulaT & _constraint )` [inline], [protected], [virtual], [inherited]

The inverse of informing about a constraint.

All data structures which were kept regarding this constraint are going to be removed. Note, that this makes only sense if it is not likely enough that a formula with this constraint must be solved again.

#### Parameters

|                          |                                                         |
|--------------------------|---------------------------------------------------------|
| <code>_constraint</code> | The constraint to remove from internal data structures. |
|--------------------------|---------------------------------------------------------|

Reimplemented in [smtrat::LRAModule< Settings >](#), [smtrat::LRAModule< LRASettingsICP >](#), and [smtrat::LRAModule< LRASettings4 >](#).

**0.15.564.4.36 `determine_smallest_origin()`** `size_t smtrat::Module::determine_smallest_origin (`  
 `const std::vector< FormulaT > & origins )` const [protected], [inherited]

#### Parameters

|                      |                              |
|----------------------|------------------------------|
| <code>origins</code> | A vector of sets of origins. |
|----------------------|------------------------------|

#### Returns

The index of the smallest (regarding the size of the sets) element of origins

**0.15.564.4.37 `eraseSubformulaFromPassedFormula()`** `ModuleInput::iterator smtrat::Module::eraseSubformulaFromPassedFormula (`  
 `ModuleInput::iterator _subformula,`  
 `bool _ignoreOrigins = false )` [protected], [virtual], [inherited]

Removes everything related to the sub-formula to remove from the passed formula in the backends of this module.  
Afterwards the sub-formula is removed from the passed formula.

#### Parameters

|                             |                                                                                                              |
|-----------------------------|--------------------------------------------------------------------------------------------------------------|
| <code>_subformula</code>    | The sub-formula to remove from the passed formula.                                                           |
| <code>_ignoreOrigins</code> | True, if the sub-formula shall be removed regardless of its origins (should only be applied with expertise). |

#### Returns

Reimplemented in [smtrat::ICPModule< Settings >](#), [smtrat::ICPModule< ICPSettings4 >](#), and [smtrat::ICPModule< ICPSettings1 >](#).

**0.15.564.4.38 `excludeNotReceivedVariablesFromModel()`** `void smtrat::Module::excludeNotReceivedVariablesFromModel ( )` const [inherited]

Excludes all variables from the current model, which do not occur in the received formula.

**0.15.564.4.39 `findBestOrigin()`** `std::vector< FormulaT >::const_iterator smtrat::Module::findBestOrigin (`  
 `const std::vector< FormulaT > & _origins )` const [protected], [inherited]

**Parameters**

|                 |  |
|-----------------|--|
| <i>_origins</i> |  |
|-----------------|--|

**Returns**

**0.15.564.4.40 `firstSubformulaToPass()`** `ModuleInput::const_iterator smtrat::Module::firstSubformulaToPass () const [inline], [inherited]`

**Returns**

The position of the first sub-formula in the passed formula, which has not yet been considered for a consistency check of the backends.

**0.15.564.4.41 `firstUncheckedReceivedSubformula()`** `ModuleInput::const_iterator smtrat::Module::firstUncheckedReceivedSubformula () const [inline], [inherited]`

**Returns**

The position of the first (by this module) unchecked sub-formula of the received formula.

**0.15.564.4.42 `freeSplittingVariable()`** `static void smtrat::Module::freeSplittingVariable (const FormulaT & _splittingVariable) [inline], [static], [inherited]`

**0.15.564.4.43 `generateTrivialInfeasibleSubset()`** `void smtrat::Module::generateTrivialInfeasibleSubset () [inline], [protected], [inherited]`

Stores the trivial infeasible subset being the set of received formulas.

**0.15.564.4.44 `getBackendsAllModels()`** `void smtrat::Module::getBackendsAllModels () const [protected], [inherited]`

Stores all models of a backend in the list of all models of this module.

**0.15.564.4.45 `getBackendsModel()`** `void smtrat::Module::getBackendsModel () const [protected], [inherited]`

**0.15.564.4.46 `getInfeasibleSubsets() [1/2]`** `void smtrat::Module::getInfeasibleSubsets () [protected], [inherited]`

Copies the infeasible subsets of the passed formula.

**0.15.564.4.47 `getInfeasibleSubsets() [2/2]`** `std::vector< FormulaSetT > smtrat::Module::getInfeasibleSubsets (const Module & _backend) const [protected], [inherited]`

Get the infeasible subsets the given backend provides.

Note, that an infeasible subset in a backend contains sub formulas of the passed formula and an infeasible subset of this module contains sub formulas of the received formula. In this method the LATTER is returned.

**Parameters**

|                       |                                                          |
|-----------------------|----------------------------------------------------------|
| <code>_backend</code> | The backend from which to obtain the infeasible subsets. |
|-----------------------|----------------------------------------------------------|

**Returns**

The infeasible subsets the given backend provides.

**0.15.564.4.48 `getInformationRelevantFormulas()`** `const std::set< FormulaT > & smtrat::Module::getInformationRelevantFormulas ( ) [protected], [inherited]`  
Gets all InformationRelevantFormulas.

**Returns**

Set of all formulas

**0.15.564.4.49 `getModelEqualities()`** `std::list< std::vector< carl::Variable > > smtrat::Module::getModelEqualities ( ) const [virtual], [inherited]`  
Partition the variables from the current model into equivalence classes according to their assigned value.  
The result is a set of equivalence classes of variables where all variables within one class are assigned the same value. Note that the number of classes may not be minimal, i.e. two classes may actually be equivalent.

**Returns**

Equivalence classes.

**0.15.564.4.50 `getOrigins()` [1/3]** `void smtrat::Module::getOrigins ( const FormulaT & _formula, FormulaSetT & _origins ) const [inline], [protected], [inherited]`

**Parameters**

|                       |  |
|-----------------------|--|
| <code>_formula</code> |  |
| <code>_origins</code> |  |

**0.15.564.4.51 `getOrigins()` [2/3]** `void smtrat::Module::getOrigins ( const FormulaT & _formula, FormulasT & _origins ) const [inline], [protected], [inherited]`

**Parameters**

|                       |  |
|-----------------------|--|
| <code>_formula</code> |  |
| <code>_origins</code> |  |

**0.15.564.4.52 `getOrigins()` [3/3]** `const FormulaT& smtrat::Module::getOrigins ( ModuleInput::const_iterator _formula ) const [inline], [protected], [inherited]`  
Gets the origins of the passed formula at the given position.

**Parameters**

|                 |                                                   |
|-----------------|---------------------------------------------------|
| <i>_formula</i> | The position of a formula in the passed formulas. |
|-----------------|---------------------------------------------------|

**Returns**

The origins of the passed formula at the given position.

**0.15.564.4.53 `getReceivedFormulaSimplified()`** `std::pair< bool, FormulaT >` `smtrat::Module::getReceivedFormulaSimplified( )` [virtual], [inherited]

**Returns**

A pair of a Boolean and a formula, where the Boolean is true, if the received formula could be simplified to an equisatisfiable formula. The formula is equisatisfiable to this module's received formula, if the Boolean is true.

Reimplemented in [smtrat::PModule](#).

**0.15.564.4.54 `hasLemmas()`** `bool smtrat::Module::hasLemmas( )` [inline], [inherited]

Checks whether this module or any of its backends provides any lemmas.

**0.15.564.4.55 `hasValidInfeasibleSubset()`** `bool smtrat::Module::hasValidInfeasibleSubset( ) const` [inherited]

**Returns**

true, if the module has at least one valid infeasible subset, that is all its elements are sub-formulas of the received formula (pointer must be equal).

**0.15.564.4.56 `id()`** `std::size_t smtrat::Module::id( ) const` [inline], [inherited]

**Returns**

A unique ID to identify this module instance.

**0.15.564.4.57 `infeasibleSubsets()`** `const std::vector<FormulaSetT>& smtrat::Module::infeasibleSubsets( ) const` [inline], [inherited]

**Returns**

The infeasible subsets of the set of received formulas (empty, if this module has not detected unsatisfiability of the conjunction of received formulas).

**0.15.564.4.58 `inform()`** `bool smtrat::Module::inform( const FormulaT & _constraint )` [inherited]

Informs the module about the given constraint.

It should be tried to inform this module about any constraint it could receive eventually before `assertSubformula` is called (preferably for the first time, but at least before adding a formula containing that constraint).

**Parameters**

|                    |                                 |
|--------------------|---------------------------------|
| <i>_constraint</i> | The constraint to inform about. |
|--------------------|---------------------------------|

**Returns**

false, if it can be easily decided whether the given constraint is inconsistent; true, otherwise.

**0.15.564.4.59 informBackends()** void smrat::Module::informBackends ( const FormulaT & \_constraint ) [inline], [protected], [inherited]

Informs all backends of this module about the given constraint.

**Parameters**

|                    |                                 |
|--------------------|---------------------------------|
| <i>_constraint</i> | The constraint to inform about. |
|--------------------|---------------------------------|

**0.15.564.4.60 informCore()** virtual bool smrat::Module::informCore (

const FormulaT & \_constraint ) [inline], [protected], [virtual], [inherited]

Informs the module about the given constraint.

It should be tried to inform this module about any constraint it could receive eventually before assertSubformula is called (preferably for the first time, but at least before adding a formula containing that constraint).

**Parameters**

|                    |                                 |
|--------------------|---------------------------------|
| <i>_constraint</i> | The constraint to inform about. |
|--------------------|---------------------------------|

**Returns**

false, if it can be easily decided whether the given constraint is inconsistent; true, otherwise.

Reimplemented in [smrat::UnionFindModule< Settings >](#), [smrat::PBPPModule< Settings >](#), [smrat::PBGaussModule< Settings >](#), [smrat::NRAILModule< Settings >](#), [smrat::NewCoveringModule< Settings >](#), [smrat::NewCADModule< Settings >](#), [smrat::LRAModule< Settings >](#), [smrat::LRAModule< LRASettingsICP >](#), [smrat::LRAModule< LRASettings1 >](#), [smrat::IntBlastModule< Settings >](#), [smrat::FPPModule< Settings >](#), [smrat::EQModule< Settings >](#), [smrat::CurryModule< Settings >](#), [smrat::BVMModule< Settings >](#), [smrat::ICPModule< Settings >](#), [smrat::ICPModule< ICPSettings4 >](#), and [smrat::ICPModule< ICPSettings1 >](#).

**0.15.564.4.61 informedConstraints()** const carl::FastSet<FormulaT>& smrat::Module::informedConstraints ( ) const [inline], [inherited]

**Returns**

The position of the first constraint of which no backend has been informed about.

**0.15.564.4.62 init()** void smrat::Module::init ( ) [virtual], [inherited]

Informs all backends about the so far encountered constraints, which have not yet been communicated.

This method must not be called twice and only before the first runBackends call.

Reimplemented in [smrat::PBPPModule< Settings >](#), [smrat::PBGaussModule< Settings >](#), [smrat::NRAILModule< Settings >](#), [smrat::NewCoveringModule< Settings >](#), [smrat::NewCADModule< Settings >](#), [smrat::LRAModule< Settings >](#), [smrat::LRAModule< LRASettingsICP >](#), [smrat::LRAModule< LRASettings1 >](#), [smrat::IntBlastModule< Settings >](#), [smrat::FPPModule< Settings >](#), [smrat::EQModule< Settings >](#), [smrat::CurryModule< Settings >](#), and [smrat::BVMModule< Settings >](#).

**0.15.564.4.63 is\_minimizing()** bool smrat::Module::is\_minimizing ( ) const [inline], [inherited]

**0.15.564.4.64 `isLemmaLevel()`** `bool smtrat::Module::isLemmaLevel (``LemmaLevel level ) [protected], [inherited]`

Checks if current lemma level is greater or equal to given level.

**Parameters**

|                    |                 |
|--------------------|-----------------|
| <code>level</code> | Level to check. |
|--------------------|-----------------|

**0.15.564.4.65 `isPreprocessor()`** `bool smtrat::Module::isPreprocessor ( ) const [inline], [inherited]`**Returns**

true, if this module is a preprocessor that is a module, which simplifies its received formula to an equisatisfiable formula being passed to its backends. The simplified formula can be obtained with [getReceivedFormulaSimplified\(\)](#).

**0.15.564.4.66 `lemmas()`** `const std::vector<Lemma>& smtrat::Module::lemmas ( ) const [inline], [inherited]`**Returns**

A constant reference to the lemmas being valid formulas this module or its backends made.

**0.15.564.4.67 `merge()`** `std::vector< FormulaT > smtrat::Module::merge (``const std::vector< FormulaT > & _vecSetA,``const std::vector< FormulaT > & _vecSetB ) const [protected], [inherited]`

Merges the two vectors of sets into the first one.

({a,b},{a,c}) and ({b,d},{b}) -> ({a,b,d},{a,b},{a,b,c,d},{a,b,c})

**Parameters**

|                       |                                  |
|-----------------------|----------------------------------|
| <code>_vecSetA</code> | A vector of sets of constraints. |
| <code>_vecSetB</code> | A vector of sets of constraints. |

**Returns**

The vector being the two given vectors merged.

**0.15.564.4.68 `model()`** `const Model& smtrat::Module::model ( ) const [inline], [inherited]`**Returns**

The assignment of the current satisfiable result, if existent.

**0.15.564.4.69 `modelsDisjoint()`** `bool smtrat::Module::modelsDisjoint (``const Model & _modelA,``const Model & _modelB ) [static], [protected], [inherited]`

Checks whether there is no variable assigned by both models.

**Parameters**

|                      |                                |
|----------------------|--------------------------------|
| <code>_modelA</code> | The first model to check for.  |
| <code>_modelB</code> | The second model to check for. |

**Returns**

true, if there is no variable assigned by both models; false, otherwise.

**0.15.564.4.70 `moduleName()`** `template<typename Settings >`  
`std::string smtrat::UFCegarModule< Settings >::moduleName ( ) const [inline], [virtual]`

**Returns**

The name of the given module type as name.

Reimplemented from [smtrat::Module](#).

**0.15.564.4.71 `objective()`** `carl::Variable smtrat::Module::objective ( ) const [inline], [inherited]`

**0.15.564.4.72 `originInReceivedFormula()`** `bool smtrat::Module::originInReceivedFormula (`  
`const FormulaT & _origin ) const [protected], [inherited]`

**0.15.564.4.73 `passedFormulaBegin()`** `ModuleInput::iterator smtrat::Module::passedFormulaBegin (`  
`) [inline], [protected], [inherited]`

**Returns**

An iterator to the end of the passed formula. TODO: disable this method

**0.15.564.4.74 `passedFormulaEnd()`** `ModuleInput::iterator smtrat::Module::passedFormulaEnd ( )`  
`[inline], [protected], [inherited]`

**Returns**

An iterator to the end of the passed formula.

**0.15.564.4.75 `pPassedFormula()`** `const ModuleInput* smtrat::Module::pPassedFormula ( ) const`  
`[inline], [inherited]`

**Returns**

A pointer to the formula passed to the backends of this module.

**0.15.564.4.76 `pReceivedFormula()`** `const ModuleInput* smtrat::Module::pReceivedFormula ( ) const`  
`[inline], [inherited]`

**Returns**

A pointer to the formula passed to this module.

**0.15.564.4.77 `print()`** `void smtrat::Module::print (`  
`const std::string & _initiation = "***" ) const [inherited]`

Prints everything relevant of the solver.

**Parameters**

|                    |                      |
|--------------------|----------------------|
| <i>_initiation</i> | The line initiation. |
|--------------------|----------------------|

**0.15.564.4.78 printAllModels()** void smtrat::Module::printAllModels ( std::ostream & *\_out* = std::cout ) const [inherited]

Prints all assignments of this module satisfying its received formula if it satisfiable and this module could find an assignment.

**Parameters**

|             |                                        |
|-------------|----------------------------------------|
| <i>_out</i> | The stream to print the assignment on. |
|-------------|----------------------------------------|

**0.15.564.4.79 printInfeasibleSubsets()** void smtrat::Module::printInfeasibleSubsets ( const std::string & *\_initiation* = "\*\*\*" ) const [inherited]

Prints the infeasible subsets.

**Parameters**

|                    |                      |
|--------------------|----------------------|
| <i>_initiation</i> | The line initiation. |
|--------------------|----------------------|

**0.15.564.4.80 printModel()** void smtrat::Module::printModel ( std::ostream & *\_out* = std::cout ) const [inherited]

Prints the assignment of this module satisfying its received formula if it satisfiable and this module could find an assignment.

**Parameters**

|             |                                        |
|-------------|----------------------------------------|
| <i>_out</i> | The stream to print the assignment on. |
|-------------|----------------------------------------|

**0.15.564.4.81 printPassedFormula()** void smtrat::Module::printPassedFormula ( const std::string & *\_initiation* = "\*\*\*" ) const [inherited]

Prints the vector of passed formula.

**Parameters**

|                    |                      |
|--------------------|----------------------|
| <i>_initiation</i> | The line initiation. |
|--------------------|----------------------|

**0.15.564.4.82 printReceivedFormula()** void smtrat::Module::printReceivedFormula ( const std::string & *\_initiation* = "\*\*\*" ) const [inherited]

Prints the vector of the received formula.

**Parameters**

|                    |                      |
|--------------------|----------------------|
| <i>_initiation</i> | The line initiation. |
|--------------------|----------------------|

```
0.15.564.4.83 probablyLooping() bool smtrat::Module::probablyLooping (
 const typename Poly::PolyType & _branchingPolynomial,
 const Rational & _branchingValue) const [protected], [inherited]
```

Checks whether given the current branching value and branching variable/polynomial it is (highly) probable that this branching is part of an infinite loop of branchings.

#### Parameters

|                                   |                                                                                     |
|-----------------------------------|-------------------------------------------------------------------------------------|
| <code>_branchingPolynomial</code> | The polynomial to branch at (in most branching strategies this is just a variable). |
| <code>_branchingValue</code>      | The value to branch at.                                                             |

#### Returns

true, if this branching is probably part of an infinite loop of branchings; false, otherwise.

```
0.15.564.4.84 receivedFormulaChecked() void smtrat::Module::receivedFormulaChecked () [inline], [inherited]
```

Notifies that the received formulas has been checked.

```
0.15.564.4.85 receivedFormulasAsInfeasibleSubset() void smtrat::Module::receivedFormulasAs<= InfeasibleSubset (
```

```
 ModuleInput::const_iterator _subformula) [inline], [protected], [inherited]
```

Stores an infeasible subset consisting only of the given received formula.

```
0.15.564.4.86 receivedVariable() bool smtrat::Module::receivedVariable (
 carl::Variable::Arg _var) const [inline], [inherited]
```

```
0.15.564.4.87 remove() void smtrat::Module::remove (
```

```
 ModuleInput::const_iterator _subformula) [virtual], [inherited]
```

Removes everything related to the given sub-formula of the received formula.

However, it is desired not to lose track of search spaces where no satisfying assignment can be found for the remaining sub-formulas.

#### Parameters

|                          |                                                    |
|--------------------------|----------------------------------------------------|
| <code>_subformula</code> | The sub formula of the received formula to remove. |
|--------------------------|----------------------------------------------------|

Reimplemented in [smtrat::PModule](#).

```
0.15.564.4.88 removeCore() template<typename Settings >
void smtrat::UFCegarModule< Settings >::removeCore (
 ModuleInput::const_iterator _subformula) [virtual]
```

Removes the subformula of the received formula at the given position to the considered ones of this module.

Note that this includes every stored calculation which depended on this subformula, but should keep the other stored calculation, if possible, untouched.

#### Parameters

|                          |                                           |
|--------------------------|-------------------------------------------|
| <code>_subformula</code> | The position of the subformula to remove. |
|--------------------------|-------------------------------------------|

Reimplemented from [smtrat::Module](#).

**0.15.564.4.89 `removeOrigin()`** `std::pair<ModuleInput::iterator, bool> smtrat::Module::removeOrigin (`

```
 ModuleInput::iterator _formula,
 const FormulaT & _origin) [inline], [protected], [inherited]
```

**0.15.564.4.90 `removeOrigins()`** `std::pair<ModuleInput::iterator, bool> smtrat::Module::removeOrigins (`

```
 ModuleInput::iterator _formula,
 const std::shared_ptr< std::vector< FormulaT >> & _origins) [inline], [protected],
[inherited]
```

**0.15.564.4.91 `rPassedFormula()`** `const ModuleInput& smtrat::Module::rPassedFormula ( ) const`  
`[inline], [inherited]`

#### Returns

A reference to the formula passed to the backends of this module.

**0.15.564.4.92 `rReceivedFormula()`** `const ModuleInput& smtrat::Module::rReceivedFormula ( ) const`  
`[inline], [inherited]`

#### Returns

A reference to the formula passed to this module.

**0.15.564.4.93 `runBackends() [1/2]`** `virtual Answer smtrat::Module::runBackends ( ) [inline],`  
`[protected], [virtual], [inherited]`

Reimplemented in [smtrat::PModule](#).

**0.15.564.4.94 `runBackends() [2/2]`** `Answer smtrat::Module::runBackends (`

```
 bool _final,
 bool _full,
 carl::Variable _objective) [protected], [virtual], [inherited]
```

Runs the backend solvers on the passed formula.

#### Parameters

|                         |                                                                                                                                       |
|-------------------------|---------------------------------------------------------------------------------------------------------------------------------------|
| <code>_final</code>     | true, if this satisfiability check will be the last one (for a global sat-check), if its result is SAT                                |
| <code>_full</code>      | false, if this module should avoid too expensive procedures and rather return unknown instead.                                        |
| <code>_objective</code> | if not set to NO_VARIABLE, the module should find an assignment minimizing this objective variable; otherwise any assignment is good. |

#### Returns

True, if the passed formula is consistent; False, if the passed formula is inconsistent; Unknown, otherwise.

Reimplemented in [smtrat::PModule](#).

**0.15.564.4.95 setId()** void smtrat::Module::setId ( std::size\_t \_id ) [inline], [inherited]  
Sets this module's unique ID to identify itself.

#### Parameters

|                                                      |                                    |
|------------------------------------------------------|------------------------------------|
| $\leftarrow$<br>$\overline{\leftarrow}$<br><i>id</i> | The id to set this module's id to. |
|------------------------------------------------------|------------------------------------|

**0.15.564.4.96 setThreadPriority()** void smtrat::Module::setThreadPriority ( thread\_priority \_threadPriority ) [inline], [inherited]  
Sets the priority of this module to get a thread for running its check procedure.

#### Parameters

|                        |                                                       |
|------------------------|-------------------------------------------------------|
| <i>_threadPriority</i> | The priority to set this module's thread priority to. |
|------------------------|-------------------------------------------------------|

**0.15.564.4.97 solverState()** Answer smtrat::Module::solverState ( ) const [inline], [inherited]

#### Returns

True, if this module is in a state, such that it has found a solution for its received formula; False, if this module is in a state, such that it has determined that there is no solution for its received formula; Unknown, otherwise.

**0.15.564.4.98 splitUnequalConstraint()** void smtrat::Module::splitUnequalConstraint ( const FormulaT & \_unequalConstraint ) [protected], [inherited]  
Adds the following lemmas for the given constraint  $p \neq 0$ .

$(p \neq 0 \leftrightarrow (p < 0 \text{ or } p > 0))$

and  $\neg(p < 0 \text{ and } p > 0)$

#### Parameters

|                           |                                                  |
|---------------------------|--------------------------------------------------|
| <i>_unequalConstraint</i> | A constraint having the relation symbol $\neq$ . |
|---------------------------|--------------------------------------------------|

**0.15.564.4.99 threadPriority()** thread\_priority smtrat::Module::threadPriority ( ) const [inline], [inherited]

#### Returns

The priority of this module to get a thread for running its check procedure.

**0.15.564.4.100 updateAllModels()** void smtrat::Module::updateAllModels ( ) [virtual], [inherited]  
Updates all satisfying models, if the solver has detected the consistency of the received formula, beforehand.  
Reimplemented in [smtrat::SATModule< Settings >](#).

**0.15.564.4.101 updateLemmas()** void smtrat::Module::updateLemmas () [inherited]  
Stores all lemmas of any backend of this module in its own lemma vector.

**0.15.564.4.102 updateModel()** template<typename Settings >  
void smtrat::UFCegarModule< Settings >::updateModel () const [virtual]  
Updates the current assignment into the model.  
Note, that this is a unique but possibly symbolic assignment maybe containing newly introduced variables.  
Reimplemented from [smtrat::Module](#).

**0.15.564.4.103 usedBackends()** const std::vector<[Module](#)\*>& smtrat::Module::usedBackends ()  
const [inline], [inherited]

#### Returns

The backends of this module which are currently used (conditions to use this module are fulfilled for the passed formula).

### 0.15.564.5 Field Documentation

**0.15.564.5.1 mAllBackends** std::vector<[Module](#)\*> smtrat::Module::mAllBackends [protected],  
[inherited]

The backends of this module which have been used.

**0.15.564.5.2 mAllModels** std::vector<[Model](#)> smtrat::Module::mAllModels [mutable], [protected],  
[inherited]

Stores all satisfying assignments.

**0.15.564.5.3 mBackendsFoundAnswer** std::atomic\_bool\* smtrat::Module::mBackendsFoundAnswer  
[protected], [inherited]

This flag is passed to any backend and if it determines an answer to a prior check call, this flag is fired.

**0.15.564.5.4 mConstraintsToInform** carl::FastSet<[FormulaT](#)> smtrat::Module::mConstraintsToInform  
[protected], [inherited]

Stores the constraints which the backends must be informed about.

**0.15.564.5.5 mFinalCheck** bool smtrat::Module::mFinalCheck [protected], [inherited]  
true, if the check procedure should perform a final check which especially means not to postpone splitting decisions

**0.15.564.5.6 mFirstPosInLastBranches** std::size\_t smtrat::Module::mFirstPosInLastBranches = 0  
[static], [inherited]

The beginning of the cyclic buffer storing the last branches.

**0.15.564.5.7 mFirstSubformulaToPass** [ModuleInput](#)::iterator smtrat::Module::mFirstSubformulaToPass  
[protected], [inherited]

Stores the position of the first sub-formula in the passed formula, which has not yet been considered for a consistency check of the backends.

**0.15.564.5.8 mFirstUncheckedReceivedSubformula** `ModuleInput::const_iterator smtrat::Module::mFirstUncheckedReceivedSubformula [protected], [inherited]`  
 Stores the position of the first (by this module) unchecked sub-formula of the received formula.

**0.15.564.5.9 mFoundAnswer** `Conditionals smtrat::Module::mFoundAnswer [protected], [inherited]`  
 Vector of Booleans: If any of them is true, we have to terminate a running check procedure.

**0.15.564.5.10 mFullCheck** `bool smtrat::Module::mFullCheck [protected], [inherited]`  
 false, if this module should avoid too expensive procedures and rather return unknown instead.

**0.15.564.5.11 mInfeasibleSubsets** `std::vector<FormulaSetT> smtrat::Module::mInfeasibleSubsets [protected], [inherited]`  
 Stores the infeasible subsets.

**0.15.564.5.12 mInformedConstraints** `carl::FastSet<FormulaT> smtrat::Module::mInformedConstraints [protected], [inherited]`  
 Stores the position of the first constraint of which no backend has been informed about.

**0.15.564.5.13 mLastBranches** `std::vector<Branching> smtrat::Module::mLastBranches = std::vector<Branching>(mNumOfBranchVarsToStore, Branching(typename Poly::PolyType(), 0)) [static], [inherited]`  
 Stores the last branches in a cycle buffer.

**0.15.564.5.14 mLemmas** `std::vector<Lemma> smtrat::Module::mLemmas [protected], [inherited]`  
 Stores the lemmas being valid formulas this module or its backends made.

**0.15.564.5.15 mModel** `Model smtrat::Module::mModel [mutable], [protected], [inherited]`  
 Stores the assignment of the current satisfiable result, if existent.

**0.15.564.5.16 mModelComputed** `bool smtrat::Module::mModelComputed [mutable], [protected], [inherited]`  
 True, if the model has already been computed.

**0.15.564.5.17 mNumOfBranchVarsToStore** `std::size_t smtrat::Module::mNumOfBranchVarsToStore = 5 [static], [inherited]`  
 The number of different variables to consider for a probable infinite loop of branchings.

**0.15.564.5.18 mObjectiveVariable** `carl::Variable smtrat::Module::mObjectiveVariable [protected], [inherited]`  
 Objective variable to be minimized. If set to NO\_VARIABLE, a normal sat check should be performed.

**0.15.564.5.19 mOldSplittingVariables** `std::vector<FormulaT> smtrat::Module::mOldSplittingVariables [static], [inherited]`  
 Reusable splitting variables.

**0.15.564.5.20 mpManager** `Manager* const smtrat::Module::mpManager [protected], [inherited]`  
A reference to the manager.

**0.15.564.5.21 mSmallerMusesCheckCounter** `unsigned smtrat::Module::mSmallerMusesCheckCounter [mutable], [protected], [inherited]`  
Counter used for the generation of the smt2 files to check for smaller muses.

**0.15.564.5.22 mSolverState** `std::atomic<Answer> smtrat::Module::mSolverState [protected], [inherited]`  
States whether the received formula is known to be satisfiable or unsatisfiable otherwise it is set to unknown.

**0.15.564.5.23 mTheoryPropagations** `std::vector<TheoryPropagation> smtrat::Module::mTheory← Propagations [protected], [inherited]`

**0.15.564.5.24 mUsedBackends** `std::vector<Module*> smtrat::Module::mUsedBackends [protected], [inherited]`  
The backends of this module which are currently used (conditions to use this module are fulfilled for the passed formula).

**0.15.564.5.25 mVariableCounters** `std::vector<std::size_t> smtrat::Module::mVariableCounters [protected], [inherited]`  
Maps variables to the number of their occurrences.

**0.15.569.3.1 addConstants()** static void smtrat::parser::AbstractTheory::addConstants (   
   qi::symbols< char, types::ConstType > & ) [inline], [static], [inherited]  
Initialize the global symbol table for constants.

**0.15.569.3.2 addSimpleSorts()** static void smtrat::parser::AbstractTheory::addSimpleSorts (   
   qi::symbols< char, carl::Sort > & ) [inline], [static], [inherited]  
Initialize the global symbol table for simple sorts.

**0.15.569.3.3 coupleBooleanVariables()** FormulaT smtrat::parser::UninterpretedTheory::coupleBooleanVariables (   
   carl::Variable v,   
   carl::UVariable uv ) [inline]

**0.15.569.3.4 declareVariable()** bool smtrat::parser::UninterpretedTheory::declareVariable (   
   const std::string &,   
   const carl::Sort &,   
   types::VariableType &,   
   TheoryError & errors ) [virtual]

Declare a new variable with the given name and the given sort.

Reimplemented from [smtrat::parser::AbstractTheory](#).

**0.15.569.3.5 expandDistinct()** template<typename T, typename Builder>   
 FormulaT smtrat::parser::AbstractTheory::expandDistinct (   
   const std::vector< T > & values,   
   const Builder & negBuilder ) [inline], [inherited]

**0.15.569.3.6 functionCall()** bool smtrat::parser::UninterpretedTheory::functionCall (   
   const Identifier &,   
   const std::vector< types::TermType > &,   
   types::TermType &,   
   TheoryError & errors ) [virtual]

Resolve another unknown function call.

Reimplemented from [smtrat::parser::AbstractTheory](#).

```
0.15.569.3.7 handleDistinct() bool smtrat::parser::UninterpretedTheory::handleDistinct (
 const std::vector< types::TermType > & ,
 types::TermType & ,
 TheoryError & errors) [virtual]
```

Resolve a distinct operator.

Reimplemented from [smtrat::parser::AbstractTheory](#).

```
0.15.569.3.8 handleFunctionInstantiation() bool smtrat::parser::UninterpretedTheory::handleFunctionInstantiation (
 const carl::UninterpretedFunction & f,
 const std::vector< types::TermType > & arguments,
 types::TermType & result,
 TheoryError & errors)
```

```
0.15.569.3.9 handleITE() bool smtrat::parser::UninterpretedTheory::handleITE (
 const FormulaT & ,
 const types::TermType & ,
 const types::TermType & ,
 types::TermType & ,
 TheoryError & errors) [virtual]
```

Resolve an if-then-else operator.

Reimplemented from [smtrat::parser::AbstractTheory](#).

```
0.15.569.3.10 instantiate() virtual bool smtrat::parser::AbstractTheory::instantiate (
 const types::VariableType & ,
 const types::TermType & ,
 types::TermType & ,
 TheoryError & errors) [inline], [virtual], [inherited]
```

Instantiate a variable within a term.

Reimplemented in [smtrat::parser::BitvectorTheory](#), and [smtrat::parser::ArithmeticTheory](#).

```
0.15.569.3.11 refreshVariable() virtual bool smtrat::parser::AbstractTheory::refreshVariable (
 const types::VariableType & ,
 types::VariableType & ,
 TheoryError & errors) [inline], [virtual], [inherited]
```

Reimplemented in [smtrat::parser::BitvectorTheory](#).

```
0.15.569.3.12 resolveSymbol() virtual bool smtrat::parser::AbstractTheory::resolveSymbol (
 const Identifier & ,
 types::TermType & ,
 TheoryError & errors) [inline], [virtual], [inherited]
```

Resolve a symbol that was not declared within the [ParserState](#).

This might be a symbol that actually uses indices, for example bitvector constants.

Reimplemented in [smtrat::parser::BitvectorTheory](#).

*Initialize the union-find datastructure with an array of entries copied from the sequence [begin\_,end\_].*

### 0.15.570.1 Detailed Description

```
template<typename T = void, bool no_compression = true, std::size_t MaxTracebackLength = 64>
class smtrat::union_find< T, no_compression, MaxTracebackLength >
```

Implements a union-find datastructure, a datastructure containing an array of entries.

Basically, this is an array of elements of type T with the following extra structure: Every entry is contained in an equivalence class identified by a single representative entry. In order to find this representative, every element has an associated parent entry; if this is the entry itself, the entry is the representative of its equivalence class. Using a rank count (basically a lower bound for the height of the tree below an entry), the height of the trees below the representative entries is ALWAYS less than  $\text{ceil}(\log_2(\#\text{entries}))$ . Moreover, while finding the parent of an entry, all entries on the path to the root are set to directly point to the root element. This improves the amortized number of steps used to find the representative of an entry from  $O(\log_2(n))$  to  $O(a(n))$  where  $a(n)$  is the inverse of the Ackermann function. All this extra structure is embedded directly within the array.

### 0.15.570.2 Constructor & Destructor Documentation

**0.15.570.2.1 union\_find() [1/4]** `template<typename T = void, bool no_compression = true, std::size_t MaxTracebackLength = 64>`  
`smtrat::union_find< T, no_compression, MaxTracebackLength >::union_find ( ) [inline]`  
Construct union-find datastructure with an empty array of entries.

**0.15.570.2.2 union\_find() [2/4]** `template<typename T = void, bool no_compression = true, std::size_t MaxTracebackLength = 64>`  
`smtrat::union_find< T, no_compression, MaxTracebackLength >::union_find (`  
`std::size_t size_ ) [inline], [explicit]`  
Construct union-find datastructure with an array of size\_ default-constructed elements.

**0.15.570.2.3 union\_find() [3/4]** `template<typename T = void, bool no_compression = true, std::size_t MaxTracebackLength = 64>`  
`template<typename InputIterator >`  
`smtrat::union_find< T, no_compression, MaxTracebackLength >::union_find (`  
`InputIterator begin_,`  
`typename std::enable_if< !std::is_void< T >::value, InputIterator >::type end_ )`  
`[inline]`  
Construct union-find datastructure, copying the sequence identified by [begin\_,end\_] into the array.

```
0.15.570.2.4 union_find() [4/4] template<typename T = void, bool no_compression = true, std::size_t MaxTracebackLength = 64>
smtrat::union_find< T, no_compression, MaxTracebackLength >::union_find (
 const union_find< T, no_compression, MaxTracebackLength > & other) [inline]
```

### 0.15.570.3 Member Function Documentation

```
0.15.570.3.1 add() template<typename T = void, bool no_compression = true, std::size_t MaxTracebackLength = 64>
template<bool Ignore = true>
std::enable_if< !std::is_void<T>::value && Ignore, std::size_t>::type smtrat::union_find< T,
no_compression, MaxTracebackLength >::add (
 const T & value) [inline]
```

Add a new default-constructed value to the end of this union find array.

This does not check for the uniqueness of this entry. This method can not be used if T is void. Returns the index associated with the new entry (i.e. the size of the UF structure before the call).

```
0.15.570.3.2 equivalent() template<typename T = void, bool no_compression = true, std::size_t MaxTracebackLength = 64>
bool smtrat::union_find< T, no_compression, MaxTracebackLength >::equivalent (
 std::size_t index1,
 std::size_t index2) const [inline], [noexcept]
```

Determines if the two entries at positions index1 and index2 are considered equivalent, that is find(index1) == find(index2).

```
0.15.570.3.3 fast_union() template<typename T = void, bool no_compression = true, std::size_t MaxTracebackLength = 64>
std::size_t smtrat::union_find< T, no_compression, MaxTracebackLength >::fast_union (
 std::size_t rep1,
 std::size_t rep2) [inline]
```

As union\_, but does NOT compute find(rep1), find(rep2), but assumes both indices are already pointing to representatives.

Returns the new representative of both elements after the operation; this will either be rep1 or rep2.

```
0.15.570.3.4 find() template<typename T = void, bool no_compression = true, std::size_t MaxTracebackLength = 64>
std::size_t smtrat::union_find< T, no_compression, MaxTracebackLength >::find (
 std::size_t index_) const [inline], [noexcept]
```

Find the index of the representative of the entry at index index\_.

Note that this method is const-qualified as it does not change the observable behaviour of this class, but it is not bitwise-const due to the path compression behaviour. Therefore it is not safe to call this method from different threads on the same UF datastructure without external synchronization.

```
0.15.570.3.5 initialize() [1/3] template<typename T = void, bool no_compression = true, std::size_t MaxTracebackLength = 64>
template<typename InputIterator >
std::enable_if<!std::is_void<T>::value && !std::is_void<InputIterator>::value, void>::type
smtrat::union_find< T, no_compression, MaxTracebackLength >::initialize (
 InputIterator begin_,
 InputIterator end_) [inline]
```

Initialize the union-find datastructure with an array of entries copied from the sequence [begin\_,end\_].

```
0.15.570.3.6 initialize() [2/3] template<typename T = void, bool no_compression = true, std::size_t MaxTracebackLength = 64>
template<bool Ignore = true>
std::enable_if<!std::is_void<T>::value && Ignore, void>::type smtrat::union_find< T, no_compression, MaxTracebackLength >::initialize (
 std::size_t new_size) [inline]
```

Initialize the union-find datastructure with an array of new\_size default-constructed entries, version for T != void.

```
0.15.570.3.7 initialize() [3/3] template<typename T = void, bool no_compression = true, std::size_t MaxTracebackLength = 64>
template<bool Ignore = true>
std::enable_if<std::is_void<T>::value && Ignore, void>::type smtrat::union_find< T, no_compression, MaxTracebackLength >::initialize (
 std::size_t new_size) [inline]
```

Initialize the union-find datastructure with an array of new\_size default-constructed entries, version for T == void.

```
0.15.570.3.8 operator=() template<typename T = void, bool no_compression = true, std::size_t MaxTracebackLength = 64>
union_find& smtrat::union_find< T, no_compression, MaxTracebackLength >::operator= (
 const union_find< T, no_compression, MaxTracebackLength > & other) [inline]
```

```
0.15.570.3.9 operator[]() [1/2] template<typename T = void, bool no_compression = true, std::size_t MaxTracebackLength = 64>
template<bool Ignore = true>
std::enable_if< !std::is_void<T>::value && Ignore, const T>::type& smtrat::union_find< T, no_compression, MaxTracebackLength >::operator[] (
 std::size_t index_) const [inline], [noexcept]
```

Access to values (only if T is not void, relies on C++11 feature: default template arguments for template methods), const.

```
0.15.570.3.10 operator[]() [2/2] template<typename T = void, bool no_compression = true, std::size_t MaxTracebackLength = 64>
template<bool Ignore = true>
std::enable_if< !std::is_void<T>::value && Ignore, T>::type& smtrat::union_find< T, no_compression, MaxTracebackLength >::operator[] (
 std::size_t index_) [inline], [noexcept]
```

Access to values (only if T is not void, relies on C++11 feature: default template arguments for template methods).

```
0.15.570.3.11 rank() template<typename T = void, bool no_compression = true, std::size_t MaxTracebackLength = 64>
std::size_t smtrat::union_find< T, no_compression, MaxTracebackLength >::rank (
 std::size_t i) [inline]
```

The rank (upper bound on the height of the tree rooted at i) of the entry at index i.

```
0.15.570.3.12 set_class() template<typename T = void, bool no_compression = true, std::size_t MaxTracebackLength = 64>
void smtrat::union_find< T, no_compression, MaxTracebackLength >::set_class (
 std::size_t i,
 std::size_t c) [inline]
```

```
0.15.570.3.13 size() template<typename T = void, bool no_compression = true, std::size_t MaxTracebackLength = 64>
std::size_t smtrat::union_find< T, no_compression, MaxTracebackLength >::size () const [inline], [noexcept]
```

Returns the number of entries in this union-find datastructure.

```
0.15.570.3.14 union_() template<typename T = void, bool no_compression = true, std::size_t MaxTracebackLength = 64>
bool smtrat::union_find< T, no_compression, MaxTracebackLength >::union_ (
 std::size_t index1,
 std::size_t index2) [inline], [noexcept]
```

Make the entries identified by index1 and index2 equivalent.

As this is determined by the union-by-rank mechanism, either one of find(index1) or find(index2) can become the index of the new representative of both entries. Returns false when this operation did no changes on the datastructure and true otherwise.

*Prints the infeasible subsets.*
- `void printModel (std::ostream &_out=std::cout) const`  
*Prints the assignment of this module satisfying its received formula if it satisfiable and this module could find an assignment.*
- `void printAllModels (std::ostream &_out=std::cout)`  
*Prints all assignments of this module satisfying its received formula if it satisfiable and this module could find an assignment.*

## Static Public Member Functions

- `static void freeSplittingVariable (const FormulaT &_splittingVariable)`

## Static Public Attributes

- `static size_t mNumOfBranchVarsToStore = 5`  
*The number of different variables to consider for a probable infinite loop of branchings.*
- `static std::vector< Branching > mLastBranches = std::vector<Branching>(mNumOfBranchVarsToStore, Branching(typename Poly::PolyType(), 0))`  
*Stores the last branches in a cycle buffer.*
- `static size_t mFirstPosInLastBranches = 0`  
*The beginning of the cyclic buffer storing the last branches.*
- `static std::vector< FormulaT > mOldSplittingVariables`  
*Reusable splitting variables.*

## Protected Member Functions

- virtual void `deinformCore` (const `FormulaT` &\_constraint)
 

*The inverse of informing about a constraint.*
- bool `anAnswerFound` () const
 

*Checks for all antecedent modules and those which run in parallel with the same antecedent modules, whether one of them has determined a result.*
- void `clearModel` () const
 

*Clears the assignment, if any was found.*
- void `clearModels` () const
 

*Clears all assignments, if any was found.*
- void `cleanModel` () const
 

*Substitutes variable occurrences by its model value in the model values of other variables.*
- `ModuleInput::iterator passedFormulaBegin` ()
- `ModuleInput::iterator passedFormulaEnd` ()
- void `addOrigin` (`ModuleInput::iterator` \_formula, const `FormulaT` &\_origin)
 

*Adds the given set of formulas in the received formula to the origins of the given passed formula.*
- const `FormulaT` & `getOrigins` (`ModuleInput::const_iterator` \_formula) const
 

*Gets the origins of the passed formula at the given position.*
- void `getOrigins` (const `FormulaT` &\_formula, `FormulasT` &\_origins) const
- void `getOrigins` (const `FormulaT` &\_formula, `FormulaSetT` &\_origins) const
- std::pair< `ModuleInput::iterator`, bool > `removeOrigin` (`ModuleInput::iterator` \_formula, const `FormulaT` &\_origin)

- void `informBackends` (const `FormulaT` &\_constraint)
 

*Informs all backends of this module about the given constraint.*
- virtual void `addConstraintToInform` (const `FormulaT` &\_constraint)
 

*Adds a constraint to the collection of constraints of this module, which are informed to a freshly generated backend.*
- std::pair< `ModuleInput::iterator`, bool > `addReceivedSubformulaToPassedFormula` (`ModuleInput::const_iterator` \_subformula)
 

*Copies the given sub-formula of the received formula to the passed formula.*
- bool `originInReceivedFormula` (const `FormulaT` &\_origin) const
- std::pair< `ModuleInput::iterator`, bool > `addSubformulaToPassedFormula` (const `FormulaT` &\_formula)
 

*Adds the given formula to the passed formula with no origin.*
- std::pair< `ModuleInput::iterator`, bool > `addSubformulaToPassedFormula` (const `FormulaT` &\_formula, const std::shared\_ptr< std::vector< `FormulaT` >> &\_origins)
 

*Adds the given formula to the passed formula.*
- std::pair< `ModuleInput::iterator`, bool > `addSubformulaToPassedFormula` (const `FormulaT` &\_formula, const `FormulaT` &\_origin)
 

*Adds the given formula to the passed formula.*
- void `generateTrivialInfeasibleSubset` ()
 

*Stores the trivial infeasible subset being the set of received formulas.*
- void `receivedFormulasAsInfeasibleSubset` (`ModuleInput::const_iterator` \_subformula)
 

*Stores an infeasible subset consisting only of the given received formula.*
- std::vector< `FormulaT` >::const\_iterator `findBestOrigin` (const std::vector< `FormulaT` > &\_origins) const
- void `getInfeasibleSubsets` ()
 

*Copies the infeasible subsets of the passed formula.*
- std::vector< `FormulaSetT` > `getInfeasibleSubsets` (const `Module` &\_backend) const
 

*Get the infeasible subsets the given backend provides.*
- const `Model` & `backendsModel` () const
 

*Stores the model of a backend which determined satisfiability of the passed formula in the model of this module.*
- void `getBackendsModel` () const

- void `getBackendsAllModels () const`  
*Stores all models of a backend in the list of all models of this module.*
- virtual `Answer runBackends (bool _final, bool _full, carl::Variable _objective)`  
*Runs the backend solvers on the passed formula.*
- virtual `Answer runBackends ()`
- virtual `ModuleInput::iterator eraseSubformulaFromPassedFormula (ModuleInput::iterator _subformula, bool _ignoreOrigins=false)`  
*Removes everything related to the sub-formula to remove from the passed formula in the backends of this module.*
- void `clearPassedFormula ()`
- std::vector< `FormulaT` > `merge` (const std::vector< `FormulaT` > &, const std::vector< `FormulaT` > &) const  
*Merges the two vectors of sets into the first one.*
- size\_t `determine_smallest_origin` (const std::vector< `FormulaT` > &origins) const
- bool `probablyLooping` (const typename Poly::PolyType &\_branchingPolynomial, const Rational &\_branchingValue) const  
*Checks whether given the current branching value and branching variable/polynomial it is (highly) probable that this branching is part of an infinite loop of branchings.*
- bool `branchAt` (const Poly &\_polynomial, bool \_integral, const Rational &\_value, std::vector< `FormulaT` > &&\_premise, bool \_leftCaseWeak=true, bool \_preferLeftCase=true, bool \_useReceivedFormulaAsPremise=false)  
*Adds a lemmas which provoke a branching for the given variable at the given value, if this module returns Unknown and there exists a preceding SATModule.*
- bool `branchAt` (const Poly &\_polynomial, bool \_integral, const Rational &\_value, bool \_leftCaseWeak=true, bool \_preferLeftCase=true, bool \_useReceivedFormulaAsPremise=false, const std::vector< `FormulaT` > &&\_premise=std::vector< `FormulaT` >())
- bool `branchAt` (carl::Variable::Arg \_var, const Rational &\_value, std::vector< `FormulaT` > &&\_premise, bool \_leftCaseWeak=true, bool \_preferLeftCase=true, bool \_useReceivedFormulaAsPremise=false)
- bool `branchAt` (carl::Variable::Arg \_var, const Rational &\_value, bool \_leftCaseWeak=true, bool \_preferLeftCase=true, bool \_useReceivedFormulaAsPremise=false, const std::vector< `FormulaT` > &\_premise=std::vector< `FormulaT` >())
- void `splitUnequalConstraint` (const `FormulaT` &)  
*Adds the following lemmas for the given constraint p!=0.*
- unsigned `checkModel () const`
- void `addInformationRelevantFormula` (const `FormulaT` &formula)  
*Adds a formula to the InformationRelevantFormula.*
- const std::set< `FormulaT` > & `getInformationRelevantFormulas ()`  
*Gets all InformationRelevantFormulas.*
- bool `isLemmaLevel (LemmaLevel level)`  
*Checks if current lemma level is greater or equal to given level.*

### Static Protected Member Functions

- static bool `modelsDisjoint` (const Model &\_modelA, const Model &\_modelB)  
*Checks whether there is no variable assigned by both models.*

### Protected Attributes

- std::vector< `FormulaSetT` > `mInfeasibleSubsets`  
*Stores the infeasible subsets.*
- Manager \*const `mpManager`  
*A reference to the manager.*
- Model `mModel`  
*Stores the assignment of the current satisfiable result, if existent.*
- std::vector< Model > `mAllModels`  
*Stores all satisfying assignments.*

- bool `mModelComputed`  
*True, if the model has already been computed.*
- bool `mFinalCheck`  
*true, if the check procedure should perform a final check which especially means not to postpone splitting decisions*
- bool `mFullCheck`  
*false, if this module should avoid too expensive procedures and rather return unknown instead.*
- carl::Variable `mObjectiveVariable`  
*Objective variable to be minimized. If set to NO\_VARIABLE, a normal sat check should be performed.*
- std::vector< `TheoryPropagation` > `mTheoryPropagations`
- std::atomic< `Answer` > `mSolverState`  
*States whether the received formula is known to be satisfiable or unsatisfiable otherwise it is set to unknown.*
- std::atomic\_bool \* `mBackendsFoundAnswer`  
*This flag is passed to any backend and if it determines an answer to a prior check call, this flag is fired.*
- Conditionals `mFoundAnswer`  
*Vector of Booleans: If any of them is true, we have to terminate a running check procedure.*
- std::vector< `Module` \* > `mUsedBackends`  
*The backends of this module which are currently used (conditions to use this module are fulfilled for the passed formula).*
- std::vector< `Module` \* > `mAllBackends`  
*The backends of this module which have been used.*
- std::vector< `Lemma` > `mLemmas`  
*Stores the lemmas being valid formulas this module or its backends made.*
- ModuleInput::iterator `mFirstSubformulaToPass`  
*Stores the position of the first sub-formula in the passed formula, which has not yet been considered for a consistency check of the backends.*
- carl::FastSet< `FormulaT` > `mConstraintsToInform`  
*Stores the constraints which the backends must be informed about.*
- carl::FastSet< `FormulaT` > `mInformedConstraints`  
*Stores the position of the first constraint of which no backend has been informed about.*
- ModuleInput::const\_iterator `mFirstUncheckedReceivedSubformula`  
*Stores the position of the first (by this module) unchecked sub-formula of the received formula.*
- unsigned `mSmallerMusesCheckCounter`  
*Counter used for the generation of the smt2 files to check for smaller muses.*
- std::vector< std::size\_t > `mVariableCounters`  
*Maps variables to the number of their occurrences.*

### 0.15.572.3 Constructor & Destructor Documentation

**0.15.572.3.1 UnionFindModule()** template<typename Settings >  
`smtrat::UnionFindModule< Settings >::UnionFindModule (`  
 `const ModuleInput * _formula,`  
 `Conditionals & _conditionals,`  
 `Manager * _manager = nullptr )`

**0.15.572.3.2 ~UnionFindModule()** template<typename Settings >  
`smtrat::UnionFindModule< Settings >::~UnionFindModule ( )`

### 0.15.572.4 Member Function Documentation

**0.15.572.4.1 add()** bool smtrat::Module::add (  
 `ModuleInput::const_iterator _subformula ) [inherited]`

The module has to take the given sub-formula of the received formula into account.

#### Parameters

|                          |                                                    |
|--------------------------|----------------------------------------------------|
| <code>_subformula</code> | The sub-formula to take additionally into account. |
|--------------------------|----------------------------------------------------|

#### Returns

false, if it can be easily decided that this sub-formula causes a conflict with the already considered sub-formulas; true, otherwise.

**0.15.572.4.2 addConstraintToInform()** void smtrat::Module::addConstraintToInform (  
 `const FormulaT & _constraint ) [protected], [virtual], [inherited]`

Adds a constraint to the collection of constraints of this module, which are informed to a freshly generated backend.

#### Parameters

|                          |                        |
|--------------------------|------------------------|
| <code>_constraint</code> | The constraint to add. |
|--------------------------|------------------------|

Reimplemented in [smtrat::SATModule< Settings >](#).

**0.15.572.4.3 addCore()** template<typename Settings >  
`bool smtrat::UnionFindModule< Settings >::addCore (`  
 `ModuleInput::const_iterator _subformula ) [virtual]`

The module has to take the given sub-formula of the received formula into account.

#### Parameters

|                          |                                                    |
|--------------------------|----------------------------------------------------|
| <code>_subformula</code> | The sub-formula to take additionally into account. |
|--------------------------|----------------------------------------------------|

#### Returns

false, if it can be easily decided that this sub-formula causes a conflict with the already considered sub-formulas; true, otherwise.

Reimplemented from [smtrat::Module](#).

**0.15.572.4.4 addInformationRelevantFormula()** void smtrat::Module::addInformationRelevantFormula (  
    const [FormulaT](#) & formula ) [protected], [inherited]

Adds a formula to the InformationRelevantFormula.

#### Parameters

|                |                |
|----------------|----------------|
| <i>formula</i> | Formula to add |
|----------------|----------------|

**0.15.572.4.5 addLemma()** void smtrat::Module::addLemma (  
    const [FormulaT](#) & \_lemma,  
    const [LemmaType](#) & \_lt = [LemmaType::NORMAL](#),  
    const [FormulaT](#) & \_preferredFormula = [FormulaT](#)( [carl::FormulaType::TRUE](#) ) ) [inline],  
[inherited]

Stores a lemma being a valid formula.

#### Parameters

|                          |                                                                       |
|--------------------------|-----------------------------------------------------------------------|
| <i>_lemma</i>            | The eduction/lemma to store.                                          |
| <i>_lt</i>               | The type of the lemma.                                                |
| <i>_preferredFormula</i> | Hint for the next decision, which formula should be assigned to true. |

**0.15.572.4.6 addOrigin()** void smtrat::Module::addOrigin (  
    [ModuleInput::iterator](#) \_formula,  
    const [FormulaT](#) & \_origin ) [inline], [protected], [inherited]

Adds the given set of formulas in the received formula to the origins of the given passed formula.

#### Parameters

|                 |                                                           |
|-----------------|-----------------------------------------------------------|
| <i>_formula</i> | The passed formula to set the origins for.                |
| <i>_origin</i>  | A set of formulas in the received formula of this module. |

**0.15.572.4.7 addReceivedSubformulaToPassedFormula()** std::pair<[ModuleInput::iterator](#),bool>  
smtrat::Module::addReceivedSubformulaToPassedFormula (  
    [ModuleInput::const\\_iterator](#) \_subformula ) [inline], [protected], [inherited]

Copies the given sub-formula of the received formula to the passed formula.

Note, that there is always a link between sub-formulas of the passed formulas to sub-formulas of the received formulas, which are responsible for its occurrence.

#### Parameters

|                    |                                                  |
|--------------------|--------------------------------------------------|
| <i>_subformula</i> | The sub-formula of the received formula to copy. |
|--------------------|--------------------------------------------------|

**0.15.572.4.8 addSubformulaToPassedFormula()** [1/3] std::pair<[ModuleInput::iterator](#),bool> smtrat↔

```
::Module::addSubformulaToPassedFormula (
 const FormulaT & _formula) [inline], [protected], [inherited]
```

Adds the given formula to the passed formula with no origin.

Note that in the next call of this module's removeSubformula, all formulas in the passed formula without origins will be removed.

#### Parameters

|                       |                                           |
|-----------------------|-------------------------------------------|
| <code>_formula</code> | The formula to add to the passed formula. |
|-----------------------|-------------------------------------------|

#### Returns

A pair to the position where the formula to add has been inserted (or its first sub-formula which has not yet been in the passed formula, in case the formula to add is a conjunction), and a Boolean stating whether anything has been added to the passed formula.

**0.15.572.4.9 `addSubformulaToPassedFormula()` [2/3] `std::pair<ModuleInput::iterator,bool>` smrat->  
::Module::addSubformulaToPassedFormula (**

```
 const FormulaT & _formula,
 const FormulaT & _origin) [inline], [protected], [inherited]
```

Adds the given formula to the passed formula.

#### Parameters

|                       |                                                                                                                           |
|-----------------------|---------------------------------------------------------------------------------------------------------------------------|
| <code>_formula</code> | The formula to add to the passed formula.                                                                                 |
| <code>_origin</code>  | The sub-formula of the received formula being responsible for the occurrence of the formula to add to the passed formula. |

#### Returns

A pair to the position where the formula to add has been inserted (or its first sub-formula which has not yet been in the passed formula, in case the formula to add is a conjunction), and a Boolean stating whether anything has been added to the passed formula.

**0.15.572.4.10 `addSubformulaToPassedFormula()` [3/3] `std::pair<ModuleInput::iterator,bool>`**

```
smrat::Module::addSubformulaToPassedFormula (
 const FormulaT & _formula,
 const std::shared_ptr< std::vector< FormulaT >> & _origins) [inline], [protected],
[inherited]
```

Adds the given formula to the passed formula.

#### Parameters

|                       |                                                                                                                                         |
|-----------------------|-----------------------------------------------------------------------------------------------------------------------------------------|
| <code>_formula</code> | The formula to add to the passed formula.                                                                                               |
| <code>_origins</code> | The link of the formula to add to the passed formula to sub-formulas of the received formulas, which are responsible for its occurrence |

#### Returns

A pair to the position where the formula to add has been inserted (or its first sub-formula which has not yet been in the passed formula, in case the formula to add is a conjunction), and a Boolean stating whether anything has been added to the passed formula.

**0.15.572.4.11 allModels()** const std::vector<[Model](#)>& smtrat::Module::allModels () const [inline], [inherited]

**Returns**

All satisfying assignments, if existent.

**0.15.572.4.12 anAnswerFound()** bool smtrat::Module::anAnswerFound () const [inline], [protected], [inherited]

Checks for all antecedent modules and those which run in parallel with the same antecedent modules, whether one of them has determined a result.

**Returns**

True, if one of them has determined a result.

**0.15.572.4.13 answerFound()** const [smtrat::Conditionals](#)& smtrat::Module::answerFound () const [inline], [inherited]

**Returns**

A vector of Booleans: If any of them is true, we have to terminate a running check procedure.

**0.15.572.4.14 backendsModel()** const [Model](#) & smtrat::Module::backendsModel () const [protected], [inherited]

Stores the model of a backend which determined satisfiability of the passed formula in the model of this module.

**0.15.572.4.15 branchAt() [1/4]** bool smtrat::Module::branchAt ( carl::Variable::Arg \_var, const [Rational](#) & \_value, bool \_leftCaseWeak = true, bool \_preferLeftCase = true, bool \_useReceivedFormulaAsPremise = false, const std::vector< [FormulaT](#) > & \_premise = std::vector<[FormulaT](#)>() ) [inline], [protected], [inherited]

**0.15.572.4.16 branchAt() [2/4]** bool smtrat::Module::branchAt ( carl::Variable::Arg \_var, const [Rational](#) & \_value, std::vector< [FormulaT](#) > && \_premise, bool \_leftCaseWeak = true, bool \_preferLeftCase = true, bool \_useReceivedFormulaAsPremise = false ) [inline], [protected], [inherited]

**0.15.572.4.17 branchAt() [3/4]** bool smtrat::Module::branchAt ( const [Poly](#) & \_polynomial, bool \_integral, const [Rational](#) & \_value, bool \_leftCaseWeak = true, bool \_preferLeftCase = true, bool \_useReceivedFormulaAsPremise = false, const std::vector< [FormulaT](#) > & \_premise = std::vector<[FormulaT](#)>() ) [inline], [protected], [inherited]

**0.15.572.4.18 branchAt() [4/4]** `bool smtrat::Module::branchAt (`

```
const Poly & _polynomial,
bool _integral,
const Rational & _value,
std::vector< FormulaT > && _premise,
bool _leftCaseWeak = true,
bool _preferLeftCase = true,
bool _useReceivedFormulaAsPremise = false) [protected], [inherited]
```

Adds a lemmas which provoke a branching for the given variable at the given value, if this module returns Unknown and there exists a preceding [SATModule](#).

Note that the given value is rounded down and up, if the given variable is integer-valued.

**Parameters**

|                                           |                                                                                                                                                                                                                |
|-------------------------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>_polynomial</code>                  | The variable to branch for.                                                                                                                                                                                    |
| <code>_integral</code>                    | A flag being true, if all variables in the polynomial to branch for are integral.                                                                                                                              |
| <code>_value</code>                       | The value to branch at.                                                                                                                                                                                        |
| <code>_premise</code>                     | The sub-formulas of the received formula from which the branch is followed. Note, that a premise is not necessary, as every branch is a valid formula. But a premise can prevent from branching unnecessarily. |
| <code>_leftCaseWeak</code>                | true, if a branching in the form of (or ( $\leq p b$ ) ( $> p b$ )) is desired. false, if a branching in the form of (or ( $< p b$ ) ( $\geq p b$ )) is desired.                                               |
| <code>_preferLeftCase</code>              | true, if the left case (polynomial less(or equal) 0 shall be chosen first. false, otherwise.                                                                                                                   |
| <code>_useReceivedFormulaAsPremise</code> | true, if the whole received formula should be used as premise                                                                                                                                                  |

**0.15.572.4.19 check() [Answer](#)** `smtrat::Module::check (`

```
bool _final = false,
bool _full = true,
carl::Variable _objective = carl::Variable::NO_VARIABLE) [virtual], [inherited]
```

Checks the received formula for consistency.

Note, that this is an implementation of the satisfiability check of the conjunction of the so far received formulas, which does actually nothing but passing the problem to its backends. This implementation is only used internally and must be overwritten by any derived module.

**Parameters**

|                         |                                                                                                                                       |
|-------------------------|---------------------------------------------------------------------------------------------------------------------------------------|
| <code>_final</code>     | true, if this satisfiability check will be the last one (for a global sat-check), if its result is SAT                                |
| <code>_full</code>      | false, if this module should avoid too expensive procedures and rather return unknown instead.                                        |
| <code>_objective</code> | if not set to NO_VARIABLE, the module should find an assignment minimizing this objective variable; otherwise any assignment is good. |

**Returns**

True, if the received formula is satisfiable; False, if the received formula is not satisfiable; Unknown, otherwise.

Reimplemented in [smtrat::PModule](#).

**0.15.572.4.20 checkCore()** `template<typename Settings >`

```
Answer smtrat::UnionFindModule< Settings >::checkCore () [virtual]
```

Checks the received formula for consistency.

**Returns**

True, if the received formula is satisfiable; False, if the received formula is not satisfiable; Unknown, otherwise.

Reimplemented from [smrat::Module](#).

**0.15.572.4.21 `checkInfSubsetForMinimality()`** `void smrat::Module::checkInfSubsetForMinimality ( std::vector< FormulaSetT >::const_iterator _infssubset,`  
`const std::string & _filename = "smaller_muses",`  
`unsigned _maxSizeDifference = 1 ) const [inherited]`

Checks the given infeasible subset for minimality by storing all subsets of it, which have a smaller size which differs from the size of the infeasible subset not more than the given threshold.

**Parameters**

|                                 |                                                                                                        |
|---------------------------------|--------------------------------------------------------------------------------------------------------|
| <code>_infssubset</code>        | The infeasible subset to check for minimality.                                                         |
| <code>_filename</code>          | The name of the file to store the infeasible subsets in order to be able to check their infeasibility. |
| <code>_maxSizeDifference</code> | The maximal difference between the sizes of the subsets compared to the size of the infeasible subset. |

**0.15.572.4.22 `checkModel()`** `unsigned smrat::Module::checkModel ( ) const [protected], [inherited]`

**Returns**

false, if the current model of this module does not satisfy the current given formula; true, if it cannot be said whether the model satisfies the given formula.

**0.15.572.4.23 `cleanModel()`** `void smrat::Module::cleanModel ( ) const [inline], [protected], [inherited]`

Substitutes variable occurrences by its model value in the model values of other variables.

**0.15.572.4.24 `clearLemmas()`** `void smrat::Module::clearLemmas ( ) [inline], [inherited]`  
Deletes all yet found lemmas.

**0.15.572.4.25 `clearModel()`** `void smrat::Module::clearModel ( ) const [inline], [protected], [inherited]`

Clears the assignment, if any was found.

**0.15.572.4.26 `clearModels()`** `void smrat::Module::clearModels ( ) const [inline], [protected], [inherited]`

Clears all assignments, if any was found.

**0.15.572.4.27 `clearPassedFormula()`** `void smrat::Module::clearPassedFormula ( ) [protected], [inherited]`

```
0.15.572.4.28 collectOrigins() [1/2] void smtrat::Module::collectOrigins (
 const FormulaT & _formula,
 FormulaSetT & _origins) const [inherited]
```

```
0.15.572.4.29 collectOrigins() [2/2] void smtrat::Module::collectOrigins (
 const FormulaT & _formula,
 FormulasT & _origins) const [inherited]
```

Collects the formulas in the given formula, which are part of the received formula.

If the given formula directly occurs in the received formula, it is inserted into the given set. Otherwise, the given formula must be of type AND and all its sub-formulas part of the received formula. Hence, they will be added to the given set.

#### Parameters

|                       |                                                                                                      |
|-----------------------|------------------------------------------------------------------------------------------------------|
| <code>_formula</code> | The formula from which to collect the formulas being sub-formulas of the received formula (origins). |
| <code>_origins</code> | The set in which to store the origins.                                                               |

```
0.15.572.4.30 collectTheoryPropagations() void smtrat::Module::collectTheoryPropagations ()
[inherited]
```

```
0.15.572.4.31 constraintsToInform() const carl::FastSet<FormulaT>& smtrat::Module::constraintsToInform () const [inline], [inherited]
```

#### Returns

The constraints which the backends must be informed about.

```
0.15.572.4.32 currentlySatisfied() virtual unsigned smtrat::Module::currentlySatisfied (
 const FormulaT &) const [inline], [virtual], [inherited]
```

#### Returns

0, if the given formula is conflicted by the current model; 1, if the given formula is satisfied by the current model; 2, otherwise; 3, if we do not know anything (default)

Reimplemented in [smtrat::LRAbstractModule< Settings >](#), [smtrat::LRAbstractModule< LRASettingsICP >](#), and [smtrat::LRAbstractModule< LRASettings >](#)

```
0.15.572.4.33 currentlySatisfiedByBackend() unsigned smtrat::Module::currentlySatisfiedByBackend (
 const FormulaT & _formula) const [inherited]
```

#### Returns

0, if the given formula is conflicted by the current model; 1, if the given formula is satisfied by the current model; 2, otherwise 3, if we do not know anything (default)

```
0.15.572.4.34 deinform() void smtrat::Module::deinform (
 const FormulaT & _constraint) [inherited]
```

The inverse of informing about a constraint.

All data structures which were kept regarding this constraint are going to be removed. Note, that this makes only sense if it is not likely enough that a formula with this constraint must be solved again.

**Parameters**

|                          |                                                         |
|--------------------------|---------------------------------------------------------|
| <code>_constraint</code> | The constraint to remove from internal data structures. |
|--------------------------|---------------------------------------------------------|

**0.15.572.4.35 `deinformCore()`** `virtual void smtrat::Module::deinformCore (``const FormulaT & _constraint ) [inline], [protected], [virtual], [inherited]`

The inverse of informing about a constraint.

All data structures which were kept regarding this constraint are going to be removed. Note, that this makes only sense if it is not likely enough that a formula with this constraint must be solved again.

**Parameters**

|                          |                                                         |
|--------------------------|---------------------------------------------------------|
| <code>_constraint</code> | The constraint to remove from internal data structures. |
|--------------------------|---------------------------------------------------------|

Reimplemented in [smtrat::LRAModule< Settings >](#), [smtrat::LRAModule< LRASettingsICP >](#), and [smtrat::LRAModule< LRASettings1 >](#).

**0.15.572.4.36 `determine_smallest_origin()`** `size_t smtrat::Module::determine_smallest_origin (``const std::vector< FormulaT > & origins ) const [protected], [inherited]`**Parameters**

|                      |                              |
|----------------------|------------------------------|
| <code>origins</code> | A vector of sets of origins. |
|----------------------|------------------------------|

**Returns**

The index of the smallest (regarding the size of the sets) element of origins

**0.15.572.4.37 `eraseSubformulaFromPassedFormula()`** `ModuleInput::iterator smtrat::Module::eraseSubformulaFromPassedFormula (``ModuleInput::iterator _subformula,``bool _ignoreOrigins = false ) [protected], [virtual], [inherited]`

Removes everything related to the sub-formula to remove from the passed formula in the backends of this module. Afterwards the sub-formula is removed from the passed formula.

**Parameters**

|                             |                                                                                                              |
|-----------------------------|--------------------------------------------------------------------------------------------------------------|
| <code>_subformula</code>    | The sub-formula to remove from the passed formula.                                                           |
| <code>_ignoreOrigins</code> | True, if the sub-formula shall be removed regardless of its origins (should only be applied with expertise). |

**Returns**

Reimplemented in [smtrat::ICPModule< Settings >](#), [smtrat::ICPModule< ICPSettings4 >](#), and [smtrat::ICPModule< ICPSettings1 >](#).

**0.15.572.4.38 `excludeNotReceivedVariablesFromModel()`** `void smtrat::Module::excludeNotReceivedVariablesFromModel ( ) const [inherited]`

Excludes all variables from the current model, which do not occur in the received formula.

```
0.15.572.4.39 findBestOrigin() std::vector< FormulaT >::const_iterator smtrat::Module::findBestOrigin (const std::vector< FormulaT > & _origins) const [protected], [inherited]
```

**Parameters**

|                 |  |
|-----------------|--|
| <i>_origins</i> |  |
|-----------------|--|

**Returns**

```
0.15.572.4.40 firstSubformulaToPass() ModuleInput::const_iterator smtrat::Module::firstSubformulaToPass () const [inline], [inherited]
```

**Returns**

The position of the first sub-formula in the passed formula, which has not yet been considered for a consistency check of the backends.

```
0.15.572.4.41 firstUncheckedReceivedSubformula() ModuleInput::const_iterator smtrat::Module::firstUncheckedReceivedSubformula () const [inline], [inherited]
```

**Returns**

The position of the first (by this module) unchecked sub-formula of the received formula.

```
0.15.572.4.42 freeSplittingVariable() static void smtrat::Module::freeSplittingVariable (const FormulaT & _splittingVariable) [inline], [static], [inherited]
```

```
0.15.572.4.43 generateTrivialInfeasibleSubset() void smtrat::Module::generateTrivialInfeasibleSubset () [inline], [protected], [inherited]
```

Stores the trivial infeasible subset being the set of received formulas.

```
0.15.572.4.44 getBackendsAllModels() void smtrat::Module::getBackendsAllModels () const [protected], [inherited]
```

Stores all models of a backend in the list of all models of this module.

```
0.15.572.4.45 getBackendsModel() void smtrat::Module::getBackendsModel () const [protected], [inherited]
```

```
0.15.572.4.46 getInfeasibleSubsets() [1/2] void smtrat::Module::getInfeasibleSubsets () [protected], [inherited]
```

Copies the infeasible subsets of the passed formula.

**0.15.572.4.47 getInfeasibleSubsets()** [2/2] std::vector< `FormulaSetT` > smtrat::Module::getInfeasibleSubsets (

    const `Module` & `_backend` ) const [protected], [inherited]

Get the infeasible subsets the given backend provides.

Note, that an infeasible subset in a backend contains sub formulas of the passed formula and an infeasible subset of this module contains sub formulas of the received formula. In this method the LATTER is returned.

**Parameters**

|                       |                                                          |
|-----------------------|----------------------------------------------------------|
| <code>_backend</code> | The backend from which to obtain the infeasible subsets. |
|-----------------------|----------------------------------------------------------|

**Returns**

The infeasible subsets the given backend provides.

**0.15.572.4.48 `getInformationRelevantFormulas()`** `const std::set< FormulaT > & smtrat::Module::getInformationRelevantFormulas ( ) [protected], [inherited]`  
Gets all InformationRelevantFormulas.

**Returns**

Set of all formulas

**0.15.572.4.49 `getModelEqualities()`** `std::list< std::vector< carl::Variable > > smtrat::Module::getModelEqualities ( ) const [virtual], [inherited]`  
Partition the variables from the current model into equivalence classes according to their assigned value.  
The result is a set of equivalence classes of variables where all variables within one class are assigned the same value. Note that the number of classes may not be minimal, i.e. two classes may actually be equivalent.

**Returns**

Equivalence classes.

**0.15.572.4.50 `getOrigins()` [1/3]** `void smtrat::Module::getOrigins ( const FormulaT & _formula, FormulaSetT & _origins ) const [inline], [protected], [inherited]`

**Parameters**

|                       |  |
|-----------------------|--|
| <code>_formula</code> |  |
| <code>_origins</code> |  |

**0.15.572.4.51 `getOrigins()` [2/3]** `void smtrat::Module::getOrigins ( const FormulaT & _formula, FormulasT & _origins ) const [inline], [protected], [inherited]`

**Parameters**

|                       |  |
|-----------------------|--|
| <code>_formula</code> |  |
| <code>_origins</code> |  |

**0.15.572.4.52 `getOrigins()` [3/3]** `const FormulaT& smtrat::Module::getOrigins ( ModuleInput::const_iterator _formula ) const [inline], [protected], [inherited]`  
Gets the origins of the passed formula at the given position.

**Parameters**

|                 |                                                   |
|-----------------|---------------------------------------------------|
| <i>_formula</i> | The position of a formula in the passed formulas. |
|-----------------|---------------------------------------------------|

**Returns**

The origins of the passed formula at the given position.

**0.15.572.4.53 `getReceivedFormulaSimplified()`** `std::pair< bool, FormulaT >` `smtrat::Module::getReceivedFormulaSimplified( )` [virtual], [inherited]

**Returns**

A pair of a Boolean and a formula, where the Boolean is true, if the received formula could be simplified to an equisatisfiable formula. The formula is equisatisfiable to this module's received formula, if the Boolean is true.

Reimplemented in [smtrat::PModule](#).

**0.15.572.4.54 `hasLemmas()`** `bool smtrat::Module::hasLemmas( )` [inline], [inherited]

Checks whether this module or any of its backends provides any lemmas.

**0.15.572.4.55 `hasValidInfeasibleSubset()`** `bool smtrat::Module::hasValidInfeasibleSubset( ) const` [inherited]

**Returns**

true, if the module has at least one valid infeasible subset, that is all its elements are sub-formulas of the received formula (pointer must be equal).

**0.15.572.4.56 `id()`** `std::size_t smtrat::Module::id( ) const` [inline], [inherited]

**Returns**

A unique ID to identify this module instance.

**0.15.572.4.57 `infeasibleSubsets()`** `const std::vector<FormulaSetT>& smtrat::Module::infeasibleSubsets( ) const` [inline], [inherited]

**Returns**

The infeasible subsets of the set of received formulas (empty, if this module has not detected unsatisfiability of the conjunction of received formulas).

**0.15.572.4.58 `inform()`** `bool smtrat::Module::inform( const FormulaT & _constraint )` [inherited]

Informs the module about the given constraint.

It should be tried to inform this module about any constraint it could receive eventually before `assertSubformula` is called (preferably for the first time, but at least before adding a formula containing that constraint).

**Parameters**

|                    |                                 |
|--------------------|---------------------------------|
| <i>_constraint</i> | The constraint to inform about. |
|--------------------|---------------------------------|

**Returns**

false, if it can be easily decided whether the given constraint is inconsistent; true, otherwise.

**0.15.572.4.59 informBackends()** `void smtrat::Module::informBackends (`

```
const FormulaT & _constraint) [inline], [protected], [inherited]
```

Informs all backends of this module about the given constraint.

**Parameters**

|                          |                                 |
|--------------------------|---------------------------------|
| <code>_constraint</code> | The constraint to inform about. |
|--------------------------|---------------------------------|

**0.15.572.4.60 informCore()** `template<typename Settings >`

```
bool smtrat::UnionFindModule< Settings >::informCore (
```

```
const FormulaT & _constraint) [virtual]
```

Informs the module about the given constraint.

It should be tried to inform this module about any constraint it could receive eventually before assertSubformula is called (preferably for the first time, but at least before adding a formula containing that constraint).

**Parameters**

|                          |                                 |
|--------------------------|---------------------------------|
| <code>_constraint</code> | The constraint to inform about. |
|--------------------------|---------------------------------|

**Returns**

false, if it can be easily decided whether the given constraint is inconsistent; true, otherwise.

Reimplemented from [smtrat::Module](#).

**0.15.572.4.61 informedConstraints()** `const carl::FastSet<FormulaT>& smtrat::Module::informedConstraints ( ) const [inline], [inherited]`**Returns**

The position of the first constraint of which no backend has been informed about.

**0.15.572.4.62 init()** `void smtrat::Module::init ( ) [virtual], [inherited]`

Informs all backends about the so far encountered constraints, which have not yet been communicated.

This method must not be called twice and only before the first runBackends call.

Reimplemented in [smtrat::PBPPModule](#)< `Settings` >, [smtrat::PBGaussModule](#)< `Settings` >, [smtrat::NRAILModule](#)< `Settings` >, [smtrat::NewCoveringModule](#)< `Settings` >, [smtrat::NewCADModule](#)< `Settings` >, [smtrat::LRAModule](#)< `Settings` >, [smtrat::LRAModule](#)< `LRASettingsICP` >, [smtrat::LRAModule](#)< `LRASettings1` >, [smtrat::IntBlastModule](#)< `Settings` >, [smtrat::FPPModule](#)< `Settings` >, [smtrat::EQModule](#)< `Settings` >, [smtrat::CurryModule](#)< `Settings` >, and [smtrat::BVMModule](#)< `Settings` >.

**0.15.572.4.63 is\_minimizing()** `bool smtrat::Module::is_minimizing ( ) const [inline], [inherited]`**0.15.572.4.64 isLemmaLevel()** `bool smtrat::Module::isLemmaLevel (`

```
LemmaLevel level) [protected], [inherited]
```

Checks if current lemma level is greater or equal to given level.

**Parameters**

|              |                 |
|--------------|-----------------|
| <i>level</i> | Level to check. |
|--------------|-----------------|

**0.15.572.4.65 `isPreprocessor()`** `bool smtrat::Module::isPreprocessor () const [inline], [inherited]`**Returns**

true, if this module is a preprocessor that is a module, which simplifies its received formula to an equisatisfiable formula being passed to its backends. The simplified formula can be obtained with [getReceivedFormulaSimplified\(\)](#).

**0.15.572.4.66 `lemmas()`** `const std::vector<Lemma>& smtrat::Module::lemmas () const [inline], [inherited]`**Returns**

A constant reference to the lemmas being valid formulas this module or its backends made.

**0.15.572.4.67 `merge()`** `std::vector< FormulaT > smtrat::Module::merge (const std::vector< FormulaT > & _vecSetA, const std::vector< FormulaT > & _vecSetB) const [protected], [inherited]`

Merges the two vectors of sets into the first one.

({a,b},{a,c}) and ({b,d},{b}) -> ({a,b,d},{a,b},{a,b,c,d},{a,b,c})

**Parameters**

|                 |                                  |
|-----------------|----------------------------------|
| <i>_vecSetA</i> | A vector of sets of constraints. |
| <i>_vecSetB</i> | A vector of sets of constraints. |

**Returns**

The vector being the two given vectors merged.

**0.15.572.4.68 `model()`** `const Model& smtrat::Module::model () const [inline], [inherited]`**Returns**

The assignment of the current satisfiable result, if existent.

**0.15.572.4.69 `modelsDisjoint()`** `bool smtrat::Module::modelsDisjoint (const Model & _modelA, const Model & _modelB) [static], [protected], [inherited]`

Checks whether there is no variable assigned by both models.

**Parameters**

|                |                                |
|----------------|--------------------------------|
| <i>_modelA</i> | The first model to check for.  |
| <i>_modelB</i> | The second model to check for. |

**Returns**

true, if there is no variable assigned by both models; false, otherwise.

**0.15.572.4.70 `moduleName()`** template<typename Settings >  
std::string smtrat::UnionFindModule< Settings >::moduleName ( ) const [inline], [virtual]

**Returns**

The name of the given module type as name.

Reimplemented from [smtrat::Module](#).

**0.15.572.4.71 `objective()`** carl::Variable smtrat::Module::objective ( ) const [inline], [inherited]

**0.15.572.4.72 `originInReceivedFormula()`** bool smtrat::Module::originInReceivedFormula ( const FormulaT & \_origin ) const [protected], [inherited]

**0.15.572.4.73 `passedFormulaBegin()`** ModuleInput::iterator smtrat::Module::passedFormulaBegin ( ) [inline], [protected], [inherited]

**Returns**

An iterator to the end of the passed formula. TODO: disable this method

**0.15.572.4.74 `passedFormulaEnd()`** ModuleInput::iterator smtrat::Module::passedFormulaEnd ( ) [inline], [protected], [inherited]

**Returns**

An iterator to the end of the passed formula.

**0.15.572.4.75 `pPassedFormula()`** const ModuleInput\* smtrat::Module::pPassedFormula ( ) const [inline], [inherited]

**Returns**

A pointer to the formula passed to the backends of this module.

**0.15.572.4.76 `pReceivedFormula()`** const ModuleInput\* smtrat::Module::pReceivedFormula ( ) const [inline], [inherited]

**Returns**

A pointer to the formula passed to this module.

**0.15.572.4.77 `print()`** void smtrat::Module::print ( const std::string & \_initiation = "\*\*\*" ) const [inherited]

Prints everything relevant of the solver.

**Parameters**

|                    |                      |
|--------------------|----------------------|
| <i>_initiation</i> | The line initiation. |
|--------------------|----------------------|

**0.15.572.4.78 printAllModels()** void smtrat::Module::printAllModels ( std::ostream & *\_out* = std::cout ) const [inherited]

Prints all assignments of this module satisfying its received formula if it satisfiable and this module could find an assignment.

**Parameters**

|             |                                        |
|-------------|----------------------------------------|
| <i>_out</i> | The stream to print the assignment on. |
|-------------|----------------------------------------|

**0.15.572.4.79 printInfeasibleSubsets()** void smtrat::Module::printInfeasibleSubsets ( const std::string & *\_initiation* = "\*\*\*" ) const [inherited]

Prints the infeasible subsets.

**Parameters**

|                    |                      |
|--------------------|----------------------|
| <i>_initiation</i> | The line initiation. |
|--------------------|----------------------|

**0.15.572.4.80 printModel()** void smtrat::Module::printModel ( std::ostream & *\_out* = std::cout ) const [inherited]

Prints the assignment of this module satisfying its received formula if it satisfiable and this module could find an assignment.

**Parameters**

|             |                                        |
|-------------|----------------------------------------|
| <i>_out</i> | The stream to print the assignment on. |
|-------------|----------------------------------------|

**0.15.572.4.81 printPassedFormula()** void smtrat::Module::printPassedFormula ( const std::string & *\_initiation* = "\*\*\*" ) const [inherited]

Prints the vector of passed formula.

**Parameters**

|                    |                      |
|--------------------|----------------------|
| <i>_initiation</i> | The line initiation. |
|--------------------|----------------------|

**0.15.572.4.82 printReceivedFormula()** void smtrat::Module::printReceivedFormula ( const std::string & *\_initiation* = "\*\*\*" ) const [inherited]

Prints the vector of the received formula.

**Parameters**

|                    |                      |
|--------------------|----------------------|
| <i>_initiation</i> | The line initiation. |
|--------------------|----------------------|

```
0.15.572.4.83 probablyLooping() bool smtrat::Module::probablyLooping (
 const typename Poly::PolyType & _branchingPolynomial,
 const Rational & _branchingValue) const [protected], [inherited]
```

Checks whether given the current branching value and branching variable/polynomial it is (highly) probable that this branching is part of an infinite loop of branchings.

#### Parameters

|                                   |                                                                                     |
|-----------------------------------|-------------------------------------------------------------------------------------|
| <code>_branchingPolynomial</code> | The polynomial to branch at (in most branching strategies this is just a variable). |
| <code>_branchingValue</code>      | The value to branch at.                                                             |

#### Returns

true, if this branching is probably part of an infinite loop of branchings; false, otherwise.

```
0.15.572.4.84 receivedFormulaChecked() void smtrat::Module::receivedFormulaChecked () [inline], [inherited]
```

Notifies that the received formulas has been checked.

```
0.15.572.4.85 receivedFormulasAsInfeasibleSubset() void smtrat::Module::receivedFormulasAs< InfeasibleSubset (
```

```
 ModuleInput::const_iterator _subformula) [inline], [protected], [inherited]
```

Stores an infeasible subset consisting only of the given received formula.

```
0.15.572.4.86 receivedVariable() bool smtrat::Module::receivedVariable (
 carl::Variable::Arg _var) const [inline], [inherited]
```

```
0.15.572.4.87 remove() void smtrat::Module::remove (
 ModuleInput::const_iterator _subformula) [virtual], [inherited]
```

Removes everything related to the given sub-formula of the received formula.

However, it is desired not to lose track of search spaces where no satisfying assignment can be found for the remaining sub-formulas.

#### Parameters

|                          |                                                    |
|--------------------------|----------------------------------------------------|
| <code>_subformula</code> | The sub formula of the received formula to remove. |
|--------------------------|----------------------------------------------------|

Reimplemented in [smtrat::PModule](#).

```
0.15.572.4.88 removeCore() template<typename Settings >
void smtrat::UnionFindModule< Settings >::removeCore (
 ModuleInput::const_iterator _subformula) [virtual]
```

Removes the subformula of the received formula at the given position to the considered ones of this module.

Note that this includes every stored calculation which depended on this subformula, but should keep the other stored calculation, if possible, untouched.

#### Parameters

|                          |                                           |
|--------------------------|-------------------------------------------|
| <code>_subformula</code> | The position of the subformula to remove. |
|--------------------------|-------------------------------------------|

Reimplemented from [smtrat::Module](#).

**0.15.572.4.89 `removeOrigin()`** `std::pair<ModuleInput::iterator, bool> smtrat::Module::removeOrigin (`

```
 ModuleInput::iterator _formula,
 const FormulaT & _origin) [inline], [protected], [inherited]
```

**0.15.572.4.90 `removeOrigins()`** `std::pair<ModuleInput::iterator, bool> smtrat::Module::removeOrigins (`

```
 ModuleInput::iterator _formula,
 const std::shared_ptr< std::vector< FormulaT >> & _origins) [inline], [protected],
[inherited]
```

**0.15.572.4.91 `rPassedFormula()`** `const ModuleInput& smtrat::Module::rPassedFormula ( ) const`  
`[inline], [inherited]`

#### Returns

A reference to the formula passed to the backends of this module.

**0.15.572.4.92 `rReceivedFormula()`** `const ModuleInput& smtrat::Module::rReceivedFormula ( ) const`  
`[inline], [inherited]`

#### Returns

A reference to the formula passed to this module.

**0.15.572.4.93 `runBackends() [1/2]`** `virtual Answer smtrat::Module::runBackends ( ) [inline],`  
`[protected], [virtual], [inherited]`

Reimplemented in [smtrat::PModule](#).

**0.15.572.4.94 `runBackends() [2/2]`** `Answer smtrat::Module::runBackends (`

```
 bool _final,
 bool _full,
 carl::Variable _objective) [protected], [virtual], [inherited]
```

Runs the backend solvers on the passed formula.

#### Parameters

|                         |                                                                                                                                       |
|-------------------------|---------------------------------------------------------------------------------------------------------------------------------------|
| <code>_final</code>     | true, if this satisfiability check will be the last one (for a global sat-check), if its result is SAT                                |
| <code>_full</code>      | false, if this module should avoid too expensive procedures and rather return unknown instead.                                        |
| <code>_objective</code> | if not set to NO_VARIABLE, the module should find an assignment minimizing this objective variable; otherwise any assignment is good. |

#### Returns

True, if the passed formula is consistent; False, if the passed formula is inconsistent; Unknown, otherwise.

Reimplemented in [smtrat::PModule](#).

**0.15.572.4.95 setId()** void smtrat::Module::setId ( std::size\_t \_id ) [inline], [inherited]  
 Sets this modules unique ID to identify itself.

#### Parameters

|                                                 |                                    |
|-------------------------------------------------|------------------------------------|
| $\leftarrow$<br>$\overline{\leftarrow}$<br>$id$ | The id to set this module's id to. |
|-------------------------------------------------|------------------------------------|

**0.15.572.4.96 setThreadPriority()** void smtrat::Module::setThreadPriority ( thread\_priority \_threadPriority ) [inline], [inherited]  
 Sets the priority of this module to get a thread for running its check procedure.

#### Parameters

|                   |                                                       |
|-------------------|-------------------------------------------------------|
| $_threadPriority$ | The priority to set this module's thread priority to. |
|-------------------|-------------------------------------------------------|

**0.15.572.4.97 solverState()** Answer smtrat::Module::solverState ( ) const [inline], [inherited]

#### Returns

True, if this module is in a state, such that it has found a solution for its received formula; False, if this module is in a state, such that it has determined that there is no solution for its received formula; Unknown, otherwise.

**0.15.572.4.98 splitUnequalConstraint()** void smtrat::Module::splitUnequalConstraint ( const FormulaT & \_unequalConstraint ) [protected], [inherited]  
 Adds the following lemmas for the given constraint  $p \neq 0$ .

$(p \neq 0 \leftrightarrow (p < 0 \text{ or } p > 0))$

and  $\neg(p < 0 \text{ and } p > 0)$

#### Parameters

|                      |                                                  |
|----------------------|--------------------------------------------------|
| $_unequalConstraint$ | A constraint having the relation symbol $\neq$ . |
|----------------------|--------------------------------------------------|

**0.15.572.4.99 threadPriority()** thread\_priority smtrat::Module::threadPriority ( ) const [inline], [inherited]

#### Returns

The priority of this module to get a thread for running its check procedure.

**0.15.572.4.100 updateAllModels()** void smtrat::Module::updateAllModels ( ) [virtual], [inherited]  
 Updates all satisfying models, if the solver has detected the consistency of the received formula, beforehand.  
 Reimplemented in [smtrat::SATModule< Settings >](#).

**0.15.572.4.101 updateLemmas()** void smtrat::Module::updateLemmas () [inherited]  
Stores all lemmas of any backend of this module in its own lemma vector.

**0.15.572.4.102 updateModel()** template<typename Settings >  
void smtrat::UnionFindModule< Settings >::updateModel () const [virtual]

Updates the current assignment into the model.

Note, that this is a unique but possibly symbolic assignment maybe containing newly introduced variables.  
Reimplemented from [smtrat::Module](#).

**0.15.572.4.103 usedBackends()** const std::vector<[Module](#)\*>& smtrat::Module::usedBackends ()  
const [inline], [inherited]

#### Returns

The backends of this module which are currently used (conditions to use this module are fulfilled for the passed formula).

### 0.15.572.5 Field Documentation

**0.15.572.5.1 mAllBackends** std::vector<[Module](#)\*> smtrat::Module::mAllBackends [protected],  
[inherited]

The backends of this module which have been used.

**0.15.572.5.2 mAllModels** std::vector<[Model](#)> smtrat::Module::mAllModels [mutable], [protected],  
[inherited]

Stores all satisfying assignments.

**0.15.572.5.3 mBackendsFoundAnswer** std::atomic\_bool\* smtrat::Module::mBackendsFoundAnswer  
[protected], [inherited]

This flag is passed to any backend and if it determines an answer to a prior check call, this flag is fired.

**0.15.572.5.4 mConstraintsToInform** carl::FastSet<[FormulaT](#)> smtrat::Module::mConstraintsToInform  
[protected], [inherited]

Stores the constraints which the backends must be informed about.

**0.15.572.5.5 mFinalCheck** bool smtrat::Module::mFinalCheck [protected], [inherited]  
true, if the check procedure should perform a final check which especially means not to postpone splitting decisions

**0.15.572.5.6 mFirstPosInLastBranches** std::size\_t smtrat::Module::mFirstPosInLastBranches = 0  
[static], [inherited]

The beginning of the cyclic buffer storing the last branches.

**0.15.572.5.7 mFirstSubformulaToPass** [ModuleInput](#)::iterator smtrat::Module::mFirstSubformulaTo←  
Pass [protected], [inherited]

Stores the position of the first sub-formula in the passed formula, which has not yet been considered for a consistency check of the backends.

**0.15.572.5.8 mFirstUncheckedReceivedSubformula** `ModuleInput::const_iterator smtrat::Module::mFirstUncheckedReceivedSubformula [protected], [inherited]`  
Stores the position of the first (by this module) unchecked sub-formula of the received formula.

**0.15.572.5.9 mFoundAnswer** `Conditionals smtrat::Module::mFoundAnswer [protected], [inherited]`  
Vector of Booleans: If any of them is true, we have to terminate a running check procedure.

**0.15.572.5.10 mFullCheck** `bool smtrat::Module::mFullCheck [protected], [inherited]`  
false, if this module should avoid too expensive procedures and rather return unknown instead.

**0.15.572.5.11 mInfeasibleSubsets** `std::vector<FormulaSetT> smtrat::Module::mInfeasibleSubsets [protected], [inherited]`  
Stores the infeasible subsets.

**0.15.572.5.12 mInformedConstraints** `carl::FastSet<FormulaT> smtrat::Module::mInformedConstraints [protected], [inherited]`  
Stores the position of the first constraint of which no backend has been informed about.

**0.15.572.5.13 mLastBranches** `std::vector<Branching> smtrat::Module::mLastBranches = std::vector<Branching>(mNumOfBranchVarsToStore, Branching(typename Poly::PolyType(), 0)) [static], [inherited]`  
Stores the last branches in a cycle buffer.

**0.15.572.5.14 mLemmas** `std::vector<Lemma> smtrat::Module::mLemmas [protected], [inherited]`  
Stores the lemmas being valid formulas this module or its backends made.

**0.15.572.5.15 mModel** `Model smtrat::Module::mModel [mutable], [protected], [inherited]`  
Stores the assignment of the current satisfiable result, if existent.

**0.15.572.5.16 mModelComputed** `bool smtrat::Module::mModelComputed [mutable], [protected], [inherited]`  
True, if the model has already been computed.

**0.15.572.5.17 mNumOfBranchVarsToStore** `std::size_t smtrat::Module::mNumOfBranchVarsToStore = 5 [static], [inherited]`  
The number of different variables to consider for a probable infinite loop of branchings.

**0.15.572.5.18 mObjectiveVariable** `carl::Variable smtrat::Module::mObjectiveVariable [protected], [inherited]`  
Objective variable to be minimized. If set to NO\_VARIABLE, a normal sat check should be performed.

**0.15.572.5.19 mOldSplittingVariables** `std::vector<FormulaT> smtrat::Module::mOldSplittingVariables [static], [inherited]`  
Reusable splitting variables.

**0.15.572.5.20 mpManager** `Manager* const smtrat::Module::mpManager [protected], [inherited]`  
A reference to the manager.

**0.15.572.5.21 mSmallerMusesCheckCounter** `unsigned smtrat::Module::mSmallerMusesCheckCounter [mutable], [protected], [inherited]`  
Counter used for the generation of the smt2 files to check for smaller muses.

**0.15.572.5.22 mSolverState** `std::atomic<Answer> smtrat::Module::mSolverState [protected], [inherited]`  
States whether the received formula is known to be satisfiable or unsatisfiable otherwise it is set to unknown.

**0.15.572.5.23 mTheoryPropagations** `std::vector<TheoryPropagation> smtrat::Module::mTheoryPropagations [protected], [inherited]`

**0.15.572.5.24 mUsedBackends** `std::vector<Module*> smtrat::Module::mUsedBackends [protected], [inherited]`  
The backends of this module which are currently used (conditions to use this module are fulfilled for the passed formula).

**0.15.572.5.25 mVariableCounters** `std::vector<std::size_t> smtrat::Module::mVariableCounters [protected], [inherited]`  
Maps variables to the number of their occurrences.

### 0.15.576.1 Detailed Description

```
template<typename Solver>
class smtrat::unsatcore::UnsatCoreBackend< Solver, UnsatCoreStrategy::ModelExclusion >
```

Implements an easy strategy to obtain an unsatisfiable core.

Essentially it computes a cover that rejects all possible models if we allow the removal of clauses.

- Allow to disable every formula  $f_i$  by encoding  $(y_i \leq f_i)$
- Find a satisfying assignment (which will set some  $f_i$  to false)
-

|----------|--|
| ↔        |  |
| ↔        |  |
| <i>a</i> |  |

```
0.15.583.2.11 operator*=(()) [2/2] template<class T >
void smtrat::lra::Value< T >::operator*=
(
 const Value< T > & _value)
```

**Parameters**

|        |  |
|--------|--|
| _value |  |
|--------|--|

```
0.15.583.2.12 operator+() template<class T >
Value<T> smtrat::lra::Value< T >::operator+
(
 const Value< T > & _value) const
```

**Parameters**

|                     |                          |
|---------------------|--------------------------|
| <code>_value</code> | <input type="checkbox"/> |
|---------------------|--------------------------|

**Returns**

**0.15.583.2.13 `operator+=()`** template<class T >  
void `smtrat::lra::Value< T >::operator+=` (  
    const `Value< T >` & `_value` )

**Parameters**

|                     |                          |
|---------------------|--------------------------|
| <code>_value</code> | <input type="checkbox"/> |
|---------------------|--------------------------|

**0.15.583.2.14 `operator-()`** template<class T >  
`Value<T>` `smtrat::lra::Value< T >::operator-` (  
    const `Value< T >` & `_value` ) const

**Parameters**

|                     |                          |
|---------------------|--------------------------|
| <code>_value</code> | <input type="checkbox"/> |
|---------------------|--------------------------|

**Returns**

**0.15.583.2.15 `operator-=()`** template<class T >  
void `smtrat::lra::Value< T >::operator-=` (  
    const `Value< T >` & `_value` )

**Parameters**

|                     |                          |
|---------------------|--------------------------|
| <code>_value</code> | <input type="checkbox"/> |
|---------------------|--------------------------|

**0.15.583.2.16 `operator()`** template<class T >  
`Value<T>` `smtrat::lra::Value< T >::operator/` (  
    const `T` & `_a` ) const

**Parameters**

|                               |                          |
|-------------------------------|--------------------------|
| $\leftrightarrow$             | <input type="checkbox"/> |
| $\underline{\leftrightarrow}$ | <input type="checkbox"/> |
| $a$                           | <input type="checkbox"/> |

Returns

**0.15.583.2.17 operator/=( )** template<class T >  
void smtrat::lra::Value< T >::operator/= ( const T & \_a )

Parameters

|                      |  |
|----------------------|--|
| $\leftrightarrow$    |  |
| $\_ \leftrightarrow$ |  |
| a                    |  |

**0.15.583.2.18 operator<() [1/2]** template<class T >  
bool smtrat::lra::Value< T >::operator< ( const T & \_a ) const

Parameters

|                      |  |
|----------------------|--|
| $\leftrightarrow$    |  |
| $\_ \leftrightarrow$ |  |
| a                    |  |

Returns

**0.15.583.2.19 operator<() [2/2]** template<class T >  
bool smtrat::lra::Value< T >::operator< ( const Value< T > & \_value ) const

Parameters

|           |  |
|-----------|--|
| $\_value$ |  |
|           |  |

Returns

**0.15.583.2.20 operator<=() [1/2]** template<class T >  
bool smtrat::lra::Value< T >::operator<= ( const T & \_a ) const

Parameters

|                      |  |
|----------------------|--|
| $\leftrightarrow$    |  |
| $\_ \leftrightarrow$ |  |
| a                    |  |

**Returns**

**0.15.583.2.21 operator<=()** [2/2] template<class T >  
bool smtrat::lra::Value< T >::operator<= (  
 const Value< T > & \_value ) const

**Parameters**

|        |  |
|--------|--|
| _value |  |
|--------|--|

**Returns**

**0.15.583.2.22 operator=()** template<class T >  
Value<T>& smtrat::lra::Value< T >::operator= (  
 const Value< T > & \_value )

Copy the content of the given value to this one.

**Parameters**

|        |                    |
|--------|--------------------|
| _value | The value to copy. |
|--------|--------------------|

**Returns**

This value after copying.

**0.15.583.2.23 operator==()** [1/2] template<class T >  
bool smtrat::lra::Value< T >::operator== (  
 const T & \_a ) const

**Parameters**

|   |  |
|---|--|
| ↔ |  |
| ↔ |  |
| a |  |

**Returns**

**0.15.583.2.24 operator==()** [2/2] template<class T >  
bool smtrat::lra::Value< T >::operator== (  
 const Value< T > & \_value ) const

**Parameters**

|        |  |
|--------|--|
| _value |  |
|--------|--|

Returns

**0.15.583.2.25 operator>() [1/2]** template<class T >  
bool smtrat::lra::Value< T >::operator> (  
 const T & \_a ) const

Parameters

|   |  |
|---|--|
| ↔ |  |
| ↔ |  |
| a |  |

Returns

**0.15.583.2.26 operator>() [2/2]** template<class T >  
bool smtrat::lra::Value< T >::operator> (  
 const Value< T > & \_value ) const [inline]

**0.15.583.2.27 operator>=()** [1/2] template<class T >  
bool smtrat::lra::Value< T >::operator>= (  
 const T & \_a ) const

Parameters

|   |  |
|---|--|
| ↔ |  |
| ↔ |  |
| a |  |

Returns

**0.15.583.2.28 operator>=()** [2/2] template<class T >  
bool smtrat::lra::Value< T >::operator>= (  
 const Value< T > & \_value ) const [inline]

**0.15.583.2.29 print()** template<class T >  
void smtrat::lra::Value< T >::print (  
 std::ostream & \_out = std::cout ) const

Parameters

|      |  |
|------|--|
| _out |  |
|------|--|

**0.15.583.2.30 sign()** template<class T>  
T smrat::lra::Value< T >::sign () const  
Computes the sign: 0 if main & delta part are unequal 0.  
Else +/- 1 determined by the sign of main part (if set) else delta part.

**0.15.583.2.31 toString()** template<class T>  
const std::string smrat::lra::Value< T >::toString () const

Returns

## 0.15.584 smrat::lra::Variable< T1, T2 > Class Template Reference

#include <Variable.h>

| <code>_id</code>                   |  |

**0.15.584.1.3 ~Variable()** template<typename T1 , typename T2 >  
virtual smtrat::lra::Variable< T1, T2 >::~Variable ( ) [virtual]

**0.15.584.2 Member Function Documentation**

**0.15.584.2.1 addEqualBound()** template<typename T1 , typename T2 >  
std::pair<const Bound<T1, T2>\*, bool> smtrat::lra::Variable< T1, T2 >::addEqualBound (   
    Value< T1 > \*const \_val,  
    ModuleInput::iterator \_position,  
    const FormulaT & \_constraint )

**Parameters**

|                          |  |
|--------------------------|--|
| <code>_val</code>        |  |
| <code>_position</code>   |  |
| <code>_constraint</code> |  |

**Returns**

**0.15.584.2.2 addLowerBound()** template<typename T1 , typename T2 >  
std::pair<const Bound<T1, T2>\*, bool> smtrat::lra::Variable< T1, T2 >::addLowerBound (   
    Value< T1 > \*const \_val,  
    ModuleInput::iterator \_position,  
    const FormulaT & \_constraint,  
    bool \_deduced = false )

**Parameters**

|                          |  |
|--------------------------|--|
| <code>_val</code>        |  |
| <code>_position</code>   |  |
| <code>_constraint</code> |  |
| <code>_deduced</code>    |  |

**Returns**

**0.15.584.2.3 addUpperBound()** template<typename T1 , typename T2 >  
std::pair<const Bound<T1, T2>\*, bool> smtrat::lra::Variable< T1, T2 >::addUpperBound (

```
Value< T1 > *const _val,
ModuleInput::iterator _position,
const FormulaT & _constraint,
bool _deduced = false)
```

**Parameters**

|                    |  |
|--------------------|--|
| <i>_val</i>        |  |
| <i>_position</i>   |  |
| <i>_constraint</i> |  |
| <i>_deduced</i>    |  |

**Returns**

**0.15.584.2.4 assignment()** template<typename T1 , typename T2 >  
 const Value<T1>& smtrat::lra::Variable< T1, T2 >::assignment () const [inline]

**Returns**

**0.15.584.2.5 conflictActivity()** template<typename T1 , typename T2 >  
 double smtrat::lra::Variable< T1, T2 >::conflictActivity () const [inline]

**Returns**

**0.15.584.2.6 deactivateBound()** template<typename T1 , typename T2 >  
 bool smtrat::lra::Variable< T1, T2 >::deactivateBound (  
     const Bound< T1, T2 > \* bound,  
     ModuleInput::iterator \_position )

**Parameters**

|                  |  |
|------------------|--|
| <i>bound</i>     |  |
| <i>_position</i> |  |

**Returns**

**0.15.584.2.7 expression()** template<typename T1 , typename T2 >  
 const PolyType& smtrat::lra::Variable< T1, T2 >::expression () const [inline]

**Returns**

**0.15.584.2.8 `factor()`** template<typename T1 , typename T2 >  
const T2& smtrat::lra::Variable< T1, T2 >::factor ( ) const [inline]

Returns

**0.15.584.2.9 `getDefiningOrigins()`** template<typename T1 , typename T2 >  
FormulasT smtrat::lra::Variable< T1, T2 >::getDefiningOrigins ( ) const

Returns

**0.15.584.2.10 `getVariableBounds()`** template<typename T1 , typename T2 >  
RationalInterval smtrat::lra::Variable< T1, T2 >::getVariableBounds ( ) const

Returns

**0.15.584.2.11 `hasBound()`** template<typename T1 , typename T2 >  
bool smtrat::lra::Variable< T1, T2 >::hasBound ( ) const [inline]

Returns

**0.15.584.2.12 `id()`** template<typename T1 , typename T2 >  
size\_t smtrat::lra::Variable< T1, T2 >::id ( ) const [inline]

**0.15.584.2.13 `inConflictWith()`** template<typename T1 , typename T2 >  
FormulaT smtrat::lra::Variable< T1, T2 >::inConflictWith (   
const RationalAssignment & \_ass ) const [inline]

Parameters

|      |                                 |
|------|---------------------------------|
| _ass | <input type="button" value=""/> |
|------|---------------------------------|

Returns

**0.15.584.2.14 `infimum()`** template<typename T1 , typename T2 >  
const Bound<T1, T2>& smtrat::lra::Variable< T1, T2 >::infimum ( ) const [inline]

Returns

**0.15.584.2.15 `involvesEquation()`** template<typename T1 , typename T2 >  
bool smtrat::lra::Variable< T1, T2 >::involvesEquation ( ) const [inline]

Returns

**0.15.584.2.16 `is_integer()`** template<typename T1 , typename T2 >  
bool smtrat::lra::Variable< T1, T2 >::is\_integer ( ) const [inline]

Returns

**0.15.584.2.17 `isBasic()`** template<typename T1 , typename T2 >  
bool smtrat::lra::Variable< T1, T2 >::isBasic ( ) const [inline]

Returns

**0.15.584.2.18 `isConflicting()`** template<typename T1 , typename T2 >  
bool smtrat::lra::Variable< T1, T2 >::isConflicting ( ) const [inline]

**0.15.584.2.19 `isOriginal()`** template<typename T1 , typename T2 >  
bool smtrat::lra::Variable< T1, T2 >::isOriginal ( ) const [inline]

Returns

**0.15.584.2.20 `isSatisfiedBy()`** template<typename T1 , typename T2 >  
unsigned smtrat::lra::Variable< T1, T2 >::isSatisfiedBy (   
const RationalAssignment & \_ass ) const [inline]

Parameters

|      |  |
|------|--|
| _ass |  |
|------|--|

Returns

**0.15.584.2.21 `lastConsistentAssignment()`** template<typename T1 , typename T2 >  
const Value<T1>& smtrat::lra::Variable< T1, T2 >::lastConsistentAssignment ( ) const [inline]

Returns

**0.15.584.2.22 lowerbounds()** template<typename T1 , typename T2 >  
const Bound<T1, T2>::BoundSet& smtrat::lra::Variable< T1, T2 >::lowerbounds ( ) const [inline]

Returns

**0.15.584.2.23 operator"!=()** template<typename T1 , typename T2 >  
bool smtrat::lra::Variable< T1, T2 >::operator!= (   
const Variable< T1, T2 > & \_variable ) const [inline]

**0.15.584.2.24 operator<()** template<typename T1 , typename T2 >  
bool smtrat::lra::Variable< T1, T2 >::operator< (   
const Variable< T1, T2 > & \_variable ) const [inline]

Parameters

|               |
|---------------|
| <i>_bound</i> |
|---------------|

Returns

**0.15.584.2.25 operator==()** template<typename T1 , typename T2 >  
bool smtrat::lra::Variable< T1, T2 >::operator== (   
const Variable< T1, T2 > & \_variable ) const [inline]

**0.15.584.2.26 operator>()** template<typename T1 , typename T2 >  
bool smtrat::lra::Variable< T1, T2 >::operator> (   
const Variable< T1, T2 > & \_variable ) const [inline]

**0.15.584.2.27 pExpression()** template<typename T1 , typename T2 >  
const Poly::PolyType\* smtrat::lra::Variable< T1, T2 >::pExpression ( ) const [inline]

Returns

**0.15.584.2.28 plInfimum()** template<typename T1 , typename T2 >  
const Bound<T1, T2>\* smtrat::lra::Variable< T1, T2 >::plInfimum ( ) const [inline]

Returns

**0.15.584.2.29 position()** template<typename T1 , typename T2 >  
size\_t smtrat::lra::Variable< T1, T2 >::position ( ) const [inline]

Returns

```
0.15.584.2.30 positionInNonActives() template<typename T1 , typename T2 >
std::list<std::list<std::pair<Variable<T1,T2>*,T2> >::iterator smtrat::lra::Variable< T1,
T2 >::positionInNonActives () const [inline]
```

Returns

```
0.15.584.2.31 print() template<typename T1 , typename T2 >
void smtrat::lra::Variable< T1, T2 >::print (
 std::ostream & _out = std::cout) const
```

Parameters

|                   |  |
|-------------------|--|
| <code>_out</code> |  |
|-------------------|--|

```
0.15.584.2.32 printAllBounds() template<typename T1 , typename T2 >
void smtrat::lra::Variable< T1, T2 >::printAllBounds (
 std::ostream & _out = std::cout,
 const std::string _init = "") const
```

Parameters

|                    |  |
|--------------------|--|
| <code>_out</code>  |  |
| <code>_init</code> |  |

```
0.15.584.2.33 pSupremum() template<typename T1 , typename T2 >
const Bound<T1, T2>* smtrat::lra::Variable< T1, T2 >::pSupremum () const [inline]
```

Returns

```
0.15.584.2.34 rAssignment() template<typename T1 , typename T2 >
Value<T1>& smtrat::lra::Variable< T1, T2 >::rAssignment () [inline]
```

Returns

```
0.15.584.2.35 removeBound() template<typename T1 , typename T2 >
void smtrat::lra::Variable< T1, T2 >::removeBound (
 const Bound< T1, T2 > * _bound)
```

Parameters

|                     |  |
|---------------------|--|
| <code>_bound</code> |  |
|---------------------|--|

**0.15.584.2.36 rFactor()** template<typename T1 , typename T2 >  
T2& smtrat::lra::Variable< T1, T2 >::rFactor ( ) [inline]

Returns

**0.15.584.2.37 rLowerbounds()** template<typename T1 , typename T2 >  
Bound<T1, T2>::BoundSet& smtrat::lra::Variable< T1, T2 >::rLowerbounds ( ) [inline]

Returns

**0.15.584.2.38 rLowerBoundsSize()** template<typename T1 , typename T2 >  
size\_t smtrat::lra::Variable< T1, T2 >::rLowerBoundsSize ( ) [inline]

Returns

**0.15.584.2.39 rPosition()** template<typename T1 , typename T2 >  
size\_t& smtrat::lra::Variable< T1, T2 >::rPosition ( ) [inline]

Returns

**0.15.584.2.40 rSize()** template<typename T1 , typename T2 >  
size\_t& smtrat::lra::Variable< T1, T2 >::rSize ( ) [inline]

Returns

**0.15.584.2.41 rStartEntry()** template<typename T1 , typename T2 >  
EntryID& smtrat::lra::Variable< T1, T2 >::rStartEntry ( ) [inline]

Returns

**0.15.584.2.42 rUpperbounds()** template<typename T1 , typename T2 >  
Bound<T1, T2>::BoundSet& smtrat::lra::Variable< T1, T2 >::rUpperbounds ( ) [inline]

Returns

**0.15.584.2.43 rUpperBoundsSize()** template<typename T1 , typename T2 >  
size\_t smtrat::lra::Variable< T1, T2 >::rUpperBoundsSize ( ) [inline]

Returns

**0.15.584.2.44 setBasic()** template<typename T1 , typename T2 >  
void smtrat::lra::Variable< T1, T2 >::setBasic (   
    bool \_basic ) [inline]

Parameters

|               |
|---------------|
| <i>_basic</i> |
|---------------|

**0.15.584.2.45 setInfimum()** template<typename T1 , typename T2 >  
void smtrat::lra::Variable< T1, T2 >::setInfimum (   
    const Bound< T1, T2 > \* \_infimum ) [inline]

Parameters

|                 |
|-----------------|
| <i>_infimum</i> |
|-----------------|

**0.15.584.2.46 setPosition()** template<typename T1 , typename T2 >  
void smtrat::lra::Variable< T1, T2 >::setPosition (   
    size\_t \_position ) [inline]

Parameters

|                  |
|------------------|
| <i>_position</i> |
|------------------|

**0.15.584.2.47 setPositionInNonActives()** template<typename T1 , typename T2 >  
void smtrat::lra::Variable< T1, T2 >::setPositionInNonActives (   
    typename std::list< std::list< std::pair< Variable< T1, T2 > \*, T2 >>>::iterator  
\_positionInNonActives ) [inline]

Parameters

|                              |
|------------------------------|
| <i>_positionInNonActives</i> |
|------------------------------|

**0.15.584.2.48 setSupremum()** template<typename T1 , typename T2 >  
void smtrat::lra::Variable< T1, T2 >::setSupremum (   
    const Bound< T1, T2 > \* \_supremum ) [inline]

Parameters

|                  |
|------------------|
| <i>_supremum</i> |
|------------------|

**0.15.584.2.49 `size()`** template<typename T1 , typename T2 >  
size\_t smtrat::lra::Variable< T1, T2 >::size ( ) const [inline]

Returns

**0.15.584.2.50 `startEntry()`** template<typename T1 , typename T2 >  
EntryID smtrat::lra::Variable< T1, T2 >::startEntry ( ) const [inline]

Returns

**0.15.584.2.51 `storeAssignment()`** template<typename T1 , typename T2 >  
void smtrat::lra::Variable< T1, T2 >::storeAssignment ( ) [inline]

**0.15.584.2.52 `supremum()`** template<typename T1 , typename T2 >  
const Bound<T1, T2>& smtrat::lra::Variable< T1, T2 >::supremum ( ) const [inline]

Returns

**0.15.584.2.53 `updateConflictActivity()`** template<typename T1 , typename T2 >  
void smtrat::lra::Variable< T1, T2 >::updateConflictActivity ( ) [inline]

**0.15.584.2.54 `upperbounds()`** template<typename T1 , typename T2 >  
const Bound<T1, T2>::BoundSet& smtrat::lra::Variable< T1, T2 >::upperbounds ( ) const [inline]

Returns

## 0.15.585 smtrat::vb::Variable< T > Class Template Reference

Class for a variable.

```
#include <VariableBounds.h>
```

### Public Member Functions

- `Variable ()`  
*Constructs this variable.*

### 0.15.585.1 Detailed Description

```
template<typename T>
class smrat::vb::Variable< T >
```

Class for a variable.

### 0.15.585.2 Constructor & Destructor Documentation

**0.15.585.2.1 Variable()** template<typename T >  
`smrat::vb::Variable< T >::Variable ( )`  
Constructs this variable.

**0.15.585.2.2 ~Variable()** template<typename T >  
`smrat::vb::Variable< T >::~Variable ( )`

### 0.15.585.3 Member Function Documentation

**0.15.585.3.1 addBound()** template<typename T >  
`const Bound<T>* smrat::vb::Variable< T >::addBound (`  
`const ConstraintT & _constraint,`  
`const carl::Variable< T > & _var,`  
`const T & _origin )`

Adds the bound corresponding to the constraint to the given variable.

The constraint is expected to contain only one variable and this one only linearly.

#### Parameters

|                          |                                                                                                                                  |
|--------------------------|----------------------------------------------------------------------------------------------------------------------------------|
| <code>_constraint</code> | A pointer to a constraint of the form $ax \sim b$ .                                                                              |
| <code>_var</code>        | Hence, the variable $x$ .                                                                                                        |
| <code>_origin</code>     | The origin of the constraint. This could be the constraint itself or anything else in the data structure which uses this object. |
| <code>_limit</code>      |                                                                                                                                  |

#### Returns

The added bound.

**0.15.585.3.2 conflicting()** template<typename T >  
bool `smtrat::vb::Variable`< T >::conflicting () const  
**Returns**

true, if there is a conflict; false, otherwise.

**0.15.585.3.3 doubleIntervalHasBeenUpdated()** template<typename T >  
void `smtrat::vb::Variable`< T >::doubleIntervalHasBeenUpdated () const [inline]  
Sets the flag indicating that the stored double interval representing the variable's bounds is up to date to false.

**0.15.585.3.4 exactIntervalHasBeenUpdated()** template<typename T >  
void `smtrat::vb::Variable`< T >::exactIntervalHasBeenUpdated () const [inline]  
Sets the flag indicating that the stored exact interval representing the variable's bounds is up to date to false.

**0.15.585.3.5 infimum()** template<typename T >  
const `Bound`<T>& `smtrat::vb::Variable`< T >::infimum () const [inline]  
**Returns**

A constant reference to the infimum of this variable.

**0.15.585.3.6 lowerbounds()** template<typename T >  
const `BoundSet`& `smtrat::vb::Variable`< T >::lowerbounds () const [inline]  
**Returns**

A constant reference to the set of lower bounds of this variable.

**0.15.585.3.7 pInfimum()** template<typename T >  
const `Bound`<T>\* `smtrat::vb::Variable`< T >::pInfimum () const [inline]  
**Returns**

A pointer to the infimum of this variable.

**0.15.585.3.8 pSupremum()** template<typename T >  
const `Bound`<T>\* `smtrat::vb::Variable`< T >::pSupremum () const [inline]  
**Returns**

A pointer to the supremum of this variable.

**0.15.585.3.9 supremum()** template<typename T >  
const `Bound`<T>& `smtrat::vb::Variable`< T >::supremum () const [inline]  
**Returns**

A constant reference to the supremum of this variable.

**0.15.585.3.10 updateBounds()** template<typename T >  
bool `smtrat::vb::Variable`< T >::updateBounds (  
    const `Bound`< T > & `_changedBound` )  
Updates the infimum and supremum of this variable.

**Parameters**

|                            |                                                                        |
|----------------------------|------------------------------------------------------------------------|
| <code>_changedBound</code> | The bound, for which we certainly know that it got deactivated before. |
|----------------------------|------------------------------------------------------------------------|

**Returns**

true, if there is a conflict; false, otherwise.

```
0.15.585.3.11 updatedDoubleInterval() template<typename T >
bool smtrat::vb::Variable< T >::updatedDoubleInterval () const [inline]
```

**Returns**

true, if the stored double interval representing the variable's bounds is up to date. false, otherwise

```
0.15.585.3.12 updatedExactInterval() template<typename T >
bool smtrat::vb::Variable< T >::updatedExactInterval () const [inline]
```

**Returns**

true, if the stored exact interval representing the variable's bounds is up to date. false, otherwise

```
0.15.585.3.13 upperbounds() template<typename T >
const BoundSet& smtrat::vb::Variable< T >::upperbounds () const [inline]
```

**Returns**

A constant reference to the set of upper bounds of this variable.

## 0.15.586 smtrat::vb::VariableBounds< T > Class Template Reference

Class to manage the bounds of a variable.

```
#include <VariableBounds.h>
```

### Public Types

- **typedef std::map< ConstraintT, const Bound< T > \* > ConstraintBoundMap**  
*A map from Constraint pointers to Bound pointers.*
- **typedef carl::FastMap< carl::Variable, Variable< T > \* > VariableMap**  
*A hash-map from arithmetic variables to variables managing the bounds.*

### Public Member Functions

- **VariableBounds ()**  
*Constructs a variable bounds manager.*
- **~VariableBounds ()**  
*Destructs a variable bounds manager.*
- **void clear ()**
- **bool empty () const**
- **bool addBound (const ConstraintT &\_constraint, const T &\_origin)**  
*Updates the variable bounds by the given constraint.*
- **bool addBound (const FormulaT &\_formula, const T &\_origin)**
- **unsigned removeBound (const ConstraintT &\_constraint, const T &\_origin)**

- *Removes all effects the given constraint has on the variable bounds.*
- unsigned `removeBound` (const `FormulaT` &\_formula, const `T` &\_origin)
- unsigned `removeBound` (const `ConstraintT` &\_constraint, const `T` &\_origin, carl::Variable \*&\_changed)
- *Removes all effects the given constraint has on the variable bounds.*
- const `EvalRationalIntervalMap` & `getEvalIntervalMap` () const
- Creates an evalintervalmap corresponding to the variable bounds.*
- const `RationalInterval` & `getInterval` (const carl::Variable &\_var) const
- Creates an interval corresponding to the variable bounds of the given variable.*
- `RationalInterval` `getInterval` (carl::Monomial::Arg \_mon) const
- Creates an interval corresponding to the bounds of the given monomial.*
- `RationalInterval` `getInterval` (const `TermT` &\_term) const
- Creates an interval corresponding to the bounds of the given term.*
- const `smrat::EvalDoubleIntervalMap` & `getIntervalMap` () const
- Creates an interval map corresponding to the variable bounds.*
- const carl::Interval< double > & `getDoubleInterval` (const carl::Variable &\_var) const
- Creates a double interval corresponding to the variable bounds of the given variable.*
- std::vector< `T` > `getOriginsOfBounds` (const carl::Variable &\_var) const
- std::set< `T` > `getOriginSetOfBounds` (const carl::Variable &\_var) const
- std::vector< `T` > `getOriginsOfBounds` (const carl::Variables &\_variables) const
- std::set< `T` > `getOriginSetOfBounds` (const carl::Variables &\_variables) const
- std::vector< `T` > `getOriginsOfBounds` () const
- Collect the origins to the supremums and infimums of all variables.*
- std::set< `T` > `getOriginSetOfBounds` () const
- std::vector< std::pair< std::vector< `ConstraintT` >, `ConstraintT` > > `getBoundDeductions` () const
- void `print` (std::ostream &\_out=std::cout, const std::string \_init="", bool \_printAllBounds=false) const
- Prints the variable bounds.*
- bool `isConflicting` () const
- std::set< `T` > `getConflict` () const

### 0.15.586.1 Detailed Description

```
template<typename T>
class smrat::vb::VariableBounds< T >
```

Class to manage the bounds of a variable.

### 0.15.586.2 Member Typedef Documentation

**0.15.586.2.1 ConstraintBoundMap** template<typename `T` >  
 typedef std::map<`ConstraintT`, const `Bound<T>*> smrat::vb::VariableBounds< T >::ConstraintBoundMap  
 A map from Constraint pointers to Bound pointers.`

**0.15.586.2.2 VariableMap** template<typename `T` >  
 typedef carl::FastMap<carl::Variable, `Variable<T>*> smrat::vb::VariableBounds< T >::VariableMap  
 A hash-map from arithmetic variables to variables managing the bounds.`

### 0.15.586.3 Constructor & Destructor Documentation

**0.15.586.3.1 VariableBounds()** template<typename T >  
`smtrat::vb::VariableBounds< T >::VariableBounds ( )`  
Constructs a variable bounds manager.

**0.15.586.3.2 ~VariableBounds()** template<typename T >  
`smtrat::vb::VariableBounds< T >::~VariableBounds ( )`  
Destructs a variable bounds manager.

#### 0.15.586.4 Member Function Documentation

**0.15.586.4.1 addBound() [1/2]** template<typename T >  
`bool smtrat::vb::VariableBounds< T >::addBound (`  
`const ConstraintT & _constraint,`  
`const T & _origin )`

Updates the variable bounds by the given constraint.

##### Parameters

|                          |                                     |
|--------------------------|-------------------------------------|
| <code>_constraint</code> | The constraint to consider.         |
| <code>_origin</code>     | The origin of the given constraint. |

##### Returns

true, if the variable bounds have been changed; false, otherwise.

**0.15.586.4.2 addBound() [2/2]** template<typename T >  
`bool smtrat::vb::VariableBounds< T >::addBound (`  
`const FormulaT & _formula,`  
`const T & _origin )`

**0.15.586.4.3 clear()** template<typename T >  
`void smtrat::vb::VariableBounds< T >::clear ( )`

**0.15.586.4.4 empty()** template<typename T >  
`bool smtrat::vb::VariableBounds< T >::empty ( ) const [inline]`

**0.15.586.4.5 getBoundDeductions()** template<typename T >  
`std::vector<std::pair<std::vector<ConstraintT>, ConstraintT> > smtrat::vb::VariableBounds< T >::getBoundDeductions ( ) const`

##### Returns

The deductions which this variable bounds manager has detected.

**0.15.586.4.6 getConflict()** template<typename T >  
`std::set<T> smtrat::vb::VariableBounds< T >::getConflict ( ) const [inline]`

##### Returns

The origins which cause the conflict. This method can only be called, if there is a conflict.

**0.15.586.4.7 getDoubleInterval()** template<typename T >  
const carl::Interval<double>& smtrat::vb::VariableBounds< T >::getDoubleInterval (

    const carl::Variable & \_var ) const

Creates a double interval corresponding to the variable bounds of the given variable.

#### Parameters

|      |                                                                     |
|------|---------------------------------------------------------------------|
| _var | The variable to compute the variable bounds as double interval for. |
|------|---------------------------------------------------------------------|

#### Returns

The variable bounds as a double interval.

**0.15.586.4.8 getEvalIntervalMap()** template<typename T >  
const EvalRationalIntervalMap& smtrat::vb::VariableBounds< T >::getEvalIntervalMap ( ) const

Creates an evalintervalmap corresponding to the variable bounds.

#### Returns

The variable bounds as an evalintervalmap.

**0.15.586.4.9 getInterval() [1/3]** template<typename T >  
RationalInterval smtrat::vb::VariableBounds< T >::getInterval (

    carl::Monomial::Arg \_mon ) const

Creates an interval corresponding to the bounds of the given monomial.

#### Parameters

|      |                                                     |
|------|-----------------------------------------------------|
| _mon | The monomial to compute the bounds as interval for. |
|------|-----------------------------------------------------|

#### Returns

The monomial bounds as an interval.

**0.15.586.4.10 getInterval() [2/3]** template<typename T >  
const RationalInterval& smtrat::vb::VariableBounds< T >::getInterval (

    const carl::Variable & \_var ) const

Creates an interval corresponding to the variable bounds of the given variable.

#### Parameters

|      |                                                              |
|------|--------------------------------------------------------------|
| _var | The variable to compute the variable bounds as interval for. |
|------|--------------------------------------------------------------|

#### Returns

The variable bounds as an interval.

**0.15.586.4.11 getInterval() [3/3]** template<typename T >  
RationalInterval smtrat::vb::VariableBounds< T >::getInterval (

    const TermT & \_term ) const

Creates an interval corresponding to the bounds of the given term.

**Parameters**

|                    |                                                 |
|--------------------|-------------------------------------------------|
| <code>_term</code> | The term to compute the bounds as interval for. |
|--------------------|-------------------------------------------------|

**Returns**

The term bounds as an interval.

**0.15.586.4.12 `getIntervalMap()`** template<typename T >  
const `smtrat::EvalDoubleIntervalMap& smtrat::vb::VariableBounds< T >::getIntervalMap ( ) const`  
Creates an interval map corresponding to the variable bounds.

**Returns**

The variable bounds as an interval map.

**0.15.586.4.13 `getOriginSetOfBounds()` [1/3]** template<typename T >  
`std::set<T> smtrat::vb::VariableBounds< T >::getOriginSetOfBounds ( ) const`

**0.15.586.4.14 `getOriginSetOfBounds()` [2/3]** template<typename T >  
`std::set<T> smtrat::vb::VariableBounds< T >::getOriginSetOfBounds (`  
`const carl::Variable & _var ) const`

**0.15.586.4.15 `getOriginSetOfBounds()` [3/3]** template<typename T >  
`std::set<T> smtrat::vb::VariableBounds< T >::getOriginSetOfBounds (`  
`const carl::Variables & _variables ) const`

**0.15.586.4.16 `getOriginsOfBounds()` [1/3]** template<typename T >  
`std::vector<T> smtrat::vb::VariableBounds< T >::getOriginsOfBounds ( ) const`  
Collect the origins to the supremums and infimums of all variables.

**Returns**

A set of origins corresponding to the supremums and infimums of all variables.

**0.15.586.4.17 `getOriginsOfBounds()` [2/3]** template<typename T >  
`std::vector<T> smtrat::vb::VariableBounds< T >::getOriginsOfBounds (`  
`const carl::Variable & _var ) const`

**Parameters**

|                   |                                                |
|-------------------|------------------------------------------------|
| <code>_var</code> | The variable to get origins of the bounds for. |
|-------------------|------------------------------------------------|

**Returns**

The origin constraints of the supremum and infimum of the given variable.

**0.15.586.4.18 `getOriginsOfBounds()` [3/3]** template<typename T >

```
std::vector<T> smtrat::vb::VariableBounds< T >::getOriginsOfBounds (
 const carl::Variables & _variables) const
```

**Parameters**

|                         |                                                 |
|-------------------------|-------------------------------------------------|
| <code>_variables</code> | The variables to get origins of the bounds for. |
|-------------------------|-------------------------------------------------|

**Returns**

The origin constraints of the supremum and infimum of the given variables.

**0.15.586.4.19 `isConflicting()`** template<typename T >  
`bool smtrat::vb::VariableBounds< T >::isConflicting ( ) const [inline]`

**Returns**

true, if there is a conflicting variable; false, otherwise.

**0.15.586.4.20 `print()`** template<typename T >  
`void smtrat::vb::VariableBounds< T >::print (
 std::ostream & _out = std::cout,
 const std::string _init = "",
 bool _printAllBounds = false ) const`

Prints the variable bounds.

**Parameters**

|                              |                                                                                  |
|------------------------------|----------------------------------------------------------------------------------|
| <code>_out</code>            | The output stream to print on.                                                   |
| <code>_init</code>           | A string which is displayed at the beginning of every row.                       |
| <code>_printAllBounds</code> | A flag that indicates whether to print also the bounds of each variable (=true). |

**0.15.586.4.21 `removeBound()` [1/3]** template<typename T >  
`unsigned smtrat::vb::VariableBounds< T >::removeBound (
 const ConstraintT & _constraint,
 const T & _origin )`

Removes all effects the given constraint has on the variable bounds.

**Parameters**

|                          |                                                                        |
|--------------------------|------------------------------------------------------------------------|
| <code>_constraint</code> | The constraint, which effects shall be undone for the variable bounds. |
| <code>_origin</code>     | The origin of the given constraint.                                    |

**Returns**

2, if the variables supremum or infimum have been changed; 1, if the constraint was a (not the strictest) bound;  
0, otherwise.

**0.15.586.4.22 `removeBound()` [2/3]** template<typename T >  
`unsigned smtrat::vb::VariableBounds< T >::removeBound (
 const ConstraintT & _constraint,`

```
 const T & _origin,
 carl::Variable *& _changedVariable)
```

Removes all effects the given constraint has on the variable bounds.

#### Parameters

|                               |                                                                                |
|-------------------------------|--------------------------------------------------------------------------------|
| <code>_constraint</code>      | The constraint, which effects shall be undone for the variable bounds.         |
| <code>_origin</code>          | The origin of the given constraint.                                            |
| <code>_changedVariable</code> | The variable whose interval domain has been changed, if the return value is 2. |

#### Returns

2, if the variables supremum or infimum have been changed; 1, if the constraint was a (not the strictest) bound; 0, otherwise.

### 0.15.586.4.23 `removeBound()` [3/3] template<typename T>

```
unsigned smrat::vb::VariableBounds< T >::removeBound (
 const FormulaT & _formula,
 const T & _origin)
```

## 0.15.587 smrat::VariableCapsule Class Reference

```

### 0.15.592 smtrat::VariantMap< Key, Value > Class Template Reference

This class is a specialization of `std::map` where the keys are of arbitrary type and the values are of type `boost::variant`.

```
#include <VariantMap.h>
```

#### Public Member Functions

- template<typename T , typename Output >  
`void assertType` (const Key &key, Output out) const  
*Asserts that the value that is associated with the given key has a specified type.*
- template<typename T >  
`bool has` (const Key &key) const  
*Checks if there is a value of the specified type for the given key.*
- template<typename T >  
`const T & get` (const Key &key) const  
*Returns the value associated with the given key as type T.*

#### Data Fields

- K keys  
*STL member.*
- T elements  
*STL member.*

#### 0.15.592.1 Detailed Description

```
template<typename Key, typename Value>
class smtrat::VariantMap< Key, Value >
```

This class is a specialization of `std::map` where the keys are of arbitrary type and the values are of type `boost::variant`.

There is no point in using this class if the values are no variants. Most probably, it would not compile anyway and fail to do so with a large bunch of compiler errors. To prevent this, we assert that the value type is indeed a `boost::variant`.

Additionally to the standard methods inherited from `std::map`, it implements three additional methods:

- `assertType<T>(key, out)`: Asserts that there is a value for the given key and that it has the type `T`. If this is not the case, an appropriate error is written to `out`.
- `has<T>(key)`: Checks if there is a value for the given key and if this value has the type `T`.
- `get<T>(key)`: Returns the value for the given key as type `T`.

#### Template Parameters

|                    |                 |
|--------------------|-----------------|
| <code>Key</code>   | Type of keys.   |
| <code>Value</code> | Type of values. |

#### 0.15.592.2 Member Function Documentation

```
0.15.592.2.1 assertType() template<typename Key , typename Value >
template<typename T , typename Output >
void smtrat::VariantMap< Key, Value >::assertType (
 const Key & key,
 Output out) const [inline]
```

Asserts that the value that is associated with the given key has a specified type.

The assertion holds, if

- there is a value in the map for the given key and
- the stored value has the type `T`.

#### Template Parameters

|                     |                                  |
|---------------------|----------------------------------|
| <code>T</code>      | Type that the value should have. |
| <code>Output</code> | Type of out.                     |

#### Parameters

|                  |                                     |
|------------------|-------------------------------------|
| <code>key</code> | Key.                                |
| <code>out</code> | Functor returning an output stream. |

```
0.15.592.2.2 get() template<typename Key , typename Value >
template<typename T >
const T& smtrat::VariantMap< Key, Value >::get (
 const Key & key) const [inline]
```

Returns the value associated with the given key as type `T`.

#### Template Parameters

|                |                    |
|----------------|--------------------|
| <code>T</code> | Type of the value. |
|----------------|--------------------|

**Parameters**

|            |      |
|------------|------|
| <i>key</i> | Key. |
|------------|------|

**Returns**

Value of key as type T.

**0.15.592.2.3 has()** template<typename Key , typename Value >  
template<typename T >

bool smtrat::VariantMap< Key, Value >::has (

    const Key & *key* ) const [inline]

Checks if there is a value of the specified type for the given key.

**Template Parameters**

|          |                                  |
|----------|----------------------------------|
| <i>T</i> | Type that the value should have. |
|----------|----------------------------------|

**Parameters**

|            |      |
|------------|------|
| <i>key</i> | Key. |
|------------|------|

**Returns**

If there is a value of this type.

**0.15.592.3 Field Documentation**

**0.15.592.3.1 elements** T std::map< K, T >::elements [inherited]  
STL member.

**0.15.592.3.2 keys** K std::map< K, T >::keys [inherited]  
STL member.

**0.15.593 smtrat::parser::conversion::VariantVariantConverter< Res > Struct Template Reference**

Converts variants to another variant type not using the [Converter](#) class.

```
#include <Conversions.h>
```

**Public Types**

- **typedef Res result\_type**

**Public Member Functions**

### 0.15.594.1 Detailed Description

Base class for variable schedulers.

Removes the need to implement stubs.

During instantiation, the Scheduler is constructed with a const [SATModule](#)& as parameter.

### 0.15.594.2 Constructor & Destructor Documentation

```
0.15.594.2.1 VarSchedulerBase() template<typename BaseModule >
smtrat::VarSchedulerBase::VarSchedulerBase (
 BaseModule & baseModule) [inline]
```

### 0.15.594.3 Member Function Documentation

```
0.15.594.3.1 attachClause() void smtrat::VarSchedulerBase::attachClause (
 Minisat::CRef) [inline]
```

```
0.15.594.3.2 decreaseActivity() void smtrat::VarSchedulerBase::decreaseActivity (
 Minisat::Var) [inline]
```

```
0.15.594.3.3 detachClause() void smtrat::VarSchedulerBase::detachClause (
 Minisat::CRef) [inline]
```

```
0.15.594.3.4 empty() bool smtrat::VarSchedulerBase::empty () [inline]
Check if empty.
```

```
0.15.594.3.5 increaseActivity() void smtrat::VarSchedulerBase::increaseActivity (
 Minisat::Var) [inline]
```

**0.15.594.3.6 `insert()`** void smrat::VarSchedulerBase::insert ( Minisat::Var ) [inline]

Insert a variable.

If already contained, do nothing.

**0.15.594.3.7 `pop()`** Minisat::Lit smrat::VarSchedulerBase::pop ( ) [inline]

Returns the next variable to be decided.

Returns and removes the next variable to be decided.

**0.15.594.3.8 `print()`** void smrat::VarSchedulerBase::print ( ) const [inline]

Check if variable is contained.

Print.

**0.15.594.3.9 `rebuild()`** void smrat::VarSchedulerBase::rebuild ( ) [inline]

Rebuild heap.

**0.15.594.3.10 `rebuildActivities()`** void smrat::VarSchedulerBase::rebuildActivities ( ) [inline]

**0.15.594.3.11 `rebuildTheoryVars()`** template<typename Constraints >  
void smrat::VarSchedulerBase::rebuildTheoryVars ( const Constraints & ) [inline]

**0.15.594.3.12 `relocateClauses()`** void smrat::VarSchedulerBase::relocateClauses ( std::function< void(Minisat::CRef &) > ) [inline]

## 0.15.594.4 Field Documentation

**0.15.594.4.1 `abstractLiteral`** std::function<const Minisat::Lit (const FormulaT&)> smrat::VarSchedulerBase::abstractLiteral [protected]

### 0.15.597.1 Detailed Description

Base class for all MCSAT variable scheduler.  
Should not be used directly.

### 0.15.597.2 Constructor & Destructor Documentation

**0.15.597.2.1 VarSchedulerMcsatBase()** template<typename BaseModule >  
smtrat::VarSchedulerMcsatBase::VarSchedulerMcsatBase (

```
 BaseModule & baseModule) [inline]
```

### 0.15.597.3 Member Function Documentation

**0.15.597.3.1 attachClause()** void smtrat::VarSchedulerBase::attachClause (

```
 Minisat::CRef) [inline], [inherited]
```

**0.15.597.3.2 decreaseActivity()** void smtrat::VarSchedulerBase::decreaseActivity (

```
 Minisat::Var) [inline], [inherited]
```

**0.15.597.3.3 detachClause()** void smtrat::VarSchedulerBase::detachClause (

```
 Minisat::CRef) [inline], [inherited]
```

**0.15.597.3.4 empty()** bool smtrat::VarSchedulerBase::empty ( ) [inline], [inherited]  
Check if empty.

**0.15.597.3.5 increaseActivity()** void smtrat::VarSchedulerBase::increaseActivity (

```
 Minisat::Var) [inline], [inherited]
```

**0.15.597.3.6 insert()** void smtrat::VarSchedulerBase::insert (

```
 Minisat::Var) [inline], [inherited]
```

Insert a variable.  
If already contained, do nothing.

**0.15.597.3.7 pop()** Minisat::Lit smtrat::VarSchedulerBase::pop ( ) [inline], [inherited]  
Returns the next variable to be decided.  
Returns and removes the next variable to be decided.

**0.15.597.3.8 print()** void smtrat::VarSchedulerBase::print ( ) const [inline], [inherited]  
Check if variable is contained.  
Print.

**0.15.597.3.9 rebuild()** void smtrat::VarSchedulerBase::rebuild ( ) [inline], [inherited]  
Rebuild heap.

**0.15.597.3.10 rebuildActivities()** void smtrat::VarSchedulerBase::rebuildActivities ( ) [inline], [inherited]

**0.15.597.3.11 rebuildTheoryVars()** template<typename Constraints >  
void smtrat::VarSchedulerBase::rebuildTheoryVars (  
    const Constraints & ) [inline], [inherited]

**0.15.597.3.12 relocateClauses()** void smtrat::VarSchedulerBase::relocateClauses (

 TheoryError & errors) const [inline]
```

## 0.15.607 smtrat::subtropical::Vertex Struct Reference

Represents a term of an original constraint and assigns him a rating variable if a weak separator is searched.  
`#include <Subtropical.h>`

## Public Member Functions

- `Vertex (const TermT &term)`
- `carl::Variable rating () const`

## Data Fields

- const [Rational coefficient](#)  
*Coefficient of the assigned term.*
- const [carl::Monomial::Arg monomial](#)  
*Monomial of the assigned term.*
- std::optional< [carl::Variable](#) > [m\\_rating](#)  
*Rating variable of the term for a weak separator.*

### 0.15.607.1 Detailed Description

Represents a term of an original constraint and assigns him a rating variable if a weak separator is searched.

### 0.15.607.2 Constructor & Destructor Documentation

**0.15.607.2.1 Vertex()** `smtrat::subtropical::Vertex::Vertex (`  
  `const TermT & term ) [inline]`

### 0.15.607.3 Member Function Documentation

**0.15.607.3.1 rating()** `carl::Variable smtrat::subtropical::Vertex::rating ( ) const [inline]`

### 0.15.607.4 Field Documentation

**0.15.607.4.1 coefficient** `const Rational smtrat::subtropical::Vertex::coefficient`  
Coefficient of the assigned term.

**0.15.607.4.2 m\_rating** `std::optional<carl::Variable> smtrat::subtropical::Vertex::m_rating [mutable]`  
Rating variable of the term for a weak separator.

**0.15.607.4.3 monomial** `const carl::Monomial::Arg smtrat::subtropical::Vertex::monomial`  
Monomial of the assigned term.

*Removes everything related to the sub-formula to remove from the passed formula in the backends of this module.*
- void [clearPassedFormula](#) ()
 

*Merges the two vectors of sets into the first one.*
- std::vector< [FormulaT](#) > [merge](#) (const std::vector< [FormulaT](#) > &, const std::vector< [FormulaT](#) > &) const
 

*Checks whether given the current branching value and branching variable/polynomial it is (highly) probable that this branching is part of an infinite loop of branchings.*
- bool [branchAt](#) (const [Poly](#) &\_polynomial, bool \_integral, const [Rational](#) &\_value, std::vector< [FormulaT](#) > &&\_premise, bool \_leftCaseWeak=true, bool \_preferLeftCase=true, bool \_useReceivedFormulaAsPremise=false)
 

*Adds a lemmas which provoke a branching for the given variable at the given value, if this module returns Unknown and there exists a preceding SATModule.*
- bool [branchAt](#) (const [Poly](#) &\_polynomial, bool \_integral, const [Rational](#) &\_value, bool \_leftCaseWeak=true, bool \_preferLeftCase=true, bool \_useReceivedFormulaAsPremise=false, const std::vector< [FormulaT](#) > &←\_premise=std::vector< [FormulaT](#) >())
 

*Adds a lemmas which provoke a branching for the given variable at the given value, if this module returns Unknown and there exists a preceding SATModule.*
- bool [branchAt](#) (carl::Variable::Arg \_var, const [Rational](#) &\_value, std::vector< [FormulaT](#) > &&\_premise, bool \_leftCaseWeak=true, bool \_preferLeftCase=true, bool \_useReceivedFormulaAsPremise=false)
 

*Adds a lemmas which provoke a branching for the given variable at the given value, if this module returns Unknown and there exists a preceding SATModule.*
- bool [branchAt](#) (carl::Variable::Arg \_var, const [Rational](#) &\_value, bool \_leftCaseWeak=true, bool \_preferLeftCase=true, bool \_useReceivedFormulaAsPremise=false, const std::vector< [FormulaT](#) > &\_premise=std::vector< [FormulaT](#) >())
 

*Adds a lemmas which provoke a branching for the given variable at the given value, if this module returns Unknown and there exists a preceding SATModule.*
- void [splitUnequalConstraint](#) (const [FormulaT](#) &)
 

*Adds the following lemmas for the given constraint p!=0.*
- unsigned [checkModel](#) () const
 

*Gets all InformationRelevantFormulas.*
- void [addInformationRelevantFormula](#) (const [FormulaT](#) &formula)
 

*Adds a formula to the InformationRelevantFormula.*
- const std::set< [FormulaT](#) > & [getInformationRelevantFormulas](#) ()
 

*Gets all InformationRelevantFormulas.*
- bool [isLemmaLevel](#) ([LemmaLevel](#) level)
 

*Checks if current lemma level is greater or equal to given level.*

## Static Protected Member Functions

- static bool `modelsDisjoint` (const `Model` &\_modelA, const `Model` &\_modelB)

*Checks whether there is no variable assigned by both models.*

## Protected Attributes

- `std::vector<FormulaSetT> mInfeasibleSubsets`

*Stores the infeasible subsets.*

- `Manager *const mpManager`

*A reference to the manager.*

- `Model mModel`

*Stores the assignment of the current satisfiable result, if existent.*

- `std::vector<Model> mAllModels`

*Stores all satisfying assignments.*

- `bool mModelComputed`

*True, if the model has already been computed.*

- `bool mFinalCheck`

*true, if the check procedure should perform a final check which especially means not to postpone splitting decisions*

- `bool mFullCheck`

*false, if this module should avoid too expensive procedures and rather return unknown instead.*

- `carl::Variable mObjectiveVariable`

*Objective variable to be minimized. If set to NO\_VARIABLE, a normal sat check should be performed.*

- `std::vector<TheoryPropagation> mTheoryPropagations`

- `std::atomic<Answer> mSolverState`

*States whether the received formula is known to be satisfiable or unsatisfiable otherwise it is set to unknown.*

- `std::atomic_bool * mBackendsFoundAnswer`

*This flag is passed to any backend and if it determines an answer to a prior check call, this flag is fired.*

- `Conditionals mFoundAnswer`

*Vector of Booleans: If any of them is true, we have to terminate a running check procedure.*

- `std::vector<Module *> mUsedBackends`

*The backends of this module which are currently used (conditions to use this module are fulfilled for the passed formula).*

- `std::vector<Module *> mAllBackends`

*The backends of this module which have been used.*

- `std::vector<Lemma> mLemmas`

*Stores the lemmas being valid formulas this module or its backends made.*

- `ModuleInput::iterator mFirstSubformulaToPass`

*Stores the position of the first sub-formula in the passed formula, which has not yet been considered for a consistency check of the backends.*

- `carl::FastSet<FormulaT> mConstraintsToInform`

*Stores the constraints which the backends must be informed about.*

- `carl::FastSet<FormulaT> mInformedConstraints`

*Stores the position of the first constraint of which no backend has been informed about.*

- `ModuleInput::const_iterator mFirstUncheckedReceivedSubformula`

*Stores the position of the first (by this module) unchecked sub-formula of the received formula.*

- `unsigned mSmallerMusesCheckCounter`

*Counter used for the generation of the smt2 files to check for smaller muses.*

- `std::vector<std::size_t> mVariableCounters`

*Maps variables to the number of their occurrences.*

### 0.15.608.1 Member Typedef Documentation

**0.15.608.1.1 SettingsType** template<class Settings >  
 typedef `Settings smtrat::VSModule< Settings >::SettingsType`

### 0.15.608.2 Member Enumeration Documentation

**0.15.608.2.1 LemmaType** enum `smtrat::Module::LemmaType` : unsigned [strong], [inherited]

Enumerator

|           |  |
|-----------|--|
| NORMAL    |  |
| PERMANENT |  |

### 0.15.608.3 Constructor & Destructor Documentation

**0.15.608.3.1 VSModule()** template<class Settings >  
`smtrat::VSModule< Settings >::VSModule` (  
 const `ModuleInput` \* ,  
`Conditionals` & ,  
`Manager` \* const = `NULL` )

**0.15.608.3.2 ~VSModule()** template<class Settings >  
`smtrat::VSModule< Settings >::~VSModule` ( )

### 0.15.608.4 Member Function Documentation

**0.15.608.4.1 add()** bool `smtrat::Module::add` (  
`ModuleInput::const_iterator` `_subformula`) [inherited]

The module has to take the given sub-formula of the received formula into account.

Parameters

|                          |                                                    |
|--------------------------|----------------------------------------------------|
| <code>_subformula</code> | The sub-formula to take additionally into account. |
|--------------------------|----------------------------------------------------|

Returns

false, if it can be easily decided that this sub-formula causes a conflict with the already considered sub-formulas; true, otherwise.

**0.15.608.4.2 addConstraintToInform()** void `smtrat::Module::addConstraintToInform` (  
`const FormulaT & _constraint`) [protected], [virtual], [inherited]

Adds a constraint to the collection of constraints of this module, which are informed to a freshly generated backend.

**Parameters**

|                          |                        |
|--------------------------|------------------------|
| <code>_constraint</code> | The constraint to add. |
|--------------------------|------------------------|

Reimplemented in [smtrat::SATModule< Settings >](#).

**0.15.608.4.3 `addCore()`** `template<class Settings >`

```
bool smtrat::VSModule< Settings >::addCore (
 ModuleInput::const_iterator formula) [virtual]
```

The module has to take the given sub-formula of the received formula into account.

**Parameters**

|                      |                                                    |
|----------------------|----------------------------------------------------|
| <code>formula</code> | The sub-formula to take additionally into account. |
|----------------------|----------------------------------------------------|

**Returns**

false, if it can be easily decided that this sub-formula causes a conflict with the already considered sub-formulas; true, otherwise.

Reimplemented from [smtrat::Module](#).

**0.15.608.4.4 `addInformationRelevantFormula()`** `void smtrat::Module::addInformationRelevantFormula`

```
(
 const FormulaT & formula) [protected], [inherited]
```

Adds a formula to the InformationRelevantFormula.

**Parameters**

|                      |                |
|----------------------|----------------|
| <code>formula</code> | Formula to add |
|----------------------|----------------|

**0.15.608.4.5 `addLemma()`** `void smtrat::Module::addLemma`

```
(
 const FormulaT & _lemma,
 const LemmaType & _lt = LemmaType::NORMAL,
 const FormulaT & _preferredFormula = FormulaT(carl::FormulaType::TRUE)) [inline],
[inherited]
```

Stores a lemma being a valid formula.

**Parameters**

|                                |                                                                       |
|--------------------------------|-----------------------------------------------------------------------|
| <code>_lemma</code>            | The eduction/lemma to store.                                          |
| <code>_lt</code>               | The type of the lemma.                                                |
| <code>_preferredFormula</code> | Hint for the next decision, which formula should be assigned to true. |

**0.15.608.4.6 `addOrigin()`** `void smtrat::Module::addOrigin`

```
(
 ModuleInput::iterator _formula,
 const FormulaT & _origin) [inline], [protected], [inherited]
```

Adds the given set of formulas in the received formula to the origins of the given passed formula.

**Parameters**

|                       |                                                           |
|-----------------------|-----------------------------------------------------------|
| <code>_formula</code> | The passed formula to set the origins for.                |
| <code>_origin</code>  | A set of formulas in the received formula of this module. |

**0.15.608.4.7 addReceivedSubformulaToPassedFormula()** `std::pair<ModuleInput::iterator,bool>`

```
smrat::Module::addReceivedSubformulaToPassedFormula (
 ModuleInput::const_iterator _subformula) [inline], [protected], [inherited]
```

Copies the given sub-formula of the received formula to the passed formula.

Note, that there is always a link between sub-formulas of the passed formulas to sub-formulas of the received formulas, which are responsible for its occurrence.

**Parameters**

|                          |                                                  |
|--------------------------|--------------------------------------------------|
| <code>_subformula</code> | The sub-formula of the received formula to copy. |
|--------------------------|--------------------------------------------------|

**0.15.608.4.8 addSubformulaToPassedFormula() [1/3]** `std::pair<ModuleInput::iterator,bool>`

```
smrat::Module::addSubformulaToPassedFormula (
 const FormulaT & _formula) [inline], [protected], [inherited]
```

Adds the given formula to the passed formula with no origin.

Note that in the next call of this module's removeSubformula, all formulas in the passed formula without origins will be removed.

**Parameters**

|                       |                                           |
|-----------------------|-------------------------------------------|
| <code>_formula</code> | The formula to add to the passed formula. |
|-----------------------|-------------------------------------------|

**Returns**

A pair to the position where the formula to add has been inserted (or its first sub-formula which has not yet been in the passed formula, in case the formula to add is a conjunction), and a Boolean stating whether anything has been added to the passed formula.

**0.15.608.4.9 addSubformulaToPassedFormula() [2/3]** `std::pair<ModuleInput::iterator,bool>`

```
smrat::Module::addSubformulaToPassedFormula (
 const FormulaT & _formula,
 const FormulaT & _origin) [inline], [protected], [inherited]
```

Adds the given formula to the passed formula.

**Parameters**

|                       |                                                                                                                           |
|-----------------------|---------------------------------------------------------------------------------------------------------------------------|
| <code>_formula</code> | The formula to add to the passed formula.                                                                                 |
| <code>_origin</code>  | The sub-formula of the received formula being responsible for the occurrence of the formula to add to the passed formula. |

**Returns**

A pair to the position where the formula to add has been inserted (or its first sub-formula which has not yet been in the passed formula, in case the formula to add is a conjunction), and a Boolean stating whether anything has been added to the passed formula.

```
0.15.608.4.10 addSubformulaToPassedFormula() [3/3] std::pair<ModuleInput::iterator,bool>
smrat::Module::addSubformulaToPassedFormula (
 const FormulaT & _formula,
 const std::shared_ptr< std::vector< FormulaT >> & _origins) [inline], [protected],
[inherited]
```

Adds the given formula to the passed formula.

#### Parameters

|                       |                                                                                                                                         |
|-----------------------|-----------------------------------------------------------------------------------------------------------------------------------------|
| <code>_formula</code> | The formula to add to the passed formula.                                                                                               |
| <code>_origins</code> | The link of the formula to add to the passed formula to sub-formulas of the received formulas, which are responsible for its occurrence |

#### Returns

A pair to the position where the formula to add has been inserted (or its first sub-formula which has not yet been in the passed formula, in case the formula to add is a conjunction), and a Boolean stating whether anything has been added to the passed formula.

```
0.15.608.4.11 allModels() const std::vector<Model>& smrat::Module::allModels () const [inline],
[inherited]
```

#### Returns

All satisfying assignments, if existent.

```
0.15.608.4.12 anAnswerFound() bool smrat::Module::anAnswerFound () const [inline], [protected],
[inherited]
```

Checks for all antecedent modules and those which run in parallel with the same antecedent modules, whether one of them has determined a result.

#### Returns

True, if one of them has determined a result.

```
0.15.608.4.13 answerFound() const smrat::Conditionals& smrat::Module::answerFound () const
[inline], [inherited]
```

#### Returns

A vector of Booleans: If any of them is true, we have to terminate a running check procedure.

```
0.15.608.4.14 backendsModel() const Model & smrat::Module::backendsModel () const [protected],
[inherited]
```

Stores the model of a backend which determined satisfiability of the passed formula in the model of this module.

```
0.15.608.4.15 branchAt() [1/4] bool smtrat::Module::branchAt (
 carl::Variable::Arg _var,
 const Rational & _value,
 bool _leftCaseWeak = true,
 bool _preferLeftCase = true,
 bool _useReceivedFormulaAsPremise = false,
 const std::vector< FormulaT > & _premise = std::vector<FormulaT>()) [inline],
[protected], [inherited]
```

```
0.15.608.4.16 branchAt() [2/4] bool smtrat::Module::branchAt (
 carl::Variable::Arg _var,
 const Rational & _value,
 std::vector< FormulaT > && _premise,
 bool _leftCaseWeak = true,
 bool _preferLeftCase = true,
 bool _useReceivedFormulaAsPremise = false) [inline], [protected], [inherited]
```

```
0.15.608.4.17 branchAt() [3/4] bool smtrat::Module::branchAt (
 const Poly & _polynomial,
 bool _integral,
 const Rational & _value,
 bool _leftCaseWeak = true,
 bool _preferLeftCase = true,
 bool _useReceivedFormulaAsPremise = false,
 const std::vector< FormulaT > & _premise = std::vector<FormulaT>()) [inline],
[protected], [inherited]
```

```
0.15.608.4.18 branchAt() [4/4] bool smtrat::Module::branchAt (
 const Poly & _polynomial,
 bool _integral,
 const Rational & _value,
 std::vector< FormulaT > && _premise,
 bool _leftCaseWeak = true,
 bool _preferLeftCase = true,
 bool _useReceivedFormulaAsPremise = false) [protected], [inherited]
```

Adds a lemmas which provoke a branching for the given variable at the given value, if this module returns Unknown and there exists a preceding [SATModule](#).

Note that the given value is rounded down and up, if the given variable is integer-valued.

#### Parameters

|                                           |                                                                                                                                                                                                                |
|-------------------------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>_polynomial</code>                  | The variable to branch for.                                                                                                                                                                                    |
| <code>_integral</code>                    | A flag being true, if all variables in the polynomial to branch for are integral.                                                                                                                              |
| <code>_value</code>                       | The value to branch at.                                                                                                                                                                                        |
| <code>_premise</code>                     | The sub-formulas of the received formula from which the branch is followed. Note, that a premise is not necessary, as every branch is a valid formula. But a premise can prevent from branching unnecessarily. |
| <code>_leftCaseWeak</code>                | true, if a branching in the form of (or ( $\leq p b$ ) ( $> p b$ )) is desired. false, if a branching in the form of (or ( $< p b$ ) ( $\geq p b$ )) is desired.                                               |
| <code>_preferLeftCase</code>              | true, if the left case (polynomial less(or equal) 0 shall be chosen first. false, otherwise.                                                                                                                   |
| <code>_useReceivedFormulaAsPremise</code> | true, if the whole received formula should be used as premise                                                                                                                                                  |

```
0.15.608.4.19 check() Answer smtrat::Module::check (
 bool _final = false,
 bool _full = true,
 carl::Variable _objective = carl::Variable::NO_VARIABLE) [virtual], [inherited]
```

Checks the received formula for consistency.

Note, that this is an implementation of the satisfiability check of the conjunction of the so far received formulas, which does actually nothing but passing the problem to its backends. This implementation is only used internally and must be overwritten by any derived module.

#### Parameters

|                   |                                                                                                                                       |
|-------------------|---------------------------------------------------------------------------------------------------------------------------------------|
| <i>_final</i>     | true, if this satisfiability check will be the last one (for a global sat-check), if its result is SAT                                |
| <i>_full</i>      | false, if this module should avoid too expensive procedures and rather return unknown instead.                                        |
| <i>_objective</i> | if not set to NO_VARIABLE, the module should find an assignment minimizing this objective variable; otherwise any assignment is good. |

#### Returns

True, if the received formula is satisfiable; False, if the received formula is not satisfiable; Unknown, otherwise.

Reimplemented in [smtrat::PModule](#).

```
0.15.608.4.20 checkCore() template<class Settings >
Answer smtrat::VSModule< Settings >::checkCore () [virtual]
```

Checks the received formula for consistency.

#### Parameters

|                   |                                                                                                                                       |
|-------------------|---------------------------------------------------------------------------------------------------------------------------------------|
| <i>_final</i>     | true, if this satisfiability check will be the last one (for a global sat-check), if its result is SAT.                               |
| <i>_full</i>      | false, if this module should avoid too expensive procedures and rather return unknown instead.                                        |
| <i>_objective</i> | if not set to NO_VARIABLE, the module should find an assignment minimizing this objective variable; otherwise any assignment is good. |

#### Returns

SAT, if the received formula is satisfiable; UNSAT, if the received formula is not satisfiable; Unknown, otherwise.

Reimplemented from [smtrat::Module](#).

```
0.15.608.4.21 checkInfSubsetForMinimality() void smtrat::Module::checkInfSubsetForMinimality (
 std::vector< FormulaSetT >::const_iterator _infssubset,
 const std::string & _filename = "smaller_muses",
 unsigned _maxSizeDifference = 1) const [inherited]
```

Checks the given infeasible subset for minimality by storing all subsets of it, which have a smaller size which differs from the size of the infeasible subset not more than the given threshold.

#### Parameters

|                           |                                                                                                        |
|---------------------------|--------------------------------------------------------------------------------------------------------|
| <i>_infssubset</i>        | The infeasible subset to check for minimality.                                                         |
| <i>_filename</i>          | The name of the file to store the infeasible subsets in order to be able to check their infeasibility. |
| <i>_maxSizeDifference</i> | The maximal difference between the sizes of the subsets compared to the size of the infeasible subset. |

**0.15.608.4.22 `checkModel()`** `unsigned smtrat::Module::checkModel ( ) const [protected], [inherited]`

**Returns**

false, if the current model of this module does not satisfy the current given formula; true, if it cannot be said whether the model satisfies the given formula.

**0.15.608.4.23 `cleanModel()`** `void smtrat::Module::cleanModel ( ) const [inline], [protected], [inherited]`

Substitutes variable occurrences by its model value in the model values of other variables.

**0.15.608.4.24 `clearLemmas()`** `void smtrat::Module::clearLemmas ( ) [inline], [inherited]`  
Deletes all yet found lemmas.

**0.15.608.4.25 `clearModel()`** `void smtrat::Module::clearModel ( ) const [inline], [protected], [inherited]`

Clears the assignment, if any was found.

**0.15.608.4.26 `clearModels()`** `void smtrat::Module::clearModels ( ) const [inline], [protected], [inherited]`

Clears all assignments, if any was found.

**0.15.608.4.27 `clearPassedFormula()`** `void smtrat::Module::clearPassedFormula ( ) [protected], [inherited]`

**0.15.608.4.28 `collectOrigins() [1/2]`** `void smtrat::Module::collectOrigins ( const FormulaT & _formula, FormulaSetT & _origins ) const [inherited]`

**0.15.608.4.29 `collectOrigins() [2/2]`** `void smtrat::Module::collectOrigins ( const FormulaT & _formula, FormulasT & _origins ) const [inherited]`

Collects the formulas in the given formula, which are part of the received formula.

If the given formula directly occurs in the received formula, it is inserted into the given set. Otherwise, the given formula must be of type AND and all its sub-formulas part of the received formula. Hence, they will be added to the given set.

**Parameters**

|                       |                                                                                                      |
|-----------------------|------------------------------------------------------------------------------------------------------|
| <code>_formula</code> | The formula from which to collect the formulas being sub-formulas of the received formula (origins). |
| <code>_origins</code> | The set in which to store the origins.                                                               |

**0.15.608.4.30 `collectTheoryPropagations()`** `void smtrat::Module::collectTheoryPropagations ( ) [inherited]`

**0.15.608.4.31 constraintsToInform()** const carl::FastSet<[FormulaT](#)>& smrat::Module::constraintsToInform( ) const [inline], [inherited]

**Returns**

The constraints which the backends must be informed about.

**0.15.608.4.32 currentlySatisfied()** virtual unsigned smrat::Module::currentlySatisfied( const [FormulaT](#) & ) const [inline], [virtual], [inherited]

**Returns**

0, if the given formula is conflicted by the current model; 1, if the given formula is satisfied by the current model; 2, otherwise; 3, if we do not know anything (default)

Reimplemented in [smrat::LRAbstractModule< Settings >](#), [smrat::LRAbstractModule< LRASettingsICP >](#), and [smrat::LRAbstractModule< LRASettings >](#)

**0.15.608.4.33 currentlySatisfiedByBackend()** unsigned smrat::Module::currentlySatisfiedByBackend( const [FormulaT](#) & \_formula ) const [inherited]

**Returns**

0, if the given formula is conflicted by the current model; 1, if the given formula is satisfied by the current model; 2, otherwise 3, if we do not know anything (default)

**0.15.608.4.34 deinform()** void smrat::Module::deinform( const [FormulaT](#) & \_constraint ) [inherited]

The inverse of informing about a constraint.

All data structures which were kept regarding this constraint are going to be removed. Note, that this makes only sense if it is not likely enough that a formula with this constraint must be solved again.

**Parameters**

|                          |                                                         |
|--------------------------|---------------------------------------------------------|
| <code>_constraint</code> | The constraint to remove from internal data structures. |
|--------------------------|---------------------------------------------------------|

**0.15.608.4.35 deinformCore()** virtual void smrat::Module::deinformCore( const [FormulaT](#) & \_constraint ) [inline], [protected], [virtual], [inherited]

The inverse of informing about a constraint.

All data structures which were kept regarding this constraint are going to be removed. Note, that this makes only sense if it is not likely enough that a formula with this constraint must be solved again.

**Parameters**

|                          |                                                         |
|--------------------------|---------------------------------------------------------|
| <code>_constraint</code> | The constraint to remove from internal data structures. |
|--------------------------|---------------------------------------------------------|

Reimplemented in [smrat::LRAbstractModule< Settings >](#), [smrat::LRAbstractModule< LRASettingsICP >](#), and [smrat::LRAbstractModule< LRASettings >](#)

**0.15.608.4.36 determine\_smallest\_origin()** size\_t smrat::Module::determine\_smallest\_origin( const std::vector< [FormulaT](#) > & origins ) const [protected], [inherited]

## Parameters

|                       |                              |
|-----------------------|------------------------------|
| <code>_origins</code> | A vector of sets of origins. |
|-----------------------|------------------------------|

## Returns

The index of the smallest (regarding the size of the sets) element of origins

**0.15.608.4.37 `eraseSubformulaFromPassedFormula()`** `ModuleInput::iterator smtrat::Module::erase<SubformulaFromPassedFormula (`

```
 ModuleInput::iterator _subformula,
 bool _ignoreOrigins = false) [protected], [virtual], [inherited]
```

Removes everything related to the sub-formula to remove from the passed formula in the backends of this module. Afterwards the sub-formula is removed from the passed formula.

## Parameters

|                             |                                                                                                              |
|-----------------------------|--------------------------------------------------------------------------------------------------------------|
| <code>_subformula</code>    | The sub-formula to remove from the passed formula.                                                           |
| <code>_ignoreOrigins</code> | True, if the sub-formula shall be removed regardless of its origins (should only be applied with expertise). |

## Returns

Reimplemented in `smtrat::ICPModule< Settings >`, `smtrat::ICPModule< ICPSettings4 >`, and `smtrat::ICPModule< ICPSettings1 >`.

**0.15.608.4.38 `excludeNotReceivedVariablesFromModel()`** `void smtrat::Module::excludeNotReceived<VariablesFromModel ( ) const [inherited]`

Excludes all variables from the current model, which do not occur in the received formula.

**0.15.608.4.39 `findBestOrigin()`** `std::vector< FormulaT >::const_iterator smtrat::Module::find<BestOrigin (`

```
 const std::vector< FormulaT > & _origins) const [protected], [inherited]
```

## Parameters

|                       |  |
|-----------------------|--|
| <code>_origins</code> |  |
|-----------------------|--|

## Returns

**0.15.608.4.40 `firstSubformulaToPass()`** `ModuleInput::const_iterator smtrat::Module::firstSubformula<ToPass ( ) const [inline], [inherited]`

## Returns

The position of the first sub-formula in the passed formula, which has not yet been considered for a consistency check of the backends.

**0.15.608.4.41 firstUncheckedReceivedSubformula()** `ModuleInput::const_iterator smtrat::Module::firstUncheckedReceivedSubformula ( ) const [inline], [inherited]`

**Returns**

The position of the first (by this module) unchecked sub-formula of the received formula.

**0.15.608.4.42 freeSplittingVariable()** `static void smtrat::Module::freeSplittingVariable ( const FormulaT & _splittingVariable ) [inline], [static], [inherited]`

**0.15.608.4.43 generateTrivialInfeasibleSubset()** `void smtrat::Module::generateTrivialInfeasibleSubset ( ) [inline], [protected], [inherited]`

Stores the trivial infeasible subset being the set of received formulas.

**0.15.608.4.44 getBackendsAllModels()** `void smtrat::Module::getBackendsAllModels ( ) const [protected], [inherited]`

Stores all models of a backend in the list of all models of this module.

**0.15.608.4.45 getBackendsModel()** `void smtrat::Module::getBackendsModel ( ) const [protected], [inherited]`

**0.15.608.4.46 getInfeasibleSubsets() [1/2]** `void smtrat::Module::getInfeasibleSubsets ( ) [protected], [inherited]`

Copies the infeasible subsets of the passed formula.

**0.15.608.4.47 getInfeasibleSubsets() [2/2]** `std::vector< FormulaSetT > smtrat::Module::getInfeasibleSubsets (`

`const Module & _backend ) const [protected], [inherited]`

Get the infeasible subsets the given backend provides.

Note, that an infeasible subset in a backend contains sub formulas of the passed formula and an infeasible subset of this module contains sub formulas of the received formula. In this method the LATTER is returned.

**Parameters**

|                       |                                                          |
|-----------------------|----------------------------------------------------------|
| <code>_backend</code> | The backend from which to obtain the infeasible subsets. |
|-----------------------|----------------------------------------------------------|

**Returns**

The infeasible subsets the given backend provides.

**0.15.608.4.48 getInformationRelevantFormulas()** `const std::set< FormulaT > & smtrat::Module::getInformationRelevantFormulas ( ) [protected], [inherited]`

Gets all InformationRelevantFormulas.

**Returns**

Set of all formulas

**0.15.608.4.49 getModelEqualities()** `std::list< std::vector< carl::Variable > > smtrat::Module::getModelEqualities ( ) const [virtual], [inherited]`

Partition the variables from the current model into equivalence classes according to their assigned value.

The result is a set of equivalence classes of variables where all variables within one class are assigned the same value. Note that the number of classes may not be minimal, i.e. two classes may actually be equivalent.

#### Returns

Equivalence classes.

**0.15.608.4.50 getOrigins() [1/3]** `void smtrat::Module::getOrigins (`

```
const FormulaT & _formula,
FormulaSetT & _origins) const [inline], [protected], [inherited]
```

#### Parameters

|                       |  |
|-----------------------|--|
| <code>_formula</code> |  |
| <code>_origins</code> |  |

**0.15.608.4.51 getOrigins() [2/3]** `void smtrat::Module::getOrigins (`

```
const FormulaT & _formula,
FormulasT & _origins) const [inline], [protected], [inherited]
```

#### Parameters

|                       |  |
|-----------------------|--|
| <code>_formula</code> |  |
| <code>_origins</code> |  |

**0.15.608.4.52 getOrigins() [3/3]** `const FormulaT& smtrat::Module::getOrigins (`

```
ModuleInput::const_iterator _formula) const [inline], [protected], [inherited]
```

Gets the origins of the passed formula at the given position.

#### Parameters

|                       |                                                   |
|-----------------------|---------------------------------------------------|
| <code>_formula</code> | The position of a formula in the passed formulas. |
|-----------------------|---------------------------------------------------|

#### Returns

The origins of the passed formula at the given position.

**0.15.608.4.53 getReceivedFormulaSimplified()** `std::pair< bool, FormulaT > smtrat::Module::getReceivedFormulaSimplified ( ) [virtual], [inherited]`

#### Returns

A pair of a Boolean and a formula, where the Boolean is true, if the received formula could be simplified to an equisatisfiable formula. The formula is equisatisfiable to this module's received formula, if the Boolean is true.

Reimplemented in [smtrat::PModule](#).

**0.15.608.4.54 hasLemmas()** `bool smrat::Module::hasLemmas () [inline], [inherited]`  
Checks whether this module or any of its backends provides any lemmas.

**0.15.608.4.55 hasValidInfeasibleSubset()** `bool smrat::Module::hasValidInfeasibleSubset () const [inherited]`

**Returns**

true, if the module has at least one valid infeasible subset, that is all its elements are sub-formulas of the received formula (pointer must be equal).

**0.15.608.4.56 id()** `std::size_t smrat::Module::id () const [inline], [inherited]`

**Returns**

A unique ID to identify this module instance.

**0.15.608.4.57 infeasibleSubsets()** `const std::vector<FormulaSetT>& smrat::Module::infeasibleSubsets () const [inline], [inherited]`

**Returns**

The infeasible subsets of the set of received formulas (empty, if this module has not detected unsatisfiability of the conjunction of received formulas).

**0.15.608.4.58 inform()** `bool smrat::Module::inform (const FormulaT & _constraint) [inherited]`

Informs the module about the given constraint.

It should be tried to inform this module about any constraint it could receive eventually before assertSubformula is called (preferably for the first time, but at least before adding a formula containing that constraint).

**Parameters**

|                          |                                 |
|--------------------------|---------------------------------|
| <code>_constraint</code> | The constraint to inform about. |
|--------------------------|---------------------------------|

**Returns**

false, if it can be easily decided whether the given constraint is inconsistent; true, otherwise.

**0.15.608.4.59 informBackends()** `void smrat::Module::informBackends (const FormulaT & _constraint) [inline], [protected], [inherited]`

Informs all backends of this module about the given constraint.

**Parameters**

|                          |                                 |
|--------------------------|---------------------------------|
| <code>_constraint</code> | The constraint to inform about. |
|--------------------------|---------------------------------|

**0.15.608.4.60 informCore()** `virtual bool smrat::Module::informCore (const FormulaT & _constraint) [inline], [protected], [virtual], [inherited]`

Informs the module about the given constraint.

It should be tried to inform this module about any constraint it could receive eventually before assertSubformula is called (preferably for the first time, but at least before adding a formula containing that constraint).

#### Parameters

|                          |                                 |
|--------------------------|---------------------------------|
| <code>_constraint</code> | The constraint to inform about. |
|--------------------------|---------------------------------|

#### Returns

`false`, if it can be easily decided whether the given constraint is inconsistent; `true`, otherwise.

Reimplemented in [smrat::UnionFindModule< Settings >](#), [smrat::PBPPModule< Settings >](#), [smrat::PBGaussModule< Settings >](#), [smrat::NRAILModule< Settings >](#), [smrat::NewCoveringModule< Settings >](#), [smrat::NewCADModule< Settings >](#), [smrat::LRAModule< Settings >](#), [smrat::LRAModule< LRASettingsICP >](#), [smrat::LRAModule< LRASettings1 >](#), [smrat::IntBlastModule< Settings >](#), [smrat::FPPModule< Settings >](#), [smrat::EQModule< Settings >](#), [smrat::CurryModule< Settings >](#), [smrat::BVMModule< Settings >](#), [smrat::ICPModule< Settings >](#), [smrat::ICPModule< ICPSettings4 >](#), and [smrat::ICPModule< ICPSettings1 >](#).

**0.15.608.4.61 informedConstraints()** `const carl::FastSet<FormulaT>& smrat::Module::informedConstraints( ) const [inline], [inherited]`

#### Returns

The position of the first constraint of which no backend has been informed about.

**0.15.608.4.62 init()** `void smrat::Module::init( ) [virtual], [inherited]`

Informs all backends about the so far encountered constraints, which have not yet been communicated.

This method must not be called twice and only before the first runBackends call.

Reimplemented in [smrat::PBPPModule< Settings >](#), [smrat::PBGaussModule< Settings >](#), [smrat::NRAILModule< Settings >](#), [smrat::NewCoveringModule< Settings >](#), [smrat::NewCADModule< Settings >](#), [smrat::LRAModule< Settings >](#), [smrat::LRAModule< LRASettingsICP >](#), [smrat::LRAModule< LRASettings1 >](#), [smrat::IntBlastModule< Settings >](#), [smrat::FPPModule< Settings >](#), [smrat::EQModule< Settings >](#), [smrat::CurryModule< Settings >](#), and [smrat::BVMModule< Settings >](#).

**0.15.608.4.63 is\_minimizing()** `bool smrat::Module::is_minimizing( ) const [inline], [inherited]`

**0.15.608.4.64 isLemmaLevel()** `bool smrat::Module::isLemmaLevel(`

`LemmaLevel level) [protected], [inherited]`

Checks if current lemma level is greater or equal to given level.

#### Parameters

|                    |                 |
|--------------------|-----------------|
| <code>level</code> | Level to check. |
|--------------------|-----------------|

**0.15.608.4.65 isPreprocessor()** `bool smrat::Module::isPreprocessor( ) const [inline], [inherited]`

#### Returns

`true`, if this module is a preprocessor that is a module, which simplifies its received formula to an equisatisfiable formula being passed to its backends. The simplified formula can be obtained with [getReceivedFormulaSimplified\(\)](#).

**0.15.608.4.66 lemmas()** const std::vector<[Lemma](#)>& smtrat::Module::lemmas ( ) const [inline], [inherited]

**Returns**

A constant reference to the lemmas being valid formulas this module or its backends made.

**0.15.608.4.67 merge()** std::vector< [FormulaT](#) > smtrat::Module::merge ( const std::vector< [FormulaT](#) > & [\\_vecSetA](#), const std::vector< [FormulaT](#) > & [\\_vecSetB](#) ) const [protected], [inherited]

Merges the two vectors of sets into the first one.

({a,b},{a,c}) and ({b,d},{b}) -> ({a,b,d},{a,b},{a,b,c,d},{a,b,c})

**Parameters**

|                          |                                  |
|--------------------------|----------------------------------|
| <a href="#">_vecSetA</a> | A vector of sets of constraints. |
| <a href="#">_vecSetB</a> | A vector of sets of constraints. |

**Returns**

The vector being the two given vectors merged.

**0.15.608.4.68 model()** const [Model](#)& smtrat::Module::model ( ) const [inline], [inherited]

**Returns**

The assignment of the current satisfiable result, if existent.

**0.15.608.4.69 modelsDisjoint()** bool smtrat::Module::modelsDisjoint ( const [Model](#) & [\\_modelA](#), const [Model](#) & [\\_modelB](#) ) [static], [protected], [inherited]

Checks whether there is no variable assigned by both models.

**Parameters**

|                         |                                |
|-------------------------|--------------------------------|
| <a href="#">_modelA</a> | The first model to check for.  |
| <a href="#">_modelB</a> | The second model to check for. |

**Returns**

true, if there is no variable assigned by both models; false, otherwise.

**0.15.608.4.70 moduleName()** template<class [Settings](#) > std::string smtrat::VSModule< [Settings](#) >::moduleName ( ) const [inline], [virtual]

**Returns**

The name of the given module type as name.

Reimplemented from [smtrat::Module](#).

**0.15.608.4.71 `objective()`** `carl::Variable smrat::Module::objective ( ) const [inline], [inherited]`

**0.15.608.4.72 `originInReceivedFormula()`** `bool smrat::Module::originInReceivedFormula ( const FormulaT & _origin ) const [protected], [inherited]`

**0.15.608.4.73 `passedFormulaBegin()`** `ModuleInput::iterator smrat::Module::passedFormulaBegin ( ) [inline], [protected], [inherited]`

**Returns**

An iterator to the end of the passed formula. TODO: disable this method

**0.15.608.4.74 `passedFormulaEnd()`** `ModuleInput::iterator smrat::Module::passedFormulaEnd ( ) [inline], [protected], [inherited]`

**Returns**

An iterator to the end of the passed formula.

**0.15.608.4.75 `pPassedFormula()`** `const ModuleInput* smrat::Module::pPassedFormula ( ) const [inline], [inherited]`

**Returns**

A pointer to the formula passed to the backends of this module.

**0.15.608.4.76 `pReceivedFormula()`** `const ModuleInput* smrat::Module::pReceivedFormula ( ) const [inline], [inherited]`

**Returns**

A pointer to the formula passed to this module.

**0.15.608.4.77 `print()`** `void smrat::Module::print ( const std::string & _initiation = "***" ) const [inherited]`

Prints everything relevant of the solver.

**Parameters**

|                          |                      |
|--------------------------|----------------------|
| <code>_initiation</code> | The line initiation. |
|--------------------------|----------------------|

**0.15.608.4.78 `printAll()`** `template<class Settings > void smrat::VSModule< Settings >::printAll ( const std::string & _init = "", std::ostream & _out = std::cout ) const`

Prints the history to the output stream.

**Parameters**

|              |                                                        |
|--------------|--------------------------------------------------------|
| <i>_init</i> | The beginning of each row.                             |
| <i>_out</i>  | The output stream where the history should be printed. |

**0.15.608.4.79 printAllModels()** void smtrat::Module::printAllModels ( std::ostream & *\_out* = std::cout ) [inherited]

Prints all assignments of this module satisfying its received formula if it satisfiable and this module could find an assignment.

**Parameters**

|             |                                        |
|-------------|----------------------------------------|
| <i>_out</i> | The stream to print the assignment on. |
|-------------|----------------------------------------|

**0.15.608.4.80 printAnswer()** template<class Settings >  
void smtrat::VSModule< Settings >::printAnswer ( const std::string & *\_init* = "", std::ostream & *\_out* = std::cout ) const

Prints the answer if existent.

**Parameters**

|              |                                                       |
|--------------|-------------------------------------------------------|
| <i>_init</i> | The beginning of each row.                            |
| <i>_out</i>  | The output stream where the answer should be printed. |

**0.15.608.4.81 printFormulaConditionMap()** template<class Settings >  
void smtrat::VSModule< Settings >::printFormulaConditionMap ( const std::string & *\_init* = "", std::ostream & *\_out* = std::cout ) const

Prints the history to the output stream.

**Parameters**

|              |                                                        |
|--------------|--------------------------------------------------------|
| <i>_init</i> | The beginning of each row.                             |
| <i>_out</i>  | The output stream where the history should be printed. |

**0.15.608.4.82 printInfeasibleSubsets()** void smtrat::Module::printInfeasibleSubsets ( const std::string & *\_initiation* = "\*\*\*" ) const [inherited]

Prints the infeasible subsets.

**Parameters**

|                    |                      |
|--------------------|----------------------|
| <i>_initiation</i> | The line initiation. |
|--------------------|----------------------|

**0.15.608.4.83 printModel()** void smtrat::Module::printModel (

```
std::ostream & _out = std::cout) const [inherited]
```

Prints the assignment of this module satisfying its received formula if it satisfiable and this module could find an assignment.

#### Parameters

|                   |                                        |
|-------------------|----------------------------------------|
| <code>_out</code> | The stream to print the assignment on. |
|-------------------|----------------------------------------|

**0.15.608.4.84 `printPassedFormula()`** void smtrat::Module::printPassedFormula ( const std::string & `_initiation` = "\*\*\*" ) const [inherited]

Prints the vector of passed formula.

#### Parameters

|                          |                      |
|--------------------------|----------------------|
| <code>_initiation</code> | The line initiation. |
|--------------------------|----------------------|

**0.15.608.4.85 `printRanking()`** template<class Settings > void smtrat::VSModule< Settings >::printRanking ( const std::string & `_init` = "", std::ostream & `_out` = std::cout ) const

Prints the history to the output stream.

#### Parameters

|                    |                                                        |
|--------------------|--------------------------------------------------------|
| <code>_init</code> | The beginning of each row.                             |
| <code>_out</code>  | The output stream where the history should be printed. |

**0.15.608.4.86 `printReceivedFormula()`** void smtrat::Module::printReceivedFormula ( const std::string & `_initiation` = "\*\*\*" ) const [inherited]

Prints the vector of the received formula.

#### Parameters

|                          |                      |
|--------------------------|----------------------|
| <code>_initiation</code> | The line initiation. |
|--------------------------|----------------------|

**0.15.608.4.87 `probablyLooping()`** bool smtrat::Module::probablyLooping ( const typename Poly::PolyType & `_branchingPolynomial`, const Rational & `_branchingValue` ) const [protected], [inherited]

Checks whether given the current branching value and branching variable/polynomial it is (highly) probable that this branching is part of an infinite loop of branchings.

#### Parameters

|                                   |                                                                                     |
|-----------------------------------|-------------------------------------------------------------------------------------|
| <code>_branchingPolynomial</code> | The polynomial to branch at (in most branching strategies this is just a variable). |
| <code>_branchingValue</code>      | The value to branch at.                                                             |

**Returns**

true, if this branching is probably part of an infinite loop of branchings; false, otherwise.

**0.15.608.4.88 receivedFormulaChecked()** void smtrat::Module::receivedFormulaChecked () [inline], [inherited]

Notifies that the received formulas has been checked.

**0.15.608.4.89 receivedFormulasAsInfeasibleSubset()** void smtrat::Module::receivedFormulasAsInfeasibleSubset (

    ModuleInput::const\_iterator \_subformula ) [inline], [protected], [inherited]

Stores an infeasible subset consisting only of the given received formula.

**0.15.608.4.90 receivedVariable()** bool smtrat::Module::receivedVariable (

    carl::Variable::Arg \_var ) const [inline], [inherited]

**0.15.608.4.91 remove()** void smtrat::Module::remove (

    ModuleInput::const\_iterator \_subformula ) [virtual], [inherited]

Removes everything related to the given sub-formula of the received formula.

However, it is desired not to lose track of search spaces where no satisfying assignment can be found for the remaining sub-formulas.

**Parameters**

|             |                                                    |
|-------------|----------------------------------------------------|
| _subformula | The sub formula of the received formula to remove. |
|-------------|----------------------------------------------------|

Reimplemented in [smtrat::PModule](#).

**0.15.608.4.92 removeCore()** template<class Settings >

void smtrat::VSModule< Settings >::removeCore (

    ModuleInput::const\_iterator formula ) [virtual]

Removes everything related to the given sub-formula of the received formula.

However, it is desired not to lose track of search spaces where no satisfying assignment can be found for the remaining sub-formulas.

**Parameters**

|         |                                                    |
|---------|----------------------------------------------------|
| formula | The sub formula of the received formula to remove. |
|---------|----------------------------------------------------|

Reimplemented from [smtrat::Module](#).

**0.15.608.4.93 removeOrigin()** std::pair<ModuleInput::iterator,bool> smtrat::Module::removeOrigin (

    ModuleInput::iterator formula,

    const FormulaT & \_origin ) [inline], [protected], [inherited]

**0.15.608.4.94 removeOrigins()** std::pair<ModuleInput::iterator,bool> smtrat::Module::removeOrigins (

    ModuleInput::iterator formula,

```
const std::shared_ptr< std::vector< FormulaT >> & _origins) [inline], [protected],
[inherited]
```

**0.15.608.4.95 rPassedFormula()** const ModuleInput& smtrat::Module::rPassedFormula ( ) const  
[inline], [inherited]

#### Returns

A reference to the formula passed to the backends of this module.

**0.15.608.4.96 rReceivedFormula()** const ModuleInput& smtrat::Module::rReceivedFormula ( ) const  
[inline], [inherited]

#### Returns

A reference to the formula passed to this module.

**0.15.608.4.97 runBackends() [1/2]** virtual Answer smtrat::Module::runBackends ( ) [inline],  
[protected], [virtual], [inherited]  
Reimplemented in [smtrat::PModule](#).

**0.15.608.4.98 runBackends() [2/2]** Answer smtrat::Module::runBackends (

```
 bool _final,
 bool _full,
 carl::Variable _objective) [protected], [virtual], [inherited]
```

Runs the backend solvers on the passed formula.

#### Parameters

|                   |                                                                                                                                       |
|-------------------|---------------------------------------------------------------------------------------------------------------------------------------|
| <i>_final</i>     | true, if this satisfiability check will be the last one (for a global sat-check), if its result is SAT                                |
| <i>_full</i>      | false, if this module should avoid too expensive procedures and rather return unknown instead.                                        |
| <i>_objective</i> | if not set to NO_VARIABLE, the module should find an assignment minimizing this objective variable; otherwise any assignment is good. |

#### Returns

True, if the passed formula is consistent; False, if the passed formula is inconsistent; Unknown, otherwise.

Reimplemented in [smtrat::PModule](#).

**0.15.608.4.99 setId()** void smtrat::Module::setId ( std::size\_t *\_id* ) [inline], [inherited]

Sets this modules unique ID to identify itself.

#### Parameters

|                                                            |                                    |
|------------------------------------------------------------|------------------------------------|
| $\leftarrow$<br>$\overleftarrow{\rightarrow}$<br><i>id</i> | The id to set this module's id to. |
|------------------------------------------------------------|------------------------------------|

**0.15.608.4.100 setThreadPriority()** `void smtrat::Module::setThreadPriority (``thread_priority _threadPriority ) [inline], [inherited]`

Sets the priority of this module to get a thread for running its check procedure.

**Parameters**

|                              |                                                       |
|------------------------------|-------------------------------------------------------|
| <code>_threadPriority</code> | The priority to set this module's thread priority to. |
|------------------------------|-------------------------------------------------------|

**0.15.608.4.101 solverState()** `Answer smtrat::Module::solverState ( ) const [inline], [inherited]`**Returns**

True, if this module is in a state, such that it has found a solution for its received formula; False, if this module is in a state, such that it has determined that there is no solution for its received formula; Unknown, otherwise.

**0.15.608.4.102 splitUnequalConstraint()** `void smtrat::Module::splitUnequalConstraint (``const FormulaT & _unequalConstraint ) [protected], [inherited]`

Adds the following lemmas for the given constraint  $p \neq 0$ .

$(p \neq 0 \leftrightarrow (p < 0 \text{ or } p > 0))$

and  $\neg(p < 0 \text{ and } p > 0)$

**Parameters**

|                                 |                                                  |
|---------------------------------|--------------------------------------------------|
| <code>_unequalConstraint</code> | A constraint having the relation symbol $\neq$ . |
|---------------------------------|--------------------------------------------------|

**0.15.608.4.103 threadPriority()** `thread_priority smtrat::Module::threadPriority ( ) const [inline], [inherited]`**Returns**

The priority of this module to get a thread for running its check procedure.

**0.15.608.4.104 updateAllModels()** `void smtrat::Module::updateAllModels ( ) [virtual], [inherited]`

Updates all satisfying models, if the solver has detected the consistency of the received formula, beforehand.

Reimplemented in [smtrat::SATModule< Settings >](#).

**0.15.608.4.105 updateLemmas()** `void smtrat::Module::updateLemmas ( ) [inherited]`

Stores all lemmas of any backend of this module in its own lemma vector.

**0.15.608.4.106 updateModel()** `template<class Settings >``void smtrat::VSMModule< Settings >::updateModel ( ) const [virtual]`

Updates the model, if the solver has detected the consistency of the received formula, beforehand.

Reimplemented from [smtrat::Module](#).

**0.15.608.4.107 usedBackends()** `const std::vector<Module*>& smtrat::Module::usedBackends ( )``const [inline], [inherited]`

**Returns**

The backends of this module which are currently used (conditions to use this module are fulfilled for the passed formula).

**0.15.608.5 Field Documentation**

**0.15.608.5.1 mAllBackends** std::vector<[Module](#)\*> smtrat::Module::mAllBackends [protected], [inherited]

The backends of this module which have been used.

**0.15.608.5.2 mAllModels** std::vector<[Model](#)> smtrat::Module::mAllModels [mutable], [protected], [inherited]

Stores all satisfying assignments.

**0.15.608.5.3 mBackendsFoundAnswer** std::atomic\_bool\* smtrat::Module::mBackendsFoundAnswer [protected], [inherited]

This flag is passed to any backend and if it determines an answer to a prior check call, this flag is fired.

**0.15.608.5.4 mConstraintsToInform** carl::FastSet<[FormulaT](#)> smtrat::Module::mConstraintsToInform [protected], [inherited]

Stores the constraints which the backends must be informed about.

**0.15.608.5.5 mFinalCheck** bool smtrat::Module::mFinalCheck [protected], [inherited]  
true, if the check procedure should perform a final check which especially means not to postpone splitting decisions

**0.15.608.5.6 mFirstPosInLastBranches** std::size\_t smtrat::Module::mFirstPosInLastBranches = 0 [static], [inherited]

The beginning of the cyclic buffer storing the last branches.

**0.15.608.5.7 mFirstSubformulaToPass** [ModuleInput](#)::iterator smtrat::Module::mFirstSubformulaToPass [protected], [inherited]

Stores the position of the first sub-formula in the passed formula, which has not yet been considered for a consistency check of the backends.

**0.15.608.5.8 mFirstUncheckedReceivedSubformula** [ModuleInput](#)::const\_iterator smtrat::Module::mFirstUncheckedReceivedSubformula [protected], [inherited]

Stores the position of the first (by this module) unchecked sub-formula of the received formula.

**0.15.608.5.9 mFoundAnswer** [Conditionals](#) smtrat::Module::mFoundAnswer [protected], [inherited]  
Vector of Booleans: If any of them is true, we have to terminate a running check procedure.

**0.15.608.5.10 mFullCheck** bool smtrat::Module::mFullCheck [protected], [inherited]  
false, if this module should avoid too expensive procedures and rather return unknown instead.

**0.15.608.5.11 mInfeasibleSubsets** std::vector<[FormulaSetT](#)> smtrat::Module::mInfeasibleSubsets  
[protected], [inherited]  
Stores the infeasible subsets.

**0.15.608.5.12 mInformedConstraints** carl::FastSet<[FormulaT](#)> smtrat::Module::mInformedConstraints  
[protected], [inherited]  
Stores the position of the first constraint of which no backend has been informed about.

**0.15.608.5.13 mLastBranches** std::vector< [Branching](#) > smtrat::Module::mLastBranches = std::vector<[Branching](#)>(mNumOfBranchVarsToStore, Branching(typename Poly::PolyType(), 0)) [static], [inherited]  
Stores the last branches in a cycle buffer.

**0.15.608.5.14 mLemmas** std::vector<[Lemma](#)> smtrat::Module::mLemmas [protected], [inherited]  
Stores the lemmas being valid formulas this module or its backends made.

**0.15.608.5.15 mModel** [Model](#) smtrat::Module::mModel [mutable], [protected], [inherited]  
Stores the assignment of the current satisfiable result, if existent.

**0.15.608.5.16 mModelComputed** bool smtrat::Module::mModelComputed [mutable], [protected], [inherited]  
True, if the model has already been computed.

**0.15.608.5.17 mNumOfBranchVarsToStore** std::size\_t smtrat::Module::mNumOfBranchVarsToStore = 5 [static], [inherited]  
The number of different variables to consider for a probable infinite loop of branchings.

**0.15.608.5.18 mObjectiveVariable** carl::Variable smtrat::Module::mObjectiveVariable [protected], [inherited]  
Objective variable to be minimized. If set to NO\_VARIABLE, a normal sat check should be performed.

**0.15.608.5.19 mOldSplittingVariables** std::vector< [FormulaT](#) > smtrat::Module::mOldSplittingVariables [static], [inherited]  
Reusable splitting variables.

**0.15.608.5.20 mpManager** [Manager](#)\* const smtrat::Module::mpManager [protected], [inherited]  
A reference to the manager.

**0.15.608.5.21 mSmallerMusesCheckCounter** unsigned smtrat::Module::mSmallerMusesCheckCounter [mutable], [protected], [inherited]  
Counter used for the generation of the smt2 files to check for smaller muses.

**0.15.608.5.22 mSolverState** std::atomic<[Answer](#)> smtrat::Module::mSolverState [protected],  
 [inherited]

States whether the received formula is known to be satisfiable or unsatisfiable otherwise it is set to unknown.

**0.15.608.5.23 mTheoryPropagations** std::vector<[TheoryPropagation](#)> smtrat::Module::mTheory←  
 Propagations [protected], [inherited]

**0.15.608.5.24 mUsedBackends** std::vector<[Module\\*](#)> smtrat::Module::mUsedBackends [protected],  
 [inherited]

The backends of this module which are currently used (conditions to use this module are fulfilled for the passed formula).

**0.15.608.5.25 mVariableCounters** std::vector<std::size\_t> smtrat::Module::mVariableCounters  
 [protected], [inherited]

Maps variables to the number of their occurrences.

### 0.15.612.1 Detailed Description

Tool wrapper for [Z3](#) for SMT-LIB.

### 0.15.612.2 Constructor & Destructor Documentation

**0.15.612.2.1 [Z3\(\)](#)** benchmax::Z3::Z3 (

```
 const fs::path & binary,
 const std::string & arguments) [inline]
```

New [Z3](#) tool.

### 0.15.612.3 Member Function Documentation

**0.15.612.3.1 [additionalResults\(\)](#)** virtual void benchmax::Z3::additionalResults (

```
 const fs::path & ,
 BenchmarkResult & result) const [inline], [override], [virtual]
```

Parse answer string from stdout.

Reimplemented from [benchmax::Tool](#).

**0.15.612.3.2 [attributeHash\(\)](#)** std::size\_t benchmax::Tool::attributeHash () const [inline], [inherited]

Hash of the attributes.

**0.15.612.3.3 [attributes\(\)](#)** const std::map<std::string, std::string>& benchmax::Tool::attributes (

```
) const [inline], [inherited]
```

A set of attributes, for example compilation options.

**0.15.612.3.4 [binary\(\)](#)** fs::path benchmax::Tool::binary () const [inline], [inherited]

Full path to the binary.

**0.15.612.3.5 canHandle()** virtual bool benchmax::Z3::canHandle ( const fs::path & path ) const [inline], [override], [virtual]  
Only handle .smt2 files.  
Reimplemented from [benchmax::Tool](#).

**0.15.612.3.6 getCommandLine() [1/2]** virtual std::string benchmax::Tool::getCommandLine ( const std::string & file ) const [inline], [virtual], [inherited]  
Compose commandline for this tool and the given input file.

**0.15.612.3.7 getCommandLine() [2/2]** virtual std::string benchmax::Tool::getCommandLine ( const std::string & file, const std::string & localBinary ) const [inline], [virtual], [inherited]  
Compose commandline for this tool with another binary name and the given input file.

**0.15.612.3.8 name()** std::string benchmax::Tool::name () const [inline], [inherited]  
Common name of this tool.

**0.15.612.3.9 parseCommandLine()** virtual std::optional<std::string> benchmax::Tool::parseCommandline ( const std::string & cmdline ) const [inline], [virtual], [inherited]  
Compose commandline for this tool and the given input file.

**0.15.612.3.10 resolveDependencies()** std::vector<std::string> benchmax::Tool::resolveDependencies () const [inline], [inherited]  
Get dependencies of binary required to run it (via ldd)

## 0.15.612.4 Field Documentation

**0.15.612.4.1 mArguments** std::string benchmax::Tool::mArguments [protected], [inherited]  
Command line arguments that should be passed to the binary.

**0.15.612.4.2 mAttributes** std::map<std::string, std::string> benchmax::Tool::mAttributes [protected], [inherited]  
Attributes of the tool obtained by introspection of the binary.

**0.15.612.4.3 mBinary** fs::path benchmax::Tool::mBinary [protected], [inherited]  
Path to the binary.

**0.15.612.4.4 mName** std::string benchmax::Tool::mName [protected], [inherited]  
(Non-unique) identifier for the tool.
